Cyanophages (i.e. viruses that infect cyanobacteria) are crucial in regulating the abundance of their host cells, affecting the clonal diversity as well as the composition of the cyanobacterial community. This study focuses on a 2-year monthly monitoring of a tropical reservoir in Singapore. Surface monthly water samples were collected from three separate sites in the reservoir and the assemblage of cyanobacteria and cyanophage were characterized by QPCR based quantification of *Microcystis* cells and the g91 gene of the Ma-LMM01-type cyanophage, infectious to *Microcystis aeruginosa*. Our findings revealed higher host and Ma-LMM01-type phage abundance during a prolonged dry spell and lower concentrations after a rainy season. During the extended period of low rainfall in 2014, higher *Microcystis* concentration and lower total nitrogen levels were observed. *Microcystis* cyanobacterium do not have heterocysts and hence, TN were likely utilized by the *Microcystis* to increase its biomass. Interestingly, during the dry spell, elevated levels of total microcystin were detected, coinciding with similar or higher viral to host concentrations in the sampled sites. The higher cyanophage abundance were hypothesized to be the result of successful infection, host cell lysis and the subsequent release of microcystin into the water. Secondly, during the high rainfall period, lower host and phage abundance were observed, likely due to unfavorable conditions for the proliferation of cyanobacteria and subsequently, averting successful phage infections. Therefore, this 2-year monthly monitoring provided an insight into the long term occurrence and dynamics of host-viral interaction coupled with environmental water quality.

Functional and Compositional Shifts in Soil Microbial Communities in Response to Long-Term Warming in Alaska

Author Block:

C. Wang[1], L. Wu[1], J. Zhou[1], E. A. G. Schuur[2], R. Bracho[3], M. Yuan[1]; [1]The Univ. of Oklahoma, Norman, OK, [2]Northern Arizona Univ., Flagstaff, AZ, [3]Univ. of Florida, Gainesville, FL

Abstract Body:

Permafrost, which stores around half of the total soil organic carbon over the world, is generally believed to be sensitive and responsive to global warming. Potential positive feedback has been anticipated since increased temperature could induce the release of old carbon through changed microbial communities. However, this process is poorly understood. We studied how the soil microbial communities respond to 5 years of experimental warming in CiPEHR (Carbon in Permafrost Experimental Heating Research) project site in Alaska. We performed comprehensive functional gene analysis using GeoChip 5.0, an advanced functional gene array, and 16S and ITS rRNA sequencing. In the organic profile, the abundance of over 80% of functional genes involved in Carbon degradation was significantly increased after warming. Warming also increased the abundance of genes involved in nutrient cyclings such as N and P. The increase could contribute to the observed higher ecosystem respiration and gross primary productivity. Also, 16S rRNA analysis showed the composition of microbial communities changed significantly in response to warming. Altogether, our results showed both the functional and phylogenetic composition of the soil microbial communities responded actively to experimental warming and the response is depth-dependent.

Successional Dynamics of Grassland Microbial Communities in Response to Annual Clipping

Author Block:

X. Guo, X. Zhou, M. Yuan, L. Wu, Z. He, J. D. V. Nostrand, J. Zhou; The Univ. of Oklahoma, Norman, OK

Abstract Body:

Plant tissue removal via grazing, mowing and clipping is a central issue in land use practices for agriculture. However, predicting the effect of clipping on the structure and function of belowground microbial communities is hampered by the lack of long term data sets tracking annual clipping manipulation. Here, using metagenomics technologies, we examined the dynamic response of soil microbial communities to annual clipping for five years (2010-2014) at a grassland ecosystem in the Great Plains of North America. Our results indicated that root and microbial activity were significantly ($P < 0.05$) increased under annual clipping based on soil respiration and heterotrophic respiration. The abundance of six bacterial phyla, including *Actinobacteria* and *Bacteroidetes*, and fungal phyla *Ascomycota* and *Zygomycota* were significantly ($p < 0.05$) changed with clipping treatment, though the overall microbial community didn't significantly change. Based on GeoChip analysis, the annual background variation within the microbial community was greater than the significant changes introduced by clipping, but cumulative effects of annual clipping were still observed over time. Five years of annual clipping significantly ($P < 0.05$) increased the abundance of genes involved in the degradation of labile C and some types of recalcitrant C. More importantly, the abundance of genes involved in the degradation of recalcitrant C, but not labile C, were consistently significantly increased in the last two years, suggesting that recalcitrant C degradation was triggered under annual clipping. Other genes involved in nutrient-cycling processes including nitrogen (N) cycling and phosphorus utilization were also significantly increased by annual clipping. The shifts in the functional composition and structure of the microbial community were significantly correlated with soil C and N contents and plant productivity. This study provides new insights into successional dynamics of soil microbial communities and associated feedback responses to annual clipping.

Rdp: Tools and Data for Gene-Targeted Metagenomics

Author Block:

B. Chai, S. Gunturu, L. Tift, T. Soares, Z. Xing, M. O'Keefe, Q. Wang, J. Tiedje, **J. R. Cole**; Michigan State Univ., East Lansing, MI

Abstract Body:

RDP offers aligned and annotated sequence data and analysis tools for rRNA genes and environmentally important protein-coding genes to the research community through its websites (http://rdp.cme.msu.edu and http://fungne.cme.msu.edu). As of January 2016, RDP's data collections include 3,224,600 16S rRNA and 108,901 fungal 28S rRNA sequences. In addition, most RDP tools are available as open source command-line versions through RDP's GitHub repository (https://github.com/rdpstaff/). This repository offers additional options for customizing high-throughput analysis.RDP's FunGene Pipeline & Repository provide databases for 264 protein coding genes useful as phylogenetic markers and for following important ecological functions. In addition to the aligned and annotated gene and protein sequences, FunGene provides online analysis functions and tools for selecting subsets of sequences for download and further analysis.To facilitate the use of the FunGene data in targeted metagenomics, we have developed and are testing efficient high throughput primer design tools. Protein-coding genes are, in general, less conserved than structural RNA genes, meaning that often no single probe or primer pair is able to target a gene's full range of diversity. New highly-parallel qPCR platforms make it cost-effective to use multiple primer pairs. Our tool helps with the design of these multiple primers. It calculates Tm values for candidate primers based on thermodynamic properties, including Tm estimates for primer mismatches and it offers several diversity weighting schemes to maximize the diversity covered by a selected number of primers of targeted diversity. We have used this tool to develop better primers targeting antibiotic resistance genes and genes involved in nitrogen cycling.RDP's mission includes user support; email rdpstaff@msu.edu or call +1(517) 432-4998.

Metagenomic and Metatranscriptomic Profiling of Human Gut Microbiota

Author Block:

P. Widmann, E. Haenssler, K. Kowalewski, N. Brinker-Krueger, **D. O'Neil**, M. Sprenger-Haussels; QIAGEN GmbH, Hilden, Germany

Abstract Body:

The human gastrointestinal tract is inhabited by a diverse community of microorganisms that affect human health and disease. Microbial communities can be comprehensively characterized based on their nucleic acid compositions via 16S rDNA-, metagenomic-, and metatranscriptomic approaches applying Next Generation Sequencing (NGS) technologies. The final information content derived from these analyses depends on high-quality starting material in the form of purified nucleic acids. The present study aimed to profile human gut microbiota based on genetic and transcriptomic levels. In order to reduce sample to sample heterogeneity which can naturally occur within stool samples and to be able to generate maximal data output from limited sample material nucleic acids were isolated from single aliquots.16S-rDNA, DNA shotgun, and RNAseq libraries were prepared and sequenced on an Illumina MiSeq system. Analysis of library and sequencing quality parameters showed that the simultaneous application of mechanical and chemical cell disruption methods in combination with an inhibitor removal component was best suited to isolate high quality RNA and DNA for NGS-downstream applications. Microbial community compositions, functional potentials and activities were determined by mapping quality controlled reads to bacterial reference genomes using the BWA-MEM alignment algorithm. Sample specific signatures confirmed that the chosen approach of nucleic acid isolation is a reliable method for extracting the collective microbial genetic material from human stool samples. The chosen approach enabled a comprehensive exploration of human gut microbiota.In conclusion, in-depth analysis of human gut microbiota compositions, functional potentials and activities were conducted based on RNA and DNA from single stool aliquots, separated into single eluate fractions. Comparative metagenomic and metatranscriptomic analyses particularly benefited from this procedure as nucleic acids for Whole Genome Sequencing and RNAseq were isolated from the same aliquot, thus eliminating aliquot-dependent heterogeneities in microbiome structure and allowing detailed analyses of limited input material.

Genomic and Functional Stability of the Human Gut Microbiome

Author Block:

R. S. Mehta[1], G. Abu-Ali[2], A. Subramanian[2], J. Lloyd-Price[2], D. A. Drew[1], P. Lochhead[1], A. D. Joshi[1], K. L. Ivey[2], H. Khalili[1], E. B. Rimm[2], J. Izard[3], C. Huttenhower[2], A. T. Chan[1];
[1]Massachusetts Gen. Hosp., Boston, MA, [2]Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, [3]Forsyth Inst., Cambridge, MA

Abstract Body:

Background: Characterizing the temporal stability of the human gut microbiome is integral to identifying diagnostic biomarkers and modifiable microbiome components for disease prevention and treatment strategies. However, we have a limited insight into the temporal dynamics of the gut microbiome and the determinants of stability that are capable of influencing transitions between health and disease states. **Methods:** We conducted metagenomic and metatranscriptomic sequencing of the human gut microbiome among 308 male participants enrolled in a sub-study of the Health Professionals Follow-up Study. Using a previously validated self-sampling collection method, participants provided up to four stool samples - one from each of two consecutive bowel motions collected 24-72 hours apart, followed by a second set collected approximately 6 months later. DNA was extracted from 929 samples and RNA was reverse-transcribed to cDNA from a subset of 378 samples. Both were sequenced with the Illumina HiSeq platform. Metagenomic and metatranscriptomic read data were profiled using the HUMAnN2 and MetaPhlAn2 platforms, respectively.**Results:** Within-person variation in taxonomic and metagenomic composition over time was consistently lower than between-person variation at any given time point, in contrast to metatranscriptomic profiles. In exploring the determinants of stability, feature prevalence and relative abundance appeared to be highly correlated with feature stability. Metagenomic stability accounted for approximately 70% of metatranscriptomic stability. Moreover, 80% of differentially regulated pathways were consistently over- or underexpressed.**Conclusions:** In one of the largest studies to date, we describe the major underpinnings of within- and between-person variation in the gut microbiome. Gut organismal composition and metagenomic profiles remain highly personalized over time while metatranscriptomic profiles are more variable. Nonetheless, these results suggest that prospective characterization of the gut microbiome at a single time-point can provide a suitable measure for long-term follow-up of disease incidence.

Clustering Proteins Into Functional Categories to Elucidate the Temporal Functional Stability of the Human Gut Metaproteome

Author Block:

J. A. Blakeley-Ruiz[1], W. Xiong[2], Y. Song[3], C. M. Fraser-Liggett[3], R. Hettich[2]; [1]Univ. of Tennessee, Knoxville, TN, [2]Oak Ridge Natl. Lab., Oak Ridge, TN, [3]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Microbes living in the human gut form a complex and dynamic ecosystem that plays an important role in human physiology; however, the details of population and functional balances of the microbiome remain poorly understood. High-throughput microbiome sequencing and high performance mass spectrometry enable measurement of the composition and metabolic activities of this ecosystem using a combination of genetic and protein information. One fundamental question is how stable is this microbiome ecosystem over time? Comparing samples over time, however, is challenging due to the necessity of acquiring and integrating separate metagenomes and metaproteomes for each sample. To address this dilemma, we undertook two informatics procedures: 1) clustering all the proteins identified in a study by sequence identity in order to remove redundancy, and 2) clustering proteins into functional groups based on annotation databases such as pfam, eggNOG, gene ontology, and KEGG to garner metabolic information. Our testbed for this work are fecal samples from two Crohn's disease patients, collected on days 0, 30, and 180 after surgical resection. The gut proteome for each sample was measured in duplicate via 2D-LC-MS/MS using an LTQ-Orbitrap-Elite-MS. Proteins for each sample were identified using a concatenated human/microbial database derived from the metagenome of each sample. Metaproteomes across samples were clustered by sequence identity at varying resolutions using the *Uclust* algorithm. Metaproteomes across samples were also clustered by functionality using HMMER on the pfam and eggNOG databases. Clustering by protein sequence identity to remove redundancy was found to be too limited for meaningful information on microbiome temporal stability. Of the approximately 3,580 (median) non-redundant microbial proteins identified in each sample, very few were found across all six samples. Depending on the resolution of the functional categories, clustering by functional groups leads to a 30-70% overlap of all the functional groups identified across all six samples, thereby yielding much more detailed information about microbiome variation over time post-surgery.

Metagenomic Analysis Reveals a Highly Dynamic Human Microbiome during Pregnancy

Author Block:

D. Aliaga Goltsman[1], C. L. Sun[1], D. B. DiGiulio[2], B. C. Thomas[3], J. F. Banfield[3], D. A. Relman[1], March of Dimes Prematurity Research Center at Stanford University School of Medicine; [1]Stanford Univ., Palo Alto, CA, [2]Stanford Univ., Stanford, CA, [3]Univ. of California Berkeley, Berkeley, CA

Abstract Body:

The human microbiome plays key roles in human health and disease, yet the impact of the microbiome on pregnancy, and of pregnancy on the microbiome, is largely unknown. Previous characterizations of the human microbiome during pregnancy have largely focused on taxonomic composition of vaginal microbial communities. Although analyses of the community genomic composition at different body sites may generate important insight about the possible role of the microbiome in gestational health, detailed functional analyses have been limited. Here we describe a longitudinal study of the vaginal, gut and oral microbiome from ten subjects during pregnancy. In total, 293 samples collected approximately every 3 weeks of gestation were subject to Illumina paired-end metagenomic sequencing. 1.53 Gb of non-human sequences were assembled into contigs and functionally annotated for pathway analysis. The community composition from vaginal, gut, and oral samples was estimated from assembled genes for 16S rRNA and single-copy ribosomal proteins. In addition, organismal bins were determined for vaginal samples. An average species richness of 9 ± 2, 101 ± 15, and 42 ± 11 was observed in vaginal, stool, and saliva samples, respectively; Shannon's index of diversity indicates a highly dynamic microbiome composition during pregnancy. Metabolic pathway analyses suggest stability of core pathways over time, but high inter-individual variability for pathways that are likely contributed by lower abundance community members. For example, non-metric multidimensional scaling separates pathways contributed by high diversity from low diversity communities in the vaginal microbiome. Our results highlight the importance of assembly-driven metagenomic and functional analyses for understanding the dynamics of the human microbiome during pregnancy.

Dietary Drivers of the Gut Microbiome in Children

Author Block:

N. S. Rhoades, G. Flores, D. Herman; California State Univ. Northridge, Northridge, CA

Abstract Body:

The human gut is home to trillions of microbial cells whose functions are essential for normal human physiology. However, quantitative linkages between diet and gut microbiome composition are lacking, particularly in post-weaned, pre-pubescent children (ages 2-8 years). To address this knowledge gap, we conducted a community-based research project at a children's center located in the San Fernando Valley, approximately 30 miles north of downtown Los Angeles, CA. Study participants (n=90) provided three fecal samples and three dietary recalls of the foods consumed 24-hours prior to fecal sampling. Microbial communities were characterized using Illumina amplicon sequencing of the variable region 4 (V4) of the 16S rRNA gene, and functional diversity was assessed using shotgun metagenomic sequencing. Dietary data was disaggregated and converted to macro- and micronutrients using the ASA24 a program developed by the USDA, which uses individual-level nutrient estimates based on the Food and Nutrient Database for Dietary Studies (FNDDS). For each individual, dietary and microbiome data were averaged across the three sampling days to account for day-to-day variability in microbiome and diet. We found that older children tended to have more diverse microbiomes but diversity did not level off by the age of three, as others have reported. When we look at the population as a whole, significant relationships between higher level dietary features such as Whole grains, Total dairy, and gut microbiome composition were found. When we bin individuals by diet related age groups (2-3 and 4-8 years), many age specific trends were revealed. For example, in children between the ages of 2-3 years, micronutrients such as selenium, niacin, and calcium were strongly related to the abundance of specific bacterial families. In the 4-8 age group, several bacterial families were differentially influenced by the amount of fatty acids consumed. While analysis of these data is ongoing, results show that diet can be used to predict features of the microbiome in an age specific way. Only by understanding these relationships in diverse populations of healthy individuals during different life-stages will we be able to link subtle changes in the gut microbiome with human health outcomes later in life.

The Oral Microbiome During Cancer Chemotherapy and Mucositis Development

Author Block:

B-y. Hong[1], A. K. Dupuy[2], L. Choquette[1], A. L. Salner[3], P. Schauer[3], J. A. Burleson[1], L. Strausbaugh[2], A. Dongari-Bagtzoglou[1], D. E. Peterson[1], P. I. Diaz[1]; [1]UConn Hlth., Farmington, CT, [2]Univ. of Connecticut Storrs, Storrs, CT, [3]Hartford Hosp., Hartford, CT

Abstract Body:

Background: Cancer chemotherapies can cause a painful complication known as oral mucositis, which can subsequently compromise treatment outcomes. It is still not clear if chemotherapy directly alters the balance of normal flora in the oral cavity, and if these alterations are related to the development of oral mucositis. The goal of this study was to evaluate changes in the oral bacterial microbiome during chemotherapy and to investigate the relationship between these changes and oral mucositis. **Methods:** Forty-nine subjects diagnosed with cancer and scheduled to receive a cycle of 5-fluorouracil or doxorubicin-based chemotherapy, and 30 non-cancer controls were enrolled. Oral mucositis incidence and severity, and the salivary bacterial microbiome were evaluated pre-chemotherapy at baseline (V1) and during one chemotherapy cycle (V2-V4). Healthy controls were followed at V1 and V4 across the same period. Bacterial DNA isolated from saliva was used to construct PCR amplicon libraries targeting hypervariable regions 1-2 of the 16S rRNA gene, which were sequenced on the 454 platform.**Results:** Overall incidence of oral mucositis among cancer subjects was 80% with severity peaking at V3. The salivary microbiome showed decreased alpha-diversity during chemotherapy (V1 vs V3-V4), independently of antibiotic treatment, while no changes occurred in non-cancer controls. Decreased diversity correlated with mucositis incidence and severity at V4. Interestingly, subjects with sustained mucositis at V4 showed, on average, significant changes in the abundance of 16% of operational taxonomic units (OTUs) in their microbiomes, while subjects who recovered from mucositis by V4 had changes in only 3% of OTUs.**Conclusions:** This study demonstrates an association between salivary bacterial diversity and oral mucositis duration and severity. Our findings suggest that the degree of perturbation of the normal oral flora during cancer chemotherapy can constitute a risk factor for oral mucositis severity and/or persistence.

Assessment of Rumen Microbiome in Indian Surti Buffalo (*Bubalus bubalis*) Adapted to a High Roughage Diet Using Shotgun Sequencing

Author Block:

A. B. Patel[1], A. K. Patel[2], N. V. Patel[2], B. Reddy[2], R. K. Shah[1], A. T. Hinsu[2], D. Madamwar[1], C. G. Joshi[2]; [1]Sardar Patel univ., Bakrol, Gujarat, India, [2]Anand Agricultural Univ., Anand, Gujarat, India

Abstract Body:

Indian buffaloes contribute significantly to the national economy by providing dairy products and meat. Ruminants mainly depend on rumen microbiota for feed digestion and energy production. Uncovering microbial diversity and functional capacity of buffalo rumen can play a vital role in the animal health and productivity. Eight healthy Indian Surti buffaloes were gradually adapted to an increasing roughage diet (4 animals each with green and dry roughage) containing 50:50 (S1), 75:25 (S2) and 100:0 (S3) roughage to concentrate mix proportion for 6 weeks. In the present study, metagenomic approach was applied to divulge rumen microbiome using shotgun sequencing by Ion Torrent PGM platform and MG- RAST annotation pipeline. Our results showed that bacteria were the major community whereas archaea, eukaryota and viruses made up the minor communities in the overall microbial diversity. A total of 34 abundant to rare bacterial phyla were detected, among them Bacteroidetes, Firmicutes, Proteobacteria, Fibrobacteres and Actinobacteria were the most predominant in decreasing order, respectively. Genera such as *Prevotella, Bacteroides,* and *Clostridium* were dominant in buffalo rumen. Functional analysis indicated abundance of protein (~26.60%) and carbohydrate (~22.64%) metabolism in buffalo rumen. Rumen fluid metabolite study revealed that nitrogen content reduced and total volatile fatty acids raised in high roughage diet fed animals. Mining of metagenome sequence by CAZyme Analysis Toolkit identified a total of 70033 contigs encoding complex plant polysaccharides degrading enzymes representing potential source of enzymes for biofuel production and other industrial applications. Analysis reveals that composition of diet and fractions of rumen content have significant impact on rumen microbiome at taxonomic as well as functional level. Our study provided a base for designing strategies to develop feed diet for successful management of rumen micoflora and improvement in animal growth performance.

Functional Type I-F of CRISPR-CAS System is Present in the Gut Metagenome of Malaria Vector Mosquitoes

Author Block:

J. Xu, D. Pei, W. Yu; New Mexico State Univ., Las Cruces, NM

Abstract Body:

Background: Mosquitoes can transmit diseases like malaria and dengue fever. Mosquito control is critical for preventing mosquito-borne diseases. Mosquito harbors a complex microbiome in the gut ecosystem. The microbial community contributes significantly to various mosquito life traits, such as fecundity and immunity. In a metagenomic ecosystem, horizontal transfer of genetic elements and host defense system like CRISPR-CAS machinery are known to be one of the crucial parameters that influence the diversity, stability and resilience of a microbial community. Understanding how a microbial homeostasis is maintained would facilitate to develop novel strategy to alter microbiome as desired to manipuate mosquito traits.**Methods:** We have generated a metagenomic assembly by NGS shotgun sequencing mosquito gut microbial DNA. We also sequenced genomes of 12 bacterial strains that were isolated from the mosquito gut microbial community. CRISPR sequences were identified by using CRISPR finder, and phage sequences were identified by PHAST. Functionality of the I-F type of CRISPR-CAS was tested by efficiency of transformation of plasmids with engineered protospacers.**Results:** We have identified type I-F and I-E subtypes of CRISPR-CAS immune system as well as prophages in the metagenomic assembly from the mosquito gut. The sequences were confirmed in the single bacterial genomes of *Serratia* and *Acinetobacter*, both were isolated from the mosquito gut. The I-F type of CRISPR-CAS in *Serratia* strain was functional, which was demonstrated by the ability to degrade plasmids with engineered protospacers that match with the spacers in the CRISPR arrays. Prophage sequences were present in the Serratia genome, which was inducible upon the treatment with mitomycin C *in vitro*. The interactions between CRISPR-CAS and phages are under investigation.**Conclusions:** Phage delivered CRISPR machinery as antimicrobials has been used for eliminating target bacteria in a metagenome. This approach can be used for manipulating mosquito gut microbiome by targeting specific bacterial members, which may lead to a synthetic microbiome for mosquito control.

Microbial Diversity Recovery in Reclaimed Surface Coal Mine Soils in the Appalachian Mountains, West Virginia

Author Block:

D. H. Huber, A. Hass, S. A. Malkaram, K. Barry, N. Montenegro-Garcia, U. K. Reddy; West Virginia State Univ., Institute, WV

Abstract Body:

Surface coal mining in the forested Appalachian Mountain region is followed by reclamation methods that are expected to restore the landscape and vegetation to a state similar to the original. Soil restoration is an important objective as well because soil structure is also destroyed. However, the extent to which current reclamation methods lead to the recovery of soil microbial diversity following severe disturbance is still not well known. We tested the hypothesis that soil structure (organic matter) will recover and microbial diversity will increase with time following standard reclamation protocols. We sampled surface coal mine sites near Charleston, West Virginia that differed in the amount of time since reclamation was begun. Four different mine sites showed a positive correlation ($R^2 = 0.81$) between time since reclamation and accumulation of soil organic matter. Metagenomic sampling was done from two sites separated by nineteen years post-reclamation: site 4M is recent, site W94 is older. Illumina sequencing produced 8 Gb of sequence from each site, representing triplicate sampling. Sequences were analyzed using the metAMOS suite of programs. Taxonomic profiling was done using Metaphyler which uses a set of 31 phylogenetic marker genes rather than simply 16S rRNA. The dominant bacterial phylum in both sites was Proteobacteria, ranging from 54 to 61% abundance. Actinobacteria were more abundant in the recently disturbed 4M site (23%) compared to W94 (12%). In contrast, Acidobacteria increased 10-fold in the older site W94 (2.3%) compared to 4M (0.23%) which is consistent with their known widespread occurrence in natural soils. Based on 16S rRNA genes, the Acidobacteria were also found to be more diverse in the older reclaimed soil. Verrucomicrobia, which are known to be a component of natural soils, also increased in abundance over time: none detected in 4M samples and 0.2% detected in W94. In conclusion, time since reclamation was associated with an increase of soil organic matter and an increase in the diversity and abundance of Acidobacteria and Verrucomicrobia.

Species-specific and Temporal Shifts in Carbon Utilization Strategies Among Filamentous Ascomycete Fungi

Author Block:

C. A. Zeiner[1], S. O. Purvine[2], E. Zink[2], S. Wu[3], L. Pasa-Tolić[2], D. L. Chaput[4], C. M. Santelli[5], C. M. Hansel[6]; [1]Boston Univ., Boston, MA, [2]Pacific Northwest Natl. Lab., Richland, WA, [3]Univ. of Oklahoma, Norman, OK, [4]Smithsonian Inst., Washington, DC, [5]Univ. of Minnesota, Minneapolis, MN, [6]Woods Hole Oceanographic Inst., Woods Hole, MA

Abstract Body:

Fungi generate a wide range of extracellular oxidative enzymes and reactive metabolites, collectively known as the secretome, that synergistically drive carbon (C) degradation in the environment. While secretome studies of model organisms have greatly expanded our knowledge of these oxidative enzymes, few have extended secretome characterization to environmental isolates or directly compared temporal patterns of enzyme utilization among phylogenetically diverse species. Thus, the mechanisms of C degradation by many ubiquitous soil fungi remain poorly understood. Here we use a combination of quantitative iTRAQ proteomics and custom bioinformatic analyses to compare the protein composition of the secretomes of four Mn(II)-oxidizing Ascomycete fungi over a three-week time course. We demonstrate that although the fungi produce a similar suite of extracellular enzymes, they exhibit striking differences in the regulation of these enzymes among species and over time, revealing species-specific and temporal shifts in C utilization strategies as they degrade the same substrate. Specifically, our findings suggest that *Paraconiothyrium sporulosum* AP3s5-JAC2a and *Alternaria alternata* SRC1lrK2f employ sequential enzyme secretion patterns concomitant with decreasing resource availability, *Stagonospora* sp. SRC1lsM3a preferentially degrades proteinaceous substrate before switching to carbohydrates, and *Pyrenochaeta* sp. DS3sAY3a utilizes primarily peptidases to aggressively attack C sources in a concentrated burst. This work highlights the diversity of operative metabolic strategies among cellulose-degrading Ascomycetes and enhances our understanding of their role in C turnover in the environment.

Publishing Title:

Strain-Specific Metatranscriptomic Evidence of Pervasive and Diverse Chemolithoautotrophy Relevant to C, S, N, and Fe Cycling in a Shallow Alluvial Aquifer

Author Block:

H. R. Beller, T. N. M. Jewell, U. Karaoz, E. L. Brodie, K. H. Williams; Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

Groundwater ecosystems are conventionally thought to be fueled by surface-derived allochthonous organic matter and dominated by heterotrophic microbes living under often-oligotrophic conditions. However, in a two-month study of nitrate amendment to a perennially suboxic aquifer in Rifle (CO), strain-resolved metatranscriptomic analysis revealed pervasive and diverse chemolithoautotrophic bacterial activity relevant to C, S, N, and Fe cycling. Prior to nitrate injection, anaerobic ammonia-oxidizing (anammox) bacteria accounted for 16% of overall microbial community gene expression, whereas during the nitrate injection, two other groups of chemolithoautotrophic bacteria collectively accounted for 80% of the metatranscriptome: (1) members of the Fe(II)-oxidizing Gallionellaceae family and (2) strains of the S-oxidizing species, *Sulfurimonas denitrificans*. Notably, the proportion of the metatranscriptome accounted for by these three groups was considerably greater than the proportion of the metagenome coverage that they represented. Transcriptional analysis revealed some unexpected metabolic couplings, in particular, putative nitrate-dependent Fe(II) and S oxidation among nominally microaerophilic Gallionellaceae strains, including expression of periplasmic (NapAB) and membrane-bound (NarGHI) nitrate reductases. The three most active groups of chemolithoautotrophic bacteria in this study had overlapping metabolisms that allowed them to occupy different yet related metabolic niches throughout the study. Overall, these results highlight the important role that chemolithoautotrophy can play in aquifer biogeochemical cycling, a finding that has broad implications for understanding terrestrial carbon cycling and is supported by recent studies of geochemically diverse aquifers.

Bacterial Growth In Coastal Marine Waters Estimated By Metagenomics And Metatranscriptomics

Author Block:

B. J. CAMPBELL[1], D. Kirchman[2]; [1]Clemson Univ., Clemson, SC, [2]Univ. of Delaware, Lewes, DE

Abstract Body:

Background: Microbial abundance is typically used as an indicator for microbial contributions to ecosystem processes. However, abundance does not account for differences in growth rates or activity of microbes. Based on prior work with 16S rRNA:rRNA gene ratios, we hypothesized that the most abundant groups may not be the most active. **Methods:** We used estimates of the expression and abundance of genes found in different cellular processes to explore seasonal activity and growth rates of bacterial taxa in coastal Delaware waters. We calculated the relative abundance of different classes of genes found in the metagenomes and metatranscriptomes from three different seasons based on both unassembled and assembled datasets. The gene classes included all assigned functional genes, different growth-related genes, rRNA, as well as those for common carbon and other metabolic pathways.**Results:** Most taxa had equal representation in the metagenome and metatranscriptome in December. However, growth-related gene clusters of many taxa were significantly more or less represented in the metatranscriptomes of samples collected in March or May. Our results suggest that abundant SAR11 and *Flavobacterales* clades grew slower than their abundance would indicate, while many *Rhodobacterales* and *Gammaproteobacteria* grew faster than expected, especially in March and May.**Conclusions:** These results highlight the power of comparative metagenomics/metatranscriptomics to explore growth rates of individual taxa and their contributions to ecosystem processes.

Impact of Seven Years of Glyphosate-Resistant Corn and Glyphosate Applications Under Conventional and Reduced Tillage on Bulk and Rhizosphere Soil Nitrification Rates and Distribution of Archaeal and Bacterial Nitrifying Communities

Author Block:

M. B. Jenkins[1], M. A. Locke[1], K. N. Reddy[2], D. S. McChesney[1], R. W. Steinriede[1]; [1]USDA-Agriculture Res. Service, Oxford, MS, [2]USDA-Agriculture Res. Service, Stoneville, MS

Abstract Body:

Background: Conservation tillage practices across the country have been implementing genetically engineered glyphosate resistant corn (GM) crops along with applications of the herbicide glyphosate (gly). We tested the null hypothesis that six and seven years of glyphosate applications to both glyphosate resistant and non-resistant corn (nonGM) under conventional tillage (CT) and reduced tillage (RT) would not impact the soil process of nitrification and the distribution of archaeal and proteobacterial nitrifying communities.**Methods:** The experimental design was a randomized complete block with glyphosate resistant (GR) and non-GR corn, with and without glyphosate applications under CT and RT. Nitrification rates of bulk and rhizosphere soils were determined and the data generated were regressed against four exoenzymes (exoenzymes , β-glucosidase (BG), β-N-acetylglucosaminidase (NAG), leucine aminopeptidase (LAP), acid phosphatase (AP)) involved in the initial steps in organic matter mineralization, and their nutrient acquisition ratios. With qPCR total archaeal and proteobacterial components of the soil microbiomes, and archaeal and proteobacterial ammonia monooxygenase gene (*amo*A) were determined.**Results:** In 2013 the nonGM-nogly treatment associated with both bulk and rhizosphere soils under RT displayed greater ($P < 0.05$) nitrification rates than other treatments. In 2014 nitrification rates of GM-nogly treatments associated with rhizosphere soil and RT were greater ($P < 0.05$) than other treatments. In 2013 correlations were observed between nitrification rates and BG:AP acquisition ratios in bulk soil no-gly treatments. In 2014 analogous correlations were observed in bulk soil +gly BG:AP and (LAP+NAG):AP ratios. Preliminary data on qPCR ratios between archaeal and proteobacterial *amo*A gene indicated differences between +gly and nogly treatments.**Conclusions:** Glyphosate applications appeared to affect nitrification rates, and the distribution of the arachaeal and proteobacterial nitrifying communities, but not the relation between nitrification and nutrient acquisition ratios related to C:P and N:P.

Primer Development to Target N_2O-Producing Fungal Community

Author Block:

H. Chen, W. Shi; North Carolina State Univ., Raleigh, NC

Abstract Body:

Background: Fungal denitrification has been increasingly investigated as an important biological source of N_2O, an important greenhouse gas and ozone-depleting substance. But the community ecology of N_2O-producing fungi is still poorly understood due to the lack of culture-independent tools, such as PCR primers.**Methods:** Degenerate primers that target fungal nitrite reductase gene (*nirK*) and nitric oxide reductase gene (P450nor), the two important genes for regulating fungal N_2O-production were designed based on the conservative protein and DNA regions in public databases and evaluated for primer specificity and efficiency using a number of N_2O-producing fungal cultures and agricultural soil samples.**Results:** Four pairs of fungal *nirK*-targeting primers (FnirK_F1/R1, F1/R2, F2/R2, and F3/R2) were developed, among which FnirK_F3/R2 appeared to be more efficient as this pair amplified ~ 80% of tested fungal cultures, including *Aspergillus*, *Fusarium*, *Penicillium*, and *Trichoderma*, etc. The soil clone sequences amplified by FnirK_F3/R2 were distributed not only in the clusters of fungal cultures isolated from the soil sample (e.g., *Fusarium* and *Aspergillus*), but also in the clusters of *Chaetomium*, *Metarhizium*, and *Myceliophthora*, which were failed to be isolated from the soil sample in our previous work. However, some bacterial *nirK* could also be amplified due to high similarities between fungal *nirK* and bacterial type II *nirK*. A pair of degenerate primers that target P450nor genes was also proved to be able to amplify diverse groups of N_2O-producing fungi from fungal cultures and soil samples. The amplicons were shown to phylogenetically relate to known denitrifying fungi.**Conclusions:** Our primers that target fungal *nirK* and P450nor genes were proved to have the wide-range capability of amplifying diverse denitrifying fungi from the environment. However, the P450nor-targetting primers may be better than *nirK*-targeting primers to explore N_2O-producing fungal community in the environment, given that high similarities between fungal *nirK* and bacterial type II *nirK* could limit the specificity of fungal *nirK* primers.

Circular Resource Flow of Wood Ash into Forest Can Have Detrimental Effects on Soil Bacterial Community

Author Block:

J. T. Nielsen[1], T. Bang-Andreasen[2], **C. S. Jacobsen**[2]; [1]Copenhagen Minicipality, Copenhagen, Denmark, [2]Aarhus Univ., Copenhagen, Denmark

Abstract Body:

Background: The high alkalinity of the waste product and fertilizer wood ash might have detrimental effects on forest soil microbial communities, hence the many essential microbial driven processes which maintain soil quality. Here we investigated responses in bacterial community in a Spruce forest soil to wood ash addition using both culture-dependent and -independent methods to obtain high resolution insight into bacterial responses.**Methods:** Microcosms were set up using soil from the O horizon of a Danish spruce plantation mixed with ash, acquired from a Danish heating plant, to the final doses of 0, 3, 12 and 90 t ash · ha^{-1} and incubated for 42 days at 10 °C. Different soil parameters were monitored during incubation: pH; quantification of viable bacteria, spore-forming bacteria and *Pseudomonas* species using agar plates with general and selective media; changes in bacterial community by Illumina MiSeq paired-end sequencing of 16S rRNA gene amplicons.**Results:** Results showed increase in pH with increasing doses of wood ash. Stimulation of the number of culturable bacteria were observed up to the dose of wood ash 12 t ha^{-1}, while a drastic decrease were observed at 90 t ha^{-1}. Substantial change in the dominant taxonomic groups was observed following the addition of wood ash and the different ash doses resulted in clearly distant bacterial community structures. Decrease in bacterial richness was observed for soil with added ash doses of 12 and 90 t ha^{-1}.**Conclusions:** Wood ash in high levels added to forest soil has detrimental effects on soil bacteria

Bacterial Communities in Cultivated and Wild Cranberry Bogs

Author Block:

G. Ebadzad, S. R. Gadagkar, **S. Soby**; Midwestern Univ., Glendale, AZ

Abstract Body:

Background: The effects of cultivation on soil microbial populations are largely unknown. Transitions in microbial population structure between fallow and cultivation, or between virgin and cultivated soils may be an important early determinant of the fertility and capacity for disease-suppression of the cultivated soil, as well as a predictor of recovery following a period of intensive agriculture. Cranberry bogs are a good model system for comparing microbes associated with native and cultivated soils because of the genetic similarity between wild and domesticated cranberry plants, and their location in the same geographic region (*e.g.* southeastern Massachusetts).**Methods:** Soil samples were collected from wild and cultivated cranberry bogs over the course of the growing season for several years to determine the diversity and composition of the respective phytobiomes in native and cultivated cranberry bogs. Population structures were determined by pyro-sequencing of the amplified V4 region of 16S rRNA genes. Paired-end reads were assembled using PANDAseq, and subsequently analyzed using the QIIME software package to call operational taxonomic units and to calculate richness and diversity indices.**Results:** Bacterial communities in both cultivated and wild bogs are composed of five dominant phyla, *Proteobacteria*, *Acidobacteria*, *Bacteriodetes*, *Verrucomicrobia* and *Actinobacteria*, but with different relative abundances, indicating possible descriptive population structures for each bog type.**Conclusions:** Principal Components Analysis based on soil bacterial populations among sampled sites suggest that sampling location or soil type are more important than cultivation effects in determining bacterial community structure.

Abundance and Diversity of Nitrite-Dependent Anaerobic Methane-Oxidizing Bacteria in a Flooded Rice Paddy Supplied with Different Amounts of Urea

Author Block:

S. Jeong, H. Lee, C. Jeon; Chung-Ang Univ., Seoul, Korea, Democratic People's Republic of

Abstract Body:

The nitrite-dependent anaerobic methane oxidation (n-damo) process that oxidizes methane using nitrite under anaerobic conditions is known to be accomplished by "*Candidatus* Methylomirabilis oxyfera" belonging to the candidate phylum NC10. *M. oxyfera*-like bacteria have been detected in rice paddies, but the ecology of *M. oxyfera*-like bacteria in rice paddies was rarely explored. The aim of this study was to investigate the abundance and diversity of n-damo bacteria in a flooded rice paddies supplied with different amounts of urea. Different amounts of urea (0, 15, 30, and 60 $kgha^{-1}$) were applied three times to a flooded rice paddy at - 1, 15, and 45 days based on the transplantation of a rice cultivar (*Oryza sativa*). Soil cores were sampled from each treatments at a flowering stage (63 days after rice transplantation, 18 days after third urea application). The soil cores were divided into top (0-5 cm), middle (10-15 cm), and bottom (20-25 cm) layers and the diversity and abundance of *M. oxyfera*-like bacteria were investigated using t-RFLP (terminal-Restriction Fragment Length Polymorphism) and quantitative PCR approaches, respectively. A 16S rRNA gene clone library of *M. oxyfera*-like bacteria in the rice paddy was constructed and a phylogenetic tree was built, showing that *M. oxyfera*-like bacteria were divided into five clades (group a, b, c, d and e). Using an online program (Restriction Enzyme Picker Online), *NciI* was selected as a suitable restriction enzyme to discriminate the *M. oxyfera*-like bacterial groups by t-RFLP. The clade d was not detected and the relative abundance of clades a and e were detected as minor clades, but abundance of *M. oxyfera*-like bacteria in a flooded rice paddy was not significantly different depending on the amount of urea application. However, the T-RFLP analysis showed that the clades b and c were dominant clades in all depths; in particular, the relative abundance of clade c were higher along a depth gradient in all urea applications, suggesting that *M. oxyfera*-like bacterial community differed depending on the depth of rice paddy.

Incidence and Ecology of *Salmonella enterica* in Public Access Watersheds in the Leafy Green Growing Region of Central California

Author Block:

L. Gorski, A. S. Liang, S. Walker, K. F. Romanolo; USDA, ARS, WRRC, Albany, CA

Abstract Body:

Consumption of contaminated produce accounts for nearly half of the foodborne illness outbreaks in the United States, and leafy greens account for a majority of produce outbreaks and recalls. Produce can become contaminated pre-harvest via contaminated water or through wildlife, and public access waterways provide a central reservoir for pathogen contamination. We are in year 4 of a 5-year survey of several public access watersheds in a major leafy green production region of Central Coastal California to determine the prevalence of foodborne pathogens, including *Salmonella enterica*. The watershed is never used for field irrigation directly, but is available to wildlife, and serves as an indicator of the levels of these foodborne pathogens in the environment.At least twice monthly Moore swab samples were collected from lakes, streams, rivers, and ponds for up to 24 hours to allow sampling of flowing water and sediment over an extended period of time. Sampling was done at 30 sites within a 500 square mile region of the Salinas Valley. Following enrichment and selection on XLD and MSRV media, *Salmonella*-presumptive colonies were confirmed by PCR. Subtyping analysis consists of rep-PCR, Pulsed-field gel electrophoresis (PFGE), and serotype analysisAfter 4 years and analysis of over 2500 samples, overall *Salmonella* prevalence was 56% among 5 interconnected watersheds, and statistical analysis indicated no significant differences between watersheds or the season. To date 1567 individual isolates of *Salmonella* are being analyzed for serotype. Over 50 different serotypes have been identified, and the top 3 are monophasic 6,8:d:-, followed by Give, and Typhimurium. Other serotypes of note that have been identified with regularity were Oranienburg, Infantis, Enteritidis, and Heidelberg. Some serotypes were localized to certain watersheds, and others were distributed among the whole region. Comparisons of PFGE profiles of *Salmonella* isolates isolated over 7 years of surveys indicates that some strains persist in the region, possibly cycling between water and wildlife. Comparison of our results with those from studies of *Salmonella* serotype distribution in other regions of the United States indicates that there may be regional biases in serotype.

Agricultural Soil Management Effect on Plant Growth Promoting Rhizobacteria Diversity

Author Block:

B. Lee, A. Caldwell, C. Ouverney; San Jose State Univ., San Jose, CA

Abstract Body:

Substituting agrochemicals with beneficial microbes, such as plant growth promoting rhizobacteria (PGPR), is a promising strategy to fertilize soils and mitigate the detrimental effects of agricultural intensification. PGPR have intrinsic properties, such as promoting phosphate (P) solubilization that can be utilized in PGPR poor systems to improve plant growth. Culture-based studies of PGPR provide a limited understanding of the complex interactions within the rhizosphere, regions near plant roots. We implemented culture-independent techniques to survey the bacterial diversity and to identify key PGPR groups in the rhizosphere of coffee plants grown under different agricultural practices. We were interested in bacterial groups associated with P cycling as a source of novel bio-inoculant candidates. Genomic DNA was extracted from 90 soil samples collected from three coffee farms, in Brazil, with distinct farming practices: Intensive, transitional, and organic. Amplicons of the V4 hypervariable region of the 16S rRNA marker gene were generated by Illumina sequencing. After performing quality control on the sequences with Trimmomatic, millions of pair-ended reads were further analyzed with the mothur pipeline and visualized with R. The bacterial consortia statistically differed in each farm based on the Analysis of Molecular Variance of the Operational Taxonomic Units (OTUs) clustered at 97% similarity ($p<0.001$). Of the OTUs discovered in the coffee rhizosphere, 3% of them were unique to each coffee farm. These discriminatory sequences could serve as signature identifiers of agricultural practices. *Arthrobacter*, *Bacillus*, *Bradyrhizobium*, and *Pseudomonas* were the dominating P-solubilizing genera identified in the coffee farms. *Bradyrhizobium* positively correlated with organic and transitional practices, while *Bacillus* and *Pseudomonas* positively correlated with intensive practices. Most of the bacteria in the three farms are not yet characterized. Our findings indicate that agricultural practices have a significant influence on the bacterial diversity in the rhizosphere. Furthermore, novel bacteria identified from the farms could serve as potential PGPR inoculants to enhance P utilization efficiency, improving the sustainability of high agricultural demands.

N_2O Consumption by G*emmatimonas aurantiaca* under Aerobic and Anaerobic Culture Conditions

Author Block:

R. A. Sanford[1], J. Chee-Sanford[2]; [1]Univ. of Illinois Urbana-Champaign, Champaign, IL, [2]USDA-ARS, Urbana, IL

Abstract Body:

Bacteria affiliated with the phylum Gemmatimonadetes are abundant in many soil microbial communities. In addition, soil metagenomes have revealed that the nitrous oxide reductase (*nosZ*) gene associated with this group is also common in soils, which is of interest since N_2O is a greenhouse gas. NosZ catalyzes the terminal step in denitrification. The only cultured representative of this group, *Gemmatimonas aurantiaca*, has never been reported to grow anaerobically with N_2O as the electron acceptor or under any denitrifying growth conditions even though it possesses a *nosZ* gene. Our experimental objective was to evaluate this organism's ability to use N_2O as an electron acceptor for growth. The ability to denitrify using nitrate or nitrite was also tested even though no nitrate reductase gene has been identified in the genome. Cultures started under anaerobic conditions on nitrate, nitrite or N_2O failed to grow or show depletion of these substrates. Nitrate and nitrite also failed to be used even when cells were grown aerobically with the O_2 allowed to deplete first. N_2O reduction only commenced in the presence of O_2 and continued to be depleted when refed to the culture. *G. aurantiaca* cells grown aerobically with N_2O were diluted by 50% into fresh anaerobic, microaerobic (5% O_2) or fully aerobic medium containing 1% N_2O. After 48h, 36.8%, 30.5%, and 15.4 % of the N_2O added was reduced in anaerobic, microaerobic and aerobic cultures, respectively. After 7 days, the microaerobic N_2O reduction reached 81.6%, slightly greater than that observed anaerobically (79.3%) even though O_2 was still detected in the headspace. Controls showed no loss of N_2O. CO_2 generation occurred under all conditions. Results show that *G. aurantiaca* does use N_2O as an e- acceptor, however it does not grow as a typical denitrifier. Evidence also suggests that this aerobic organism may reduce N_2O even in the presence of O_2 and that only under high O_2 conditions is the N_2O reduction rate reduced. Our results demonstrate that N_2O consumption may be mediated in soil by members of the Gemmatimonadetes, incapable of typical denitrification, but representing a potential sink for this greenhouse gas.

Farming Systems Modify the Impact of Inoculum on Soil Microbial Diversity

Author Block:

S. L. Ishaq[1], S. P. Johnson[1], Z. J. Miller[2], E. A. Lehnhoff[3], C. J. Yeoman[1], F. D. Menellad[1]; [1]Montana State Univ., Bozeman, MT, [2]Montana State Univ., Conrad, MT, [3]New Mexico State Univ., Las Cruces, NM

Abstract Body:

Background: This study hypothesized that bacterial diversity in soil growing redroot pigweed (*Amaranthus retroflexus* L.) or wild oat (*Avena fatua* L.) would differ using soil inoculum from organic or conventional farms. **Methods:** Eight paired USDA-certified organic (tillage-intensive diverse crop rotation) and conventional (no-tillage wheat-fallow rotation) farms in north-central Montana, growing wheat or *Triticum turanicum* Jakubz. (var. Kamut), a close relative, had soil sampled and used as living or sterile (autoclaved for two 1 hr sessions 24 hr apart) inoculant into potting soil to examine biotic influences. *A. retroflexus* or *A. fatua* was planted and grown for 16 wk, after which the 16S rRNA gene V3-V4 region was sequenced by Illumina MiSeq, and analyzed using PANDAseq, MOTHUR, R, and PRIMER-E. **Results:** Treatments clustered (AMOVA, ANOSIM, UniFrac, $P < 0.05$), with living/sterile inoculum being the largest delineating factor (ANOSIM $R = 0.492$). Living was more diverse than sterile (Shannon, Inverse Simpson, $P < 0.05$), shared the most taxa within the treatment, and had more discriminant taxa ($P < 0.05$). Organic had more diversity (Shannon, $P < 0.05$) and discriminant taxa ($P < 0.05$) than conventional. The most abundant genus, of 854 found, was *Arthrobacter* (up to 13% abundance). Proteobacteria was most abundant (35 - 50% abundance), followed by Actinobacteria (11 - 24% abund.). Farm pair 1 (organic and conventional) with sterile inoculum and *A. fatua* had more Firmicutes (19.7% and 22.6% abund., respectively) than other samples (2.3 - 6.9% abund.). Living soil had more ($P < 0.05$) Chloroflexi, unclassified bacteria, and especially Acidobacteria (mean 7.2% versus sterile mean 3.8% abund.), and sterile had more Bacteroidetes, Firmicutes, Gemmatimonadetes, and especially Verrucomicrobia (mean 3.9% versus living mean 1.5% abund.). Cyanobacteria were higher in soil from three organic farms growing *A. retroflexus* for living (9.8 - 11.6% abund.) and sterile soil (8.9 - 10.5% abund.), than other samples (1 - 7.7% abundance). **Conclusions:** Living organic soil inoculum increased diversity and selected for certain bacteria, consistent with previous studies. A complementary study indicated that diverse soil microbiota is associated with increased crop-weed competitive ability.

Microbial Activity of Cemetery and Agricultural Soils on Maryland's Eastern Shore

Author Block:

E. A. B. Emmert, C. H. Briand, A. Hawkins, G. Seho-Ahiable, A. Evans, K. Baker, A. Mrozinski, S. Geleta; Salisbury Univ., Salisbury, MD

Abstract Body:

Anthropogenic activities on the Eastern Shore of Maryland have caused soil erosion and degradation due to deforestation, intensive agriculture, and poor soil conservation practices. Geleta et al (2014) compared the physical and chemical properties of agricultural soil to that of soil in small, undisturbed family cemeteries on Maryland's Eastern Shore. Farm fields surrounding the cemeteries were eroded with the cemeteries as elevated regions within the fields. Agricultural fields contained lower organic matter, carbon, and total nitrogen compared to the cemetery soils. Since microbes are essential for maintaining soil fertility, we examined the microbial activity in these soils to determine the effect of human activity and agriculture on soil health. We sampled seven sites in Wicomico County, Maryland containing a family cemetery and a surrounding agricultural field (5 sites) or suburban lawn (2 sites). We collected soil monthly for a year from both the cemeteries and adjacent fields or lawns and measured microbial activity in all soils via fluorescein diacetate hydrolysis (FDA) and dehydrogenase activity. FDA results were more consistent among sites compared to dehydrogenase activity. Of the 83 soil sample pairs across all 12 sampling dates and 7 sites, 57% exhibited significantly greater ($P \leq 0.05$) FDA hydrolysis in the cemetery soil compared to the agricultural or lawn soil. However dehydrogenase activity was only significantly higher in cemetery soils for 27% of the soil sample pairs. Much less frequently did the agricultural or lawn soil have significantly higher microbial activity compared to the cemetery soil (10% of sample pairs for FDA and 7% for dehydrogenase). Both measurements for soil microbial activity were highest in the spring and lowest in late summer at all seven sites. Based on the more consistent measurement of FDA hydrolysis, microbial activity is greater in cemetery soils, supporting the earlier work of Geleta et al, and providing additional evidence to suggest human activity has greatly altered the physical, chemical, and biological properties of these soils.

Impact of Winter Cover Crops on Microbial Soil Activities in Tillage and no Tillage Soybean Fields

Author Block:

H. L. TYLER; USDA-ARS, Stoneville, MS

Abstract Body:

Conventional agriculture has negative effects on soil quality and several conservation practices have been implemented to alleviate these effects. The practices of no tillage and winter cover crops can improve soil structure and lead to the accumulation of plant residues in soil. Agricultural management practices impact soil microbial communities, which play an important role in nutrient mineralization and organic matter turnover. The effect of different tillage and cover crop treatments on soil microbial activity in soybean (*Glycine max* L.) fields was examined in a study conducted in Stoneville, Mississippi. The experiment was set up as a randomized block with four blocks of tillage or no tillage plots, each planted with winter cover crops of elbon rye (*Secale cereal* L.), crimson clover (*Trifolium incarnatum* L.), or no cover crop. Soil samples were collected prior to cover crop planting in the fall, at spring soybean planting, and once a month over the course of the summer growing season. All samples were assayed for the activities of enzymes linked to organic matter processing (cellobiohydrolase and β-glucosidase), nutrient mineralization (phosphatase and N-acetylglucosaminidase [NAGase]), and general microbial activity (fluorescein diacetate [FDA] hydrolysis). Differences between treatments varied over the course of the growing season, but with the exception of phosphatase and FDA, cover crops had a greater impact on enzyme activities than tillage. All enzyme activities assayed were significantly higher in rye than non-cover crop plots for most of the growing season ($p<0.05$), up to 84 and 87% in the cases of cellobiohydrolase and NAGase. With crimson clover, NAGase, phosphatase, and FDA hydrolysis were higher than non-cover crop plots ($p<0.05$), but tended to be lower than rye plots, increasing activity by no more than 50%. These results indicate the organic matter deposited by cover crops, particularly rye, fuels microbial organic matter turnover and nutrient cycling over the entire soybean growing season. This enhancement of microbial activity can promote soil fertility and could potentially minimize the need for fertilizer application. Future work will examine microbial activity and community composition, as well as soil nutrient levels, over successive growing seasons to gain a better understanding of how cover crops and no tillage enhance soil biological quality.

Differential Responses in Nitrogen Cycling Processes By Soil Microorganisms Exposed to Diurnal- versus Constant Temperature Conditions

Author Block:

J. C. Chee Sanford[1], L. Connor[1], E. Claussen[2], J. Marqui[2], R. Sanford[2]; [1]USDA-ARS, Urbana, IL, [2]Univ. of Illinois, Urbana, IL

Abstract Body:

The recurring spatiotemporal patterns observed in agricultural soil microbial communities largely occur due to legacy effects from long-term responses to annual climate cycles and cropping systems. Temperature (T) effects on soil microbes are well known but often observed using a fixed mean T, yet large diurnal swings occur seasonally, especially in surface (0-5cm) soils. Here, we looked closely at how soil diurnal T influences microbial N- and C- cycling and related gene expression. Triplicate microcosms with soils taken at 0-5 cm and 20-30 cm from an agricultural field (Havana, IL) were amended with urea-ammonium-nitrate and incubated under a 24h T regimen typical of June diurnal cycles; 18.9°C-37°C (large T flux, mean 25°C, 0-5 cm depth) and 23°-25°C (near constant T flux, mean 24°C, 20-30 cm depth). Unamended controls (No N added) were set up in parallel. N-compounds and CO_2 were measured over 21d along with community T-RFLP profiling and qPCR of 16S rRNA-, *nosZ, amoA, nrfA* genes (DNA) and gene transcripts (cDNA). The net cumulative N_2O concentrations were highest in the 0-5 cm soil under large diurnal T flux throughout the 21d with the highest net N_2O production rate occurring after 24h (76 nmol/d), greater than any other soil treatment. Net cumulative N_2O in the 0-5 cm soil under near constant T were next highest and were always greater than any 20-30 cm soil microcosm at any time. Net CO_2 production was highest in the 0-5 cm soils, however a greater flux was observed with the 18°C diurnal T change, 1250- vs 1131 nmol CO_2 after 21d, respectively. Measured processes were similar in the 20-30 cm soils regardless of T. Microbial communities showed distinctions at soil depths, but shifted accordingly with activity measurements upon exposure to treatments. Collectively, the data suggests surface soils harbored populations that were differentially active in response to T and distinct from those at the 20-30 cm soil depth, the latter exhibiting similar characteristics regardless of temperature. Overall, we showed significant differences in how microbial communities can respond to natural diurnal temperature conditions in contrast to fixed temperatures, with impact particularly attributed to surface soils on gaseous N-losses and greenhouse gas emissions.

Ancient Gut Resistomes are Reservoirs of Antimicrobial Resistance Genes

Author Block:

T. Santiago-Rodriguez[1], J. Pace[2], G. Fornaciari[3], S. Luciani[4], G. A. Toranzos[5], **R. J. Cano**[1]; [1]California Polytech. State Univ., San Luis Obispo, CA, [2]ATCC-CTM @ ILSE, Union, NJ, [3]California Polytech. State Univ., Pisa, Italy, [4]Univ. of Camerino, Camerion, Italy, [5]Univ. of Puerto Rico, Rio Piedras, PR

Abstract Body:

Background: Up to 50% of antimicrobials in the USA are inappropriately prescribed, leading to antimicrobial-resistant (AMR) bacteria, a public health hazard. Also, antimicrobials in animal feed as growth promoters exacerbate this problem. Recent data provide insights into ancient human gut microbiomes as reservoirs of AMR genes and represent an opportunity to study the evolution of AMR genes prior to the antimicrobial era.**Materials and Methods:** Metagenomic analyses were conducted to identify sequences homologous to antibiotic-resistance genes in seven mummified human gut remains. DNA was sequenced using an Illumina MiSeq and the pair-ends joined using QIIME 1.9. Contigs were assembled using the CLC software and BLASTx carried out against the CARD database. The results were parsed based on the type of antibiotic.**Results:** AMR classes identified included β-lactamases, mutated penicillin-binding proteins (PBPs), multidrug transporters and resistance to quinolones, tetracyclines and vancomycin. Several taxa, including genera in the Enterobacteriaceae and Clostridiaceae carried the *mutS* and *mutL*, which mediate mutator phenotypes. Categories associated with β-lactamases, resistance to tetracycline and vancomycin were the most abundant. Four classes of β-lactamases were identified including Class A, C and D, and metallo-β-lactamases, with the Proteobacteria as the major reservoir. 30 different tetracycline-resistance determinants, including efflux pump proteins, ribosomal protection and inactivating enzymes were present. Firmicutes, Proteobacteria, Actinobacteria and Bacteroidetes were the primary reservoirs. Vancomycin-resistance genes associated with the VanA, VanB, VanC and VanD phenotypes were identified, as well as genes of the vancomycin-resistance operon, including *vanB, vanR, vanH* and *vanS*. *Enterococcus faecalis* and *E. faecium* were the primary reservoirs of resistance genes in the mummified gut remains.**Conclusions:** This study suggests that antibiotic-resistance may not necessarily be solely associated with antibiotic misuse and predates antibiotic therapy, and that the gut microbiome can serve as reservoirs for AMR genes in humans.

Profiling of Gut Microbiota and Antibiotic Resistant Bacteria in Zoo Animals

Author Block:

Y. Li, L. Zhang, H. Wang; The Ohio State Univ., Columbus, OH

Abstract Body:

Background: Besides antibiotic selective pressure, the host gastrointestinal tract system also has a recognized contribution to antibiotic resistance (AR) ecology.**Methods:** To assess the potential impact of non-food animals and diet on AR ecology, we investigated the prevalence of AR gene reservoir, profile of antibiotic resistant bacteria in zoo animals using metagenomic approach and traditional culture dependent/independent methods. Twenty-seven zoo animal fecal samples were collected from a local zoo from 2013 to 2015. Fecal DNAs were extracted and subjected to 16S metagenomics analysis on an Illumina Miseq. Metagnomic data were processed and analyzed with Mothur (v1.36.1) and further statistical analysis was performed using R (v3.2.3). Meanwhile, representative AR gene reservoirs were examined by Taqman qPCR, and antibiotic resistant bacteria were recovered on Columbia blood agar (CBA), supplemented with antibiotics including tetracycline, erythromycin, or cefotaxime.**Results:** Our data showed that herbivores possess significantly more diversified gastrointestinal microbiota compared to carnivores, with 106 ± 25 to 63 ± 18 OTUs (p=0.015), respectively. PCA analysis and cluster analysis with Ward's Method showed that gut microbiota of herbivores and carnivores clustered to distinct groups. In addition, antibiotic resistant bacteria were found prevalent in zoo animal fecal samples, with up to 17% of recovered bacteria resistant to at least one of Tet, Erm or Ctx. Up to 9.0, 8.7, 8.2 $\log_{10}$ copies/g of *tetM*, *ermB*, and bla_{TEM} genes, respectively, were found in the zoo animal fecal samples, though the abundance of the AR gene pools varied significantly among subjects.**Conclusions:** Data from this study illustrated that zoo animal feces also disseminate antibiotic resistant bacteria and AR genes, even though these animals were not exposed to growth promoting antibiotics. Furthermore, there is a clear difference in the profiles of gut microbiota between herbivores and carnivores, which suggests that changing diet may modulate gut health.

Presence of Class 1 Integron and Multidrug Resistance in *Escherichia coli* Carried by Flies

Author Block:

T. S. Alves[1], M. M. G. Ferraz[1], J. Gurgel[1], G. H. B. Lara[2], M. G. Ribeiro[2], **D. S. Leite**[1];
[1]UNICAMP, Campinas, Brazil, [2]UNESP, Botucatu, Brazil

Abstract Body:

The flies are known for their role as vectors of various pathogens. Furthermore, recently flies have been identified as vehicles of multidrug resistant bacteria. This study aimed to characterize *Escherichia coli* isolates from flies regarding the presence of integrons, occurrence of antimicrobial resistance and virulence factors. The strains were obtained from the external surface of flies collected in dairy farm in Brazil and analyzed through antimicrobial susceptibility testing. The antibiotic resistance genes, *intI* gene and variable region 5'CS-3'CS, associated with class 1 integron, and virulence factors related to bovine diseases were investigated by PCR. Integron-positive *E. coli* were subjected to restriction fragment-length polymorphism analysis of the variable region and classified into phylogenetic groups. Statistical analysis was performed using Fisher's exact test. We isolated 135 *E. coli* from 57 flies. From these, 89/135 (65.9%) had at least one resistance gene. The highest relative frequencies were obtained for the genes *gyrA* (49.6%), bla_{TEM} (36.3%), *parC* (28.1%), and *tetA* (14.8%). Multidrug resistance (MDR, resistant to ≥ 3 antimicrobial classes) was observed in 52/89 (58.4%) isolates, and 8/89 (9%) showed class 1 integron. This eight integron-positive strains generated the same pattern in RFLP assay and were allocated in the phylogenetic group B1 (6/8), A (1/8) and D (1/8). In this study, virulence factors *hlyA* (12.4%), STa (5.6%) and *stx1* (7.9%) were associated with the absence of multidrug resistance, whereas, *eae*, K99 (F5) and LTII no showed any association. Our results indicate that flies can carry multiresistant non-pathogenic strains which contain mobile genetic elements and thus it can constitute an essential element in the spread of antimicrobial resistance in the environment and to animals of farms.

Metagenomic Survey for Important Reservoirs of Antibiotic Resistance Genes

Author Block:

C. Pal[1], J. Bengtsson-Palme[1], E. Kristiansson[2], D. Larsson[1]; [1]Univ. of Gothenburg, Gothenburg, Sweden, [2]Chalmers Univ. of Technology, Gothenburg, Sweden

Abstract Body:

Background: Use and abuse of antibiotics have increased the abundance of resistance genes in bacteria associated with humans and animals over the last 70 years. It is also possible that use of biocides and metals has contributed to the promotion of antibiotic resistance via co-selection. However, knowledge about the environments outside of the human body that may be important reservoirs of resistance genes (i.e. resistome) is currently scarce, and reliable large-scale quantitative data on the abundance and diversity of resistance genes and taxa is lacking. **Methods**: We screened metagenomes covering external environments (n=358) and animal-associated environments (n=145) from MG-RAST, and human body sites (n=350) from the Human Microbiome Project. We also conducted shotgun metagenomics for 11 samples collected from antibiotic-polluted sites in India. In total, 864 metagenomic Illumina datasets with >10 million reads (9.2 Tb of data) were investigated. Resistance genes were examined in all metagenomes using our recently developed databases of resistance genes to antibiotic (Resqu) and biocide and metals (BacMet) and taxonomic affiliations of 16s rRNA from all metagenomes were assigned by Metaxa2. **Results & conclusions:** We identified potential hotspots for resistance development, such as antibiotic-polluted environments and wastewater treatment plants, where abundance and diversity of resistance genes and mobile genetic elements (MGEs) were high. Human microbiota carried a comparatively much lower number of MGEs than do all other investigated animal and external environments, indicating a higher potential of external environments for horizontal gene transfer via MGEs. Resistance profiles of different environments clustered by habitat, as did taxonomic profiles. Most external environments hosted a larger diversity of taxa than the human microbiota, suggesting that the resistome not yet encountered in pathogens is large. Surprisingly, high numbers of resistance genes and MGEs were detected in Beijing smog, suggesting that air pollution may be important for resistance transmission. **Significance:** These results expand our knowledge of human, animal and external environmental resistomes and can aid in identifying risk environments, thereby providing guidance on risk-reducing actions.

Publishing Title:

Antibiotic Resistance Profiles Derived from Metagenome Sequencing Data are Highly Dependent on the Database Used for Analysis

Author Block:

E. Gómez-Sanz[1], S. Jaenicke[2], R. Wittwer[3], A. Goesmann[2], M. van der Heijden[3], B. Duffy[1], T. H. Smits[1]; [1]Zurich Univ. for Applied Sci., Waedenswil, Switzerland, [2]Justus-Liebig-Univ., Giessen, Germany, [3]Agroscope, Zürich, Switzerland

Abstract Body:

Here we compared the output of commonly used databases from the analysis of antimicrobial resistance (AMR) in (meta)genome sequencing data from 6 different agricultural soil systems. Four AMR databases were used: MvirDB (Zhou *et al.,* 2006), ARDB (Liu *et al.,* 2009), CARD (McArthur *et al.,* 2013) and ARG-ANNOT (Kumar Gupta *et al.,* 2014). Two soil systems were located at the Swiss alpine Glaspass: one free of and one where manure was applied over 6 centuries. The other 4 systems belong to a Swiss experimental farming trial: organic (manured) and conventional (NPK fertilization) systems ploughed and no tilled. Soil DNA was extracted and sequenced using a single run of Illumina MiSeq per per soil management system. The four databases give a relative low but consistent number of read counts for all six systems, with percentages between 0.011-0.016% (ARDB), 0.005-0.006% (ARG-ANNOT), 0.125-0.151% (CARD), and 1.115-1.694% (MVirDB). However, from the predominant hits per database and per soil, we concluded that i) number and nature of hits differed dependent on the database used, ii) hits to efflux pumps were highly abundant, and iii) resistance to fluoroquinolones, tetracyclines, aminoglycosides, macrolides-lincosamides-streptogramins, and β-lactams were most common. Comparing hits for the different soil systems from each database showed that these were very similar. MVirDB and CARD retrieved hits to a broader dataset, including more general transporters and housekeeping genes, while ARG-ANNOT gives the most specific output based on gene names. On the other hand, the reliability of the hits can be questioned for the used cutoff value in the database search. Although appearing quite widespread, AMR genes are present only at low copy numbers in Swiss soils. TaqMan qPCR assays on shared genes from the database searches are now under development to consolidate the specificity and abundance in soil samples.

Publishing Title:

A Sewage Microbiome is Dominated by *Arcobacter cryaerophilus* that Expresses Multiple Drug Resistance and Virulence Genes

Author Block:

J. A. Millar, R. Raghavan; Portland State Univ., Portland, OR

Abstract Body:

Background: Wastewater treatment plants (WWTP) are good indicators of a community's microbial burden. WWTP are also important hubs for horizontal gene transfer (HGT) of antibiotic resistance genes (ARGs) and virulence factors (VFs). *Arcobacter*, a bacterium commonly found in sewage communities, has become a growing public health concern in the past decade due to its pathogenicity and growing antibiotic resistance. Our study explored the bacterial diversity of a WWTP, and characterized the putative ARGs and VFs present in an *Arcobacter* species that dominates this microbiome.**Methods:**DNA and RNA were extracted from untreated sewage samples from Tucson, AZ over 2 days. Contigs and draft genome were assembled using IDBA and Albertsen *et al.* 2013. Gene expression was measured in CLC. ARGs and VFs were annotated using PHMMER and the ARDB and PATRIC databases. Putative HGT events were detected using HGTector and phylogenetic analyses.**Results:**15 phyla were present and stable across the three samples. We identified 162 ARGs belonging to 60 antibiotic types and 177 VFs belonging to 46 virulence categories. The emerging human pathogen *Arcobacter cryaerophilus* dominated all samples. Its draft genome contained 48 putative ARGs against 27 antibiotic types, dominant expression belonging to Tetracycline. We also found 74 putative VFs belonging to 22 virulence categories, highest expression relating to Adhesion and Invasion.The *A. cryaerophilus* genome also contained genes related to mobile genetic elements (phages, 227; transposases, 58); in sum, about 4% of its genome appears to be horizontally acquired from outside the order of Campylobacterales. Of interest, about 5% of VFs show signs of HGT, mostly relating to Intracellular Survival and Replication.**Discussion:**Our results show that even with the continuous influx of sewage, the microbial diversity in a WWTP remained constant across 25 hours, suggesting that the urban population hosts a fairly stable microbial community. Additionally, high levels of expression of ARGs among the sewage microbes indicate the presence of large number of antibiotics in the urban sewage, highlighting the urgent need to better manage antibiotic use. *A. cryaerophilus*, which contains multiple ARGs, thrive in this environment. As treatment of sewage is not always very effective, this emerging human pathogen could pose a threat to public health.

Barriers to Dissemination of Antibiotic Resistance Genes from Wastewater

Author Block:

J. Z. Kubicek-Sutherland[1], C. Weibel[1], M. O. A. Sommer[2], D. I. Andersson[1]; [1]Uppsala Univ., Uppsala, Sweden, [2]Technical Univ. of Denmark, Hørsholm, Denmark

Abstract Body:

Background: Horizontal gene transfer contributes to the spread of antibiotic resistance among bacterial pathogens. It is thought that wastewater treatment plants (WWTPs) provide an ideal location for the dissemination of resistance genes from environmental reservoirs due to the accidental exposure to pathogenic bacteria in effluent. However, recent metagenomic studies have shown that despite isolating a large number of functional resistance genes in WWTPs, these genes display little to no homology with genes found in pathogens indicating that dissemination of these genes occurs rarely. Here, we investigate some of the possible barriers of dissemination by characterizing the expression of these genes in *Escherichia coli*, a common human pathogen. **Methods:** Resistance genes that were previously isolated from several WWTPs in Denmark were cloned into a single copy vector under the control of an inducible promoter. Assessments of resistance and bacterial growth rate were made as a function of the level of induced gene expression.**Results:** A large fraction, 44% (28/64), of the WWTP genes identified by functional screens displayed no resistance compared to wild type when expressed in our system. 19% (12/64) showed intermediated resistance levels (2-5 fold over wild type). 37% (24/64) were highly resistant to antibiotics (over 5-fold) with 16 genes displaying over 50-fold increased resistance. Fitness assays indicate that over 70% of these genes exhibit a growth defect of at least 20% compared to wild type. However, 5 of 16 genes displaying high-level resistance exhibit little to no fitness defect in *E. coli*.**Conclusions:** These results indicate that the majority of resistance genes found in the WWTPs display low levels of resistance and/or a high fitness cost both of which likely circumvent their utility in pathogenic isolates. However, we did identify several genes conferring high-level resistance in *E. coli* with minimal fitness effects, which should be characterized further as these may be of future clinical importance. Understanding the dynamics of horizontal gene transfer between pathogens and their environment will aid in the development strategies to control the emergence of antibiotic resistant pathogens.

High Diversity Of Environmental A*cinetobacter S*pecies Recovered from Mexican Rivers Uncovered with A Novel MLSA Scheme Reveals Contrasting Patterns Of Antimicrobial Resistance And Mobile Genetic Elements

Author Block:

L. Ochoa Sánchez, J. Rivera, P. Vinuesa Fleischmann; Univ. Natl. Autónoma de Mèxico-CCG, Cuernavaca, Morelos, Mexico

Abstract Body:

Background: *Acinetobacter* is an important genus because some species cause extremely serious problems in hospitals due to antimicrobial and antiseptic resistance. Little is currently known about the genetic diversity and distribution of the genus in natural environments. There isn't an MLSA scheme available for this genus. An MLST scheme is available only for *A. baumanni*. Here we report an MLSA study of environmental *Acinetobacter* strains isolated from rivers and sediments with contrasting levels of contamination.**Methods:** *Acinetobacter* strains were isolated on different media supplemented or not with antibiotics (ceftazidime, cefotaxime, imipenem, ciprofloxacin), and their resistance profiles against 11 antibiotics in five families were determined. Sampling of the water column and sediments of two heavily contaminated and two conserved rivers was performed in the state of Morelos (Central Mexico). The core genome of the genus was computed with GET_HOMOLOGUES using all available genome sequences. Six loci were selected to design PCR primers using Primers4clades. ML phylogenies were inferred using PhyML3. Statistical analyses were performed in R. Profile of plasmid were visualized using Kaisser's method.**Results:**All Acinetobacter strains (n=35), reported here in were MDR and were classified in 8 known and 3 possibly new species. The mean number of resistances was not significantly higher (chi-squared $p < 0.17$, df=1) in strains recovered from contaminated rivers. However, the number of plasmids was significantly higher in those rivers.**Conclusions:** A high diversity of MDR environmental Acinetobacter species (11 out of 35 isolates) diversity was recovered and robustly classified with the new MLSA scheme. Isolates from contaminated sites displayed a significantly higher number of plasmids.

Multiple Genes Encoding Resistance to Human Clinical Antibiotics Identified on Captured Stream Plasmids

Author Block:

K. G. Libuit[1], C. Kapsak[1], E. Gehr[1], S. Turner[2], J. Herrick[1]; [1]James Madison Univesity, Harrisonburg, VA, [2]Univ. of Virginia, Charlottesville, VA

Abstract Body:

Background: Plasmids in agriculturally-impacted bodies of water may play a significant role in the dissemination of antibiotic resistance (AR). High bacterial loads in stream sediment and selective pressures introduced by agricultural practices may facilitate the exchange and recombination of genetic material, creating reservoirs of AR genes that can potentially be accessed by fecal and other animal and human pathogens. **Methods:** Transmissible plasmids were captured "exogenously" from stream sediment samples by conjugating sediment cells with a rifampicin-resistant strain of *Escherichia coli*. Transconjugants were selected on tetracycline- and rifampicin-amended medium. Plasmids were isolated from transconjugants using an alkaline-based plasmid prep developed in our lab, electroporated into an electrocompetent *E. coli* strain, and tested for decreased antibiotic susceptibility, relative to the un-electroporated strain, using a modified Stokes disk diffusion method. Plasmid pEx1-20 was sequenced on the Oxford Nanopore MinION and Ion Torrent PGM DNA sequencers. MinION reads were assembled using PBcR, polished with PGM reads using Pilon, typed using PlasmidFinder and annotated using both automated (Prokka) and manual approaches.**Results:** Twenty-three of thirty captured plasmids conferred decreased susceptibility to multiple antibiotics in addition to tetracycline. One plasmid, pEx1-20, conferred resistance to tet, kan, tic, pip, and cip. MinION and PGM sequencing, assembly, and polishing of pEx1-20 resulted in a single, 90kb contig. The web tool PlasmidFinder was used to classify pEx1-20 into the incompatibility (inc) group IncP1-β, a group of plasmids capable of transfer and replication in nearly all Gram-negative bacteria. Automated and manual annotation revealed multiple AR genes (*tetA, tetR, tetG, aadA9, sul1, floR*, and *pse-4*) clustered on transposable genetic elements (transposons and integrons) throughout the plasmid genome.**Conclusions:** Captured stream plasmids harbor a surprising suite of linked genes encoding resistance to multiple late-generation clinical antibiotics. The presence of these AR genes suggests that there may be a significant reservoir of AR genes in streams capable of transmission to human and animal bacterial pathogens and commensals.

Antibiotic Resistance Scenario in Bangladesh; Mechanism and Ecological Impact

Author Block:

M. Sultana[1], S. Bashar[1], Y. Ahmed[1], T. A. Siddiquee[2], M. Khan[2], M. A. Hossain[1]; [1]Univ. of Dhaka, Dhaka, Bangladesh, [2]BCSIR, Dhaka, Bangladesh

Abstract Body:

Clinical overuse or misuse of antibiotics, inappropriate clinical liquid waste (CLW) management and it's discharge to ecological water (EW), and mismanagement of clinical patients create antibiotic resistance situation alarming in developing countries; and this antibiotic resistance markers may spread beyond the boarder. Here we report antibiotics and resistome pollution, mechanism of resistance harborage and its spreading scenario in Bangladesh.Active antibiotics in CLW, admixing point of EW (Buriganga River) and sediment were analyzed using Liquid Chromatography Mass Spectrometry (LCMS/MS) after solid phase extraction. Resistome marker integron class 1 and resistant genes were analyzed using PCR in total DNA isolated from CLW, EW and from phenotypically screened MDR bacteria.CLW and admixing point of Buriganga river (10 m down) contained Ciprofloxacin, Cloxacillin, Amoxicillin and Tetracycline at sub-MIC level. Accumulation of antibiotics at sediment soil (per gm) around admixing point amounted high Ciprofloxacin (4.255 ng), Cloxacillin (4.365 ng) and Tetracycline (5.55 ng). CLW is also loaded with MDR bacteria ($1x10^5$~$1.2x10^7$cfu/ml) and resistant gene pool *qnr*S, bla_{CTX-M} and integron class 1. About 47.13% isolates showed MDR properties among which 31.2% were ESBL-positive harboring specific genes (bla_{CTX-M}, bla_{TEM} and bla_{SHV}). On the other hand, 96.7% ESBL isolates showed resistance towards Ciprofloxacin with harborage of *qnr*S gene in plasmid and/or the presence of *acrA*, *acr*B and tolC genes encoding AcrAB-TolC efflux pump. Imipenem resistance was screened among 434 clinical isolates of which 16.8% showed Imipenem resistance with MIC_{IMP} value as high as 256 µg/ml. The carbapenem resistant bla_{VIM-2} gene was detected to be encoded in chromosomally harbored Integron class 1 associated gene cassette in resistant *Pseudomonas stutzeri*.Antibiotics and resistome pollution is increasing alarmingly in Bangladesh and may spread beyond its origin to environments. Selective pressure of antibiotics in EWB and mixing of autochonous species with allochthonous may influence horizontal gene transfer (HGT) resulting origin of new species of clinical importance.

Antibiotics and Antibiotic Resistance Genes in Surface Waters Associated with Livestock Operations

Author Block:

C. D. Ecker[1], C. E. Givens[2], J. W. Duris[2], D. W. Kolpin[3], M. J. Focazio[4], M. T. Meyer[5], S. K. Haack[2]; [1]United States Geological Survey, Columbus, OH, [2]United States Geological Survey, Lansing, MI, [3]United States Geological Survey, Iowa City, IA, [4]United States Geological Survey, Reston, VA, [5]United States Geological Survey, Lawrence, KS

Abstract Body:

Antibiotic resistant bacteria have rapidly become the focus of a well-documented global medical challenge. To assess the potential contribution of livestock production to antibiotic resistance genes in the environment, 78 samples (stream water, bed sediment, and manure) were collected from 19 strategically selected sites across 12 states. Fifteen sites were selected at locations with small (<32 km^2) drainage areas with one primary livestock type (poultry, beef, dairy or swine). In addition, four sites were selected as control sites that had similar agricultural land use (e.g. crop production), but had no livestock operations or manure application practices occurring within the drainage area (i.e. rural background sites). At each site, one bed sediment, representative manure and two stream water samples (i.e. before manure application and after manure application/runoff) were collected and analyzed for the following: fecal indicator bacteria (FIB), 33 antibiotics by HPLC/MS-MS, and 9 antibiotic resistance genes. Antibiotic resistance genes analyzed included 6 subfamilies in the β-lactamase *ampC* family and quinolone resistance genes *qnrABS*. There were few detections (5 of 36) of antibiotics in stream water samples. Almost all of stream water samples having an antibiotic detected (4 of 5) were samples collected during runoff conditions. Dairy and poultry sites showed a statistically higher number of detections ($p = 0.03$) for the $ampC_{CIT}$ gene family in runoff water samples as compared to runoff water samples from rural background sites. Other statistically significant ($p < 0.05$) findings included an increase in *qnrABS* genes in poultry runoff, and *ampC* genes in dairy and swine runoff as compared to rural background runoff samples. Overall, livestock operations appear to be contributing more antibiotic resistance genes to stream waters than agricultural practices that do not involve manure application. Identifying hotspots of antibiotic resistance genes and their potential sources is critical in ultimately understanding the spread of antibiotic resistance genes to pathogenic bacteria in the environment.

Persistence of DNA Encoding Antibiotic Resistance Genes in Poultry Litter

Author Block:

S. Young[1], B. Nayak[2], J. Weidhaas[3], V. Harwood[1]; [1]Univ. of South Florida, Tampa, FL, [2]Pinellas County, Largo, FL, [3]West Virginia Univ., Morgantown, WV

Abstract Body:

Antibiotic use in animal agriculture such as poultry farming can contribute to the spread of antibiotic resistance through fecal pollution released into the environment. Understanding survival and persistence of antibiotic resistant bacteria and associated resistance genes can help assess the role of the environment in the spread of antibiotic resistance. Fecal indicators *Escherichia coli* and enterococci are commonly used as water quality determinants, but their association with antibiotic resistance genes in poultry waste is unclear. The persistence of antibiotic resistance genes was assessed in fresh and saltwater mesocosms inoculated with fecal-contaminated poultry litter (bedding) over seven days. Mesocosms were inoculated with litter from broiler chickens raised in conventional poultry houses at West Virginia University. Antibiotic resistance genes were chosen for analysis based on their mechanisms of resistance and their use in poultry production. PCR was performed on water and sediment samples to detect genes that carry resistance to β-lactams ($bla_{\text{CMY-2}}$), tetracyclines (*tetB*, *tetM*), quinolones (*qnrS*), erythromycin (*ermB*) and aminoglycosides (*aadA*). Fecal indicators were quantified by culture and qPCR. Antibiotic resistance genes relevant to human health and animal agriculture persisted for up to seven days in water and sediment from both marine and freshwater. Presence or absence of antibiotic resistance genes *tetB*, *tetM* and *ermB* were not significantly correlated to the level of enterococci by culture (p=0.329), *E. coli* by culture (p=0.137) or the poultry marker LA35 by qPCR (p=0.295). Other genes will be tested for correlation to FIB and MST markers to determine whether these can predict the presence of antibiotic resistance genes in the environment. Preliminary results reinforce the need for integrative approaches in assessing antibiotic resistance in environmental matrices. FIB and MST markers are important for regulatory purposes and assessing contamination sources, but may not correlate well with resistance genes. These methods can be used as part of a larger toolkit that includes identification of potential pathogens carrying antibiotic resistance genes.

Triclosan Affects Bacterial Community Composition and the Quantities of Antibiotic Resistance Genes in Model Wastewater Treatment Bioreactors

Author Block:

J. W. Beni[1], B. B. McGivern[2], J. J. Donato[2], T. M. LaPara[1]; [1]Univ. of Minnesota, Minneapolis, MN, [2]Univ. of St. Thomas, St. Paul, MN

Abstract Body:

Triclosan is a widely used antimicrobial found in numerous household items from cosmetics and soap to plastics and fabrics. Triclosan is also commonly detected in untreated wastewater where it could act as a selective agent for antibiotic resistance in bioreactors used for treatment. The goal of our research is to understand the effect of triclosan on wastewater microbial communities. Triplicate enrichment cultures were grown in the presence of different concentrations of triclosan (0 to 15 μg/L) for eight weeks. Bacterial community composition was determined by deep sequencing (Illumina MiSeq) of PCR-amplified 16S rRNA gene fragments. Triclosan concentrations were determined using liquid chromatography tandem mass spectrometry (LC-MS/MS). Antibiotic resistance levels were determined by both shotgun metagenomics (Illumina HiSeq) and by microfluidic qPCR targeting more than 25 genes encoding resistance to a myriad of antibiotics. Chemical analysis confirmed a range of triclosan concentrations in the biomass samples. Bacterial community composition exhibited statistically significant differences in response to triclosan concentrations according to an Adonis test of Bray-Curtis dissimilarity matrix. Antibiotic resistance levels exhibited similarly different levels as a function of triclosan concentration. From these results we conclude that triclosan demonstrably and significantly alters microbial community composition and the selection of antibiotic resistance genes.

An *In Vitro* Study to Assess the Effects of Tetracycline on the Human Intestinal Microbiota

Author Block:

J. Y. Jung[1], Y. Ahn[1], S. A. Piñeiro[2], C. E. Cerniglia[1]; [1]Natl. Ctr. for Toxicological Res., U.S. FDA, Jefferson, AR, [2]Ctr. for Vet. Med., U.S. FDA, Rockville, MD

Abstract Body:

Background: The human intestinal microbiota community is a stable ecosystem that could be altered by the ingestion of antibiotic residues in or on foods derived from food-producing animals. These potential perturbations are evaluated by national regulatory authorities as part of the safety evaluation of veterinary antimicrobial agents used in food-producing animals. **Methods:** We investigated using an *in vitro* culture test system the effects of 0.15, 1.5, 15, and 150 µg/ml tetracycline on the intestinal microbiota composition, the prevalence of tetracycline resistance genes (TRGs), and fecal binding after 1 (short-term) and 40 (long-term) days of exposure in 3% human fecal suspensions collected from two individuals. **Results:** Binding of tetracycline to fecal suspensions showed that 41.4 ± 14.8% of tetracycline was bound. Bacterial community analysis using rRNA-based pyrosequencing revealed that *Firmicutes* and *Bacteroidetes* were the most dominant phyla in fecal samples; however, interpersonal variation occurred between the two subjects in terms of the ratio of phylotypes. While the impact of tetracycline on intestinal microbiota varied between the two subjects, evaluation of changes at the genus level from control to tetracycline-treated fecal samples showed that a fraction of the members of *Bacteroides* that belong to *Bacteroidetes* increased at low concentrations as well as higher concentrations of tetracycline in both short- and long-term exposure for both subjects. Principal component analysis confirmed the pyrosequencing findings of interpersonal variability of intestinal microbiota and despite that interpersonal variability, one genus of *Bacteroides* was the most affected group of the microbial community. Among the 23 TRGs screened, four *tet* genes (*O*, *Q*, *W*, and *X*) were found as major TRGs in fecal samples. Quantitative real-time PCR showed that *tetX*, which is responsible for inactivating tetracycline, had a high positive relationship with an increase in tetracycline concentration. In addition, *Bacteroides* had positive correlations with the increase of *tetX*. **Conclusions:** Overall, this pilot study indicated interpersonal variability regarding the effects of tetracycline on microbial composition and prevalence of TRGs at various dose levels of tetracycline and times of exposure.

Widely Used Benzalkonium Chloride Disinfectants Co-select for Bacterial Antibiotic Resistance

Author Block:

M. Kim, S. Oh, M. R. Weigand, J. K. Hatt, R. Krishnan, K. T. Konstantinidis; Georgia Inst. of Technology, Atlanta, GA

Abstract Body:

Background & Materials: Whether disinfectant exposure promotes antibiotic resistance (Ab^R) has been a long-standing debate with major practical consequences. To obtain insights into this issue, we exposed a microbial community originating from a contaminated river sediment (Calcasieu River, LA, USA) to benzalkonium chlorides (BAC; a family of quaternary ammonium compounds widely-used as disinfectants) for 3 years in fed-batch bioreactors. From bioreactors, one with dextrin peptone as the sole carbon source and no BAC present (DP) and one with dextrin peptone plus BAC (DPB), two *Pseudomonas aeruginosa* strains from the same ancestor were isolated and used to study adaptive evolution that occurs during BAC exposure.**Results:** Metagenomics of the bioreactors, coupled with genetic manipulations of derived isolates revealed that BAC exposure induced the spread of Ab^R in several species by selecting for the horizontal transfer of mobile DNA elements that encode a BAC efflux pump together with Ab^R genes. Although several BAC-exposed isolates exhibit higher resistance to certain antibiotics, other isolates did not likely due to their intrinsic resistance mechanisms. To further investigate the underlying molecular mechanisms, the two *P. aeruginosa* isolates were exposed to increasing concentrations of BAC, up to 1640 mg/L, when no growth was observed due presumably to BAC toxicity. Transcriptomics revealed overexpression of several Ab^R genes such as the MexCD-OprJ multidrug efflux genes, encoded in chromosomal DNA of the evolved strain relative to the ancestor in response to BAC presence and also higher MIC values for tetracycline and ciprofloxacin with supplementation of BAC were observed in the BAC-evolved DPB populations.Fixed mutations in the histidine kinase A domain of the *pmrB*, which regulates resistance to polymyxin B, were identified in BAC-evolved DP populations by whole genome sequencing. Consistent with this finding, MIC tests showed higher MIC values for polymyxinB resistance in the BAC-evolved DP populations.**Conclusion:** All together, our results showed that BAC exposure could co-select for increased resistance to antibiotics, and the underlying molecular mechanisms varied based on the genetic make-up of the species considered and the concentration of BACs used.

WGS Characterization of *Campylobacter* and *Enterococcus* Mutants from Exposure to Low Concentrations of Erythromycin

Author Block:

Q. Yang, C. Li, K. Domesle, T-T. Tran, **B. Ge**; U.S. Food and Drug Admin., Laurel, MD

Abstract Body:

Macrolides, such as erythromycin and azithromycin, remain the frontline agents for treating human bacterial infections. The mechanisms underlying the development of macrolide resistance in *Campylobacter* and *Enterococcus* are not yet fully understood. In this study, a collection of macrolide-resistant *C. jejuni /C. coli* (*n* = 67) and *E. faecium /E. faecalis* (*n* = 85) mutants selected by exposure to low concentrations of erythromycin was analyzed using WGS and an in-house bioinformatics pipeline for mutations in target genes (23S rRNA, ribosomal proteins, *cmeR*) and the acquisition of new resistance genes (*erm*(B) and others). For *Campylobacter*, no mutations in L4, L22, *cmeR*, or acquisition of new resistance genes were observed in mutants when comparing to corresponding parent strains. Point mutations in the 23S rRNA gene, consisting of A2074C (4/67, 6.0%), A2074G (9/67, 13.4%), and C2627G (37/67, 55.2%), occurred in a total of 50 (74.6%) mutants. Interestingly, no mutants possessed more than one of these mutations and the A2074C (or G) mutations were only observed in *C. coli* mutants. In the majority (11 out of 13) of *C. coli* mutants, mutations at the A2074 position were found in two out of three copies of the 23S rRNA gene except in two cases where the mutation (A2074G) was homozygous. The majority of mutations occurred in mutants that were isolated in later transfers, which also coincided with having an erythromycin MIC greater than 512 µg per ml. To our knowledge, the high prevalence of C2627G mutation occurred in the 23S rRNA gene has not been reported before. For *Enterococcus* mutants, no mutation was found in L16 or acquisition of new resistance genes when comparing to corresponding parent strains. Point mutations in the 23S rRNA gene including A2058, A2059, G2581 and G2535 were not detected either. In summary, WGS is a powerful tool to efficiently identify gene mutations and new resistance genes in a large panel of bacterial strains. Further analysis on mutants lacking point mutations in the 23S rRNA gene is warranted.

Survival of Daptomycin-Resistant MRSA Under Different Conditions

Author Block:

I. Kanesaka[1], S. Fujisaki[1], A. Kanayama[2], A. Kaneko[3], H. Takahashi[2], I. Kobayashi[2]; [1]Toho Univ., Chiba, Japan, [2]Toho Univ., Tokyo, Japan, [3]Tokai Univ., Kanagawa, Japan

Abstract Body:

Background: We have previously reported on the isolation of daptomycin (DAP)-resistant MRSA isolates from patients on daptomycin therapy. As reports of outbreaks due to DAP-resistant isolates are extremely rare, we studied the viability of DAP resistant MRSA in different conditions in order to determine whether DAP resistant organisms are less adapted to survive in the environment compared to DAP sensitive MRSA.**Materials and Methods:** A total of 10 isolates were studied: 4 DAP-resistant MRSA isolates recovered from patients undergoing DAP therapy; 6 DAP-sensitive MRSA isolates, *Staphylococcus aureus* ATCC 25923 and *S. aureus* ATCC 43300. A total of 20 Polypropylene (PP) and Silicone (SI) plates (1 cm^2) were used for adherence of isolates. Each of the 10 PP and 10 SI plates were seeded with 10^5 CFU of the test isolate. After allowing plates to dry, viability at 20 °C was assessed at days 1, 2, 3, 7, 15 and 30 by vigorous mixing to suspend the organisms following by plating for colony counts. Further, Each organism were suspended with distilled water and physiological saline to achieve the desired final inoculum (10^5 CFU/mL) and incubated at 20 °C up to 30 days to assess viability.**Results:** ATCC and DAP-susceptible MRSA isolates were viable for over 15 days. There was no difference in viability of DAP-resistant and DAP-susceptible MRSA applied to PP using a saline suspension; however, DAP-resistant MRSA attached to SI was not detected viability after 2 to 3 days. Cells viability were not observed at 6 days for some isolates in DW. DAP-resistant MRSA isolates with an amino acid substitution at *mprF* and increased cell-wall thickness showed decreased viability over time.**Conclusions:** Our results indicate that DAP-resistant MRSA possessing a *mprF* mutation and increased cell-wall thickness have greater difficult of surviving in the environment which may account for decreased likelihood of outbreaks caused by DAP-resistant MRSA.

Intrinsic Resistance of *Burkholderia cepacia* Complex to Benzalkonium Chloride

Author Block:

Y. AHN[1], J. Kim[1], O. Kweon[1], S-J. Kim[1], R. C. Jones[2], K. Woodling[1], G. G. d. Costa[1], J. J. LiPuma[3], D. Hussong[4], B. S. Marasa[4], C. E. Cerniglia[1]; [1]NCTR / US FDA, Jefferson, AR, [2]MS Bioworks LLC, Ann Arbor, MI, [3]Univ. of Michigan, Ann Arbor, MI, [4]CDER / US FDA, Silver Spring, MD

Abstract Body:

Background: Pharmaceutical products that are contaminated with *B. cepacia* complex (BCC) may pose serious consequences to vulnerable patients. Benzyldimethylalkylammonium chloride (BZK) cationic surfactants are extensively used in medical applications and have been implicated in the co-selection of antimicrobial resistance.**Methods:** The capability of BCC to degrade BZK, tetradecyldimethylbenzylammonium chloride (C_{14}BDMA-Cl), dodecyldimethylbenzylammonium chloride (C_{12}BDMA-Cl), decyldimethylbenzylammonium chloride (C_{10}BDMA-Cl), hexyldimethylbenzylammonium chloride (C_6BDMA-Cl), benzyltrimethylammonium chloride (BTMA-Cl) was determined by incubation in 1/10 diluted Tryptic Soy Broth (TSB) to determine if BCC has the ability to survive and inactivate these disinfectants . For BZK, C_{14}BDMA-Cl, and C_{12}BDMA-Cl, growth inhibition was observed for the 20 BCC strains in disinfectant solutions that ranged from 64 to 256 µg/ml.**Results:** The efflux pump inhibitor carbonyl cyanide-m- chlorophenylhydrazone (CCCP) increased the sensitivity of bacteria to 64 µg/ml of BZK. The 20 BCC isolates grew well in 1/10 diluted TSB medium with BZK, C_{12}BDMA-Cl, and C_{10}BDMA-Cl and degraded these compounds. Formation of benzyldimethylamine (BDMA), and benzylmethylamine (BMA) as initial metabolites suggested that the cleavage of C alkyl-N bond occurred as the first step of BZK degradation by BCC. Proteomic data further confirmed that efflux pump activity and metabolic inactivation are involved in the resistance of BCC to BZK.**Conclusions:** This study provides a systematic methodological approach to determine the intrinsic resistance mechanisms of BCC to BZK.

Characterization of Plasmids Harboring *bla*$_{VEB}$ in *Vibrio parahaemolyticus* Strains

Author Block:

R. Li[1], L. Ye[2], D. Lin[1], Y. Zhou[1], E. W. Chan[1], S. Chen[1]; [1]The Hong Kong Polytechnic Univ., Hung Hom, Hong Kong, [2]Hong Kong PolyU Shen Zhen Res. Inst., Shenzhen, China

Abstract Body:

Background: *Vibrio parahaemolyticus* is one of the important foodborne pathogens worldwide and causes severe infections, which may need antimicrobial therapy. Extended-spectrum beta-lactamases (ESBLs) producing producing *V. parahaemolyticus* has been reported, while the data is still very limited. In this study, for the first we detected *bla*$_{VEB}$ in *V. parahaemolyticus* isolates and depicted the genetic structure of *bla*$_{VEB}$. **Methods:** *V. parahaemolyticus* were isolated from different food products in Shenzhen, China. Twenty-one ESBL-producing *V. parahaemolyticus* isolates were subjected to MIC determination, screening of resistance genes, conjugation and S1-PFGE characterization. The plasmids encoding *bla*$_{VEB}$ were sequenced by Illumina and Pacbio platforms. Annotation was performed with RAST tool.**Results:** Two *V. parahaemolyticus*(VP72, VP92) were found positive for *bla*$_{VEB}$. S1-PFGE indicated the *bla*$_{VEB}$ genes are located on plasmids (ca. 60K, 320K) and the second plasmid was transferable by conjugation. After sequencing, *bla*$_{VEB-2}$ were positive for VP92. A new *bla*$_{VEB}$ -like variant was found in VP72 and harboring three substitutions (V19A, T104M and N294D) compared with *bla*$_{VEB-1}$. One complete plasmid (Genbank no. KU356480) with 338, 538bp in length was obtained and the core *bla*$_{VEB}$-like gene harboring MDR region was got for another plasmid. Annotations shown that the *bla*$_{VEB-2}$ was located on a class 1 integron (*bla*$_{VEB-2}$- *aadB- arr2- cmlA-bla*$_{OXA-10}$- *aadA1*) and *bla*$_{VEB}$ -like gene was in a genetic environment of *mobA-aac(6')-II-bla*$_{VEB}$-like-*aadB-tnpA*. After BLAST, the *bla*$_{VEB-2}$ genetic environment was identical to that of *bla*$_{VEB-1}$ in *Acinetobacter baumannii*(CU459141). The plasmid backbone of *bla*$_{VEB-2}$ was only similar to a *V. cholera* plasmid pNDM-116-14(99% identity in 78% coverage). *bla*$_{VEB}$-like genetic arrangement was novel and similar *bla*$_{VEB}$-*aadB* sequences were found in NCBI database.**Conclusions:** The genetic structure of *bla*$_{VEB-2}$ indicates this structure may derived from *A. baumannii*, incorporated into a *Vibrios* plasmid and evolved into a *bla*$_{VEB-2}$. *bla*$_{VEB}$-like gene was supposed to originate from integron structure and recombine into new plasmid by *bla*$_{VEB}$-*aadB* circular cassette. The emergence of *bla*$_{VEB}$ in *Vibrios* constitutes a potential public health threat.

Molecular Characterization of the Mechanisms of Carbapenem Resistance in *E. coli* Isolated from Pig in China

Author Block:

D. Lin[1], R. Li[1], M. Xie[2], E. W. Chan[1], S. Chen[1]; [1]PolyU, Hong Kong, China, [2]PolyU Shen Zhen Res. Inst., 南京, China

Abstract Body:

Background: The prevalence of carbapenem-resistance in organisms recovered from animals was reported to be extremely low. This study aims to investigate the prevalence of carbapenem-resistant strains of Enterobacteriaceae in animals and the underlying resistance mechanisms concerned. **Methods:** 220 faecal samples from pigs were tested. 11 carbapenem-resistant E. coli strains were isolated from 5 faecal samples in 1 farm located in Henan province. PCR assay showed that all these strains harboured blaNDM-1. A total of 5 PFGE patterns and 4 ST types were detectable, with identical PFGE and ST types detectable in different samples and organisms of different PFGE and ST types recoverable from the same sample. Conjugation experiments indicated that the carbapenem resistance phenotypes could be transferred to the E. coli J53 strain. All the plasmids belonged to the IncFII type, but two different sizes of plasmids were identified by S1-PFGE. Complete plasmid sequence was obtained for one each of these two different sizes of plasmid, pHNEC55 with size of 81.498kb and pHNEC46 of 74.046kb, using the illumina and SMAT sequencing platforms. These two plasmids were shown to share the similar backbone as a plasmid harbouring multiple resistance genes, namely pHN7A8, which was previously recovered from E. coli isolated from animal in China several years ago. The major structural difference between them was that the blaCTX mobile element fragment in pHN7A8 was replaced by the blaNDM-1 mobile element fragment of pHNEC55. The difference between pHNEC55 and pHNEC46 was that the smaller plasmid, pHNEC46, lacked the fosA3 mobile element fragment. **Conclusions:** The study characterized two new plasmids carrying $bla_{\text{NDM-1}}$ in *E. coli* isolated from pig. The backbone of these two plasmids was different from the common blaNDM-1-borne plasmid recoverable from clinical Enterobacteriaceae strains, but was highly similar to blaCTX-M encoding plasmid isolated from animals, suggesting that these two new plasmids may be formed by inserting the blaNDM-1 mobile element into the common IncFII plasmid in animal *E coli* strains. Successful detection of these plasmids in different *E. coli* strains constitutes evidence of effective transmission of these plasmids among animal bacterial isolates.

***Escherichia coli* Producing CTX-M-Type Extended-Spectrum β-Lactamase (ESBL) Isolated from an Urban River, Drinking Water and Raw Vegetables in Quito, Ecuador**

Author Block:

D. Ortega-Paredes[1], P. Barba[2], N. Espinel[1], S. Mena[1], V. Crespo-Pérez[1], **J. Zurita**[1]; [1]Pontificia Univ. Catolica del Ecuador, Quito, Ecuador, [2]BioMed. Res. Unit. Zurita & Zurita Lab., Quito, Ecuador

Abstract Body:

Background: *Enterobacteriaceae* producing Extended-Spectrum β-lactamases (ESBL) is a global concern. In Latin America, the variant CTX-M-15 is the most frequently reported in clinical settings. In recent years, increasing evidence about food and environmental location of *E. coli* producing ESBL indicate a growing problem of dissemination. This issue compromises food safety and environmental integrity. The aim of this study was to identify and characterizing *E. coli* producing CTX-M-type ESBL in the principal urban river, drinking water and fresh vegetables in Quito-Ecuador.**Methods:** Quito city is located in the Andean Region of Ecuador at an altitude of 2,850 m. Most of the wastewater of the city is discharged in Machángara river. The drinking water collected in the highlands is treated and distributed to city. The fresh vegetables mostly come from the valleys and highlands around Quito. In 2015, nine points were sampled in the river, twenty one samples of drinking water were collected in different points of the city and nine fresh vegetables mostly raw consumed were sampled. *E coli* was isolated using filtering method in ColiBlue24® medium supplemented with cefotaxime 5 µg/ml. Species identification were achieved by MALDI-TOF. ESBLs production was confirmed with Double Disk Test and MIC was made by Vitek2. ESBL genes and integron 1 variable region were amplified and sequenced.**Results:** *E. coli* producing ESBLs were isolated in the points at the river with anthropogenic disturb. Only lettuce and alfalfa were positive for *E. coli* ESBL. All drinking water samples were negative for all *Enterobacteriaceae* studied. CTX-M-15 was the most prevalent ESBL identified in the urban river, followed to CTX-M-18, CTX-M-3, CTX-M-65 and CTX-M-20. Isolates from fresh vegetables presented only CTX-M-15. Variable region of integrons class 1 presented several variants of *dfrA* (trimethoprim resistance) and *aadA* (aminoglycoside resistance) gene cassettes. These findings were related with multi-resistance profile of isolates.**Conclusions:** Our results show that the urban river and fresh vegetables contribute to the presence of multi-drug-resistant *E. coli* in urban environment.

Detection of *Klebsiella pneumoniae* Carbapenemase and New Delhi Metallo-Beta-Lactamase Genes in Wastewater from Pretoria, South Africa

Author Block:

R. Dos Santos[1], M. Ehlers[2], M. de Jesus[1], **M. Kock**[2]; [1]Univ. of Pretoria, Pretoria, South Africa, [2]Univ. of Pretoria/Natl. Hlth.Lab. Service, Pretoria, South Africa

Abstract Body:

Bacterial antibiotic resistance is a major threat to human health and is a phenomenon that is on the rise. The aquatic environment, including wastewater, is often regarded as a reservoir for antibiotic resistant bacteria (ARB) and antibiotic resistance genes (ARGs) and is a suitable environment for the transfer of antibiotic resistance determinants. The lack of removal of antibiotic resistance determinants from wastewater treatment plants (WWTPs) may allow its spread into the environment and may negatively impact on treatment of community-associated infections. The aim of this study was to identify beta-lactamase genes, including *Klebsiella pneumoniae* carbapenemase (KPC) and New Delhi metallo-beta-lactamase (NDM) genes from wastewater collected from three WWTPs (in and around the Pretoria/Tshwane area, South Africa) in winter and late spring/early summer in 2013 from the influent and effluent zones. Total genomic DNA was extracted directly from the wastewater using a phenol/chloroform extraction method. Selected beta-lactamase genes, which included Cefotaximase-Munich (CTX-M), Sulfydryl variable (SHV), Oxacillinase-48-(OXA-48)-like, Temionera (TEM), OXA-1-like, KPC and NDM were tested for using molecular methods. The wastewater treatment process of two of the three WWTPs showed promising results in the removal of the targeted β-lactamase genes but the wastewater treatment process of the third WWTP was less efficient as several genes were detected in the effluent. Identifying the KPC and NDM genes within wastewater was a significant find. The identification of the β-lactamase genes over both collection periods highlights that wastewater is a reservoir for β-lactamase genes. If the wastewater treatment process does not remove ARGs, as was the case in one of the WWTPs, the effluent can become a reservoir for the ARGs. This study identified a dissemination route of β-lactamase genes into the environment, which can lead to more resistant bacteria in the community and in turn exacerbate community-associated infections. The possibility of implementing additional treatment of raw sewage before its entrance into WWTPs should also be considered. To our knowledge, this is the first identification of NDM-1 in wastewater in South Africa.

Presence Of β-Lactamases In *Acinetobacter baumannii* Isolated from the Antarctic Continent

Author Block:

A. Opazo-Capurro[1], C. Cigarroa[1], A. Fuentealba[1], C. Lima[1], M. Dominguez-Yevenes[1], H. Bello-Toledo[1], L. Vergara[2], **G. Gonzalez-Rocha**[1]; [1]Univ. of Concepcion, Concepcion, Chile, [2]San Sebastian Univ., Concepcion, Chile

Abstract Body:

Background: *A. radioresistens* (Ara) possesses a remarkable ability for surviving in extreme environmental conditions being rarely associated with clinical infections. Despite its low incidence in human infections compared to other members of the *Acinetobacter* genus, it is important to remark its role as a reservoir of antibiotic resistance genes. The carbapenemase-encoding gene *bla*$_{\text{OXA-23-like}}$ has been identified in the chromosome of this bacterium, being a potential source of carbapenems-resistance genes. Due to the above, the aim of this work was to investigate the presence of β-lactams resistance genes in Ara isolates collected in the Antarctic continent. **Methods:** Two Ara isolates, A145 and A154, were collected from soil samples at Ardley Island in the Fildes Peninsula, Antarctica, in 2013. The species identification was achieved by the 16S rRNA gene sequencing. The antibiotic susceptibility patterns to different classes of antibiotics were determined by disk diffusion. The genetic relatedness analysis was carried out by rep-PCR and the presence of β-lactamases genes, such as those encoding ESBLs and carbapenemases, and the presence of the IS*Aba1* element was investigated by standard PCR.**Results:** Both isolates showed identical rep-PCR patterns, being classified as clones. Both isolates resulted resistant to diverse β-lactams, such as ampicillin, cefuroxime, cefotaxime, ceftazidime and cefepime, and susceptible to carbapenems. The *bla*$_{\text{TEM-1}}$ and *bla*$_{\text{PER-2}}$ genes were found in both isolates, which could explain the resistance to aminopenicillins, second- and third-generation cephalosporins. Both isolates were found to carry *bla*$_{\text{OXA-23-like}}$ although none was resistant to imipenem or meropenem. PCR to detect IS*Aba1* upstream to *bla*$_{\text{OXA-23-like}}$ proved negative .**Conclusions:** This work represents the first description of β-lactam resistance genes in Ara from Antarctica, which is a place without the selective antibiotic pressure that occurs in hospitals and which nonetheless represents a potential source of antibiotic-resistance genes. In conclusion, the results reassure the potential role of Ara as a reservoir of antibiotic-resistance genes, which could have an important impact in the nosocomial environment.

Molecular Epidemiology of Carbapenem-Resistant *Burkholderia cepacia* Complex from Pharmaceutical Wastewaters from South-Western Nigeria

Author Block:

A. I. Obasi[1], E. O. Ugoji[1], S. C. Nwachukwu[1], C. Kohler[2], K. Breitbach[2], A. Gholer[2], V. Balau[2], Y. Pfeifer[3], I. Steinmetz[2]; [1]Univ. of Lagos, Yaba, Lagos, Nigeria, [2]Univ. of Greifswald, Greifswald, Germany, [3]Robert Koch Inst., Werringerode, Germany

Abstract Body:

The occurrence of antibiotics and other pharmaceuticals in the environment has become an increasing public concern. The emergence of antimicrobial-resistant bacteria presents a major threat to public health because it reduces the effectiveness of antimicrobial treatment, leading to increased morbidity, mortality and healthcare expenditure; therefore we assayed for carbapenemase production in *Burkholderia cepacia* complex isolated from pharmaceutical wastewaters in Nigeria.Untreated Wastewaters from ten pharmaceutical industries located in Nigeria were sampled during April 2011 to June 2012. Gram Negative bacteria were isolated, Gram stain, morphology on blood agar, test on ashdown agar, oxidase test, growth at 42^{o}C and lactose fermentation test were carried out. Identification of isolates and antibiotic susceptibility test on eighteen antibiotics were done with the VITEK 2 machine. The Hodge test was carried out to determine the production of the carbapenemase enzyme. Molecular analysis with *recA* gene and sequencing was carried out to identify the strains. Detection of the presence of carbapenamase genes *VIM, KPC, OXA-48, NDM, IMP* and *GIM* was also determined by PCR.Ninety-seven Gram-negative bacteria were isolated. Two isolates of *Burkholderia cepacia* complex were resistant to imipenem amongst other bacterial isolates; they were also resistant to the cephalosporins and the fluoroquinolones. However the hodge test and the PCR results on the production of the carbapenamase genes were negative for both isolates. Further results with *recA* PCR and sequencing clearly identified the strains as *Burkholderia cepacia* and *Burkholderia cenecepacia*.The results showed that the resistance mechanism of *Burkholderia cepacia and Burkholderia cenocepacia* to imipenem was not the production of carbapenamase enzyme, but likely because of their intrinsic characteristics, mutation, porin loss or efflux pump resulting to their ability to be resistant to imipenem.

Detection of *meca* Gene in *Staphylococcus aur*eus Isolated from Animal and Sea Foods

Author Block:

R. Anandan, D. Lakshmipriya, V. Nithyakalyani, C. Banurekha, S. Rajkumar; Dr MGR Janaki Coll. of Arts and Sci. for, Chennai, India

Abstract Body:

Background: In recent times, methicillin resistant *Staphylococcus aureus* (MRSA) has become a serious problem and challenge to health care facilities. Rapid and accurate diagnosis is the key factor for the successful therapeutic intervention and to reduce morbidity and mortality due to this pathogen. Molecular techniques are increasingly popular to detect the presence of specific drug resistant genotype in clinical isolates but due to economic and/or diagnostic sensitivity issues, time consuming culture methods are still in practice. With the increased and indiscriminate use of antibiotics in food industry, we hypothesized that there is a high propensity for drug resistant strains among the *S. aureus* animal and sea foods isolates. Simultaneously, we have also planned to screen these isolates for *mecA* gene (confers methicillin resistance) and its use in deducing the drug resistance profile of these isolates in comparison to conventional techniques.**Methods:** A total of 57 samples drawn from meat and sea foods were screened for *S. aureus* using standard microbiological techniques. *S. aureus* food isolates were tested for their antibiotic sensitivity/resistance profile using standard Kirby-Bauer disc diffusion method. These bacterial isolates were also investigated for the presence of *mecA* gene with standard PCR technique. This was also tested for PBP2 protein on SDS-PAGE to confirm the expression profile of the *mecA* gene harbored in these isolates. Attempt was made to understand the diagnostic value of conventional disc diffusion technique, *mecA* PCR and the combination.**Results:** Among the food samples (n=57), 47 (84%) were found positive for *S. aureus*. Of these *S. aureus* food isolates, 32 (68%) were methicillin resistant (MRSA) by disc diffusion technique. Among these MRSA isolates, 96.8% (31/32) were *mecA* positive by PCR. SDS-PAGE confirmed the *mecA* expression profile based on PBP2 detection.**Conclusions:** Presence of MRSA in animal food product is indeed a cause of concern and warrants stringent monitoring. *mecA* PCR is an extremely useful MRSA diagnostic technique with just 6 hour turnaround time. Establishing appropriate laboratory diagnostic guidelines on the use of *mecA* PCR especially in developing and underdeveloped countries may help reduce the MRSA disease burden and transmission.

Specificity of Bacteriophage for Antibiotic-Resistant *Salmonella typhimurium*

Author Block:

J. Kim, A. Jo, L-S. Jung, J. Ahn; Kangwon Natl. Univ., Chuncheon, Korea, Republic of

Abstract Body:

Background: The rapid spread of new antibiotic-resistant bacteria has become a global concern because of frequent failure in treatment and delay in antibiotic development. Recently, bacteriophage therapy has received much research attention as a viable alternative to conventional antibiotics. Therefore, this study describes a new effort toward understanding the interaction mechanisms between antibiotic-resistant *Salmonella* Typhimurium and phages.**Methods:** The antibiotic susceptibility, β-lactamase activity, bacterial motility, gene expression, and lytic activity were evaluated in ciprofloxacin-induced antibiotic-sensitive *Salmonella* Typhimurium ($ASST^{CIP}$) and ciprofloxacin-induced antibiotic-resistant *S.* Typhimurium ($ARST^{CIP}$), which were compared to the parent strains ($ASST^{WT}$) and $ARST^{WT}$).**Results:** The multiple resistance to different classes of antibiotics was developed in the $ARST^{CIP}$, showing the increased MIC values of ampicillin (AMP) from 512 to >512 μg/ml, norfloxacin (NOR) from 0.125 to 16 μg/ml, chloramphenicol (CHL) from 4 to 16 μg/ml, and tetracycline (TET) from 128 to 256 μg/ml, respectively. The lowest and highest lactamase activities were observed in $ASST^{WT}$ (6-20 μmol/min/ml) and $ASST^{CIP}$ (46-49 μmol/min/ml), respectively. The inducible β-lactamase activity was more considerably increased in the $ASST^{CIP}$ (49 μmol/min/ml) than $ARST^{CIP}$ (7 μmol/min/ml). The *acrA, lpfE,* and *hilA* genes were significantly upregulated by more than 10-fold in in both $ASST^{CIP}$ and $ARST^{CIP}$. The induction of multiple antibiotic resistance resulted from the increased efflux pump activity (AcrAB-TolC). The highest phage adsorption rates were more than 95% for $ASST^{WT}$, $ASST^{CIP}$, and $ARST^{WT}$, while the lowest adsorption rate was 52% for $ARST^{CIP}$ at 15 min of infection. The least lytic activity of phage was 20% against the $ARST^{CIP}$, followed by $ASST^{CIP}$ (30%). The adsorption rate of phage against $ARST^{CIP}$ was 52% at 15 min of infection, which resulted in the decrease in lytic activity (12%).**Conclusions:** Understanding the interaction of phage and bacteria is essential for the practical application of phage to control and detect antibiotic-resistant bacteria. The results provide useful information for understanding the binding specificity of phages for multiple antibiotic-resistant pathogens.

Efficacy of Colistin Combined with Meropenem, Gentamicin or Rifampicin Against Carbapenem-resistant *Pseudomonas aeruginosa* Biofilms

Author Block:

A. Geladari, M. Simitsopoulou, I. Stamouli, C. Antachopoulos, **E. Roilides**; Aristotle Univ. of Thessaloniki, Thessaloniki, Greece

Abstract Body:

Background: While biofilm (BF)-associated infections due to carbapenem-resistant *Pseudomonas aeruginosa* (CR-Pa) are a therapeutic challenge, new antibiotics are lacking. Since colistin monotherapy can lead to emergence of resistance, combination therapies are employed. We investigated the bactericidal activities of colistin (COL), meropenem (MER), gentamicin (GEN) and rifampicin (RIF) in the double combinations of COL-MER, COL-GEN and COL-RIF against CR-Pa mature BF. **Methods:** Four CR-Pa BF-producers, isolated from the sputum of CF patients, were incubated at 5x10^6 CFU/mL in microtiter plates at 37°C for 48h. BF were then incubated with COL, MER, GEN and RIF at 0.007-256mg/L for 24h. Drug combinations of COL (0.06-32mg/L) with MER, GEN or RIF (0.007-64mg/L) at 37°C for 24h were examined using a checkerboard microdilution method. BF damage measured as % reduction of metabolic activity was assessed by XTT assay. The MIC50 for BF was determined as the minimum concentration that caused ≥50% bacterial damage compared to that for the untreated controls. The combination effect was defined according to Bliss model as synergistic, antagonistic or indifferent when the observed BF damage was significantly higher than, lower than or equal to the expected damage, respectively. All the isolates were tested in triplicate.**Results:** All the 4 CR-Pa isolates produced weak biofilm. BF MIC50 of COL, MER, GEN and RIF for the 4 CR-Pa isolates was 64mg/L, 16mg/L, 64mg/L and 16mg/L, respectively. Synergistic activity was found for one isolate at 0.25-2mg/L of COL combined with 0.5-2mg/L of RIF (mean ΔE value of significant interactions, 23% [range, 8% to 38%]; mean SE, 2% [range, 0.09% to 3.76%]). For this isolate antagonistic interactions were observed at 1-2mg/L of COL combined with 4-16mg/L of GEN (mean ΔE value of significant interactions, -15% [range, -2% to -22%]; mean SE, 1.3% [range, 0.4% to 2.5%]). For the remaining three isolates, drug combinations showed indifferent results.**Conclusion:** Although CR-Pa strains were weak BF producers, high BFMIC50 were observed. Interactions of COL with MER, GEN or RIF are mostly indifferent; occasionally COL-RIF combination may be synergistic and COL-GEN antagonistic.

Adherence and Proliferation of *Propionibacterium acnes* on Materials of Orthopaedic Relevance

Author Block:

C. K. Mayfield[1], A. Zega[1], D. G. Deckey[1], **D. Garcia**[2], A. Green[1], J. Jarrell[2], R. Hayda[2], C. Born[2]; [1]Brown Univ., Providence, RI, [2]Rhode Island Hosp., Providence, RI

Abstract Body:

Background: Wound infections after shoulder surgery substantially affect patient outcomes; deep infections typically result in loss of shoulder strength and range of motion[1]. *Propionibacterium acnes* is a slow-growing, anaerobic-aerotolerant, Gram-Positive bacteria commonly found as part of the natural flora of the large intestine, conjunctiva, oral cavity and in the pilosebacous follicles of the skin[2]. An opportunistic pathogen most notably recognized for its role in acne vulgaris, it is the most common organism to colonize the skin surface around the shoulder. Due to requirement of extended culture of at least 13 days, *P. acnes* is often under diagnosed as a cause of pain, loosening and chronic inflammation. In this study we aimed to develop an understanding of the adherence times required by *P. acnes* on five common implant materials.**Methods:** Five common orthopaedic spinal implant materials: Polyether Ether Ketone (PEEK), Cobalt Chromium, Stainless Steel, Titanium and Titanium Alloy were inoculated with $1x10^7$ CFU/ml *Propionibacterium acnes*. Hours allowed for adherence and proliferation of *P. acnes* were varied over a 24 hour period. Implants were fixed, dehydrated, submitted to critical point dry, sputter coating, and visualized using Scanning Electron Microscopy (SEM). SEM images and data were processed using Microsoft Excel and ImageJ.**Results:** Adherence to PEEK increases significantly over the first 24 hours with respect to the other materials. Preliminary biofilm formation occurs exclusively on PEEK in the first 24 hours of growth with significant formation occurring when adherence allowed is 20 hours. Stainless steel was shown to be the most resistant to adherence of *P. acnes.***Conclusion:** The results observed in this study are consistent with previous studies conducted with other pathogens in our laboratory suggesting rougher surfaces are more permissive for bacterial adherence. The data presented in this study may help surgeons and manufacturers make more informed decisions when designing implants at risk of *P. acnes* colonization.

Characterization of Antimicrobial Peptides for Treatment of *Pseudomonas aeruginosa*

Author Block:

M. Kay, J. Titus, Y. Hwang; Naval Med. Res. Unit San Antonio, San Antonio, TX

Abstract Body:

Background: Dental infections including gingivitis and periodontitis are major issues in the military. In deployed military personnel, 12% of dental emergencies involve gingivitis or periodontitis. *Pseudomonas aeruginosa* is one bacteria associated with these infections. Because traditional periodontal treatment is time consuming and repetitive, innovative antimicrobial and antibiofilm compounds need to be discovered for the effective prevention and eradication of bacterial biofilms in dental plaques. Antimicrobial peptides (AMPs) have novel modes of antibacterial activity allowing for effective treatment of biofilm and drug resistant infections.**Objectives:** Screen the antimicrobial activity of AMPs against *P. aeruginosa*, investigate variances in reported minimal inhibitory concentrations (MICs), determine the cytotoxicity of AMPs against human gingival epithelial cells (HGEPs), and measure AMP antibiofilm activity determining minimal biofilm inhibitory concentrations (MBICs).**Materials/Methods:** Two laboratory strains (PAO1 and PA14) and two drug-resistant clinical *P. aeruginosa* strains which were isolated locally, were tested using five AMPs including 1018, KSL-W, K4K20S4, K4S(1-15), and K6L9. MIC values in multiple growth media and the LIVE/DEAD bacterial viability assay were used to assess antimicrobial activity. Measurement of AMP cytotoxicity using lactate dehydrogenase and water soluble tetrazolium cell proliferation assays were performed with HGEPs. MBICs were determined using standardized biofilm assays.**Results:** AMPs possessed a broad range of activity against all *P. aeruginosa* strains, with less effective results in enriched media compared with minimal media. The most effective antimicrobial AMPs were K4K20S4, K4S(1-15) and K6L9, with some activity in 1018 and KSL-W. However, the AMPs rich in lysine residues proved to be cytotoxic to HGEPs, with more tolerance present in KSL-W and 1018. Antibiofilm results for 1018 showed a range of antibiofilm activity from 10-20 µg/ml.**Conclusions:** KSL-W and 1018 appear to be suitable candidates for use against gingival and periodontal pathogens. The peptide 1018 also appeared to have activity against *P. aeruginosa* biofilms. Further testing is underway to identify additional AMPs against periodontal pathogens.

Multidrug Resistance and Biofilm Formation of *Staphylococcus aureus* and Coagulase-Negative *Staphylococci* Species Isolated from Clinical Specimens

Author Block:

K. Sung[1], J-W. Chon[1], R. Bensen[2], S. Iram[3], S. Khan[1]; [1]NCTR, FDA, Jefferson, AR, [2]Michigan Technological Univ., Houghton, MI, [3]Quaid-I-Azam Univ., Islamabad, Pakistan

Abstract Body:

Staphylococci are ubiquitous skin microbiota, and important nosocomial and community-acquired pathogens, and becoming increasingly resistant to many commonly used antibiotics. Staphylococcal biofilm is one of the virulence factors and resistant to host innate immune response and systemic antimicrobial therapeutic treatment. A total of 28 *Staphylococcus* species isolates from nasal and perirectal swabs of patients were obtained from a tertiary health care facility in Karachi, Pakistan. These isolates were identified as 15 *S. aureus*, 8 *S. sciuri*, 3 *S. hemolyticus*, 1 *S. lentus* and 1 *S. epidermidis*. They were resistant to multiple antibiotics. The highest antibiotic resistances were to lincomycin (85.7%), followed by oxacillin (82.1%), and ciprofloxacin and erythromycin (78.6%), tetracycline and cefazolin (71.4%), gentamicin (67.9%), and kanamycin (53.6%). All isolates were resistant to ampicillin and penicillin while susceptible to vancomycin. The antimicrobial resistance rates varied between *S. aureus* and coagulase-negative *Staphylococci* isolates. The resistance percentage of *S. aureus* isolates was higher than coagulase-negative *Staphylococci* for all the antibiotics tested except for oxacillin and lincomycin. Alpha and beta hemolysins were present in 5 (17.9%) and 10 (35.7%) of isolates, respectively. Both DNase and gelatinase were produced more in *S. aureus* isolates than coagulase-negative *Staphylococci*. By microtiter plate method, we found that most of the isolates were able to form biofilm and two *S. sciuri* (3S and 56S) and one *S. aureus* (41S) were strong biofilm producers. The adhesin genes varied among different strains. The *fnbB* and *fib* genes were only detected in one and three strains, respectively. The detection rates of other adhesin genes were as follows: *eno* (92.9%), *icaA* (82.1%), *cna* and *bap* (75.0%), *bbp* (60.1%), *ebpS* and *clfA* (57.1%), *clfB* (53.6%), and *fnbA* (46.4%). There was no direct correlation in distribution of adhesin genes and biofilm formation. This study indicates multidrug-resistant coagulase-positive and -negative clinical *Staphylococcus* species have the great ability to produce biofilm and virulence potential, and health risks posed by such isolates should not be underestimated.

Identification of Membrane Proteins Related to Quorum Sensing Mechanism of Uropathogenic *E.coli* Se15, a Common Causative Pathogens Indwelling Catheters

Author Block:

S. Kang[1], H-S. Choe[2], S-S. Lee[1]; [1]Kyonggi Univ., Suwon, Korea, Republic of, [2]The Catholic Univ. of Korea, Suwon, Korea, Republic of

Abstract Body:

The organisms of interest in catheter associated urinary tract infections (CA UTIs) are *E. coli*, *P. aeruginosa* and *S. aureus.* Especially, uropathogenic *E.coli* (UPEC) is a major pathogen which account for more than 80% in UTIs. These bacteria are common causative pathogens which colonize the catheter by quorum sensing (QS) mechanism. In case of pathogenic bacteria, OMPs interact with other bacteria or host and act as adhesions or receptors to facilitate colonization. Consequently, the study of inner and outer membrane proteins (IMPs/OMPs) is essential to understand microbe-microbe interactions and to identify key targets for development of therapeutic agents. Therefore, this study is focused on expressional changes of membrane proteins of uropathogenic *E.*coli. In addition, this study also compares and identify membrane proteins that are differentially expressed under *E.coli* single culture and mixed culture of *E.coli*, *P. aeruginosa* and *S. aureus*. Two-dimensional gel electrophoresis and matrix associated laser desorption ionization-time of flight mass spectrometry analysis was adopted to analyze the membrane proteins involved in quorum sensing mechanisms. It was observed that, in mixed cultures, IMPs/OMPs of uropathogenic *E.coil* showed differential expression of virulence related proteins (ColE, CvaA, FocC, StfD, TomB) and QS related proteins (LsrA, OppD, FbpC, DorA and FabG). Interestingly, the proteins (LsrA, and OppD) which import the QS signal molecules to cytoplasm were increased in the mixed culture conditions than those in the single culture of *E.coli*. And also, the virulence factors related to biofilm formation (TomB) and fimbrial chaperone proteins (StfD and FocC,), were highly expressed in the mixed culture condition in compare to single culture of *E.coli*. Based on this study, it was observed that receptor proteins related to QS and virulence proteins were more affected by mixed cultures than those of the single culture of *E.coli*. Overall, these findings indicate that uropathogenic *E.coli* dominates the interspecies competition between common pathogens indwelling catheters.

***streptococcus Agalactiae* Biofilm Production Is Influenced By Environmental Ph, Glucose, And Zinc Availability**

Author Block:

R. S. Doster[1], V. Kothary[1], L. M. Rogers[1], C. A. Wakemen[1], E. P. Skaar[1], S. D. Manning[2], D. M. Aronoff[1], J. A. Gaddy[3]; [1]Vanderbilt Univ. Sch. of Med., Nashville, TN, [2]Michigan State Univ., East Lansing, MI, [3]Tennessee Vally Hlth.care System, Nashville, TN

Abstract Body:

Background: Group B *Streptococcus* (GBS) infections are important causes of preterm birth and neonatal sepsis. Approximately 30% of pregnant women are colonized with GBS, but recto-vaginal colonization can be transient or persistent. We hypothesize that biofilm production is important to maintain vaginal colonization by GBS. We sought to define environmental characteristics that influence GBS biofilm production *in vitro*.**Methods:** Clinical GBS isolates were grown in Todd Hewitt Broth that varied in pH, glucose content, and zinc availability. *In vitro* biofilm production at 24 hours was determined by measuring the OD_{600} (bacterial biomass) and OD_{540} after crystal violet staining. Biofilms were also grown in a lateral drip flow reactor and on explanted fetal membranes. These samples were evaluated by scanning electron microscopy and confocal microscopy to visualize biofilm production.**Results:** 6 clinical GBS isolates were evaluated for biofilm production at pH 5, 6, and 7.8 with or without 1% glucose supplementation. 5/6 of these isolates grew the most biofilm at pH 5.0 with 1% glucose. We then completed a more detailed biofilm comparison using 2 of these strains, GB37, an invasive capsular type V, and GB590, a colonizing capsular type III strain. These were compared in a lateral drip flow reactor, where marked differences in biofilm production were seen with GB37 producing more biofilm with a higher carbohydrate content. We assessed these strains' ability to form biofilms in media with limited zinc availability. In the presence of TPEN, a zinc chelator, both strains produced greater than 3 times amount of biofilm/biomass compared to media alone. Biofilm production returned to baseline with the addition of exogenous zinc. Biofilm production on explanted fetal membranes was also reduced at 24 hours with the addition of 10 μM zinc.**Conclusions:** GBS clinical isolates vary in their ability to produce biofilm. *In vitro* biofilm production was improved with low pH (5.0), glucose supplementation, and limited zinc availability. These environmental conditions may be important for vaginal colonization of GBS during pregnancy and subsequent ascending infections.

Antimicrobial Activity and Phytochemical Properties of C*roton zambesicus* on S*taphylococcus aureus* and S*treptococcus* Species

Author Block:

O. A. Ajayi; Adekunle Ajasin Univ.,, Akungba-Akoko, Ondo State, Nigeria

Abstract Body:

Background: Antimicrobial activity of *Croton zambesicus* on *Staphylococcus aureus* and *Streptococcus* species was determined during the study. *Croton zambesicus* belongs to the family, Euphorbiaceae and order, Malpighiales. It has its common name as 'Ajekobale' (Yoruba language, Nigeria). **Methods:** About 200g of the powdered leaves of the *Croton zambesicus* plant were soaked in 400ml of 95% Ethanol, Distilled water and Petroleum ether in a 500ml reagent bottle and stoppered. This was allowed to stand for 14 days to permit full extraction of the active ingredients. It was filtered and the extracts were rotary dried to obtain the concentrate kept in fridge prior to use. A 2.0µg/ml solution of each extract was prepared with DMSO (dimethyl sulfoxide) and fractionated into 0.6µg/ml, 0.4µg/ml and 0.2µg/ml concentrations needed for the bioassay. The antimicrobial properties of the extracts were determined using the agar diffusion method on Mueller Hinton agar culture.**Results:** Ethanolic extract of *Croton zambesicus* has the highest antimicrobial effect on *Staphylococcus aureus* with the 0.6g/ml concentration giving the highest zone of inhibition. However, aqueous extract of *Croton zambesicus* on *Staphylococcus aureus* and *Streptococcus* species respectively was low. Phytochemical screening of *Croton zambesicus* shows the presence of constituents such as Cyanogenic Glucoside, Steroid, Anthraquinone, Phenol, Saponins and Flavonoids, except alkanoid and tanins. Quantitative analyses of mineral elements in *Croton zambesicus* shows the presence of Sodium (Na), Potassium (K), Calcium (Ca), Magnesium (Mg), Zinc (Zn), Iron (Fe), Lead (Pb), Cupper (Cu), Manganese (Mn) and Potassium (P). Magnesium has the highest composition and lead was not detected. Its proximate nutrients have highest composition of carbohydrate.**Conclusions:** Observations made in this study will help to identify some active agents responsible for antimicrobial potentials of *Croton zambesicus* especially in subduing aetiologic agents tested under this context among others. Thus, the study ascertains the value of this medicinal plant in the development and production of new drugs or antibiotics.

Quorum Sensing-Mediated Social Cooperation is Required for *Streptococcus mutans* to Compete with Related Species in Biofilms

Author Block:

Y-H. Li, X-L. Tian, Oral Biofilm Ecology Group; Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Background: Natural life of bacteria in biofilms often involves complex interactions that can be either competitive or cooperative. Competition between species is a well-known ecological force to drive bacterial metabolism, diversity and evolution. However, relatively little is known of bacterial cooperative activities in inter-species interactions. **Methods:** In this study, we first examined quorum sensing (QS)-mediated cooperation for bacteriocin production in *Streptococcus mutans* UA159 (Sm) and its isogenic mutant SmΔCDE (QS negative). We then examined interspecies interactions of Sm with Ss (*S. sanguinis* SK108) and An (*Actinomyces naeslundii* WVU627) in dual- or three-species biofilms.**Results:** The results showed that SmΔCDE was defective in QS-mediated bacteriocin activity, but had the higher growth yield than the parent, suggesting that QS-mediated cooperation was metabolically costly. We also found that QS-activated population (Sm) was susceptible to exploitation by QS mutant (SmΔCDE) in a mixed culture system. Interestingly, the populations began to shift with dominance by Sm (wt) over SmΔCDE when the culture was introduced with a competing species, either Ss that was sensitive to bacteriocins produced by Sm or An that was more effective to form a biofilm but not sensitive to bacteriocins. Even more interestingly, all four populations of Sm, SmΔCDE, Ss and An (three species) co-existed with frequencies of 40% of Sm, 10% of SmΔCDE 30% of Ss and 20% of An in the biofilm. The results suggest that QS-mediated social cooperation in *S. mutans* may be limited by metabolic cost or by the invasion of a QS mutant or 'cheater'. However, the presence of one or more competing species can limit or reduce the spread of QS mutants in the community.**Conclusions:** We conclude that QS-mediated social cooperation is required for *S. mutans* to compete with related species in biofilms.

Characterizationof a Biofilm Formation-associated Histidine Kinase in *Listeria monocytogenes*Egd-e

Author Block:

A. A. Khan[1], D. Bae[1], H. Abdelhamed[2], A. Karsi[2], T. Zhang[3], C. Wang[2]; [1]U.S. FDA/Nat'l. Ctr. for Toxicol. Res., Jefferson, AR, [2]Mississippi State Univ., Mississippi State, MS, [3]Harvard Med. Sch., Boston, MA

Abstract Body:

Background: *Listeria monocytogenes* biofilm formation is a concern in food processing plants and as a result their presence has been has been widely studied. However, identification of genes associated with biofilm formation in *L. monocytogenes* is limited. Histidine kinases (HKs) can act as sensors for cell to cell communication responsible for environmental stresses in *L. monocytogenes*. Through our preliminary study, we found that *L. monocytogenes* serovar 1/2a food-related isolates (FRIs) produce more biofilm than serovar 4b FRIs, and 4b strains do not have an ortholog corresponding to *lmo1061*, a putative HK of *L. monocytogenes* EGD-e (serovar 1/2a). We then hypothesized that *lmo1061* may play a significant role in biofilm formation. **Methods:** Using a reverse genetic approach, an in-frame deletion mutant of *lmo1061* (Δ*lmo1061*) was constructed to characterize the role of *lmo1061* in biofilm formation. The abilities of *L. monocytogenes* EGD-e wild-type (WT) strain, the Δ*lmo1061* strain, and the complemented strain on cell growth, biofilm formation using the crystal violet binding assay, and antimicrobial resistance were further determined. **Results:** The results demonstrate that Δ*lmo1061* produced less biofilm than WT and complemented strains for the whole experiment period of 5 weeks at 4 °C. However, a significant difference in antimicrobial resistance between WT and *Δlmo1061*strains was not found. The growth of Δ*lmo1061* tended to decrease with increased time when compared to WT strain. After three weeks, the OD_{600} value of Δ*lmo1061* strain was significantly less than that of WT strain with downregulation in the mRNA expression level of genes, encoding sugar uptake transporters. **Conclusions:** Data from our biofilm-associated phenotypes suggests that a HK *lmo1061*may be involved in biofilm formation. However, a notable difference in the abilities of the WT and mutant strains on cell growth and stress adaptation was not found. A further study may be required to examine functional redundancy among *lmo1061* paralogs with the molecular mechanisms involved in biofilm formation by the gene.

Comparison of *Salmonella enterica* typhimurium and *Escherichia coli* o157:H7 Survival and Adaptation to Desiccation, Low Water Activity, and Thermal Tolerance

Author Block:

A. Maserati[1], F. Diez-Gonzalez[2], A. Lourenco[2], **R. C. Fink**[3]; [1]Univ. of Minnesota, St. paul, MN, [2]Univ. of Minnesota, St. Paul, MN, [3]St. Cloud State Univ., St. Cloud, MN

Abstract Body:

Background: *Salmonella* and *Escherichia coli* O157 are important foodborne pathogens, responsible for multiple outbreaks every year in the US. *Salmonella* species are different to *E. coli* because they are more resistant to desiccation and develop thermal tolerance when exposed to low water activity. The objective of this study was to compare the morphological and phenotypical characteristics of both pathogens. **Methods:** The ability to survive desiccation and low water activity (a_w 0.11) was tested by inoculating *Salmonella* ser. Typhimurium and *E. coli* O157:H7 cultures on micro glass-beads and polystyrene microplates. Cells were dried at 38.5°C for 4 days and then equilibrated to a_w 1.0 and 0.11 for 7 d. Cell counts were determined for each strain and treatment. Scanning electron microscopy (SEM) was used to analyze phenotypic and morphological changes of cells under each condition. For thermal treatment, cells equilibrated on micro glass beads were exposed to 75°C.**Results:** On both beads and microplates, *E. coli* O157 counts were reduced at least 2 log CFU after drying compared to *Salmonella* ($p \leq 0.05$). *E. coli* was never recovered at a_w 0.11 in both matrices after 7 d, but *Salmonella* counts remained at more than 10% of the initial count. SEM images of cells dried on glass beads showed differences in biofilm formation during drying between *Salmonella* and *E. coli* O157. *Salmonella* cells were covered by a thick layer of exopolisaccharides, whereas *E. coli* produced very little glycocalyx. No differences between the two were detected at a_w 1.0. At a_w 0.11, *E. coli* biofilm appeared flattened and damaged compared to *Salmonella*'s, where a thick layer of matrix was still present. After thermal treatment, the *E. coli* biofilm presented damaged and detached spots.**Conclusions:** Our results show that, differently from *E. coli* O157, *Salmonella* is able to readily produce a structured biofilm during the early stages of desiccation. *E. coli* eventually forms a biofilm morphologically similar to *Salmonella*. However, the different thermal tolerance of these structures suggests that there may be important chemical factors that play a role.

Attachment and Viability Properties of *Acinetobacter baumanii* with Different Antimicrobial Susceptibility Profiles

Author Block:

I. Kanesaka[1], A. Kanayama[1], A. Kaneko[2], H. Takahashi[1], I. Kobayashi[1]; [1]Toho Univ., Tokyo, Japan, [2]Tokai Univ., Kanagawa, Japan

Abstract Body:

Background: Attachment to environment surfaces and long-term survival of bacteria in the hospital environment poses a serious risk of hospital-acquired infections as transmission of resistant organisms from the inanimate hospital environment can occur. In this study, we studied the viability of *A. baumannii* after artificial contamination of surfaces of material commonly used in the hospital environment. **Materials and Methods:** A total of 8 *A. baumannii* isolates consisting of seven clinical isolates of *A. baumannii* including 4 multi-drug resistant *Acinetobacter* (MDRA) and ATCC 15308 were applied to polypropylene (PP) and silicone (SI) plates (1 cm^2). A 10^5 inoculum of each organism was added to PP and SI plates for a total of 16 plates. After allowing plates to dry, viability at 20 °C was assessed at days 1, 2, 3, 7, 15 and 30. One ml of BHI broth was added and plates were shaken to remove attached organisms followed by quantitative culture. **Results:** Including the ATTC strain and 3 clinical isolates of non-MDRA, about 10^2 CFU were recovered on PP at 7 days and 15 days on SI. All MDRA isolates were not detected on PP and SI after 1 day (p<0.01). The viability of A. baumannii differed based on the material to which attachment occurred. Furthermore, non-MDRA isolates had longer survival compared to MDRA. **Conclusions:** The data shows that viability of *A. baumannii* attached to environmental surfaces differs based on whether it is non-MDRA and MDRA.

Biofilm Formation Is Clonal Specific among *Staphylococcus aureus* Isolated from Selected Vermont Dairy Farms

Author Block:

R. Mugabi, J. Barlow; Univ. of Vermont, Burlington, VT

Abstract Body:

Staphylococcus aureus remains an animal and public health burden; in cattle, it causes mastitis one of the leading causes of production losses in the dairy sector. The ability of *S. aureus* to form biofilm is believed to contribute to chronicity and persistence of infections. The objective of this study was to evaluate whether clonal lineage and surface type significantly affect biofilm formation. Isolates used in this study were from two previous epidemiologic studies in Vermont.One hundred isolates were from bulk tank milk of 43 organic dairy farms and fifty-nine from various sources (cow milk, teat end, human hand and nose, dog and bulk tank) of four farmstead cheese conventional dairy farms. All the isolates (159) were strain typed by multilocus sequence typing (MLST) and assigned to their respective clonal complexes using MLST eBURST software. The isolates were PCR screened for presence of icaA, icaD and Bap genes. Biofilm formation was evaluated using the standard microtiter plate *in Vitro* assay using two 96 well plate type surfaces (treated and untreated). All isolates were positive for icaA and icaD but negative for Bap gene. Among the organic isolates, CC97 isolates significantly formed biofilm ($p<0.05$) on untreated plates in comparison to other clonal complexes (CC8, CC151) whereas CC8 isolates formed strong biofilms on treated plates. In a linear regression model, plate surface and clonal lineage were significant predictors of biofilm formation. There was no significant difference in biofilm formation among *S. aureus* isolates from the four conventional farms on the two plate surfaces regardless of the source. However CC8 isolates significantly ($p<0.05$) formed biofilm compared to CC5, CC30 and CC97 on the two plate surface types.Overall, this work shows that *S. aureus* biofilm formation is lineage specific and may contribute to the dominance of a given lineage. The difference seen in the isolates between the two studies (conventional vs organic) may be attributed to differences in diversity. Organic isolates had twenty strain types from 43 farms compared to 8 strain types from 4 conventional dairy farms. This work lays a platform to investigate *S. aureus* surface markers that drive the differences in biofilm formation between surface types and within *S. aureus* lineages.

Listeria Adhesion Protein Augments Antilisterial and Antibiofilm Activity of Peptide Functionalized Gold Nanoparticles

Author Block:

A. K. SINGH, M. A. R. Amalaradjou, A. K. Bhunia; Purdue Univ., West Lafayette, IN

Abstract Body:

Background: Tunable surface chemistry of citrate-stabilized gold nanoparticles[1] (GNP) provides suitable and flexible platform for stable conjugation and targeted delivery of various biomolecules in theranostic applications. Gold nanoconjugates can be applied as an antibacterial and antibiofilm agents. Bacterial infections such as listeriosis caused by foodborne pathogen, *Listeria monocytogenes* poses a serious threat to human health worldwide. In this study, we synthesized and assessed the antilisterial and antibiofilm properties of a novel gold nanocomposite, functionalized with antilisterial peptide Pediocin AcH[2] and *Listeria* adhesion protein[3] (LAP) for targeted destruction of *L. monocytogenes*. **Methods:** Biophysical (TEM, Zeta potential, FTIR, Spectroscopy, Fluorimetry) methods were adopted to characterize the nanocomposite. Bioassay, plate counts, and mammalian cell culture-based cytotoxicity assays were used to assess antilisterial and antibiofilm activity of GNP composites. Biocompatibility of the composite was also assessed using the LDH-based cytotoxicity assay on Caco-2 cells after treatment with GNP alone or gold nanocomposites.**Results:** TEM results revealed that the GNP and the nanoconjugate sizes were about 20 nm and 40 nm, respectively. Biophysical experiments underscored electrostatic interactions between citrate-stabilized GNP and biomolecules (Pediocin, LAP). Compared to the GNP-Pediocin conjugate, treatment of *L. monocytogenes* with the GNP-Pediocin-LAP conjugate resulted in 11.1% higher zone of inhibition in bioassay, and higher reduction (1.5 $\log_{10}$ CFU/mL) in bacterial counts. In the antibiofilm test, similar treatments resulted in 24% and 31% more reduction in *Listeria* counts after 24 h and 48 h of incubation, respectively. Also, in cytotoxicity assay, *L. monocytogenes* induced cytotoxicity was lowered by 16% for pre-treatment of Caco-2 cells with the GNP-Pediocin-LAP conjugate compared to the GNP-Pediocin alone. Neither GNP nor nanocomposite exposure resulted in any significant cytotoxicity (p <0.05) on the Caco-2 cells.**Conclusions:** Gold nanocomposites were biocompatible and when functionalized with both the Pediocin and the LAP, revealed higher antilisterial and antibiofilm activities compared to just Pediocin functionalized GNP or Pediocin alone.

The Effect of Nicotine and Sugar on the Growth and Biofilm Formation of *Pseudomonas aeruginosa*

Author Block:

G. A. De Leon, N. Chalongwongse, J. K. Chan; Cal Poly Pomona, Pomona, CA

Abstract Body:

Nicotine is the addictive chemical found in tobacco and is consumed by millions of people daily. It has been proven that smokers experience more bacterial infections than non- smokers. In addition, sugars are also known to be a health risk and can lead to obesity and tooth decay. Pseudomonas aeruginosa (PA) is a gram-negative opportunistic bacterium that is found in the human body, including the oral cavity. The ability of PA to form biofilms allows the bacteria to survive in adverse conditions and to be more tolerant to antibiotics than stationary-phase planktonic bacteria. The objective of this study is to examine how nicotine and various sugars affect the growth and biofilm formation of PA. To determine the effect of nicotine on the growth, different concentrations of nicotine ranging from $1x10^{-1}$ M to $1x10^{-11}$ M were added to a flat bottom 96-well microtiter plate containing a 1:10 dilution of the 24 hour culture of PA in M63 liquid media. After 48 hours of incubation, the growth of the PA was evaluated using a spectrophotometer. The results were analyzed using a sample t-test to observe for significant differences ($p<0.05$). To study the effect of nicotine and sugars on biofilm formation, the crystal violet biofilm assay was used. After 48 hours of incubation of the fresh culture PA, the non-adhered PA bacteria were washed and decanted and the adhered PA bacteria were stained with crystal violet. The amount of stain in the bacteria was released with acetic acid and was then measured and analyzed using a sample t-test for significance ($p<0.05$). All data represented quadruplicate runs and the results indicated that nicotine at the concentrations used had no significant effect on the growth of PA, but significantly decreased the biofilm formation, with higher concentrations of nicotine suppressing biofilms formed ($p<0.05$). Results also showed that of the sugars tested, sucrose, maltose and galactose all significantly suppressed biofilm formation of PA, while glucose had no significant effect. When combined with nicotine at a concentration of $1x10^{-3}$ M, the results showed that the suppressing effect of nicotine with sugar is not additive.

Coexistence of *Streptococcus gordonii* and *Streptococcus mutans* in a Cariogenic Mixed-Species Biofilm

Author Block:

M. I. Klein[1], C. Getaz[2], J. Kreth[3]; [1]Araraquara Dental Sch., Univ Estadual Paulista, UNESP, Araraquara, Brazil, [2]Eastman Inst. for Oral Hlth., Univ. of Rochester, Rochester, NY, [3]Sch. of Dentistry, Oregon Hlth.& Sci. Univ., Portland, OR

Abstract Body:

Background: *Streptococcus mutans* is associated to the pathogenesis of dental caries while *Streptococcus gordonii* is linked to healthy biofilms, as an antagonist of *S. mutans*. Hence, we studied whether *S. gordonii* (Sg) and *S. mutans* (Sm) co-exist in a cariogenic mixed-species biofilm, and whether specific *Sg* genes affect the formation of mixed-species biofilm.**Methods:** The strains *S. gordonii* DL-1 (parental and knockout mutant strains for genes *ccpA, gtfG,* and *pox), Actinomyces naeslundii* ATCC 12104 and *S. mutans* UA159 were used to grow mixed-species biofilms on saliva-coated hydroxyapatite discs in the presence of 1% (w/v) sucrose and 25% whole saliva. Biofilms were evaluated at 3 distinct ages (29, 67 and 115h) for viable population, and for architecture and biomass composition using confocal microscopy.**Results:** In the mixed-species biofilm formed with parental strains, both *Sm* and *Sg* populations increased over time. However, the proportions of the three mutant strains did not increase while *Sm* thrived in these biofilms. *A. naeslundii* population declined in the biofilm formed with *Sg* parental strain, while it increased in biofilms containing *Sg* mutant strains. Moreover, the mixed-species biofilms with the *Sg* parental strain lacked well-defined microcolonies (vs. biofilm with *mutant* strains). The amount of bacteria and exopolysaccharides matrix biomass were distinct for mixed-species biofilms formed with *Sg* parental strain (*vs*. the three mutant strains; $p<0.05$).**Conclusions:** Therefore, *S. gordonii* can co-exist well in a cariogenic mixed-species biofilm with *S. mutans*, and the disruption of *S. gordonii* genes *ccpA*, *gtfG* and *pox* affects the fitness of this species in biofilms.

Differential Production of Pyocins by Environmental and Cf-Associated Pseudomonas Aeruginosa

Author Block:

J. J. Bara, A. W. Diddle, S. K. Remold; Univ. of Louisville, Louisville, KY

Abstract Body:

Bacteriocins are narrow spectrum, anticompetitor toxins, produced by bacteria in response to environmental stress and are important mediators of competitive interactions. The opportunistic pathogen *Pseudomonas aeruginosa,* which is the most dominant bacterium causing chronic infections in individuals with cystic fibrosis (CF), is distinct among studied bacteria in the extent to which strains produce bacteriocins, known in *P. aeruginosa* as pyocins. However, despite their ubiquitous production by *P. aeruginosa*, we lack a comprehensive understanding regarding the role of pyocins during chronic infection of the CF upper respiratory tract. Furthermore, recent studies suggest that pyocin production may be pleiotropically linked to performance in response to certain abiotic stressors that induce their expression. In this study, we used a set of 63 environmental and CF-associated *P. aeurginosa* strains collected from sites in and around 15 different homes in the Louisville, KY metropolitan area to investigate 1) the number and diversity of pyocins found in environmental and CF strains 2) the ability of environmental and CF strains to inhibit the growth of a competitor via pyocins, and 3) the correlation between pyocin production and sensitivity to ciprofloxacin, or oxidative stress. Using a standard PCR protocol, we screened each *P. aeruginosa* strain for the presence of 5 S-type pyocin genes (S1, S2, S4, S5, and AP41), as well as the R/F-type pyocin gene cluster. Using a subset of 29 *P. aeruginosa* strains we conducted a bidirectional inhibition assay to assess the ability of the strains to inhibit or be inhibited of via pyocins. For each strain, we determined the ciprofloxacin and hydrogen peroxide minimum inhibitory concentration using a broth microdilution method in 96-well plates. We found no significant difference in the number or composition of pyocin genes in environmental and CF strains, but found that CF strains were more susceptible and inhibited growth at a significantly lower rate relative to environmental strains. Additionally, we found no significant correlation between pyocin inhibition rate and sensitivity to either ciprofloxacin or hydrogen peroxide. Our results suggest that while environmental and CF strains have a similar array of pyocins, they may be differentially expressed or regulated, as inhibition and susceptibility rates were significantly different.

The Role of *Rpoe* Gene in Biofilm Formation and Virulence of S*almonella typhimurium*

Author Block:

D. Peng, J. Huang, S. Chen; Coll. of Vet. Med., Yangzhou Univ., Yangzhou, China

Abstract Body:

Salmonella Typhimurium is one of the most important food-borne pathogens for humans, and its formation of a biofilm may improve its resistance to environmental stress. However, the roles of the *rpoE* gene in biofilm formation and virulence of *S. Typhimurium* remain unclear. In this study the *rpoS* gene-dependent or -independent strain for biofilm formation was determined by crystal violet staining and catalase test. The Real-time PCR method was established to compare the expression of six different Sigma factors during the period of biofilm formation. Deletion mutants were constructed using the Red recombination system, and their biofilm-forming ability and LD_{50}s were determined. The results showed that the expression of *rpoE* gene was the highest in an *rpoS*-independent strain S016 after an 24-hour incubation, while the expression of *rpoS* gene was the highest in an *rpoS*-dependent strain S025. Both S025ΔrpoS and S025ΔrpoE mutants could not produce biofilm. However, S016ΔrpoS kept the biofilm-forming ability, while S016ΔrpoE could not produce biofilm. The LD_{50}s in chickens of all ΔrpoS mutants were similar as that of the wild-type strains, while LD_{50}s of all ΔrpoE mutants were lower than that of the wild-type strains. Our data indicate that **t**he *rpoE* gene acts as a regulator in biofilm formation and virulence of *S. typhimurium*.

D-Tagatose Inhibits *Streptococcus mutans* Biofilm Formation

Author Block:

K. Hasibul, T. Ogawa, H. Nakayama-Imaohji, T. Kuwahara, M. Miyake, M. Tokuda; Faculty of Med., Kagawa Univ., Miki, Kita, Japan

Abstract Body:

Background: Dental caries is one of the important global oral health burdens. Mutans streptococci have been established as a major cariogenic bacterial species. Among the hundreds of rare sugars, some (e.g. D-allose & D-pscicose) show the pharmacological effects that could be applied to medicine. We previously reported that a rare sugar, D-tagatose, suppresses the acid production & water insoluble glucan synthesis in *Streptococcus mutans*.**Methods:** In this study, we evaluated the inhibitory effect of D-tagatose on the *S. mutans* biofilm formation. Effect of different percentages of D-glucose, xylitol & D-tagatose on *S. mutans* GS5 biofilm production was compared by microplate assay with crystal violet. Growth monitoring of *S. mutans* until 24-h incubation showed that 1% D-tagatose only prolonged the lag-phase without interference in the final cell growth, indicating the *S. mutans* biofilm inhibition by this rare sugar is due to the mechanisms other than bacteriostatic effect.**Results:** D-tagatose (1.0 to 4.0%) significantly decreased *S. mutans* biofilm after 72-h incubation and its effect was dose-dependent. Consistently, 4% D-tagatose reduced insoluble glucan production from *S. mutans* in the presence of 1% sucrose to 17% of control. Scanning electron microscopy showed that D-tagatose was more effective for the *S. mutans* biofilm mass reduction than xylitol.**Conclusions:** From these findings, we conclude that the foods or preparations containing D-tagatose are useful tools for oral health care, which inhibit the initial stage of cariogenesis.

Bacterial Attachment and Biofilm Formation by Pathogenic Bacteria are Hindered by Small Nanoscale Pores

Author Block:

Y. Cheng[1], G. Feng[1], S. Wang[2], D. A. Borca-Tasciuc[2], R. W. Worobo[1], C. I. Moraru[1]; [1]Cornell Univ., Ithaca, NY, [2]RPI, Troy, NY

Abstract Body:

Background: Prevention of biofilm formation by bacteria is a prominent challenge in many areas affecting human health and life, including medicine, dentistry, food processing, and water treatment. This work showcases an effective solution for reducing attachment and biofilm formation by several pathogenic bacteria frequently implicated in foodborne illnesses and medical infections, by enhancing the repulsive force exerted on the bacterial cells.**Methods:** Using anodization, alumina surfaces featuring cylindrical nanopores with pore diameters of 15 to 100 nm were created and evaluated for attachment by *Escherichia coli* ATCC 43894, *Listeria monocytogenes* 10403S, *Staphylococcus aureus* 9144, and *Staphylococcus epidermidis* ATCC 35984. The attachment studies were conducted in tryptic soy broth, at 37 °C, in static mode. After 48 h, the attached cells were stained with a fluorescent dye and attachment evaluated by Confocal Laser Scanning Microscopy. Surface properties of the cells and anodic substrates (zeta potential, surface energy), size and topography were determined experimentally and used to calculate the cell-surface interaction forces based on the extended Derjaguin-Landau-Verwey-Overbeek theory. The maxima of the interaction forces were then correlated with the attachment data. The study was replicated a minimum of three times. **Results:** Anodic alumina surfaces with pore diameters of 15 and 25 nm were shown to effectively reduce bacterial attachment or biofilm formation by all strains, while larger pore sized increased attachment. The observed effects are likely due to the amplification of repulsive cell-surface interactions by the large surface area of the high density, small-diameter pores. Biological factors, including cellular appendages and the exopolysaccharide secreted by the cells, are also likely to affect attachment.**Conclusions:** This work enhances our understanding of the effect of nanoscale topography on bacterial attachment to abiotic surfaces. Moreover, this demonstrates how to optimize the elements of surface topography and further enhance the observed bacteria-repelling effects, which could have implications and applications in the health care field and food industry.

Inactivation of *Reca* in *Enterococcus faecalis* Decreases Biofilm Formation on Various Surfaces

Author Block:

S. M. Lee, L. Chua; Monash Univ. Malaysia, Petaling Jaya, Malaysia

Abstract Body:

Enterococcus faecalis is a major nosocomial pathogen worldwide. Many *E. faecalis* isolates are able to produce biofilms which increase their recalcitrance to antibiotic therapy. Interestingly, subinhibitory concentrations of ciprofloxacin (an antibiotic which inhibits DNA replication) can actually stimulate biofilm production in other bacteria such as *Pseudomonas aeruginosa*. This phenomenon is linked to the SOS response, where the RecA protein acts as a sensor for DNA damage. Furthermore, repression of bacterial motility appears to play a role in the repression of SOS-inducible biofilm formation. The aim of this study was to determine if the inactivation of the *recA* gene would have an impact on the ability of *E. faecalis*, which are non-motile bacteria, to attach to various surfaces and to form biofilms. In this study, three strains were used: Wild type, *E. faecalis* JH2-2 (WT), insertionally inactivated *recA* mutant (M) and a complemented *recA* mutant strain (C). All three strains had growth rates that were not significantly different from one another. When all three strains were treated with subinhibitory concentrations of ciprofloxacin (MIC = 4 µg/ml) and levofloxacin (MIC = 2 µg/ml), the WT and C strains did not show increased biofilm production on 96-well microtiter plates. However, the M strain showed significantly lower biofilm production compared to the other two strains when grown with or without antibiotics. Additionally, all three strains were able to form biofilm on various surfaces such as glass, stainless steel and polypropylene. However, the *recA* mutant had significantly and consistently lower ($p<0.05$) biofilm formation for all surfaces compared to the WT and C strains. Similarly, the recA mutant has significantly lower ($p<0.05$) cell surface hydrophobicity (via contact angle measurement), initial attachment to polystyrene and aggregation ability. However there was no significant difference in terms of cell surface charge among the three strains when measured with a zetasizer. The results of this study suggest that RecA can affect the cell surface properties of *E. faecalis*, which in turn can affect the bacteria's ability to attach to surfaces and form biofilms.

The Influence of Culture Media on Biofilm Formation by Dermatophytes

Author Block:

C. B. Costa-Orlandi[1], R. H. Pires[2], J. D. Nosanchuk[3], A. M. Fusco-Almeida[1], M. J. S. Mendes-Giannini[1]; [1]UNESP - Univ.e Estadual Paulista, Araraquara, SP, Brazil, [2]UNIFRAN - Univ.e de Franca, Franca, SP, Brazil, [3]Albert Einstein Coll. of Med., Bronx, NY

Abstract Body:

Background: Over the last few years, filamentous fungi, particularly the dermatophytes, have been recognized as biofilm-forming microorganisms. Nutrients in the environment can influence the development and final chemical composition of biofilms, suggesting the correlation between metabolic substrates and biofilm architecture. This work aims to evaluate the influence of four different culture mediums on biofilm formation by *Trichophyton rubrum* and *T. mentagrophytes*.**Methods:** The biofilms of two ATCC strains and two clinical isolates of *T. rubrum* and *T. mentagrophytes* were observed following cultivation in RPMI 1640, Brain-heart infusion (BHI), Dulbecco's Modified Eagle's media (DMEM) and serum free medium for keratinocytes culture. After 72 hours of growth, the biomass and the extracelular matrix (ECM) were quantified using the crystal violet (CV) and safranin methods, respectively. The ultrastructures of the mature biofilmes were visualized by scanning electron microscopy (SEM) and confocal laser scanning microcopy (CLSM).**Results:** Overall, cultivation in RPMI, DMEM and BHI resulted in the most robust production of biomass and ECM. The biofilms of *T. rubrum* ATCC 28189, *T. rubrum* 143 and *T. mentagrophytes* 66 produced higher amounts of ECM compared to *T. mentagrophytes* ATCC 11481 ($p<0.05$). SEM images showed that the biofilms formed in RPMI, BHI and DMEM exhibited a highly organized ECM, covering and connecting the hyphae. CLSM images showed that RPMI and DMEM produced thicker biofilms, while the BHI produced denser biofilms.**Conclusions:** These results demonstrate that *T. rubrum* and *T. mentagrophytes* are able to form biofilms in diverse culture mediums with varying characteristics and these variations can contribute significantly to future studies of dermatophyte biofilms.

Publishing Title:

Biodegradation of Environmental Contaminants by Acidophilic Methanotrophs

Author Block:

Y. Shao; Texas A&M Univ., COLLEGE STATION, TX

Abstract Body:

Methanotrophs, ubiquitous in the environment, can oxidize methane by expressing soluble methane monooxygenase (sMMO) or particulate methane monooxygenase (pMMO). Compared to pMMO, sMMO is nonspecific and known for its ability to degrade a wide range of pollutants, including halogenated hydrocarbons. Among many acidophilic methanototrophs recently identified, *Methylocella* is one genus of methanotrophs which possess only sMMO. *Methylocella* species not only grow on one-carbon compounds like methane and methanol but also multicarbon compounds like acetate, pyruvate, succinate, malate, and ethanol. However, using multicarbon compounds, like acetate, may repress the expression of sMMO in some *Methylocella* species. The goal of this study is to investigate the ability of known Methyocella strains to degrade common groundwater contaminants in the absence and the presence of multicarbon substrates.Methylocella strains, *Methylocella tundra* and *Methylocella silvestris* BL2 and another facultative methanotrophs, *Methylocystis bryophila* are used as model strains, and trichloetheylene (TCE), 1,4 dioxane, and 1,2,3-trichloropropane (TCP) are used as model contaminants in this study. Our preliminary results show that *Methylocella tundra* growed on both methane and acetate. Bacteria grew faster when acetate as carbon source. The optical density at 600 nm (OD_{600}) reached 0.28 after 48 hours, while OD_{600} was only 0.13 growing on methane. *Methylocella silvestris* BL2 grew slowly than *Methylocella tundra*. It took *Methylocella silvestris* BL2 two weeks to reach OD_{600} 0.21. *Methylocystis bryophila* also grow on both carbon sources. OD_{600} reached 0.14 growing on methane and 0.18 growing on acetate. Three strains can survive at low pH..The results of naphthalene assay shows the *Methylocella tundra* can constitutively express sMMO with only acetate. *Methylocella silvestris* can express sMMO to degrade TCE. *Methylocella silvestris* also can grow with propane, with the express of sMMO, which may shows another metabolism involved in multicarbon compounds utility.The findings of this study are valuable to further study future research on the biodegradation of TCE in many environments where multicarbon compounds occur.

Probing Active Acidophilic Methanotrophs Involved in Chlorinated Solvent Biodegradation

Author Block:

Y. Shao; Texas A&M Univ., College Station, TX

Abstract Body:

Chlorinated solvents, including trichloroethylene (TCE), are common groundwater contamination. Aerobic and anaerobic biodegradation of chlorinated solvent occurs under neutral pH. However, many of acidic aquatic systems (pH < 5.5) in the United State exist and degradation of chlorinated under acidic environment is thus potentially inhibited.Methanotrophs are capable of degrading TCE through cometabolic reactions using methane monooxygenase (MMO). Several groups of acidophilic methanotrophs, capable of growing well under acidic conditions, have been recently identified. However, little is known about the potential the acidophilic methanotrophs during TCE biodegradation in acidic aquifers. The goal of this study is to use molecular techniques (stable isotope probing and real-time-t-RFLP) to identify active methanotrophs capable of degrading TCE under acidic conditions.A series of microcosms were constructed with soil and groundwater from acidic aquifers, ^{13}C- methane or ^{12}C- methane as carbon source, and TCE. Samples were collected over time for TCE, methane, and microbial community analysis. Our preliminary data showed methane consumption of 2000 µg/L in 72 hours in microcosms incubated. Biodegradation of TCE was observed after 3 weeks of incubation, with 80% removal of TCE initially spiked on week 8^{th}. Our on-going research efforts to separate the heavier DNA (^{13}C-DNA) fractions separated from genomic DNA of collected samples, use the ^{13}C-DNA fractions as templates for determining microbial community structures in the microcosms, and for identification of active acidophilic methanotrophs via cloning and sequencing.The findings of this study will provide a better understanding of potential of using acidophilic methantorophs for TCE biodegradation in acidic aquifers.Keyword : Identification; Active Acidophilic Methanotrophs; SIP; Sequencing; TCE Biodegradation;

***Dehalococcoides* and General Microbial Ecology of Differentially Trichloroethene Dechlorinating Flow-through Columns**

Author Block:

B. Mirza, D.L. Sorensen, R.R Dupont, J.E. McLean; Utah State Univ., Logan, UT

Abstract Body:

The microbial ecology of partial or complete organohalide respiration of the common groundwater contaminant trichloroethene (TCE) has been poorly understood. The ecology of general microbial communities and *Dehalococcoides mccartyi* (*Dhc*) populations that developed in the TCE-dehalogenating layer (0–10 cm) of flow-through columns continuously fed TCE for 7.5 years was studied. Duplicate columns biostimulated with one of three different carbon sources and duplicate non-stimulated controls developed into complete (whey amended), partial- (Newman Zone® nonionic surfactant oil formulation with lactate), limited- (Newman Zone® oil standard surfactant formulation with lactate) and non-TCE dehalogenating systems (controls). Bioaugmentation with Bachman Road culture four years prior to dismantling the columns did not influence the extent of TCE dehalogenation. Three distinct microbial communities were established; one for whey, oils and control treatments. The whey columns exhibited relatively low concentrations of *Proteobacteria* sequences and high *Bacteriodetes* sequences. A significant increase in bacterial genera *Dehalobacter*, *Desulfitobacterium*, *Sulfurospirillum*, *Desulfuromonas*, and *Geobacter* was observed in the columns with limited and partial TCE dehalogenation. These genera may include members capable of partial TCE dehalogenation and use of alternative terminal electron acceptor (Fe^{III}, NO_3, SO_4).*Dhc* formed two taxonomic clusters. Whey column sequences were dominated by Cornell group strains, while all other dehalogenating columns contained Pinellas group strains. Different biostimulation treatments influenced general microbial communities that altered *Dhc* populations either directly through their syntrophic interaction or indirectly by altering predominant column biogeochemical processes. Change in the *Dhc* composition rather than their overall abundance was critical for complete TCE dehalogenation.

Complete Mineralization of Methyl Parathion and Lindane by *Pseudomonas putida* kt2440

Author Block:

T. Gong, Environmental Microbiology and Microbial Manufacture; Nankai Univ., Tianjin, China

Abstract Body:

Currently, we can use the approaches of synthetic biology to creat a strain that processes various catabolic pathways that do not exist in the same strain in nature. Here, we describe the metabolic engineering of a biosafety *Psudomonas putida* stain KT2440 for complete mineralization of methyl parathion (MP) and lindane. A chromosomal DNA scarless modification method (I.e., suicide plasmid in combination with a counter-selection marker *upp*) was adopted to construct a stable and unmarked engineering strain *P. putida* KT2440 can efficiently mineralize MP and lindane. The engineered strain can effiently mineralize 100mg/l MP and 25mg/l lindane within 24 and 60 h, respectively, using MP or lindane as the sole carbon source and inoculum cell density of OD_{600}=0.05. Such a strain not only would reduce the toxicity of MP and lindane but also would prevent the accumulation of potentially toxic intermediates in the environment. A significant metabolic bottleneck, i.e., growth inhibition by the intermediates *p*-nitrophenol and 2,5-dichlorohydroquinone was resolved by introducing two mineralization pathways into *P. putida* KT2440. Due to heterologous expression of *Vitreoscilla* hemoglobin, the engineered strain showed a higher growth rate than wild-type strain in oxygen-limited conditions. Due to heterologous expression of green fluorescent protein, the fate and activity of engineeried strain in soil could be easily monitored by fluorescence. The inoculation of engineered strain (10^6 cells/g) to soil treated with MP and lindane resulted in a higher degradation rate than in noni oculated soils. MP (50 mg/kg) and lindane (25 mg/kg) could be degraded completely in soil within 6 and 11 d, respectively. Soil remediation experiments to demonstrate the viability of the engineered strain in soil may highlight the power of synthetic biology to create novel strains for *in situ* bioremediation of organics contaminated soil.

Transcriptomic and Proteomic Studies of *Dehalobacter* UNSWDHB Reveal Major Changes During Its Organohalide Respiration

Author Block:

B-E. Jugder, H. Ertan, Y. K. Wong, N. Braidy, M. Manefield, C. P. Marquis, M. Lee; Univ. of New South Wales, Sydney, Australia

Abstract Body:

Background: *Dehalobacter* strain UNSWDHB is an organohalide respiring bacteria (ORB) capable of respiring with chloroform (CF, or trichloromethane) as an electron acceptor for the generation of cellular energy and as a consequence, dechlorinating CF to dichloromethane. **Methods:** Comparative genomic, transcriptomic and label-free quantitative proteomic analyses were undertaken to investigate the global response of UNSWDHB strain to CF respiration with a particular focus on its respiratory pathway and formate metabolism.**Results:** We detected the up-regulation of key proteins involved in dehalogenation and electron shuttling, including a CF reductive dehalogenase with its membrane docking protein and putative transcriptional regulator (TmrABC), different types of uptake hydrogenases (membrane-associated Hup-, Hyc- and Ech-type Ni-Fe hydrogenase complexes as well as soluble Hym- and Hyd-type Fe-Fe hydrogenases), formate dehydrogenases (a periplasmic Fdh-N/Fdh-O and a cytoplasmic Fdh-H), a 11-subunit complex I and a pyrophosphate-energized proton pump. Our analysis on the Wood Ljungdahl pathway and its proposed association with formate metabolism expands current knowledge of its role in ORB and it paves the way for future studies on its functional role.**Conclusion:** Taken together, this study provides a broader view on the energy conservation and general physiology of *Dehalobacter* UNSWDHB cells during its respiration utlising CF as an electron acceptor.

Biotransformation of Hexabromocyclododecane with the Haloalkane Dehalogenase $LinB_{UT}$ Isoform

Author Block:

T-H. Chang[1], **Y-H. Peng**[1], S. Wu[1], C-H. Hsu[1], C-W. Chou[1], Y. Nagata[2], Y-h. Shih[1]; [1]Natl. Taiwan Univ., Taipei, Taiwan, [2]Tohoku Univ., Sendai, Japan

Abstract Body:

Brominated flame retardants (BFRs) have been widely used in many industries over decades. Hexabromocyclododecane (HBCD) is one of the most commonly used BFRs, and it has just listed on the table of persistent organic pollutants. In order to develop cost-effective remediation methods for this emerging pollutant, we evaluate the transformation ability of $LinB_{UT}$, a haloalkane dehalogenase from *Sphingomonas paucimobilis* UT26, toward HBCD. The catalysis activity of purified $LinB_{UT}$ was analyzed according to the concentration of residual HBCD and releasing bromide ion after the reaction. The results showed that degradation and debromination of HBCD catalyzed by $LinB_{UT}$ were both dose-dependent. From the kinetics under different enzyme/substrate ratios, the Michaelis-Menten parameters, K_m (0.75 μM) was deduced and the k_{cat} (4.5×10^{-4} s^{-1}) was calculated. The affinity of $LinB_{UT}$ toward HBCD was high while the turn over number was low, leading to similar catalytic activity when compared to other subtracts. According to circular dichroism spectra, the protein structure of $LinB_{UT}$ was loosening at 50 °C, which explained the optimum temperature for enzyme activity. The key residuals for better transformation efficiency of $LinB_{UT}$ than $LinB_{B90A}$ isoform (derived from *Sphigobium indicum* B90A) was also discussed. In this study, the HBCD biotransformation activity of $LinB_{UT}$ was characterized, which provides an alternative remediation strategy for treating HBCD in the environment with one possible effective detoxifying agent.

Anaerobic Dechlorination of Lightly Chlorinated Dibenzo-*p*-Dioxins in Contaminated Sediments

Author Block:

D. E. Fennell, C. Schneider, H. Zhen, J. Liu, R. Caba, S. Ogungbile, V. Krumins, L. Rodenburg; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Background: During remediation of environmental media contaminated with organohalide pollutants, removal of all chlorines from the organic molecule through organohalide respiration is desired. This may detoxify the compound and ultimately allow further biodegradation to occur. We examined the dechlorination of polychlorinated dibenzo-p-dioxins (PCDDs) with four or fewer chlorines in aquatic sediments. **Methods:** Sediment samples from several sites including Gulf Island Pond, ME and Lake Roosevelt, WA, originally contaminated with environmental polychlorinated dibenzo-p-dioxins (PCDDs), were placed in serum bottles with anaerobic minimal medium. The sediments were amended with 1,2,3,4-tetrachlorodibenxo-p-dioxin to study methods for enhancing reductive dechlorination. Triplicate microcosms were amended with electron donor (organic acids), and other treatments were amended with alternate soluble organohalides intended to enhance organohalide-respiring bacteria that may also dechlorinate dioxin. GC-MS was used to monitor dioxins. **Results:** After prolonged incubation (>5 years) abundant 2-monochlorobibenzo-p-dioixn was detected in most treatments and lesser amounts of non-chlorinated dibenzo-p-dioxin (up to 9.8 mol% of the original parent compound) was detected in some treatments. Analysis of sediment microbial communities is being conducted to determine whether specific organohalide-respiring bacteria are present.**Conclusions:** Production of abundant mono-chloro and non-chlorinated dibenzo-p-dioxin from TetraCDD after long incubation times was observed in sediments from multiple locations. Detection of non-chlorinated dioxin raises the possibility that anaerobic dechlorination could result in complete removal of chlorines from polychlorinated dioxins. This would lessen toxicity and allow further degradation of the dioxin molecule.

Dioxin Substrate Range of Dibenzofuran-degrading Bacteria Isolated from Contaminated Sediments

Author Block:

H. AL mnehlawi, D. E. Fennell; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Background/Objectives: The Passaic River/Newark Bay in New Jersey is heavily polluted by hazardous contaminants such as dioxins, polychlorinated biphenyls and heavy metals that are contained in the sediments. Highly chlorinated dioxins may be anaerobically dechlorinated in aquatic sediments and the daughter products of this process may be lightly chlorinated dioxin congeners and non-chlorinated dioxin. The goal of this project is to identify bacteria that aerobically biotransform non- and lightly-chlorinated dioxins.**Approach/Activities:** Sediment samples were collected from the mouth of the Passaic River as it enters Newark Bay. Sediment aliquots were incubated aerobically with dibenzofuran as the sole source of carbon and energy. After activity was noted, enrichments were transferred to fresh minimal medium several times with dibenzofuran as the sole carbon and energy source. Finally, enrichments were plated on minimal agar media and single colonies were transferred to fresh agar plates to obtain pure cultures. Single colonies were transferred back to minimal medium with dibenzofurans the sole carbon and energy source and growth was confirmed by OD increase. The resulting isolates were identified by sequencing partial 16S rRNA genes. The ability of the isolates to use non- and lightly-chlorinated dioxins as a sole energy and carbon sources is being investigated.**Results:** Several bacterial isolates characterized as dibenzofuran degraders, were enriched from the sediments. According to 16S rRNA gene sequencing analysis, they belong to the following genera: *Panibacillus, Janibacter* and *Achromobacter.* The isolates' ability to use non- and lightly-chlorinated dioxin congeners including 2,7-dichlorodibenzo-*p*-dioxin, 2-mon-chlorodibenzo-*p*-dioxin, and dibenzo-*p*-dioxin is being investigated.In conclusion, several dibenzofuran degrading bacterial isolates have been obtained. If the transformation of highly chlorinated dioxins occurs in the river sediment and produce lightly chlorinated dioxins, further degradation or complete aerobic degradation of the daughter compounds by these or other organisms would be an important mechanism to ensure complete removal of the contaminants.

***Frankia* sp. Strains Eui1c and Eun1f Have the Potential to Degrade Dioxins and Dioxin-like Compounds**

Author Block:

E. C. Swanson[1], M. Rehan[2], L. S. Tisa[1]; [1]Univ. of New Hampshire, Durham, NH, [2]Kafrelsheikh Univ., Kafr El Sheikh Governorate, Egypt

Abstract Body:

Frankia sp. are soiling dwelling, nitrogen-fixing, actinobacteria that form facultative symbiotic associations with 8 families of actinorhizal plants. *Frankia* sp. are resistant to numerous heavy metals and toxic organic pollutants which makes the *Frankia*-plant symbiosis a promising candidate for bioremediation applications. We tested the ability of *Frankia* to resist and degrade three dioxin-like organic compounds: biphenyl (BP), 4-chlorobiphenyl (4CBP), and dibenzofuran (DBF). A comparative genomics approach was used to detect regions in *Frankia* genomes homologous to a known dioxin-degrading operon (*bph*) in a closely related species, *Rhodococcus* RAH1. Only 2 of the 19 available *Frankia* genomes, strains EuI1c and EUN1f, contained a putative dioxin-degrading operon homologous to the *bph* operon in *Rhodococcus* RHA1. Growth assays demonstrated that *Frankia* strains EuI1c and EUN1f were able to resist concentrations of BP, 4CBP, or DBF up to 5mM. However, *Frankia* strain CN3, a representative strain lacking the *bph* operon, is only able to resist BP concentrations up to 2mM. Both strains EuI1c and EUN1f also exhibited linear growth with BP or DBF as a sole carbon and energy source at concentrations up to 1.0mM. However, neither strain was able to grow with 4CBP as a sole carbon and energy source. Expression of the putative *bph* operon in strain EuI1c in response to BP exposure was determined through RT-qPCR. This analysis revealed that three representative genes (*bphA, bphC*, and *bphE*) of the *bph* operon were upregulated in response to BP exposure. These findings suggest that *Frankia* sp. strains EuI1c and EUN1f degrade dioxin-like compounds and could be used to remediate land contaminated by dioxin-like compounds.

Identification and Characterization of Bacterial Genes Utilized in Triclosan Degradation

Author Block:

T. K. O'Neal, S. M. NI CHADHAIN; Univ. of South Alabama, Mobile, AL

Abstract Body:

Triclosan is an antimicrobial incorporated into a wide variety of personal care products including soaps, toothpastes, cleaning agents and medical instruments. It is now known that triclosan can bio-accumulate in higher organisms. Studies have suggested that this may lead to negative effects such as disruption of T4 thyroid hormone. This research project is focused on both identifying and characterizing the genes bacteria utilize to degrade triclosan within contaminated environments. Enrichment cultures were previously established using soil and water collected on the University of South Alabama campus in Mobile, AL. Incubations were supplemented with triclosan as the sole source of carbon and energy and serially diluted onto agar plates in order to obtain pure cultures of triclosan degrading bacteria. Amplified ribosomal DNA restriction analysis (ARDRA) and ribosomal intergenic spacer analysis (RISA) of the culture collection was performed to separate the bacteria into different operational taxonomic units (OTU). Forty-eight triclosan degrading bacterial isolates were obtained and grouped into 18 different OTUs. The 16S rRNA gene from representatives of each OTU was sequenced to identify the bacteria to genus or species. The majority of the bacteria were classified as pseudomonads (60%) with other gammaproteobacteria, betaproteobacteria, and bacilli also identified. Triclosan degradation assays indicated that select isolates were capable of degrading triclosan when grown alone with triclosan as the sole carbon source. The isolates were screened by PCR for the recently described *tcsA* and *tcsB* triclosan degradation genes. Ten isolates tested positive for the *tcsA* amplicon. PCR primers were also designed to chlorophenol-4-monooxygenase (*tftD*) and 2,4-dichlorophenol 6-monooxygenase (*tfdB*), genes involved in degradation of the previously identified triclosan degradation intermediates 3-chlorophenol and 2,4-dichlorophenol. To date 10 isolates have yielded *tftD* amplicons which are currently being sequenced. Our results indicate that the ability to degrade triclosan is widespread among bacteria. Furthermore, while PCR results indicate that some of our isolates use previously described degradation genes, it is likely that others utilize novel degradation genes.

Exploring Microbial Genomes in Search of Novel Rieske Oxygenase Guided by Evolutionary Studies

Author Block:

J. Chakraborty[1], C. Suzuki-Minakuchi[1], K. Okada[1], T. K. Dutta[2], H. Nojiri[1]; [1]Univ. of Tokyo, Tokyo, Japan, [2]Bose Inst., Kolkata, India

Abstract Body:

Background: Degradation by bacterial aromatic ring-hydroxylating Rieske oxygenases (ROs) is a major pathway by which wide range of aromatic compounds are mineralized in the environment. Though their structure, mechanism and involved metabolic pathways have been widely studied, a complete understanding of the diversity and evolution of this enzyme system have never been explored. In this study, phylogenetic analyses with set of homologous sequences were used to propose a rational classification scheme and to generate a mathematical model describing the evolution of multi-component RO system. The dataset has further been extended to construct a database and prediction server.**Methods:** Representative sequences from each subgroup of RO family were used as probes to identify homologous sequences using an iterative psi-blast search against GenBank. ClustalX and MEGA were used for phylogenetic analyses. The relational database was built on Apache HTTP web server executing SQL queries. Sequence-dependent search has been implemented using blast algorithm while for cheminformatics, JME molecular editor, Open Babel and Chemminer have been used.**Results:** 411 RO homologues were identified from 260 bacterial strains. As per their phylogenetic relationships and combination of electron transport components, ROs were categorized into 11 different types, 4 of them being identified for the first time, falling within distinct 'similarity classes'. A 'trace-back' approach was followed to predict the components of each peripheral node, gradually proceeding towards preceding nodes using a heuristic algorithm, effectively depicting the entire pathway of evolution of ROs. A manually curated database, RHObase, was developed to provide comprehensive information on all biochemically characterized bacterial ROs, along with integral prediction tools. It is currently being used to characterize ROs from environmental isolates as well as to scan genome sequences of thermophiles with an aim to identify novel ROs.**Conclusion:** Apart from exploring the potential of novel ROs, this study is believed to aid in designing new bioremediation strategies along with application in industrial biosynthetic processes.

Bacterial Community Analysis of a Wastewater Treatment Plant in Colombia and Screening for Lipid-Degrading Microorganisms

Author Block:

L. M. Silva-Bedoya[1], J. Morales-Rodríguez[1], M. S. Sánchez-Pinzón[2], G. E. Cadavid-Restrepo[1], **C. X. Moreno-Herrera**[1]; [1]Univ. Natl. de Colombia, Medellín, Colombia, [2]Compañía Natl. de Chocolates S. A. S., Rionegro, Colombia

Abstract Body:

Background: Removal of organic pollutants in the form of fats, oils and greases is a demanding procedure in wastewater treatment. Microorganisms present in wastewater play essential roles in the degradation and removal of these compounds and the analysis of their population structure and function has become the basis for problem solving and optimization of existing and new WWTPs. Microbial lipases have distinctive industrial attention because they can catalyze other synthetic reactions like transesterification making them an environmentally relevant class of enzymes, contributing to the improvement of wastewater treatment and biofuel synthesis. In Colombia, wastewater bacterial community studies have been focused on cultivable populations and there is little information regarding the general bacterial communities that inhabit these ecosystems. **Methods:** In this study, culture-dependent, rDNA based molecular techniques and enzymatic methods were used to estimate bacterial diversity, monitor temporal and spatial bacterial community changes and to screen for lipolytic microorganisms. **Results:** TTGE microbial community analysis revealed predominant bacterial families Acetobacteraceae, Bacillaceae, Prevotellaceae, Pseudomonadaceae and Veillonellaceae. Bacterial and fungal isolates were affiliated to the genera Cronobacter, Leclercia, Enterobacter, Klebsiella, Bacillus, Enterococcus, Escherichia, Kosakonia, Serratia, Chromobacterium, Mucor and Trichoderma. Several bacterial and fungal isolates tested positive for lipase enzyme production by qualitative and quantitative methods. **Conclusions:** Culture dependent and culture independent methods are complementary techniques that should be used hand in hand for a better understanding of bacterial communities and for studies regarding the potential functional properties of the isolates.

Involvement of Laccase-Like Multicopper Oxidase in Humic Substances Degradation by Diverse Polar Soil Bacteria

Author Block:

H. Park, H. Do, J. Lee, H. Park, **D. Kim**; Korea Polar Res. Inst., Incheon, Korea, Republic of

Abstract Body:

Background: Soil humic substances (HS) are widely distributed in cold environments and comprise a significant fraction of soil organic carbon. Although bacteria dominate cold environment, there have been few studies on the mechnisms of HS biodegradation and alteration by them. Until recently, the HS degradatiopn has been focused on fungi associated with their nonspecific oxidizing enzymes such as laccase.**Methods:** Bacterial strains (n=281) were isolated at 15°C using a minimal medium containing humic acids (HA), a principal component of HS, from various polar soil samples: 217 strains from the Antarctic and 64 strains from Arctic soil. Among them, 73 potential HA-degrading bacteria were phylogenetically identifiedand then laccase-like multicopper oxidase (LMCO) gene fragments were obtained from them by PCR.**Results:** The 73 selected bacteria were affiliated with phyla *Proteobacteria* (73.9%), *Actinobacteria* (20.5%), and *Bacteroidetes* (5.5%). Most of them degraded HA at 10°C to 25°C, but not at temperatures over 30°C, indicating their cold-adapted degradative abilities. Thirty unique LMCOgene fragments were PCR-amplified from 71% of the isolated HA-degrading bacteria, all of which included the conserved copper binding regions (CBR) I and II, both essential for laccase activity. The bacterial LMCO sequences differed from known fungal laccases; for example, a cysteine residue between CBR I and CBR II of fungal laccases was not detected in the bacteria LMCOs. In addition, computer-aided molecular modeling showed these LMCOs contain a highly conserved copper-dependent active site formed by three histidine residues between CBR I and CBR II.**Conclusions:** Phylogenetic- and modeling-based methods confirmed the wide occurrence of LMCO genes in HA-degrading polar soil bacteria and linked their putative gene functions with initial oxidative reaction for HA degradation.

Identification of Bacterial Consortia Members Able to Grow in a Polyether-Polyurethane Varnish

Author Block:

H. Loza-Tavera, A. Savín-Gámez, L. Domínguez-Malfavón, M. Vargas-Suárez, C. Peña-Montes, M. Quirasco; Facultad de Química, Univ. Natl. Autónoma de México, México, D.F., Mexico

Abstract Body:

Background: Polyurethanes (PUs) are synthetic polymers widely used in modern life due to their high durability and versatility. Because of their diverse chemical composition, recycling is complex and toxic, generating accumulation in landfills. There are two types of PUs: polyester (Ps) and polyether (Pe), being PePU the most recalcitrant. While there are many reports on bacterial and fungal species that degrade PsPUs, there are fewer reports on microorganisms able to degrade PePUs. Here we explored PePU biodegradation by microbial consortia.**Methods:** Eight microbial consortia (BP1-BP8) were obtained by culture enrichment in mineral medium with a PePU varnish (Polykack®) as the sole carbon source, inoculated with PU foams collected in a dumpsite. PePU biodegradation by these microbial consortia was evaluated by microbial growth, and analyzed by Fourier Transform Infrared Spectroscopy (FTIRS). Bacterial diversity analysis was performed by PCR-DGGE using consortia's V3 region of 16S rDNA gene. Selected DGGE bands from five consortia were cloned for bacterial identification.**Results:** Consortia BP5 and BP6 generated the largest biomass. FTIRS analysis showed that all the consortia were able to reduce or eliminate carbonyl (1726 cm^{-1}), and urethane (1532 and 1223 cm^{-1}) signals. Consortia BP3, BP6, BP7, and BP8 were also able to reduce ether signal (1108 cm^{-1}). Based on the reduction or elimination of FTIRS signals, consortia BP8, BP4, BP2 and BP6 were the most PePU degradative. Six uncultured bacteria and 16 different genera such as *Paracoccus*, *Advenela*, *Microbacterium*, *Propionibacterium*, *Lysinibacillus*, *Acinetobacter* and *Pseudomonas*, previously reported as xenobiotic degraders, were identified. The genera present in the most degradative consortia were *Mesorhizobium*, *Paracoccus* and *Bartonella* and an uncultured member of the *Jonesiaceae* family.**Conclusions:** These results show that microbial consortia present in PU foams collected from a dumpsite were able to attack Polylack's urethane, carbonyl and ether bonds. They represent microorganisms that could interact to obtain organic molecules from PePU for their living, and that can be useful for developing biotechnological processes for PU biodegradation.

***In Vivo* and *In Vitro* Degradation Studies for Poly(3-Hydroxybutyrate-*co*-3-Hydroxyhexanoate) Biopolymer**

Author Block:

A. Kehail, V. Boominathan, K. Fodor, T. Ferreira, V. Chalivendra, C. Brigham; Univ. of Massachusetts - Dartmouth, Dartmouth, MA

Abstract Body:

Polyhydroxyhexanoates (PHAs) are a family of naturally synthesized polymers that have shown promise as replacements for conventional, petrochemical polymers. These biopolymers are synthesized by bacteria like the Gram-negative betaproteobacterium *Ralstonia eutropha* under conditions of non-carbon nutrient stress. Typically, *R. eutropha* produces the homopolymer poly(3-hydroxybutyrate) [PHB]. However, recently, strains of *R. eutropha* have been developed that can biosynthesize the copolymer poly(3-hydroxybutyrate-*co*-3-hydroxyhexanoate) [P(HB-*co*-HHx)]. Studies have shown that this copolymer possesses favorable mechanical properties for use in medical devices and products (*e.g.*, sutures, scaffolds, bone plates). One of the major under-addressed issues associated with the use of biodegradable, bio-based PHA polymers in resorbable medical products is the correlation between the mechanical properties and the *in vivo* material degradation over time. In this study, P(HB-*co*-17%mol HHx) matrices were mechanically tested after either incubation in cultures of human embryonic kidney cells (HEK) for *in vitro* degradation studies for up to 4 weeks, or inserted into *Danio rerio* (zebrafish) tissues for *in vivo* degradation studies for up to 7 weeks. Young's modulus, tensile strength, elongation at break, toughness, and scanning electron microscopy (SEM) images of these samples were examined and compared to control samples that were not exposed to tissues by using a microindenter, tensile-tester setup, and SEM. Experiments have shown that Young's modulus of P(HB-*co*-17mol%HHx) during *in vitro* studies dropped from 3.26 MPa to 2.42 MPa within 4 weeks, and *in vivo* breakdown resulted in a significant decrease in Young's modulus with a drop from 3.26 MPa to 0.51 MPa within 7 weeks. Plasticization and recrystallization were observed and they would be reason for change in mechanical properties.

Accelerated Biodegradation of Polystyrene and Polyethylene by Mealworms (Larvae of *Tenebrio molitor)* from Various Sources in the USA and China

Author Block:

S. Yang[1], Y. Yang[2], A. Brandon[1], Z. Wang[1], N. Ren[3], J. Yang[2], C. S. Criddle[1], **W. Wu**[1]; [1]Stanford Univ., Stanford, CA, [2]Beihang Univ., Beijing, China, [3]Harbin Inst. of Technology, Harbin, China

Abstract Body:

Polystyrene (PS) and polyethylene (PE) have long been considered resistant to biodegradation. Mealworms (larvae of *Tenebrio molitor*) are common food storage pests and have been cultivated commercially for use as animal and bird food and as a source of insect protein. In 2015, a Beihang-Stanford research team demonstrated PS biodegradation in mealworms obtained in Beijing, China. From a mass balance, the PS ingested by mealworms was converted to CO_2 (up to 48%) and the balance excreted as granule-like fecula (ID < 0.2 mm). PS depolymerization within the guts was demonstrated by a decrease in the average molecular weight and by formation of likely daughter products. The generality of plastic eating behavior of mealworms has been further confirmed by cultivation of mealworms from seven different sources in China (Beijing; Qinghuangdao, Heibei; Shanghai) and the USA (Ham Lake, MN; Marion, IL; Newport News, VA; Trexlertown, PA). All of the mealworms tested to date consume PS, but at different relative rates. At ambient temperature (20-24 ^{o}C), the average daily consumption rate of PS ranged from 0.01 to 0.3 mg per 100 mealworms when fed PS alone. The mealworms also eat low density polyethylene (LDPE) foam as well as high density polyethylene (HDPE) in provided as powder particles as sole diet food. When mealworms (120 in each incubator) from Marion, IL, USA, were fed PS alone, the consumption rate and total amount consumed increased as a function of temperature from 20 to 30 ^{o}C by approximately 3.5±0.3%. Supplementing the diet with normal food (bran) enhanced the PS consumption rate and mass consumed. Higher ratios of bran to PS increased the percentage of added PS (1.80 g) that degraded over a 32 day period: 51.0±0.7% degraded at a ratio of 0:1; 59.1±1.5% at 1:6; 65.5% at 1:3; and 82.5±1.4% at 1:1 . Microbial community analysis indicated that the microbial structure changed significantly after the diet was switched from normal food bran to PS or PS plus bran. No biodegradation was detected when antibiotics were added to the feed, implicating gut microbial activity as the mechanism of PS biodegradation.

Environmental Microbial Community Tolerance and Adaptation to Biocides Use in Hydraulic Fracturing Operations

Author Block:

M. F. Campa[1], S. Techtmann[2], M. Patterson[1], A. Garcia de Matos Amaral[3], R. Lamendella[4], C. Grant[4], T. C. Hazen[1]; [1]Univ. of Tennessee, Knoxville, TN, [2]Michigan Technological Univ., Houghton, MI, [3]Federal Univ. of Bahia, Salvador, Brazil, [4]Juniata Coll., Huntingdon, PA

Abstract Body:

Hydraulic fracturing (HF) in the process of injecting a cocktail of chemicals, sand, and water into an underground rock formation to create fractures and release natural gas. Commonly, biocides are added to prevent biofouling of equipment and prevent microbial growth during gas extraction and gas souring. During extraction some of the injected water and chemicals returns to the surface; this flowback has been accidentally released into the environment, potentially exposing streams to HF chemicals such as biocides. To understand the effect biocides have in steams, microcosms were inoculated using stream water impacted by HF operations (three streams), and as control pristine stream water from the same area were used. Two groups of microcosms were set using the two more commonly used biocides, glutaraldehyde and DBNPA. The microcosms were incubated at ambient temperature over a period of 8 weeks. The microbial community adaptation to biocide was tracked by sampling every two weeks and performing 16s rRNA amplicon sequencing as compared to a biological control (no biocide added). Chemical degradation of the biocide was tracked every week by HPLC, as compared to an autoclaved control to track abiotic degradation. Finally, RNA was sampled at time zero and at the end of the experiment to understand what transcripts were upregulated by the presence of biocide, and hence allow the bacteria to adapt and tolerate the biocide. Our aim is that the results of this experiment will help understand the pathways of biocide resistance and the effect they have in the native microbial community.

Effect of Cathode Depth on Sediment Microbial Fuel Cell Performance

Author Block:

J. M. PISCIOTTA, P. Minka; West Chester Univ., West Chester, PA

Abstract Body:

Sediment microbial fuel cells (sMFC) are a type of bioelectrochemical system (BES) that generate electric current coupled with catabolism of organic material in sediments. In sMFC a conductive anode is buried in anoxic sediment and electrically connected to a cathode placed in the overlying aerobic water column. SMFCs harness microbial breakdown of organic matter in sediment using autochthonous exoelectrogens to generate an electrical current. SMFCs have been demonstrated to power small-scale devices but most studies to date have been carried out under laboratory conditions. Understanding the microbial communities that develop in field sites and their role as exoelectrogens is important for optimizing sMFC performance. In this study, four sMFC were constructed and deployed for 80 days in a freshwater pond in Chester County, PA to study the power output and electrode microbial communities that develop under field conditions. Anodes were buried in sediment in water 1 m deep. We hypothesized that an illuminated cathode 5 cm below the water's surface would generate higher power output compared to the less well illuminated cathode 750 cm below the water's surface. A weatherproofed datalogger recorded voltage and temperature, and the resulting power output was analyzed. Triplicate electrode biofilm scrapings were collected from three locations on each anode totaling 36 samples analyzed, and triplicate samples were also taken from each harvested cathode. Interestingly, sMFCs with dark submerged lower cathodes resulted in higher power output (0.66 mW/m^2) in duplicate reactors and showed less operating variability over the 80 day experiment compared to duplicate sMFC with cathodes near the pond sun-lit surface. Fluctuations in voltage observed in sMFCs with upper cathodes may be due to greater environmental variability at the water's surface. PCR and denaturing gradient gel electrophoresis (DGGE) was used to compare the microbial communities present on the electrodes. These results indicate that pond sMFCs featuring an illuminated near-surface cathode have a quicker start up time, but that sMFC submerged cathodes produce a higher and more stable electrical current.

Activity-Based Protein Profiling of Ammonia Monooxygenase in *Nitrosomonas europaea*

Author Block:

K. Bennett[1], N. C. Sadler[2], A. T. Wright[2], C. Yeager[3], M. R. Hyman[1]; [1]North Carolina State Univ., Raleigh, NC, [2]Pacific Northwest Natl. Lab., Richland, WA, [3]Los Alamos Natl. Lab., Los Alamos, NM

Abstract Body:

The nitrifying bacterium *Nitrosomonas europaea* oxidizes ammonia (NH_3) to nitrite (NO_2^-) through the sequential activities of ammonia monooxygenase (AMO) and hydroxylamine oxidoreductase (HAO). 1,7-octadiyne (17OD) was evaluated as a mechanism-based inactivator of AMO and used as an activity-based protein profiling probe for AMO. Inactivation of NH_4^+-dependent O_2 uptake by *N. europaea* was time and concentration dependent in the presence of 17OD, and there was no effect of 17OD on HAO activity. The effects of 17OD were irreversible and *de novo* protein synthesis was required for the recovery of ammonia-oxidizing activity following exposure to 17OD. Cells exposed to 17OD were reacted with Alexafluor 647-azide using a copper-catalyzed azide-alkyne cycloaddition reaction and analyzed by SDS-PAGE and IR scanning. A fluorescent 28 kDa polypeptide consistent with the mass of AmoA was observed in cells exposed to 17OD but not in cells that were pretreated with either allylthiourea or acetylene before 17OD. The 28 kDa polypeptide was membrane-associated and aggregated when SDS-solubilized samples were heated in the presence of β-mercaptoethanol. The same fluorescent polypeptide was also observed in cells pre-treated with several other diynes, but not in cells that were pre-treated with the structural homologs of these diynes, which contained only a single ethynyl functional group. Proteomic analyses including in gel digestion and MALDI-TOF/TOF analysis of the fluorescent polypeptide and on-bead digestion of biotin/streptavidin purified proteins from 17OD-treated cells confirmed the target of 17OD was AmoA, the active-site-containing polypeptide of AMO.

Characterization of Lipase from *Bacillus subtilis* Isolated from Oil-Contaminated Soil

Author Block:

T. O. Femi-Ola; Ekiti State Univ., Ado Ekiti, Nigeria

Abstract Body:

Lipases are glycerol ester hydrolases (EC: 3.1.1.3) which hydrolyses ester linkages of glycerides at water-oil interfaces. They occupy a prominent place among biocatalysts owing to their novel and divergent industrial applications. The interest in microbial lipase production has increased mainly because of its vast potential application in various industries ranging from pharmaceutical, bioremediation and waste water treatment. An extracellular lipase from *Bacillus subtilis* isolated from oil polluted soil was partially purified and characterized in this study. The enzyme was purified to 19.36 fold and the molecular weight was estimated to be 48.63 kDa by SDS-PAGE. The temperature optimum was 60 ^{o}C, while the enzyme exhibited appreciable thermostability retaining 70 % of activity at 70 ^{o}C for 1h. The lipase was most active in the pH range of 7-9 with an optimum activity at pH 8.0. The enzyme activity declined in the presence of Al^{3+} and Fe^{2+}, while Na^{+} stimulated the activity. Olive oil was found to be the preferred substrate. The maximum velocity V_{max} and K_m of the lipase during the hydrolysis of olive oil were 39.45 μmol/min/mil and 20.01 mM respectively.

Reduction of *Salmonella* Populations on Cucumber Fruit by Application of Lytic Bacteriophages

Author Block:

M. Sharma[1], G. Dashiell[2], E. T. Handy[1], C. East[1], R. Reynnells[3], P. D. Millner[1], C. White[4], F. Hashem[5], E. Nyarko[6], S. Micallef[7], A. Collins[8]; [1]USDA Agricultural Res. Service, Beltsville, MD, [2]Univ. of Maryland Eastern Shore, Princess Anne, MD, [3]Univ of Maryland Eastern Shore, Beltsville, MD, [4]Unviersity of Maryland Eastern Shore, Princess Anne, MD, [5]Univ. of Marlyand Eastern Shore, Princess Anne, MD, [6]Unviersity of Delaware, Newark, DE, [7]Univ. of Maryland, College Park, MD, [8]State Univ. of Pennsylvania, Manheim, PA

Abstract Body:

Background: Foodborne illness outbreaks of *Salmonella enterica* associated with consumption of cucumbers (*Cucumis sativus*) in the U.S. in 2014 and 2015 sickened over 1000 people and caused 5 deaths. Whole and fresh-cut cucumbers are susceptible to *Salmonella* contamination during growing and harvesting. We evaluated the effectiveness of applying lytic bacteriophages, a non-chemical intervention, to reduce *Salmonella* populations on cucumbers.**Methods:** Unwaxed cucumbers (greenhouse-grown, 'Lisboa' variety, or mini-cucumbers purchased at retail) were inoculated with 5 log CFU/cucumber *Salmonella* Newport, and then sprayed with 3.2 mL of 9 log PFU/ml SalmoFresh, a *Salmonella*-specific bacteriophage preparation (phage), or phosphate-buffered saline (control). Whole cucumbers were stored at 10 or 22^{o}C for 7 days. Mini-cucumbers were sliced with a sterile knife to investigate *Salmonella* transfer to mesocarp, and fresh-cut pieces were stored at 4^{o}C for 2 days. *Salmonella* populations from whole and fresh-cut cucumbers were recovered on selective media. Three replicates of each trial were conducted, and statistical analysis (Student *t*-Test) was performed.**Results:** Populations (log CFU/cucumber) of *Salmonella* on phage-treated whole cucumbers stored at 10^{o}C were 2.44, 1.72, and 1.56, which were significantly ($p < 0.05$) lower than those on control-treated cucumbers (4.27, 3.20, and 2.33) on days 0, 1, and 4, respectively. There were no significant differences in *Salmonella* populations between phage- and control-treatments of a) whole cucumbers at 22^{o}C, or b) fresh-cut cucumbers stored at 4^{o}C.**Conclusions:** Direct application of lytic bacteriophages (through spraying) to whole cucumbers was more effective in reducing *Salmonella* populations than indirect transfer of phages (through slicing) to the mesocarp of cucumbers. The greatest reduction in *Salmonella* populations occurred immediately after spraying phages onto cucumbers.

***Salmonella*-Phage Diversity in Different Animals: Are Phages from Cattle, Pigs, and Wild Animals the Same?**

Author Block:

D. Rivera[1], F. Duenas[1], R. Tardone[1], C. Caceres[1], V. Toledo[1], C. Hamilton-West[2], **A. I. Moreno Switt**[1]; [1]Univ. Andres Bello, Santiago, Chile, [2]Univ. de Chile, Santiago, Chile

Abstract Body:

Salmonella is a widely distributed zoonotic pathogen that can be transmitted to humans as foodborne or by animal contact. *Salmonella* has 2,600 serovars that show distinct distribution in different animals and geographic regions; being a few serovars (e.g., Enteritidis) globally distributed. While phages infecting *Salmonella* are very abundant, our understanding on *Salmonella*-phage diversity is very limited. The aim of this study was to investigate the diversity of *Salmonella* -phage systems in different animals and geographic locations in Chile. *Salmonella* and phages were isolated from samples obtained on continental Chile of 49 llamas and small ruminants, 10 pig farms, 35 backyard poultry, 80 wild birds, and 28 reptiles, 8 dairy farms, along with backyard cows from Eastern Island. Isolates representing the most common serovars (Enteritidis, Typhimurium, Infantis, and Heidelberg) were used to isolate phages. On the isolated phages we tested the host range using i) a set of foreign isolates (26 *Salmonella* serovars obtained from the US), and ii) a set of native isolates (31 *Salmonella* obtained from the locations studied above). We have isolated 105 *Salmonella* isolates (9 from pigs, 31 from poultry, 31 from wild bird, 28 from reptiles, and one from a goat). Phages were more abundant than *Salmonella* with 201 phage isolates obtained. Most of the phages (40-60%) were isolated in *S.* Enteritidis, which was also the most susceptible serovar. Host range characterization with foreign isolates displayed that phages show a narrow host range (mean=4 isolates lysed), but with native isolates, phages show a wide host range (mean=13 isolates lysed). All *Salmonella* of serogroups D were the most susceptible to phages. Clustering also showed a group of widely distributed phages that are very specific to *Salmonella* of the serogroups D. Phages from remote location as Eastern Island showed distinct host specificity. *Salmonella* phages appears to be adapted to local isolates; while wide host range and narrow host range phages are co-existing on animals, resistant and susceptible *Salmonella* are also present indicating a dynamic that need to be further investigated.

Evaluation of the Lytic Efficacy of Novel Bacteriophage Φ241 Against *Escherichia coli* O157:H7 in Model Food Systems

Author Block:

H. Deepnarain[1], Z. Lu[2]; [1]Kennesaw State Univ., Smyrna, GA, [2]Kennesaw State Univ., Kennesaw, GA

Abstract Body:

Background: Bacteriophages are emerging as alternative biocontrol agents against foodborne pathogens such as *Escherichia coli* O157:H7. A novel bacteriophage Φ241 specific to *E. coli* O157:H7 was previously isolated from a cucumber fermentation. Although the phage showed a great potential as a biocontrol agent of *E. coli* O157:H7, its lytic activity in real foods has not yet been studied. The objective of this study was to evaluate the lytic efficacy of Φ241 against *E. coli* O157:H7 in three model food systems (cucumber juice, beef broth, and apple juice). **Methods:** The lytic activity of Φ241 in each food was evaluated at three different multiplicities of infection (MOIs 1, 10, and 100). A filter-sterilized food system was inoculated with E. coli O157:H7 to achieve the initial cell concentration of 1.2 x 106 CFU/mL and with an appropriate amount of phage stock to reach the target MOI. The inoculated food was incubated at 37°C, and sampled in 1-h intervals for 10 h. The cell concentration in each sample was determined by the plate count method. The phage titer at the end of the experiment was determined through a plaque assay. **Results:** In cucumber juice, the phage infection at MOI 100 caused a rapid cell lysis within 1 h, resulting in 4.6-log-unit reduction in cell concentration compared with the control. Infection at MOIs 10 and 1 resulted in 4.8- and 2.5-log-unit reduction in cell concentration within 2 h, respectively. Infection at any of the three MOIs caused at least 5.3-log-unit reduction in cell concentration compared with the control. In beef broth, phage infection at MOIs 100, 10, 1 caused 2, 1, and 0.2 log reduction in cell concentration within 1 h, respectively, compared with the control. Infection for 3 h at MOIs 100, 10, and 1 caused 3, 4.3, and 3.7 log reduction, respectively. In contrast, the cell concentration in apple juice remained unchanged regardless of the presence or absence of the phage over the 10-h period.**Conclusions:** The data showed that the infection by Φ241 caused a rapid decrease in *E. coli* O157:H7 concentration in both cucumber juice and beef broth within 1 to 3 h depending on the MOI. This suggested that phage Φ241 could be used as a biocontrol agent for *E. coli* O157:H7 in certain vegetables and meats.

Effect Of Combined Stressors Added Sequentially Or Simultaneously On *listeria Monocytogenes* growth

Author Block:

L. Henderson, V. Guariglia-Oropeza, M. Wiedmann; Cornell Univ., Ithaca, NY

Abstract Body:

Listeria monocytogenes (*Lm*) is a bacterial pathogen that not only stands out due to its ability for extended survival and growth in a variety of environments, but also causes the third highest number of deaths among the major foodborne pathogens, making it essential to find ways to prevent transmission. On foods, *Lm* is exposed to many stresses, and is able to survive and grow under high salt and low temperature conditions. This research focuses on controlling *Lm* in the food supply, specifically reducing or eliminating its ability to multiply under conditions of high salt and low pH. We are interested in determining the efficiency of combined stresses on *Lm*, specifically whether the efficiency changes when stressors are added simultaneously or sequentially. We hypothesized that increased salt concentration and decreased pH work synergistically to inhibit *Lm* growth. However, prior exposure to salt would improve *Lm* growth in both WT and mutant strains. A "checkerboard" assay was used to determine the combined effects of salt and pH on WT (10403S) and sigma factor mutant (ΔBCHL) strains of *Lm*. Both strains were grown at 37C to mid-log phase (OD 0.4) in BHI and then inoculated in BHI containing 0, 2, 4, or 8% salt and pH 2, 3, 4, 5, 6, or 7. Growth was determined using a plate reader (OD 600). Data showed no difference in growth between strains that had prior exposure to salt and those that did not. The mutant strain is killed more quickly under combined stressors, and pH 3 medium showed the greatest amount of killing, regardless of strain. Surprisingly, strains grown in pH 4 medium showed a protective trend. Understanding stress conditions under which *Lm* can survive and grow can lead to different approaches to prevent contamination of foods and infections caused by foodborne pathogens.

Environmental Factors Impact the Expression of *Listeria monocytogenes* Attachment Factors

Author Block:

S. Levadney Smith, B. M. Prüß, T. M. Bergholz; North Dakota State Univ., Fargo, ND

Abstract Body:

Foodborne illness attributed to *Listeria monocytogenes* and contaminated fresh produce has increased significantly within the past two decades. *L. monocytogenes* is able to attach to produce and various surfaces in the processing environment. Once attached, *L. monocytogenes* can form biofilms that allow the bacteria to survive stressful conditions, such as low temperature, osmotic stress, and low nutrients. Attachment factors have been identified, such as Lcp, a cellulose binding protein, known to aid in the attachment of *L. monocytogenes* to the surface of produce. However, little is known about how environmental stresses impact the expression of attachment factors. Understanding environmental signals that affect attachment will allow targeted development of control measures aimed at reducing pathogens in the food supply. The expression of a known attachment factor, Lcp, in *L. monocytogenes* was evaluated upon exposure to stress.Single copy chromosomal reporter fusions were constructed in isolates from fresh produce outbreaks using pMJG2, and β-glucuronidase (GUS) as the reporter protein to assay the promoter activity of *lcp*. Reporter fusions were also constructed from the promoter of *uspA*, a SigB regulated gene, known to be induced under NaCl stress, as a positive control. The promoter activity was observed under conditions, including lettuce lysate, 5 ppm chlorine, 4.5% NaCl and 4°C. Cells were harvested at 6 time points, lysed, exposed to 4-MUG (4-Methylumbelliferyl-b-D-glucuronide), and promoter activity was reported as µM MUG/log CFU/Min. Log CFU was obtained by cell count.With initial exposure to lettuce lysate at 25°C, expression of GUS by the *lcp* promoter was elevated 1.43 fold compared to the control (minimal media, 25°C). There was no induction of GUS by the *lcp* promoter at 4°C. There was an initial increase followed by an overall reduction in GUS by the *uspA* promoter for all stresses at 4°C and NaCl at 25°C.Our findings indicate that expression of attachment factors are impacted by stress, such as the initial induction of GUS by the *lcp* promoter for lettuce lysate at 25°C and the induction of, followed by gradual decrease in expression of GUS by the *uspA* promoter, which indicates adaptation to stress over time. Finding conditions that can reduce the expression of attachment factors could be substantial in developing control measures that prevent initial attachment.

Internalization and Survival of *Salmonella enterica* and *E. coli* O157:H7 in Growing Lettuce (*Lactuca sativa*)

Author Block:

D. Deng[1], Z. Shen[2], M. Reed[1], **G. ZHENG**[1]; [1]Lincoln Univ., Jefferson City, MO, [2]Univ. of Missouri-Columbia, Columbia, MO

Abstract Body:

Background: Foodborne disease outbreaks associated with fresh produce have been increasing in recent years in the U.S., due to increasing consumption of these products as a healthy diet. The current post-harvesting washing and sanitization processes do not always effectively reduce pathogen contamination of produce. Some of human pathogens, such as *Salmonella* spp. and *E. coli* O157:H7, can internalize in produce and therefore, are protected by plant tissues from disinfectant washes. It is believed that understanding the internalization and survival of the pathogens in produce can facilitate developing novel methods to reduce pathogen contamination of produce.**Methods:** Salad bowl green lettuce (Lactuca sativa) were seeded and grown in soil or hydroponic media and red florescent-protein-expressing *Salmonella enterica* ATCC 13036 or *E. coli* O157:H7 ATCC700728 was spiked into the growth media at different stages of growing lettuce. In a separate test, the pathogens were injected into the growing lettuce by syringes. The internalization and survival of the pathogens in the growing lettuce were then monitored by recovering the microbes from the edible portions of the vegetables.**Results:** Cells of *S. enterica* and *E. coli* O157:H7 appeared to be able to internalize into lettuce via root-to-shoot pathway, but the internalization efficacy of this route decreased with the maturing of the lettuce. The internalization rate (CFU/per lettuce) of the pathogens was higher in the hydroponic than in the soil system. Overall, internalized pathogens decayed rapidly in 20 days after the spike or injection.**Conclusions:** The results of this study suggest that cells of *S. enterica* and *E. coli* O157:H7 may be uptaken by growing lettuce via roots or wounds and that the survival of internalized pathogens may be longer than 20 days inside the vegetable, underlining the importance of preharvest controlling management.

Development of Predictive Model for the Growth of *Salmonella* spp. in Liquid Whole Egg, Egg Yolk, and Egg White

Author Block:

J-S. Moon; Animal and Plant, Quarantine Agency, Anyang-si, Gyeonggi-go, Korea, Republic of

Abstract Body:

Background: The food-borne illness by *Salmonella* in egg has recently become an issue in the United States. With the increasing demand of consumers on the safety of eggs in Korea, it was also important for us to systematically evaluate the risk of egg. Therefore, the objective of this study was to determine the risk of *Salmonella* by investigating the growth rate according to the time of various storage temperatures of the liquid whole egg, egg yolk, and egg white.**Methods:** We investigated and analyzed the growth rate of each samples. Fresh eggs (< 1 day after lay) collected were prepared by liquid whole egg, egg yolk, and egg white, and 10 ml aliquots of each sample were transferred to corresponding tubes. Samples were inoculated with a mixed culture (approximately 2.0-3.0 log CFU/ml) containing equal proportions of five species of *Salmonella* (S. bareilly, S. richmond, S. typhimurium monophasic, S. enteritidis and S. gallinarum). **Results:** After inoculating *Salmonella* onto the liquid whole egg, liquid yolk, and liquid egg white, the effects of storage temperatures (5, 10, 15, 20, 25, 30, 35, and 40℃) on the growth of *Salmonella* mixture were investigated. Lag time decreased and specific growth rate increased with a storage temperature (10℃<40℃) but not changed 5℃ in the liquid whole egg, liquid yolk, and liquid egg white. The growth of *Salmonella* was hardly made in the egg white. A Baranyi model was fitted for each temperature growth data and corresponding maximum growth rates were estimated as primary model. Pseudo-R2 values were greater than 0.98 for primary models. The maximum growth rates were obtained from each primary model in liquid whole egg, liquid egg yolk, and egg white and then plotted against temperature. The maximum growth rate was modeled using the modified Baranyi model for the secondary model, respectively. Combination of primary and secondary models resulted in a dynamic model whose predictions were also validated for two sinusoidal profiles. **Conclusions:** The model developed in this study can be used for predicting the growth of *Salmonella* spp. in liquid egg under a variety of temperature conditions in Korea.

Publishing Title:

The Potential Binding of Tulane Virus to Human Intestinal Caco-2 Cells

Author Block:

K. Kniel, Q. Wang, J. Teichman; Univ. of Delaware, Newark, DE

Abstract Body:

The newly discovered Tulane virus (TV) is structurally similar to human norovirus (huNoV), and can recognize and bind to specific cellular receptors (e.g., HBGAs); however, specific binding has not been observed using human or animal cell lines rather only with chemical modulators. Here the binding between TV and cultured human Caco-2 cells is studied to better understand the early processes of infection during huNoV replication. This study aims to evaluate the binding capability of TV to differentiated and undifferentiated Caco-2 cells. The role of heparin sulfate during binding was also measured. After Caco-2 cells (ATCC #HTB-37) were seeded in 6-well plates. Undifferentiated Caco-2 (U-Caco-2) cells was obtained after reaching confluency, whereas differentiated Caco-2 cells (D-Caco-2) were obtained at 10 days post-confluency. Cells were washed with HBSS 3x and chilled to 4°C. Virus samples included ten-fold series dilutions of TV and TV pre-incubated in heparin sodium salt solutions (0-200 µg/ml) for 1 h at 37 °C. Virus samples were added into wells and incubated at 4°C for 1 h with gentle agitation. After three washes with cold PBS to remove the unbound TV, binding was determined by plaque assay. The data (3-replicates/3-samples each) were analyzed by ANOVA on JMP. TV can bind both U- and D- Caco-2 cells significantly, and the binding levels decreased with the initial inoculum concentration. With initial inoculum titers of 5.48 ± 0.18 log PFU, it was determined the binding levels were 2.23± 0.07 log PFU and 2.94 ± 0.15 log PFU for U- and D- Caco-2 cells, respectively. D-Caco-2 cells bound TV more significantly than U-Caco-2 cells ($p<0.05$). In addition, with increasing levels of heparin sulfate salts, the binding for both U-and D- cells was substantially inhibited from 2.85 ± 0.46 (at 0 µg/ml) to 2.19 ± 0.36 (at 200 µg/ml), and from 3.03 ± 0.66 (at 0 µg/ml) to 1.88 ± 0.24 (at 200 µg/ml), respectively. TV is more likely to bind D-Caco-2 cells indicating these cells may express molecules during differentiation that enhance binding affinity. Heparin sulfate may play a role in binding, or may act as a receptor.

Comparison of the Activity of Monomeric, Dimeric and Polymeric Polyphenols from Blueberries Against Hepatitis A Virus

Author Block:

S. Joshi[1], A. Howell[2], **D. H. D'Souza**[1]; [1]The Univ. of Tennessee-Knoxville, Knoxville, TN, [2]Rutgers Univ., Chatsworth, NJ

Abstract Body:

Background: Blueberry polyphenols are reported to have antiviral properties against foodborne human norovirus surrogates. Blueberry polyphenols include anthocyanins, flavonoids and proanthocyanidins (PAC), also known as condensed tannins. PACs are dimers, oligomers, and polymers of catechins that contain linkages between C4 and C8 (or C6). PACs in blueberries vary in profile and quantity that contain B-type linkages compared to cranberry PACs that have A-type linkages. These linkages and structures affect activity. The objective of this research was to elucidate the mode of action of blueberry polyphenols against HAV by (a) comparing the anti-HAV activity of monomeric catechin, procyanidin B2, blueberry B-type PAC and A-type PAC from cranberries (C-PAC) at 37ºC using plaque assays; (b) determining the effect of B-PAC on viral adsorption and replication using pre- and post-infection treatment; and (c) determining the effects of B-PAC on HAV structure using Transmission Electron Microscopy (TEM).**Methods:** Equal amounts of HAV at 5 log PFU/ml were mixed with equal amounts of catechin hydrate, procyanidin B2, or B-PAC and treated for 3, 6 and 24 h at 37ºC. Viral infectivity of three replicate treatments carried out in duplicate was evaluated using standardized plaque assays and treated viruses were also visualized by TEM. Pre- and post-infection treatments of host cells with B-PAC were carried out and data were statistically analyzed.**Results:** No significant effect with 1 mg/ml catechin or 1 mg/ml procyanidin B2 was observed on HAV titers after 24 h. Both polymeric B-PAC and C-PAC reduced HAV titers to non-detectable levels after 3 h at 37ºC. Viral infection of host cells after treatment with 0.5 mg/ml B-PAC showed that HAV titers were reduced by 0.34 log PFU/ml indicating that B-PAC had modest effects on preventing viral adsorption. However, no significant reduction was obtained after post-infection treatment and thus was ineffective against viral replication. TEM observations revealed moderate effect on viral structure with either damaged viral capsid or binding by PAC, possibly preventing their attachment to host cells.**Conclusions:** These results provide insights on the mode of action and information for use in developing preventive antiviral therapies.

Vacuum Steam Pasteurization for Inactivation of Pathogens on Flaxseed and Improvement of Shelf Life

Author Block:

M. K. Shah[1], B. Eklund[1], G. Asa[2], K. Graber[2], J. Sherwood[1], T. M. Bergholz[1]; [1]North Dakota State Univ., Fargo, ND, [2]Napasol North America, Fargo, ND

Abstract Body:

Low moisture foods have been implicated in several outbreaks due to *Salmonella* and *E. coli* O157:H7 contamination. While numerous thermal inactivation studies have been conducted for *Salmonella* on nuts, studies on other seeds and grains are minimal. We wanted to determine the efficacy of vacuum steam pasteurization (VSP) for inactivation of pathogens on whole and milled flaxseed. We also wanted to determine if VSP impacted the water activity (a_w) and microbial counts during storage. For the inactivation studies, whole flaxseed was separately inoculated with *Salmonella* PT30, *E. coli* O157:H7 and *Enterococcus faecium*, and milled flaxseed was inoculated with only *Salmonella* PT30 directly with bacterial lawns grown on brain heart infusion agar plates. Following equilibration of a_w to the initial a_w, 25g of inoculated samples were pasteurized for varying times (0.5-5.0 min) at 75°C, 85°C, 95°C, and 105°C in triplicate. On average, reductions of 5.5 ± 1.2, 5.7 ± 0.4, and 5.3 ± 0.5 log CFU/g were observed for *Salmonella, E. coli* O157:H7 and *E. faecium* respectively at 75°C after treatment for 1 minute on whole flaxseed whereas a reduction of 5.6 ± 1.3 log CFU/g was observed for *Salmonella* on milled flaxseed when treated for 30 seconds at 85C. For the shelf life study, whole and milled flaxseed were treated at 75°C, 90°C, and 105°C for 3 minutes and for 9 minutes at 90°C in triplicate. A_w and plate counts for total aerobes, *B. cereus*, yeast and mold were measured for 4 months. Over this period, microbial counts on the treated samples at all conditions remained lower than unpasteurized samples, and a decrease in a_w of the treated products were observed. Vacuum steam pasteurization can be effectively used for inactivation of pathogens on low moisture seeds with a positive impact on microbial shelf life and a_w, and *E. faecium* may be used as a surrogate when evaluating vacuum steam pasteurization.

Cross-Reaction of *Legionella* Loop-Mediated Isothermal Amplification (LAMP) and PCR Primers with Other Clinically and Environmentally Important Bacterial Species: A Caution for DNA Based Assays for Pathogen Detection

Author Block:

J. L. Baron[1], J. L. Jacobs[2], J. J. Martinson[1], J. E. Stout[2]; [1]Univ. of Pittsburgh, Pittsburgh, PA, [2]Special Pathogens Lab., Pittsburgh, PA

Abstract Body:

Many molecular detection assays including PCR, qPCR, and Loop-mediated isothermal amplification (LAMP), have been developed to identify microorganisms, which can be highly beneficial for rapidly detecting and diagnosing contamination or infection with pathogenic microbes, such as *Legionella* species. However, comparing results of the gold standard method of microbiological culturing and these new tests shows discordance between the two, with molecular assays exhibiting positivity when culture shows little or no *Legionella* spp. In our attempt to develop LAMP and PCR primers specific for the detection of *Legionella* spp. targeting the 16S rRNA gene we noted numerous cross-reactions with other clinically and environmentally relevant pathogens in each assay. This non-overlapping pattern of cross-reaction was explained phylogenetically based on the relationship of observed sequence similarity of these organisms to *Legionella* spp. We believe that findings of *Legionella* spp. PCR or qPCR positivity in environmental water samples that contain little or no culturable *Legionella* species may be due to unwanted primer cross-reaction with other species of commonly isolated waterborne pathogens. We suggest that other protein-encoding genes be chosen for genus level identification instead and/or that primer specificity be exhaustively tested, especially in their design for pathogen detection.

Comparison Of Pcr And Lamp Techniques To Detect Ompw In Viable But Nonculturable *vibrio Cholerae* O1 In Water Samples

Author Block:

P. Chamanrokh, A. Huq, R. Colwell; Maryland Pathogen Res. Inst., College Park, MD

Abstract Body:

Background: *Vibrio cholerae* can enter to the viable but nonculturable (VBNC) state which is difficult to detect by conventional bacteriological culture methods (Colwell et al., 1994; Chaiyanan et al., 2007). VBNC cells cannot be considered dead but rather a potential hazard to public health (Huq et al., 2000). Loop-mediated isothermal amplification (LAMP) is a gene amplification method in which all reactions are conducted under isothermal conditions without requiring for a thermocycler. (Mazaheri assadi et al., 2015). In this study, ompW gene in VBNC *V. cholerae* O1 employing LAMP and to compare results with PCR for specificity and sensitivity. **Methods:** VBNC cells of *V. cholerae* were prepared in four laboratory microcosms with 1% Instant Ocean (IO) and 60 samples collected at five locations in Maryland. The spiked samples incubated at 4˚C and 25˚C for one year. Samples were examined by culture and also using direct fluorescent antibody-direct viable count (DFA-DVC) (Huq et al., 2012). Chromosomal DNA was extracted from coccoid VBNC cells to detect presence of ompW, using PCR and LAMP and employing specific primers.**Results:** PCR and LAMP showed 100% specificity. PCR was positive at a concentration of 10 copies of targeted DNA. However, LAMP was positive with 5 copies, i.e., twice sensitive than PCR. All microcosm samples entered into VBNC stage determined by plating on non-selective LB agar and selective TCBS agar. All cells of *V. cholerae* O1 were coccoid and however, viable as determined by DFA-DVC. The ompW gene was detected in VBNC coccoid forms of *V. cholerae* O1 in the samples incubated for one year at two different temperatures 4 and 25°C and 49 (76.5%) out of 64 samples were positive by PCR while 60 (93.75%) were positive by LAMP.**Conclusion:** LAMP has higher specificity, is more sensitive, and accurate than PCR in detecting ompW gene in VBNC forms of *Vibrio cholerae* O1.

Building a Freshwater Bacterial Flora Database for Remote Sensing Applications

Author Block:

D. Zimmerman[1], L. A. Moore[1], J. A. Concha[2], N. Raqueño[2], M. A. B. Herman[1], **F. Ontiveros**[1]; [1]St. John Fisher Coll., Rochester, NY, [2]RIT, Rochester, NY

Abstract Body:

The identification and classification of microbial flora in bodies of fresh water has the potential of enhancing our understanding of this ecosystem and improving water management and bioremediation. This effort may be facilitated by the use of remote sensing technologies. For the last 3 years our undergraduate students have collected water samples in the Lake Ontario Rochester Embayment and Irondequoit Bay with the goal of constructing a database of bacterial species and water parameters (e.g. organic matter and chlorophyl content). Such a database is necessary to establish potential correlations between the presence of certain bacterial species and water parameters that can be measured using satellite imagery collected by the Landsat 8 OLI and TIRS sensors. In the past we reported initial efforts at mapping the distribution of bacterial species using 16S rRNA. Here we present our results for the summer of 2015 and present a compounded analysis of 3 consecutive summers. Of approximately 450 bacterial isolates, we have cultured and identified more than 40 different species spanning over 20 genera. Several fish and human pathogens were identified, and antibiotic-resistance profiles determined. Year to year variation of the flora's composition at individual locations has emerged as the main challenge in establishing reproducible patterns that may be linked to satellite measurements. We discuss this variability and potential solutions.

Droplet Digital PCR as an Efficient Tool for the Detection of *Salmonella* in Sediments

Author Block:

G. Singh, T. Stenstrom; Durban Univ. of Technology, Durban, South Africa

Abstract Body:

Background: *Salmonella* is one of the major causes of intestinal diseases globally and etiological agent of more severe systemic illnesses such as paratyphoid and typhoid fevers. Despite the advances in microbial identification and detection techniques like quantitative PCR (qPCR), *Salmonella* quantification in complex environmental samples remains a challenge due to the presence of PCR inhibitors. Sediments are the indicators of sources of microbial contamination and presents a clear picture of microbial load than aquatic resources. The relatively new droplet digital PCR (ddPCR) has emerged as a direct quantitative method which is highly tolerant to PCR inhibitors and relinquishes the necessity for calibration/standard curve. However, only limited information is available on the application of ddPCR to detect *Salmonella* in sediments.**Methods:** This study examined the efficacy of ddPCR assay for quantitative enumeration of *Salmonella* in sediments retrieved from the four sites of Palmeit river near the Quarry road informal settlements, Durban. ddPCR performance was evaluated simultaneously with qPCR targeting *ttr* gene in spiked water samples as well as sediment samples.**Results:** ddPCR significantly improved the analytical sensitivity over that of qPCR, in the sediment samples and improved the detection of low concentrations of *Salmonella* even in presence of PCR inhibitors. The expected copy numbers measured from both the methods (qPCR and ddPCR) showed good R^2 values of 0.999 and 0.994, respectively. The Palmeit river site within the informal settlements exhibits *Salmonella* in the range of 255±37 and 818±30 *Salmonell*a/gram ($p \leq 0.0001$) in qPCR and ddPCR respectively. The significantly higher numbers encountered with ddPCR at all the four sites of Palmeit river, may be due to the partitioning strategy where the PCR reaction is split into 20,000 droplets, ideally each droplet contains 1 or less copies of targeted DNA and efficiently reducing the effect of PCR inhibitors.**Conclusions:** The improved detection of *Salmonella* in sediments makes droplet digital PCR a viable quantification method and a promising technology for the quantification of *Salmonella* in multifarious environmental samples.

Validation Of A Method For Isolation Of *clostridium Difficile* From Environmental Samples

Author Block:

C. Beato-Melendez, N. Goodyear; Univ. of Massachusetts Lowell, Lowell, MA

Abstract Body:

Community-acquired *C. difficile* infections are increasing in incidence and severity. While healthcare facilities strive to eliminate environmental *C. difficile*, the incidence and significance of *C. difficile* in home, workplace, and other public environments is unclear. Most isolation protocols are designed for use with stool specimens, therefore effective methods for environmental samples must be validated. In this study, 3 initial enrichment broths, 2 spore enrichment techniques, and 2 agars were compared for their ability to recover *C. difficile* from spiked and environmental samples.For spiked samples, *C. difficile* (ATCC 43255) was inoculated to TSB and incubated (37°C, 48h). Fresh TSB, BHIB and chopped meat broth (CMB) were inoculated (100 µL) and incubated (37°C, 48h). Broths were subjected to no treatment, absolute alcohol shock or heat shock (65°C, 20 min). Post-treatment, 100 µL was inoculated to Columbia CNA (CNA) and *C. difficile* selective (CCFA) agars and incubated anaerobically (37°C, 48h). Colonies were counted and the identification confirmed with a commercial kit. While CMB provided the best overall recovery, TSB with alcohol shock and CCFA was equivalent (see Table). TSB is less costly than CMB therefore we selected TSB, alcohol shock and CCFA as our protocol. In addition, we used blood agar to ensure recovery of susceptible strains.

Enrichment Broth	Agar	No Treatment	Alcohol Shock	Heat Shock
BHIB	CCFA	16	19	22
	CNA	4	4	8
CMB	CCFA	24	24	21
	CNA	23	21	19
TSB	CCFA	21	24	18
	CNA	6	8	9

The protocol was tested environmentally in 2 public restrooms at UMass Lowell and 2 homes. Swiffer cloths were used to sample toilet seats and the floor by the toilet. Swiffers were immersed in 25 mL PBS for 10 min; half the PBS was inoculated directly to TSB and half was spiked with stock *C. difficile* and inoculated. All TSBs were processed as described above. All

spiked samples were positive on all media. All home samples and 1 university restroom were negative, but 1 university restroom floor sample was positive for *C. difficile* (nontoxigenic). This pilot study demonstrates that TSB as an initial enrichment broth followed by alcohol shock and plating to CCFA and BA is a lower cost, effective method of isolating *C. difficile* from environmental sites.

Use of DNA Aptamers as Alternative Ligands for Estimation of Infectious Human Norovirus Particles

Author Block:

M. Moore, B. Mertens, B. Bobay, L-A. Jaykus; North Carolina State Univ., Raleigh, NC

Abstract Body:

Background: Study of human norovirus is hindered by the lack of an *in vitro* cultivation method. Because of this, discrimination of infectious virus particles is not possible. Binding assays with histo-blood group antigens (HBGAs) in conjunction with RT-qPCR have been used for infectivity discrimination based on the hypothesis that loss of binding correlates with loss of infectivity. HBGAs are expensive, hard to purify, and not broadly reactive; however broadly reactive norovirus antibodies and ssDNA aptamers have been identified. The purpose of this study is to determine if a broadly reactive norovirus aptamer can be used to evaluate capsid integrity, serving as a proxy for infectivity discrimination.**Methods:** Virus-like particles (VLPs) of norovirus GII.4 Sydney (SYV) were subjected to various time-temperature combinations resulting in differing degrees of degradation. The binding of aptamer M6-2, HBGA, and antibody NS14 was then assessed by plate-based assay. Binding to completely denatured VLPs was also measured to determine the degree of target sequence-dependent recognition. The structure of aptamer M6-2 was predicted using the MC-Fold/MC-Sym webserver and its binding to the SYV capsid predicted using HADDOCK.**Results:** Aptamer M6-2 binding to heat treated VLPs was more similar to that of HBGAs than antibody NS14. For example, treatment of VLPs at 75^{o}C for one min resulted in 98.1 ± 1.9% and 79.9 ± 10.2% signal loss for HBGA and M6-2, respectively; while only 24.7 ± 9.7% of signal was lost for NS14. M6-2 and HBGA displayed small amounts of capsid protein sequence-dependent binding (2.0 ± 1.3% and 0.5 ± 1.2%, respectively), while NS14 displayed significantly more (26.4 ± 3.9%). These data suggest that binding to M6-2 and HBGA is highly dependent on capsid integrity, making it a good proxy for infectivity. Predicted docking of M6-2 to SYV revealed binding interactions in the P2 and N terminal P1 subdomains in residues that are close to those involved in HBGA binding; whereas NS14 binds the C terminal P1 subdomain.**Conclusions:** Taken together, the binding, structural prediction, and docking analyses suggest that nucleic acid aptamers may serve as favorable alternative ligands to HBGAs for estimating viral infectivity.

Optimization of Species Directed Isolation Method Using Magnetic Nanoparticles

Author Block:

E. I. Hussein, A. A. Aljabali, O. I. Aljumaili; Yarmouk Univ., Irbid, Jordan

Abstract Body:

Nanoparticles hold great potential in broad range of applications from biological detection to drug delivery and targeting in the medical field. The research work presented in here will focus on the bacterial detection using magnetic nanoparticles labeled with specific antibodies. *Serratia marcescens* is a gram-negative bacillus that has been recognised as a cause of hospital-acquired infection. According to that we developed a simple and reliable method to capture the bacteria specifically and with high precision. The nanoparticles were labelled with specific antibody that is specifically bind to *Serratia marcescens* as a model and proof-of-concept. Although various diagnostic approaches for pathogen detection have been reported in the literature, most are too expensive, lengthy or limited in specificity for clinical use. Nanoparticle with unique and fascinating properties offers improved accuracy in the specific detection over current laboratory methods. Here, this work presents novel magnetic nanoparticles-antibody probes capable of rapid and specific profiling of pathogens directly in clinical/food samples. A nanoparticle modified with antibodies that is targeted toward the desired species was designed to detect *Serratia marcescens* using simple magnetic devices. Ultimately, antibody labelled magnetic nanoparticle platform will allow both universal and specific detection of various clinically/food relevant bacterial species, with sensitivity down to single bacteria. Furthermore, the generic platform described could be used to rapidly identify and phenotype pathogens for a variety of applications.

How Accurate Is my Metagenomic Analysis? Depends on Diversity of 16s Rrna Gene Targets in Pcr

Author Block:

J. Zrimec[1], T. Rijavec[2], A. Lapanje[3]; [1]Faculty of Hlth.Sci., Univ. of Primorska, Izola, Slovenia, [2]Inst. of Metagenomics and Microbial Technologies, Ljubljana, Slovenia, [3]Saratov State Univ., Saratov, Russian Federation

Abstract Body:

Metagenomic analyses are crucial to study the diversity, activity and dynamics of uncultivable microbes. An integral part in the analyses is the polymerase chain reaction (PCR), which can also present a bottleneck, such as when amplifying parts of 16S rRNA genes. Often in agarose electrophoresis gels we see smeared DNA bands of wrong size, which are considered to be non-specific PCR errors and are eliminated. However, if these amplicons are not errors, then a part of the sample's true diversity is lost. Therefore, we explored if band smearing after PCR is in fact caused by imperfectly paired strands of the amplified DNA. Using synthetic oligonucleotides that mimic 16S rRNA in PCR, we determined that the amount of smear in agarose gels was proportional to DNA sequence heterogeneity of the 16S rRNA variable regions. Since in denaturing alkaline gels, lack of smear showed that amplified DNA had a uniform size, we suspected that two separate groups of structures had formed - correctly and imperfectly paired DNA strands. This was confirmed, by isolating and sequencing the two groups of structures using a newly developed electroelution procedure and characterizing the pairing of the sequenced DNA strands using a bioinformatics approach. When amplifying highly heterogeneous target DNA, such as 16S rRNA, imperfect pairing of the amplified DNA can lead to band smearing in agarose gels, which is not an indicator of low specificity of the PCR. Since the smear in agarose gels is only a structural part of the correctly amplified DNA, it carries important information about the richness and diversity of the analysed microbial communities. Incorrect handling of 16S rRNA samples, e.g. eliminating smearing by increasing PCR amplification stringency or excision of amplified DNA, thus leads to an underestimation of the richness and diversity of microbial species.

Evaluation of Hygienic Hand Washing Practices of the University Community of Moncton Campus

Author Block:

A. C. Diallo, E. DAKO, P. AUDET, R. Baudouin; Université de Moncton, Moncton, NB, Canada

Abstract Body:

Background: Infectious diseases of bacterial or viral origin are often the cause of a high rate of absenteeism of students and staff at the university. This has been inferred that it leads to a reduction in their academic and/or work performance. **Objective:** The objective of this study was to estimate the general knowledge of hygienic practices of the students and the staff the Université de Moncton and to carry out microbiological samplings of the environmental surfaces of the campus. **Methods:** A campaign to promote hand washing and general hygiene practices was undertaken on the campus. Surveys, performed on university students and staff before and after the campaign, were used to assess the impact of this campaign on their knowledge about hand washing and general hygiene practices. Environmental sampling was conducted before and after the campaign for the presence of certain pathogenic microorganisms i.e. total coliforms, *E. coli*, *Staphylococcus aureus*, and Methicillin-resistant *S. aureus* (MRSA). Care was taken to ensure the sampling was done on the surfaces that come into direct contact with the hands in both the toilet facilities and classrooms. The sampling methods used in this work are those described in the The Compendium of Analytical Methods (Health Canada, 2010). **Results:** The second survey scores are slightly higher than the first survey, The ANOVA (α=0.05), shows there is no significant difference between the scores of the two surveys ($p > 0.05$) except for the scale of questionnaires regarding general knowledge of hygienic practices, for which $p = 0.03$. The statistical results show that the general knowledge of the procedures have been improved, but the behavior of the respondents and their emphasis on hygienic practices were not significantly improved after the awareness campaign. Sampling and microbiological analyzes meanwhile, confirmed the presence of all bacteria except MRSA. After the awareness campaign, the average number of microorganisms has generally declined, especially the total count of *S. aureus* on sampled surfaces. **Conclusion:** This study generated results promising enough to warrant further study on other university campuses. These results highlight the necessity of having reminders regarding hygienic practices and proper handwashing on campus and the value of having awareness campaigns at regular frequencies.

Bacteria on Paper Currency: Methods, Survival and Implications

Author Block:

R. Wolff, A. Stewart-Akers; South Univ., Columbia, SC

Abstract Body:

Background: Paper currency is probably the most handled fomite where transmission of pathogenic microbes occurs in the general public. Because of very limited data on U.S. currency contamination this study was undertaken to examine the methods and biology used, including almost eight years of sampling dollar bills as a classroom project.**Methods:** Sampling of currency, collected from many business locations, includes direct contact pressing one half of a folded bill onto the media surface of a petri plate. This method was compared to using a moistened swab for bacterial recovery. As only ¼ of a bill is sampled onto each type of media in surveillance studies, all four surfaces were sampled to determine sampling efficiency. Bacterial survival was also studied by spraying *E. coli* and *Staphylococcus aureus* onto the bills and sampling over time.**Results:** Direct contact was more effective than swabbing paper currency, resulting in bacterial recovery from 100% greater numbers on Nutrient Agar to more than 1000%, with only 11% showing a lower recovery. When all four quarter surfaces were sampled, 42/45 (93.3%) had mannitol fermenters (on MSA) on the first surface sampled if they were present on another surface. 10 bills had a surface where no MF grew, and all but one had only several total fermenters on the bill. All surfaces of all bills had non-mannitol fermenters. Survival of *E. coli* on the dried bills was less than 48 hours while *Staphylococcus aureus* survived over 3 weeks. Over 300 bacterial species have been identified via 435 pyrosequencing on local currency.**Conclusions:** The simple method of pressing dollar bills onto agar media with direct contact is both a simple and effective procedure for sampling the microbes and pathogens found contaminating paper currency in circulation in the U.S. The method has demonstrated in previous studies both seasonal and weather changes, allows monitoring of specific organisms, and longer term changes in abundance (decline in numbers of MRSA over the past two years). This is an underutilized and underappreciated technique that could be highly valuable for BioSurveillance of disease organisms and even some biothreats.

Synthesis of Metal Nanoparticles Using *Stenotrophomonas maltophilia* and *Bacillus subtilis* Isolated from the Natural Habitats of Uae

Author Block:

G. Ganesh, P. Srinivasan, N. Sood, T. Gokhale; Birla Inst. of Technology and Sci. Pilani, Dubai, United Arab Emirates

Abstract Body:

Biological synthesis of nanoparticles is an ecofriendly process that makes use of biological systems such as bacteria, fungi and also plants whereas physical and chemical methods which are routinely used produce toxic substances to the environment. A number of bacteria were screened from the garden soil of Dubai International Academic City, Dubai, UAE for their potential to synthesize metal nanoparticles amongst which two isolates exhibited a high potential to synthesize copper nanoparticles. These isolates were identified using 16s rRNA sequencing as *Stenotrophomonas maltophilia* and *Bacillus subtilis* and could tolerate more than 2mM of Copper Sulphate. The isolates were also able to tolerate high concentrations of different metals. Therefore, we investigated the ability of the two isolates to synthesize extracellular nanoparticles using UV Visible spectrophotometer, whereas the intracellular accumulation of metal nanoparticles was studied using ICP-OES. *S.maltophilia* and *B.subtilis* were grown in presence of 2mM Copper Sulphate, 5mM Lead Nitrate, 2mM Zinc Sulphate, 2mM Sodium Tungstate, 1.7mM Molybdenum Trioxide, 5mM Barium Chloride, 0.2mM Cadmium Sulphate, 5mM Manganese Chloride, 0.2mM Cobalt Chloride in sterile Luria Bertani broth. Spectrophotometric analysis of culture supernatants and media controls exhibited a shift in absorption wavelength from the control to the supernatants of *S.maltophilia* and *B.subtilis*, eg: in presence of zinc, a shift in absorption was observed from 200nm for control to 290nm for *S.maltophilia* and 270nm for *B.subtilis*. This indicates the presence of nanoparticles in the culture supernatant. The ICP-OES analysis of bacterial cells showed *S.maltophilia* and *B.subtilis* accumulated 23650ppm and 596ppm of copper, 234.9ppm and 238.7ppm of lead, 46.1ppm and 28.83ppm of Barium, 74.7ppm and 23.9ppm of manganese respectively. The particle size analysis of the culture supernatant of *S.maltophilia* grown in presence of 34mM Molybdenum Trioxide and 2mM Lead Nitrate showed the presence of 74nm size molybdenum and 160nm size lead nanoparticles. We have demonstrated for the first time synthesis of molybdenum trioxide nanoparticles using bacteria. This work is the first report of such study on bacterial synthesis of nanoparticles from the natural isolates of UAE.

Elucidation Of Anti-Leptospiral Efficacy Of Indian Herbal Preparations In Mouse Model

Author Block:

R. Anandan, A. Lakshmipriya, V. Nithyakalyani, C. Banurekha, S. Rajkumar; Dr MGR Janaki Coll. of Arts and Sci. for, Chennai, India

Abstract Body:

Background: Bacteria belonging to the genera *Leptospira* can cause disease in humans and animals (Leptospirosis). Leptospirosis can cause a wide range of symptoms and can be asymptomatic as well. If untreated can lead to kidney damage, meningitis, liver failure, respiratory distress, and even death. Leptospirosis is most common in temperate and tropical countries like India and workers who work outdoors or with animals are particularly predisposed. Antibiotics are the standard treatment strategy. In this study, three Indian herbs were screened for anti-leptosprial efficacy *in vitro* and *in vivo* using a mouse model. **Methods:** Aqueous and organic solvent extracts of three Indian herbs, *Hemisdesmus Indicus*, *Phyllanthus niruri*, and *Alium sativum* were tested *in vitro* for anti-leptospiral effcicacy against *Leptospira gripphotyphosa* and examined dark field microscopically. Aqueous herbal extracts were tested for *in vivo* toxicity in Swiss Webster mice. Mice were infected intraperitoneally with *L. gripphotyphosa* and treated orally with aqueous extracts of the three Indian herbs for 7 consecutive days from day 0. Blood samples were drawn and tested for leptospira with microscopic slide agglutination test (MSAT). Mice kidney and liver were histopathologically examined for specific changes and reversal in response to treatment. **Results:** Aqueous extracts of *H. indicus* exhibited greater anti-leptospiral activity *in vitro* compared to *P. niruri* and *A. sativum*. This superior anti-leptospiral activity of *H. indicus* was more evident in the hepato- and renal-protective effects, as evidenced by histopathological examination of the treated animals. Mice tolerated these Indian herbal preparation to the maximum dose of 2000 mg/Kg body weight without moribundity or histological changes. Further phytochemical studies are in progress to identify the active anti-leptospiral molecules.**Conclusions:** Tropical countries like India, hold a treasure trove of innumerable herbs and native medications that offer tremendous potential to treat a variety of diseases. More Governmental and non-Governmental resources need to be channelized to support research and development efforts to exploit these herbs for public health benefits.

Optimization of a Quick Protocol for Extracting DNA from Environmental Water Samples to Use in Pcr Assays

Author Block:

A. G. Burruss, V. Casas, S. Maloy; San Diego State Univ., San Diego, CA

Abstract Body:

Microbial metagenomic techniques have vastly improved what we know about the bacteria in our environments. Using metagenomic data we now better understand the microbial landscape of our environments and the processes contained therein. Most notably, the process of horizontal gene transfer (HGT) between bacteria and mobile genetic elements such as plasmids and phage. In the case of phage carrying exotoxin genes, the transfer of these genes can lead to the evolution of novel pathogens. Tracking these events at the genetic level therefore becomes a critical component in understanding how and at what frequency these pathogens evolve in our environments. In an effort to study these events in "real time" we found that one major hurdle was the number and volumes of environmental samples we would need to gather and process for DNA to screen by PCR. We needed a DNA extraction method that used a low volume of sample, yielded PCR ready DNA, and was quick enough to process large numbers of samples at one time. We optimized a commercial DNA extraction card kit to extract PCR ready DNA from water samples using small volumes of the sample, an efficient extraction time per sample, and allowing for DNA extraction from large numbers of samples. DNA extraction from the cards was optimized based on volume of sample added to the card, drying time in between sample addition, drying source, and the number of card discs added to a PCR. We added from one to five milliliters of sample water at one ml increments to five separate PCR cards. We also compared the effectiveness of drying them in incubators as opposed to air drying under a biosafety cabinet. To test the quality of DNA extracted from the cards, we ran them in a 16S rDNA PCR assay and compared results. The results showed that adding three ml of sample water in one ml increments, with drying time in a BSC in between, and one DNA card disc per reaction, yielded the best results in a 16S PCR. Overall, DNA extraction from water samples using this alternative protocol was simple, yielded PCR quality DNA, and most favorably, reduced total extraction time per sample. We intend to apply this efficient extraction technique to monitor HGT between phage and bacteria across time in small scale, aquatic mesocosms.

Biodiversity and Enrichment of Organic Sulfur-Driven Iron-Respiring Microorganisms from Marine Sediments

Author Block:

A. M. Zwolinski[1], S. L. Seston[1], N. H. Szeinbaum[2], S. Ganesh[2], F. J. Stewart[2], M. Taillefert[2], T. J. DiChristina[2]; [1]Alverno Coll., Milwaukee, WI, [2]Georgia Inst. of Technology, Atlanta, GA

Abstract Body:

Anaerobic iron respiration may have been one of the very first forms of microbial metabolism to evolve early on in the history of life; yet up until recent years, little has been known about the mechanisms that drive such ancient respiration processes. The biodiversity of microbial communities capable of iron-reduction in anoxic environments has been previously overlooked and the significance of this activity is not fully understood. To better understand the phylogenetic and metabolic diversity of iron-reducing bacteria (FeRB), sediment samples from the salt marsh ecosystem of Skidaway Island (GA), were obtained and used to test the hypothesis that organic sulfur (S) compounds can act as electron shuttles for FeRB to extracellular insoluble Fe(III) oxides. The chemical composition of multiple core samples collected from Skidaway Island were analyzed, and core sediments exhibiting overlapping peaks of ferrous iron (Fe^{2+}) and organic sulfur compounds (thiols) were used for subsequent microbial community analysis and enrichment of organic S-driven FeRB. Organic S-driven FeRB were enriched in cultures by providing an environment without oxygen (N_2 headspace) with the following conditions i) lactate or acetate as electron donors, ii) various thiols as electron shuttles and iii) solid Fe(III) oxide as electron acceptor. Enrichment of FeRB was also performed in the presence of rifamycin to select for *Archaea*. Microbial community structure in core sediments and enrichment cultures was analyzed via deep sequencing of the 16S rRNA hypervariable V4 region with bacterial and archaeal specific primer sets. Results indicate that thiols increase FeRB iron activity in enrichments and impact the community structure of enriched microorganisms. Molybdenum-containing controls suggest that sulfide-catalyzed electron shuttling is not a dominant mechanism for microbial Fe(III) reduction in marine sediments.

Groundwater Microbial Communities Across Contamination Gradients At A Nuclear Waste Site

Author Block:

P. Zhang[1], A. Rocha[2], Z. He[1], J. Zhou[1]; [1]Univ. of Oklahoma, Norman, OK, [2]Oak Ridge Natl. Lab., Oak Ridge, TN

Abstract Body:

Nuclear waste contamination of aquifers poses an extensive range of environmental conditions such as U(VI), nitrate, pH and other heavy metals and the contaminated groundwater presents a great human-health concern, thus understanding how the groundwater microbial communities function under different environmental conditions is of high importance for predicting the fate of U(VI) in the environment. In this study, we profiled microbial communities using a functional gene microarray (GeoChip 5.0), which infers functional roles of microbial community members. Groundwater samples were collected from 69 wells at the Oak Ridge site, representing an extensive range of contamination, e.g., U(VI) from 0.002 to 9 mg/L, nitrate from 0.1 to 10,000 mg/L, pH from 3.4 to 10.5, Al from 0 to 120 mg/L. The results showed that microbial communities were distinct among wells differing in groundwater geochemistry characteristics. Canonical correspondence analysis and Mantel tests showed that groundwater U(VI), nitrate, pH, metals (such as Al, Ca), dissolved organic carbon and sulfate were key factors shaping the microbial functional communities. In particular, substantial variations were apparent in stress, C, N, and S cycling genes and genes involved in metal reduction and resistance, and abundances of these genes correlated with their functional roles. However, while high contamination decreased both functional and phylogenetic diversity, the impact was more severe on phylogenetic diversity than community metabolic potential based on GeoChip and 16S rRNA gene sequencing results. This study improves our understanding of microbial communities across a large-scale contamination gradient at a typical nuclear waste site.Acknowledgments: ENIGMA (http://enigma.lbl.gov) at LBNL supported by Office of Biological and Environmental Research US Dept of Energy Contract No: DE-AC02-05CH11231

Publishing Title:

Methylphosphonate Degradation May Contribute To Methane Production In The Oxic Water Column Of Lake Matano

Author Block:

M. Yao, J. Maresca; Univ. of Delaware, Newark, DE

Abstract Body:

Methane is an important greenhouse gas, and global methane emissions from lakes account for 6 - 16 % of total natural methane emissions. The oxic water column of ultra-oligotrophic Lake Matano is a net methane source: the methane concentration is 0.003 mmol L^{-1}, which is supersaturated compared to the atmosphere. The active methanogenesis in the anoxic bottom waters and sediments does not completely explain the high methane concentration in the oxic surface waters. Here, we demonstrate that 4 out of 7 heterotrophic bacteria isolated from the surface water of Lake Matano can produce methane when using methylphosphononic acid as the only phosphorus source. To determine how phosphate influences methane production, we added 0.2 mM phosphate into the medium with methylphosphonic acid. After adding phosphate, methane production by strain LM-Y was completely inhibited, while the other three strains LM-1, LM-5 and LM6-1 were inhibited 40 - 50%. Metagenomic analysis results also demonstrate that the C-P lyase pathway, a multienzyme complex responsible for phosphonate degradation, is enriched in the surface water. The C-P lyase pathway has broad substrate specificity, and methane is produced when methylphosphonate is the substrate. We further demonstrate that our isolates encode *phnJ*, a component of the C-P lyase complex, and that this gene is expressed when the isolates use methylphosphonic acid as a phosphorus source. Therefore, our results show that methane produced by methylphosphonate degradation may contribute to the high methane concentration in the oxic surface water of Lake Matano.

Coupled Quantitative Proteomic and Genomic Strategies to Elucidate Shifts in Carbon Utilization of Filamentous Ascomycete Fungi

Author Block:

S. Purvine[1], C. A. Zeiner[2], E. M. Zink[1], S. Wu[3], L. Paša-Tolić[1], D. L. Chaput[4], C. M. Santelli[5], C. M. Hansel[6]; [1]PNNL - Battelle, Richland, WA, [2]Boston Univ., Boston, MA, [3]Univ. of Oklahoma, Norman, OK, [4]Smithsonian Inst., Washington D.C., DC, [5]Smithsonian Inst., Washington, DC, [6]Woods Hole Oceanographic Inst., Woods Hole, MA

Abstract Body:

Proteomics information can be used to identify and quantify gene products expressed under different cellular conditions. Using bottom-up proteomics coupled with isotopic labeling such as Isobaric tags for Relative and Absolute Quantification (iTRAQ), multiple experimental conditions can be compared in a single Liquid Chromatography Mass Spectrometry (LC-MS/MS) experiment, with pooled samples allowing comparison across multiple experiments. Furthermore, using initial genomic sequence information from the Joint Genome Institute (JGI), organisms previously not well characterized can be studied. We applied the proteomics pipeline capability housed at the Environmental Molecular Sciences Laboratory (EMSL) at Pacific Northwest National Laboratory (PNNL) to a multi-genome microbial system, specifically to the secretomes of four poorly characterized, cellulose-degrading Ascomycete fungi over a three-week time course in conjunction with a joint proposal with JGI for genome sequencing. This work employed: iTRAQ labelling of multiple time points from multiple secreted protein sources; LC-MS/MS analysis using Thermo Velos Orbitrap with higher-energy collisional dissociation (HCD); data extraction of reporter ion abundances using in house software (MASIC); limit of detection assessment (2 sigma of median abundance as LOD); significant differential expression analysis (+/- 2 sigma from mean log ratio across any two compared time points); and BLAST analysis to assign annotations to extracellular enzymes utilized for carbon degradation by each fungus. We present the methods applied to these samples and demonstrate striking differences in the regulation of extracellular enzymes across the four species over time. This work highlights the utility of quantitative iTRAQ proteomics coupled to genome sequencing in directly comparing metabolic processes across diverse microbial species.

Overexpression of the Phosphoketolase Pathway Increases Carbon Conversion Efficiency in an Obligate *Methanotrophic bacterium*

Author Block:

C. A. Henard, Holly K Smith, Loretta Lutackas, Michael T Guarnieri; Natl. Renewable Energy Lab., Golden, CO

Abstract Body:

Microbial conversion of methane to value-added chemicals offers a path to mitigate GHG emissions and valorize this abundant, squandered gas. Preliminary techno-economic analysis has identified carbon conversion efficiency (CCE) as a key cost driver in these processes, underscoring the need for rational methanotrophic bacterial strain engineering. The phosphoketolase pathway functions in a subset of microbes, including several methylotrophs, as an alternative route to produce acetyl-CoA, bypassing the CO_2 lost in the Embden-Meyerhof-Parnas pathway through pyruvate decarboxylation. Based on its ability to limit CO_2 loss, the phosphoketolase pathway can be leveraged for carbon efficient biocatalysis. Here, we show that the promising industrial methane biocatalyst, *Methylomicrobium buryatense*, encodes two phosphoketolase isoforms that are highly expressed in methane-grown cells. Phosphoketolase overexpression increased the CCE of *M. buryatense* by decreasing methane consumption while maintaining similar growth compared to wild-type in stirred-tank bioreactors. Further analysis of carbon partitioning indicated that the increased CCE observed in this engineered strain was partially due to decreased flux through the C1 dissimilatory pathway. Based on these data and that phosphoketolase orthologues are found in most alpha- and gammaproteobacterial methylotroph genomes sequenced to date, these enzymes can be used to increase CCE in methane biocatalytic processes and play an important role in C1 metabolism.

Exploring Anaerobic 4-Hydroxyproline Metabolism in Bacteria

Author Block:

Y. Huang[1], A. Martinez-del Campo[1], S. H. Kopf[2], Y. Wei[3], J. R. Leadbetter[4], D. K. Newman[4], E. P. Balskus[1]; [1]Harvard Univ., Cambridge, MA, [2]Princeton Univ., Princeton, NJ, [3]Metabolic Engineering Res. Lab., Singapore, Singapore, [4]California Inst. of Technology, Pasadena, CA

Abstract Body:

4-Hydroxyproline is one of the most abundant post-translationally modified amino acid and is highly abundant in collagen, a structural protein in animals, and proteins in the plant cell wall. A pathway for anaerobic metabolism of 4-hydroxyproline was first described in Stickland fermentation where 4-hydroxyproline is used by Clostridial species as an electron acceptor (Stickland, L.H., 1934, Biochem. J., **28**:1746-1759). The enzymes and intermediates involved in this pathway have not been previously identified. We designed a chemically defined medium to enrich for microbes that can reduce 4-hydroxyproline anaerobically for energy generation. Sediment samples collected from marshes and swamps in Woods Hole, MA were used to inoculate the enrichment cultures and 4-hydroxyproline concentrations were monitored over time by HPLC. In all enrichment cultures, 4-hydroxyproline concentration decreased over time. To better understand the pathway involved in anaerobic 4-hydroxyproline metabolism, we designed and optimized degenerate primers to amplify a novel 4-hydroxyproline dehydratase strictly found in facultative and obligate anaerobes. We will present our work on the identification of this dehydratase gene using degenerate primers and the characterization of bacterial communities in the enrichment cultures.

Presence of the Anaerobic Benzoyl-CoA Degradation Pathway in Animal Samples

Author Block:

K. Fullerton, A. W. Porter, L. Y. Young; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Under anaerobic conditions, aromatic compounds are metabolized to a common intermediate, benzoyl-CoA, which is further degraded to enter central metabolism. This pathway has been shown to be widely distributed in environmental samples, including freshwater pond sediment, digester sludge, and agricultural soil, but its presence in animal systems has not been evaluated. Due to the ubiquitous nature of the benzoyl-CoA pathway in the environment and the presence of aromatic residues in animal feedstocks, we predict that this pathway is present in the anaerobic gut environment of animals. Methanogenic enrichment cultures were established from bovine rumen fluid and were amended with lignoaromatic monomers or the aromatic amino acids. HPLC analysis shows loss of substrate within two weeks with no apparent accumulation of intermediates in the enrichments, establishing that aromatics are rapidly metabolized in the rumen. DGGE fingerprints of tyrosine and tryptophan enriched cultures show distinct community profiles with different dominant banding patterns. Culture-independent studies were performed using fecal samples from a variety of domesticated farm animals to understand the prevalence of the benzoyl-CoA pathway in a wider scope. The presence of methanogens in these samples implies that these environments are highly reducing and that oxygen-dependent methods of aromatic catabolism are not likely to be utilized. However, these fecal samples show no amplification with common molecular probes of the benzoyl-CoA pathway, including the benzoate reductase and the BamA hydrolase, indicating that this pathway may not be abundant in the gut or that existing probes do not account for the added microbial diversity seen in the gut environment. These results suggest that aromatic metabolism in the gut is more complex than initially believed, and further investigations into its role in global carbon cycling is needed.

Entomopathogenic Activity of *Lysinibacillus sphaericus* on the Life Cycle of *Aedes aegypti* ≪and≫ Expression of the Hemolysin ≪and≫ Chitinase Genes

Author Block:

P. Rojas Pinzón, J. Dussán Garzón, Microbiological Research Center(CIMIC); Univ. de los Andes, Bogotá, Colombia

Abstract Body:

Lysinibacillus sphaericus (Ls) has been used for the biological control of *Culex* <and> *Anopheles* but not for *Aedes*, the main vectors of tropical diseases. Some strains of *Ls* used for this purpose were isolated in Colombia, a country with reports of dengue, Chykungunya <and> the most recent Zika virus. Due to the genome sequencing of the native strains III(3)7 <and> OT4b.25 genes of pathogenic importance as hemolysins (*hly*) <and> chitinases (*cda*) were annotated. The objective of this study was to monitor the effect of the OT4b.25, III(3)7 <and> 2362 (WHO reference) strains on the mosquito life cycle and determining the expression of chitin-binding protein <and> hemolysin genes on third instar larvae.The larvicidal bioassays were tested following the WHO guidelines for mosquito. The number of hatched eggs <and> live larvae were recorded every 24 h until 72 h. Triplicates for each stage were performed <and> the results were analyzed with ANOVA <and> Tukey test. The expression of a chitin-binding domain <and> hemolysin genes were determinated through RTPCR in the strain III(3)7, after 24h <and> 48h of exposure to instar 3 larvae. The samples were run in triplicate <and> the results were analyzed with a t-test.The bioassays with each stage revealed that native strains retard hatching <and> once the larvae emerge, they die. Likewise, the first larval stages (instar 1-3) are more sensitive to the three *L. sphaericus* strains, which presented 98% of mortality at 48h. With the instar 4 the mortality was 58% at 72h. The expression of a chitin-binding domain was greater at 24 h (ΔRn = 13, 9± 0, 16) than at 48 h (ΔRn = 12, 34± 0, 22) <and> the hemolysin genes are expressed more at 48 h (ΔRn= 17, 45± 0, 26) than at 24 h (ΔRn = 12, 89 ± 0, 58). Although, there are only significant differences in the hemolysin expression.We found that the native strains of *L. sphaericus* have entomopathogenic activity on the *Ae. aegypti* life cycle <and> the expression of chitin-binding domain <and> hemolysin genes may be another important factors in the pathogenicity of this bacteria.

Conidiation by *Isaria fumosorosea* Under Oxidant Pulses Relates to Initial Substrate

Author Block:

F. R. Muñiz Paredes[1], P. M. Garza-López[2], G. Viniegra-González[1], O. Loera Corral[1]; [1]Univ. Autónoma Metropolitana, Iztapalapa, Mexico, [2]Univ. Autónoma del Estado de Hidalgo, Pachuca de Soto, Mexico

Abstract Body:

Background: Conidia are the main propagules for pest control by entomopathogenic fungi. Hyperoxidant atmospheres (26% O_2) improved conidia production for *Metarhizium anisopliae* and *Isaria fumosorosea* (Tlecuitl-Beristain *et al.* 2010; Miranda-Hernández *et al.* 2014) on agar cultures. However the effect of 26% O_2 pulses remains unclear in solid-state cultures (SSC), the preferred method for large scale production. We determined the effect of 26% O_2 pulses on conidia production in SSC with *I. fumosorosea* strains ARSEF 3302 and CNRCB1, measuring residual O_2 and CO_2 accumulation as indicatives of metabolic activity.**Methods:** SSC were carried out in bottles with 1 or 5 g of initial dry substrate (gds), and inoculated with $1x10^6$ conidia gds^{-1} At 60 h, cotton caps were replaced by rubber seals and 26% O_2 pulses were administrated. Conidia were quantified periodically. Determination of O_2 and CO_2 was carried out by gas chromatography for treatments with 26% O_2 pulses. Bottles maintained with cotton caps throughout culture were used as controls. Variables were determined by triplicate.**Results:** The effect of O_2 pulses on conidia production depended on the initial amount of substrate, since with 1 gds, conidia production increased compared to control in both strains. In contrast, 26% O_2 pulses with 5 gds decreased conidia production. For both strains with 1 gds, O_2 levels were maintained between 20 to 25% and CO_2 remained lower than 7%. Oxidant pulses may increase reactive oxygen species that trigger differentiation of hyphae to conidia. In cultures with 5 gds, O_2 levels were depleted after first pulse and CO_2 accumulated up to 26%, and then cultures decreased respiration leading to conidial inhibition. Even when respiration reassumed at later stages, conidiation did not recover.**Conclusion:** Oxidant pulses improved conidia production in SSC, although amount of initial substrate has to be optimized and considered as a criterion for scaling up SSC with oxidant pulses.

Newly Isolated Member of the Genus *Shewanella* Couples Anaerobic Acetate Oxidation to Metal Reduction

Author Block:

N. Szeinbaum, H. Lin, M. Taillefert, T. DiChristina; Georgia Inst. of Technology, Atlanta, GA

Abstract Body:

Background: Mn-linked redox transformations drive a variety of environmental processes in marine and freshwater environments. Mn(III) is a likely significant yet overlooked terminal electron acceptor in modern and ancient metal-rich anaerobic environments. Acetate widely fuels heterotrophic microbial activity in the modern biosphere, and is one of the primordial forms of organic carbon. The microorganisms responsible for coupling anaerobic acetate oxidation to Mn(III) reduction, however, have yet to be identified. **Methods:** Enrichment cultures were initially inoculated with Mn(II)-rich sediments from a perennial creek bank on Skidaway, Georgia. Cultures were incubated in serum bottles under a 100% N_2 atmosphere with acetate and Mn(III)-pyrophosphate as sole electron donor and acceptor, respectively, and maintained by periodic transfers to fresh medium. Bacterial 16S rDNA amplicons were sequenced with Ion Torrent technology. Purified colonies were obtained by standard agar plating techniques. Whole genome sequences were obtained using an Illumina sequencing platform and analyzed using CLC genomic workbench V8, RAST and BioCyc and NCBI databases. Mn(III) and Fe(III) reduction were monitored spectrophotometrically. Acetate concentrations were measured by HPLC. **Results:** After seven successive transfers spanning two years, *Shewanella* (90% 16S rDNA amplicon abundance) dominated the resulting Mn(III)-reducing microbial community. Isolated strain (MN-01) displayed 99% 16S rDNA sequence similarity to *S. haliotis*. MN-01 coupled anaerobic lactate oxidation to Mn and Fe reduction. However, unlike other metal-reducing members of the *Shewanella* genus, strain MN-01 also coupled anaerobic acetate oxidation to Mn(III)-PP and Fe(III)-citrate reduction. Comparative genomic analyses of strain MN-01 and strains within and outside of the genus revealed that AOMR metabolism may utilize the tetrahydrofolate branch of the Woods-Ljungdahl pathway and the extracellular electron transfer conduit of metal-reducing bacteria.**Conclusions:** Strain MN-01 is the first reported *Shewanella* strain to couple anaerobic acetate oxidation to metal reduction thus extending their known ecological niche. These findings highlight a potentially significant link between the reductive acetyl-coenzyme A pathway and metal reduction.

Spatial and Temporal Variation in Enzymatic Activities of St. Claire River and Lake Sediments via API ZYM Method

Author Block:

D. Patel, R. Gismondi, M. Fenner; Univ. of Michigan-Dearborn, Dearborn, MI

Abstract Body:

Background: Spatial and temporal variations in enzymatic activities of lake and river sediments were determined using API ZYM assay. API ZYM is a semi-quantitative micromethod designed to determine activities of 19 different enzymes. **Methods:** Three sites were selected on St Claire River (SC1, SC2, and SC3) and three sites on Lake St. Clair (LC1, LC2, LC3). A 1:10 sediment : water extract was prepared; and 30 l of the extract was dispensed in each of the 20 cupules. Each of the 19 cupules contained substrate for the 19 enzymes and and one cupule served as a control. Once incubated one drop of ZYM A and ZYM B were added to the cupules and results were collected after 10 mins. **Results:** Results were analyzed with a variety of tests. T-test was used to compare activities between river and lake. There was no significant distinction between the river and the lake except for lipase and leucine aminopeptidase, of which St. Claire river sediments had more enzymatic activities. ANOVA test was used to compare lake and river site sediments for enzymatic acitvities. Leucine aminopeptidase and valine aminopeptidase activities were significantly among the three sites. SC3 had highest activities of leucine, valine aminopeptidase and β-glucuronidase. Leucine aminopeptidase activity was significantly different in each of the three lake sites and with the highest activity in LC3. **Conclusion:** The research results give an important insight on different contaminants lake and river water are being exposed to and how these contaminants influence the diversity of the microbial community.

***Varunavibrio sulfuroxidans* gen. Nov., Sp. Nov., A Novel Facultatively Chemoautotrophic Alphaproteobacterium from a Shallow-Water Hydrothermal Vent in the Tyrrhenian Sea**

Author Block:

S. Patwardhan, C. Vetriani; Rutgers Univ., New Brunswick, NJ

Abstract Body:

A mesophilic, anaerobic, chemolithoautotrophic bacterium, designated strain $TC8^T$, was isolated from the surface sediment of a shallow-water hydrothermal vent located in the Tyrrhenian Sea. The cells were Gram-negative, vibrio-shaped with one or more polar flagella. Cell size was approximately 1-1.5μm in length and 0.6 μm in width. Strain $TC8^T$ grew between 20 and 35°C (optimum 30°C), 0.5 and 4.50g NaCl l^{-1}(optimum 15-20 g l^{-1}) and pH 4.5 and 8.5(optimum pH 6.0-7.0). Generation time under optimal conditions was 8 hours. Strain $TC8^T$ was a facultative chemolithoautotroph, facultative chemoorganautotroph as well as a facultative chemoorganoheterotroph and growth occurred with sulfur, thiosulfate, sulfate, tryptone, peptone, and casamino acids as the energy source, CO_2 as the carbon source, and nitrate, 5%(w/v) oxygen and ferric ions as electron acceptors. Growth was not inhibited by the presence of acetate, lactate, D- (+) -glucose, sucrose, casamino acids, tryptone, peptone,yeast extract and all of them could be used as sole sources of carbon too. Reduced growth occurred in the presence of formate. $TC8^T$ grew on selenate and arsenate as electron acceptors but the growth rate was very slow.The G + C content of the genomic DNA was 59.9mol%. Phylogenetic analysis of the 16S rRNA gene of strain $TC8^T$ showed that this organism formed a divergent lineage within the family '*Rhodospirillaceae* ', which branched separately from the two closest clades representing the genera *Magnetovibrio*, *Magnetospira*, both of which are magnetotactic bacteria. However, $TC8^T$did not show magnetosome formation in the growth conditions under which it was tested for. Strain $TC8^T$ contained several unique fatty acids in comparison to the two closest relatives. Based on phylogenetic, physiological and chemotaxonomic characteristics, it is proposed that the organism represents a novel genus within the family *Rhodospirillaceae, Varunavibrio sulfuroxidans,*gen. nov., sp. nov.

Sample Acquisition and Preservation on Mobile Ecogenomic Sensors in Support of Microbial Studies

Author Block:

C. M. Preston[1], D. Pargett[1], K. Yamahara[1], S. Jensen[1], B. Roman[1], A. Romano[2], J. Cardwell[2], B. Hobson[1], B. Kieft[1], J. Ryan[1], Y. Zhang[1], J. Birch[1], E. DeLong[3], J. Bellingham[4], C. Scholin[1]; [1]MBARI, Moss Landing, CA, [2]Univ. of Hawaii, Honolulu, HI, [3]Univ. of Hawaii, Moss Landing, CA, [4]WHOI, Woods Hole, MA

Abstract Body:

Twenty-five years of near-monthly observations at Station ALOHA suggest that certain microbial processes are under-sampled, especially those operating on diel to weekly time scales, due to short-lived but ecologically significant aperiodic excursions from the mean state. There is strong evidence that short-lived (<5 days), stochastic events contribute significantly to integrative ecosystem properties such as nutrient loading, total primary production and carbon export. Since most oceanographic and planktonic microbial processes remain undescribed, new approaches are required to improve our understanding of the metabolic balance in the sea.One approach for expanding observational frequencies and resolution of microbial processes involves implementation of automated sensing and sampling systems. To achieve this goal, we are developing a cohort of long-range autonomous underwater vehicles known as MiVEGAS (Multiple Vehicle EcoGenomic Automated Sampler). MiVEGAS represents the merger of the 3rd generation Environmental Sample Processor (3G ESP) and Long-Range AUV (LRAUV), that were developed at MBARI. The biological material recovered using MiVEGAS will capture the native state of organisms, which in turn will enable a wide range of laboratory based -omic analyses.Here, we report results on testing the MiVEGAS prototype to collect and preserve material for subsequent analyses that include qPCR, tag sequencing, and metatranscriptomics. We show the abundance and diversity of microbial genes and transcripts from samples collected and preserved using the 3G ESP sampling strategies are statistically similar to those processed using more standard field sampling procedures. Initial field trials in Monterey Bay, CA, illustrate autonomous feature finding and adaptive sampling. Material recovered from native samples was used to survey the genetic diversity using SSU tag sequencing. Those same samples were also subjected to qPCR as a means to look for the presence of exogenous DNA indicative of anchovy and to access changes in the abundance and expression of wide range of microbial genes. The MiVEGAS fleet is projected to be operational by 2017.

Fluorescence Activated Cell Sorting Reveals Active Microbial Community Structure In Ancient Permafrost

Author Block:

A. Burkert, R. Mackelprang; California State Univ., Northridge, Northridge, CA

Abstract Body:

Permafrost microbial communities must contend with extreme conditions such as water stress, subzero temperatures, high salinity, and low nutrient availability. Previous studies have used metagenomic and 16S rRNA gene sequencing to characterize community structure. However, freezing temperatures may preserve DNA from dead organisms for extended periods of time (1). Because metagenomic and 16S rRNA gene sequencing does not distinguish between live, dead, and dormant cells, it is difficult to determine which organisms are viable and active.In order to circumvent this problem, we combined Live/Dead differential fluorescent staining with flow cytometry to sort cells before sequencing. Samples, ranging in age from 12kyr to 35kyr, were collected from the Cold Regions Research and Engineering Laboratory permafrost tunnel near Fairbanks, Alaska. Cells were separated from soil matrix using a Nycodenz density cushion and stained using SYTO 9 and SYTOX 13 which differ in their ability to penetrate the membrane of live cells. After staining, cells were sorted using a BD Calibur fluorescent cell sorter. DNA was extracted from live, dead, and dormant pools and 16S rRNA genes were sequenced to characterize community structure.This approach revealed the ratios of live, dead, and dormant cells in permafrost and how the ratios changed with increasing age. Microbial community structure changed, likely due to adaptations to the harsh environment. Further, we identified the taxa more likely to persist in permafrost. These data suggest that permafrost age is strongly selective for traits that enable bacteria and archaea to survive over geologic time.

Quantification of Total and Active Gut Microbiota in Healthy Subjects

Author Block:

S. Tamburini, J. C. Clemente; Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract Body:

Advances in high-throughput sequencing and computational methods have allowed us to characterize the wide variety of bacteria that are harbored in the human gut. However, sequencing alone cannot determine whether the bacterial DNA observed in a sample originates from a viable, damaged, or dead bacterial cell. Here we develop a method that combines sonication, fluorescence-activated cell sorting (FACS), and viability fluorescent markers to absolutely quantify and characterize at a single cell level the bacterial viability of the gut microbiota of healthy subjects. Viability was assessed based on membrane integrity while cells with high or low activity were identified on the basis of their DNA content. Sonication was able to disaggregate bacterial cell clusters without damaging the bacterial membrane. Through our FACS analysis we estimate that a gram of gut microbiota from healthy subjects contains on average $5.0x10^{10}$ bacterial cells and distinctive subpopulations of high nucleic acid content (HNA), low nucleic acid content (LNA), viable, damaged and dead bacterial cells. Viable bacteria (61%) and bacteria with HNA (75%) are the largest subpopulations in the gut microbiota with $3.4x10^{9}$ cells/g and $3.7x10^{10}$ cells/g, respectively. Our results highlight the variability in physiologically distinct bacterial cell subpopulations, suggesting that microbiome studies should take into account these factors in order to better characterize bacterial composition.

Surface-Attached Phototrophic Communities Assemble i*n situ* with Narrow-Spectrum Led Illumination

Author Block:

S. M. Kearney[1], S. H. Kopf[2], K. Hanselmann[3], D. K. Newmann[4], J. R. Leadbetter[4]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]Univ. of Colorado - Boulder, Boulder, CO, [3]Swiss Federal Inst. of Technology (ETH), Zuerich, Switzerland, [4]California Inst. of Technology, Pasadena, CA

Abstract Body:

Background: Chlorophyll-based phototrophy spans multiple, phylogenetically diverse bacterial groups. The phylogenetic dispersion of this functional trait reflects its evolutionary success as a metabolic strategy for organisms living in the light. Each wavelength of the solar spectrum represents a potential niche for phototrophy.Isolation of specific phototrophic microorganisms in the laboratory can best be achieved by using radiation at different wavelengths aimed at characteristic photon-absorbing pigments in combination with various electron donors. This strategy has led to the successful enrichment of numerous phototrophic microorganisms with absorption characteristics that span the spectrum from blue to the infrared. **Methods:** We expanded on this classical approach by developing an inexpensive, reusable, submersible battery-powered narrow-spectrum LED illumination chamber with a 3D printed, environmentally exposed microscope slide holder. The method allows phototrophs to grow on glass slides exposed directly to the chemical environment of their natural habitat while illuminated in situ with selected LED light sources. **Results:** We deployed several devices to enrich for phototrophic communities in situ at Trunk river basin, an organic-rich, sulfidic brackish habitat. LED/wavelength-specific biofilm growth could be observed within several hours to a few days. Phototrophic organisms present in the formed biofilm communities could then be directly differentiated and were characterized in detail based on their topographical, spectral, and morphological features. **Conclusions:** This approach proved to be a reliable strategy for selectively enrichingphototrophs and provides a simple and effective means to conduct culture-independent profiling of phototrophic communities as they are present in the environment.

Soil Printing as a High Throughput Method to Isolate and Culture Environmental Microorganisms

Author Block:

B. R. Ringeisen[1], P. A. Fulmer[1], L. A. Fitzgerald[1], M. Montgomery[1], J. Bethancourt[1], J. P. Goetz[1], A. Li[1], P. K. Wu[2]; [1]Naval Res. Lab., Washington, DC, [2]Southern Oregon Univ., Ashland, OR

Abstract Body:

Background: Culturing environmental microorganisms is one of the biggest challenges facing microbial ecologists and microbiologists today. High throughput, nanoporous membrane and microarray approaches have recently emerged to help improve culturing success rates; however, laboratory culture rates remain far behind metagenomics approaches with respect to characterizing environmental biodiversity. **Methods:** High throughput biological laser printing, or BioLP, was employed as a novel method to isolate near-neighbor consortia and microbial isolates directly from soil samples without the need to vortex or sonicate to dislodge microorganisms from their solid-phase microenvironment prior to culture. BioLP is an orifice-free printing technique that uses laser pulses to initiate the transfer of micron-scale portions of soil from a transparent support ribbon while maintaining the viability of printed microorganisms attached to the soil. Culturing and subsequent metagenomics analysis was used to characterize the soil printing process. **Results:** Printing soil microniches to culture microtiter plates resulted in isolation of microorganisms and microbial consortia in a single step. Significant colony morphology was observed upon streaking microtiter plate cultures. Printing to ten 96 well plates resulted in over 500 pure culture isolates from an agricultural soil sample. Metagenomics was used to analyze the difference when utilizing different methods to culture the sample (dilution, batch or soil printing). Soil printing resulted in the highest number and diversity at the bacteria genus level, closely followed by dilution. Batch culture reduced the diversity by 12%. **Conclusions:** The results indicate that soil printing exceeds manual dilution and batch culture with respect to the biodiversity of culturable bacteria from soil. Additionally, BioLP is a high throughput (hundreds of soil portions isolated per second) and unique approach that isolates microorganisms while still attached to soil, enabling near-neighbor relationships and consortia to be explored.

Optimization Rk2(Rp4) Conjugal Transfer System for *B. subtilis*

Author Block:

T. Yokoi; Shinshu Univ., Nagano, Japan

Abstract Body:

Bacillus subtilis is one of the most widely used bacteria in the Industrial Biotechnology. It is well known that *B. subtilis* and the closely related species show non pathogenic and endotoxin free. Their fermentation method has been well optimized for producing various enzymes, antibiotics, and chemicals. However, the genetic manipulation system including transformation method has not been maintained in the most B. subtilis strains except the well characterized laboratory strain. Natural isolates strains of B. subtilis are often show difficulty of transformation due to their lack of natural competency.In this meeting, we will present the in vivo heterogeneous gene transfer system between E. coli and *B. subtilis* by using RP4 conjugation system. We used the mobility plasmid pUB307 Tn5, a conjugative plasmid carrying RP1 tra genes. pUB307 could be mobilized other plasmids containing transfer origin(oriT) sequence. We constructed the series of shuttle vector containing various lengths of transfer origin (oriT) to assess the effect on heterogeneous DNA transfer. The plasmid containing a Wild Type oriT showed well conjugation efficiency between E.coli and B.subtilis. In contrast, other plasmids containing partial deleted oriT showed the smaller frequency. To optimize the inter-genus conjugation, we examined the time required for DNA conjugation. Conjugation for 1 hour gave enough number of the trans conjugants. Finally our optimized conjugation method showed more effective DNA transfer than the natural transformation usually used.

Identification Of Spacecraft-Associated Microorganisms Using Matrix-Assisted Laser Desorption/Ionization Time-Of-Flight Mass Spectrometry

Author Block:

W. W. Schubert, H. Aronson, P. A. Vaishampayan; Jet Propulsion Lab., Pasadena, CA

Abstract Body:

Microbes collected from robotic spacecraft and cleanroom assembly areas are archived in JPL's microbial culture collection. The microbial isolates that have been identified by 16SrRNA gene sequence (2318) most frequently belong to the following major genera: *Bacillus* (64%), *Staphylococcus* (18%) and *Paenibacillus* (3%) with other genera composing the remaining 15%. As an alternate, rapid and more sensitive approach, a subgroup of these isolates were identified by Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Spectrometry (MALDI-TOF) and compared to their 16S rRNA gene sequence identifications. An in-house database was created using bacterial isolates with known 16S rRNA identifications collected from Phoenix Mars lander hardware and was used to validate the correlation between 16S rRNA-based identifications and MALDI-TOF identifications. Similar gene sequences at the 99% homology level were grouped into operational taxonomic units (OTUs), and MALDI-TOF spectral profiles (MSP) were created for one representative isolate from each OTU and added to the in-house database. Fifty-three unique OTUs were produced from 147 Phoenix isolates based on 16S rRNA gene sequencing. Using MALDI-TOF based real time classification (RTC), 74% of Phoenix isolates matched their 16S rRNA gene identifications. RTC analysis was able to detect sub-species variations that were not possible by 16S rRNA sequencing. Creation of a more comprehensive database is required in order to correctly identify the cleanroom microbial isolates.

Novel Workflows for Advanced Analysis of Human Microbiota Communities by Sequencing and Qpcr

Author Block:

A. Vlassov, S. Larocca, 78744, M. Li, 78744, R. Setterquist; Thermo Fisher Scientific, Austin, TX

Abstract Body:

Background: Recent studies had a shocking finding that human body is populated by 10(14) bacteria and other members of the microbiota community, that outnumber human cells 10-fold. Microbes have multiple beneficial functions, and interestingly deviations from the "normal" microbial compositions have been linked with many human diseases. Although our understanding of the microbiome is in the nascent stages, it's clear that we need to treat it as a sophisticated system, much like the circulatory and immune systems, playing multiple roles within the human body. Our team's goal is to address the urgent needs of the microbiome community and provide the complete arsenal of tools to the scientists exploring microbiota through nucleic acids analysis. **Methods:** We developed tools and a workflow enabling: (1) sample collection; (2) storage; (3) isolation of microbial DNA with novel PureLink Microbiome DNA Purification Kit; (4) initial DNA analysis by NanoDrop spectrophotometer, Qubit fluorometer, and agarose gel electrophoresis; (5) qPCR with TaqMan assays, and next gen sequencing.**Results:** The PureLink kit enables fast purification of inhibitor-free microbial and host DNA from a wide variety of sample types, including stool, urine, saliva, swabs, transport/growth media, and combines efficient triple lysis approach and unique inhibitor removal technology. Investigation of the "healthy" microbial communities in the gut will be exemplified by 16S Sequencing of stool-derived microbial DNA. Utility of the kit and downstream assays for rapid detection of *C.difficile* and other pathogens will be demonstrated as well, with 2h sample-to-answer workflow.**Conclusions:** Microbiome is a hot topic of research, growing exponentially due to the fact that it has high potential to revolutionize medicine. We developed the complete workflow solution for microbiome research, starting from sample collection and storage, to DNA isolation and downstream analysis.

Reclassification of *Clostridium cocleatum, Clostridium ramosum, Clostridium spiroforme* and *Clostridium saccharogumia* to a Novel Genus, "*flintia*" Gen. Nov

Author Block:

L. Saavedra[1], S. Finegold[2], P. A. Lawson[1]; [1]Univ. of Oklahoma, Norman, OK, [2]UCLA Sch. of Med., Los Angeles, CA

Abstract Body:

Background: The recent proposal to restrict the genus *Clostridium* to *C. butyricum* (rRNA cluster I) and relatives indicates that many species will no longer be considered as true members of this genus (1). *Clostridium cocleatum, Clostridium ramosum, Clostridium spiroforme* and *Clostridium saccharogumia* are located in clostridial rRNA cluster XVIII and form a robust phylogenetic group based on 16S gene sequencing. In this study, in addition to molecular analysis *Clostridium cocleatum, Clostridium ramosum, Clostridium spiroforme* and *Clostridium saccharogumia* were subjected to morphological, phenotypic, biochemical and chemotaxonomic investigations. **Materials and Methods/Results:** *C. cocleatum, C. ramosum, C. spiroforme* and *C. saccharogumia* were recovered from children with late-onset autism. For chemotaxonomic data, fatty acids were analyzed using the MIDI system (2). The profiles showed that *C. cocleatum, C. spiroforme, C. ramosum* and *C. saccharogumia*'s dominant fatty acids were $C_{14:0}$, $C_{16:0}$ and $C_{18:1\ w7c}$. Whole-cell sugar analysis (3) also held concordance between all organisms for the presence of galactose, while analysis of the peptidoglycan (4) showed that *meso*-2,6-diaminopimelic acid was present as the diagnostic diamino acid. The biochemical profiles derived from API test systems were consistent with being closely related species. Negative staining and thick sectioning performed at the University of Oklahoma provided highly defined visual images that complimented morphological descriptions of cellular parameters provided in Bergey's Manual of Systematic Bacteriology. **Conclusion:** According to these findings, it is proposed to create a novel genus, "*Flintia"* to accommodate *Clostridium cocleatum, Clostridium ramosum, Clostridium spiroforme* and *Clostridium saccharogumia* as "*Flintia* cocleatum gen. nov. comb. nov.", "*Flintia ramosum* comb. nov.", "*Flintia saccharogumia* comb. nov." and "*Flintia spiroforme* comb. nov". The genus is named in honor of the British microbiologist Harry Flint for his many contributions to anaerobic microbiology of the human gut.

Use of a Global Survey to Direct the Implementation of Alternative/Rapid Microbiological Methods Supporting Microbiological Quality Across Multiple Pharmaceutical Manufacturing Sites

Author Block:

D. Gessell-Lee, M. Luebke; Baxter Hlth.care Corp., Round Lake, IL

Abstract Body:

Background: Current pharmaceutical microbiology laboratories are continually challenged to produce faster, more accurate data using century-old, labor intensive techniques. To address this need, a variety of Alternative/Rapid Microbiological Methods (ARMMs) have been developed to support microbiological quality and facilitate improved product and process control. The application of ARMMs in the pharmaceutical industry, however, may be hindered by a range of challenges; a globally harmonized validation approach is essential for successful implementation. In an effort to purposefully direct the purchase and implementation of new methodologies within the microbiology laboratories of a large pharmaceutical company, a global survey was conducted. Our objective was to identify the highest priority needs across a global landscape, assess these needs to guide appropriate ARMM choices, and subsequently identify and remediate potential barriers to successful ARMM implementation.**Methods:** An online survey tool was utilized to develop and distribute a global questionnaire evaluating potential applications and barriers preventing the use of ARMM technology within microbiology laboratories. The data were analyzed to identify and prioritize the ARMM applications providing the greatest impact to pharmaceutical microbiology operation efficiencies.**Results:** The survey results directly influenced global ARMM implementation. Two microbiological tests, sterility and microbial identification, were identified as candidates for ARMM applications. As a result, a qualitative ATP-based system for finished product sterility and a MALDI TOF-based microbial identification system were successfully validated in several laboratories. A number of real-world industrial challenges and lessons learned were uncovered during the evaluation and validation of the two ARMM platforms.**Conclusions:** The pragmatic application of a global microbiological methods survey was instrumental in the successful implementation of two ARMMs within a large pharmaceutical company. The identification and remediation of a number of technical and non-technical challenges enabled a harmonized validation approach across multiple manufacturing sites and regulatory landscapes.

***In-Silico* Analysis of Bacterial Polar Lipid Synthesis as a Tool for Chemotaxonomy**

Author Block:

N. Patel, K. Sankaranarayanan, P. A. Lawson; Univ. of Oklahoma, Norman, OK

Abstract Body:

Background: The characterization of novel microorganisms traditionally requires a polyphasic approach that includes phylogenetic, biochemical and chemotaxonomic investigations. Chemotaxonomic traits such as polar lipids help augment the data obtained from physiological tests to achieve a complete profile in microbial taxonomy. However, the labor intensive nature of these analyses coupled the lack of curated databases makes reproducibility and comparative analysis of results difficult. Alternatively, the ease of generating complete/draft genome assemblies allows for rapid *in silico* characterization of functional potential for novel microbial strains. Embracing this *in silico* approach to screen for genes associated with polar lipid synthesis can thus be a powerful tool for microbial systematics.**Methods:** This study focused on the biosynthetic pathways for four common polar lipids found in bacterial membranes: Diphosphatidylglycerol (DPG), Phosphatidylglycerol (PG), Phosphatidylethanolamine (PE), and Phosphatidylserine (PS). Fifty organisms with sequenced genomes and published polar lipid data (TLC/Mass Spectrometry) were selected from across six bacterial phyla (Firmicutes, Bacteroidetes, Actinobacteria, Acidobacteria, Spirochaetes and Proteobacteria). For each organism, genomic annotations derived through the KEGG automatic annotation server (KAAS) were compared to published polar lipid data and patterns of concordance/discordance were documented.**Results:** For polar lipids PE and PS, strong concordance between the genomic and *in vitro* characterizations was observed across all phyla examined. In contrast, the lipid DPG showed phylum specific trends, with a strong concordance among Firmicutes, and discordance among Actinobacteria and Acidobacteria. Finally, the lipid PG showed discordance for one of two genes required for its synthesis, across most organisms examined.**Conclusion:** Collectively, these results highlight the need for (a) standardized *in vitro* polar lipid characterization, and (b) experimental characterization of polar lipid biosynthesis pathways in a phylogenetically diverse range of organisms. Addressing these challenges are critical to evaluating the predictive accuracy of *in silico* models, and their broader application as a tool for chemotaxonomy.

An Improved Method for Inferring Accurate Co-Occurrence Networks from Microbial Metagenomes Based on Random Matric Theory and Machine Learning

Author Block:

Z. Shi, Y. Xu, Y. Qin, Z. He, J. Zhou; Univ. of Oklahoma, Norman, OK

Abstract Body:

The emerging metagenomics technologies have advanced the characterization of interactive patterns among the microorganisms, and provided opportunities better understanding microbial responses to perturbations and even improving the predictive capability of ecosystem models. Because of its straight-forward calculation procedure and high processing speed, co-occurrence network inference has become a widely adopted method for efficiently identifying networks from large and complex microbial community systems. While this method is neither sufficient to determine the causality between given pair of variables, nor does it reflect true microbial interactions, it allows to examine meaningful co-occurrence patterns in large data sets without prior knowledge of the relationships. However, determining a threshold or cutoff value for real world studies to exclude weak and random co-occurrence patterns is problematic, but necessary in order to obtain accurate and reliable networks. Most studies have selected thresholds empirically, so the constructed networks are inevitably subject to artificial deviations and inaccurate structure. We previously proposed a random matrix theory (RMT)-based approach for detecting such thresholds automatically and objectively, but this method still had issues with detection limit and slow processing speed. Here we developed an improved RMT method to determine appropriate thresholds based on Nearest Neighbor Spacing Distribution (NNSD) characterization and Support Vector Machine (SVM) learning, to further extend the capability of the method . Results showed that the improved method successfully determined the thresholds of systems for which the previous method failed. Meanwhile, the original RMT method and the improved version were consistent with each other on the threshold values from the systems that can be determined by the both methods. In addition, the processing speed was increased many fold in our test runs. Based on these results, we concluded that the RMT-based method is reliable, robust and consistent in tackling the mathematical challenge of refining microbial interactions. In addition, the improvements described in this study increase our ability to accurately determine co-occurrence networks from microbial metagenomes with minimal randomness and noise.

Development of a Biosensor Using *Photobacterium* spps for the Detection of Environmental Pollutants

Author Block:

T. Gokhale, S. Biswal, A. Thapa, 345055, N. Sood; BITS Pilani Dubai Campus, Dubai, United Arab Emirates

Abstract Body:

Bioluminescence is a natural phenomenon in which energy is spent to emit light. It is exhibited by many organisms. These organisms emit light through a enzymatic reaction between the substrate Luciferin, which is a pigment and an enzyme Luciferase. The *Lux* operon in bacteria controls the process of luminescence, which follows the quorum sensing mechanism. We used the idea of bioluminescence of develop a photobiosensor to detect the presence of environmental pollutants. *Photobacterium spps* was isolated from the squid using BOSS media and identified using the 16s rRNA analysis. The effect of environmental pollutants was studied in *Photobacterium spps* by analyzing the luminescence exhibited by the bacterium in presence and absence of the pollutant. The luminescence was recorded using Perkin Elmer Victor 320. Metals were selected as environmental pollutants for the study, as metal contamination is a major concern in many parts of the world and the concentration of heavy metals have increased in soil and water beyond the safe limit. The effect of varying concentrations of different metals such as cadmium (0-1mg/ml), barium (0-150mg/ml), zinc (0-0.05mg/ml), cobalt (0-1.25mg/ml) and copper (0-1.5mg/ml) was studied on the luminescence of *Photobacterium spps*. A linear decrease in the luminescence was observed with the gradual increase in the concentration of the heavy metals. This signifies the ability of the bacterium to sense the presence of the pollutant and estimate the quantity. This luminescence property of *Photobacterium spps*. can be exploited for the development of the photobiosensor. *Photobacterium* is a non-pathogenic organism and hence can be safely used for the development of biosensors. Biosensors are analytical devices that are constituted of a biological element like an enzyme, an analyte, which is generally a substrate for the enzyme and a transducer that converts the chemical signal or light into an easily measurable signal. The *Photobacterium* species isolated in this work can be efficiently used in developing the biosensor where the biological element can be the whole bacterial cells. An optical biosensor is designed using fiber optic technique and photodiodes to detect the luminescence and convert it into a measurable signal.

Culturing the Unculturables: Strategies for Closing the Sequenced vs Cultured Gap

Author Block:

P. A. Fulmer[1], L. A. Fitzgerald[1], J. Goetz[2], A. Li[2], J. Bethencourt[3], P. K. Wu[4], D. Haridas[1], L. J. Hamdan[1], B. R. Ringeisen[1]; [1]Naval Res. Lab., Washington, DC, [2]Thomas Jefferson High Sch. for Sci. and Technology, Alexandria, VA, [3]Florida Intl. Univ., Miami, FL, [4]Southern Oregon Univ., Ashland, OR

Abstract Body:

Background: With the advancement of next-generation sequencing technologies, the vast diversity of environmental microbes has become apparent. While sequencing technologies have advanced at a rapid pace the ability to culture these microbes has lagged behind, despite the fact that these environments have proved to be extremely rich depositories of functional molecules and synthetic pathways. **Methods:** A variety of techniques were employed to increase the speed with which previously uncultured microbes can be isolated from three environments: 1) topsoil from an active corn field; 2) marine sediments; 3) marine water column. A variety of growth condition variables were employed, including media formulation, carbon source, and temperature. Cultures were produced by traditional plate streaking (water column), followed by colony isolation as well as high-throughput biological laser printing methods (soil and sediment). Candidates for further study were identified by sequencing of 16s rRNA followed by additional analysis of *rpoB* and *gyrB* sequences.**Results:** All environments tested resulted in the growth and subsequent identification of novel microbes. Due to the large number of isolates generated (~750), a relatively conservative threshold of ≤90% 16s rRNA identity to cultured microbial sequences in the BLAST database was used to identify candidates for further study. Topsoil (15), marine sediments (25), and marine water column samples (16) resulted in the identification of unique, culturable isolates. Subsequent *rpoB* and *gyrB* sequencing, and phenotypic assays were employed to further characterize novel isolates.**Conclusion:** These results show that a variety of methods, both traditional and high-throughput, can be successfully utilized to increase the diversity of cultured microbes, even in environments which, to date, have been heavily studied. High-throughput culture methods of unique, rare, or difficult to sample environments in particular show themselves to be extremely rich in culturable, but yet to be cultured microbes.

Heterotrophic Bacterial Production Measured on Soil Microaggregates Sampled Using a Biological Laser Printer

Author Block:

M. T. MONTGOMERY, P. A. Fulmer, J. Gaston, N. McAuliff, J. Compton, B. Ringeisen; NAVAL RESEARCH LABORATORY, WASHINGTON, DC

Abstract Body:

Background: Although routinely measured in aquatic systems over the last 30 years, heterotrophic bacterial production (^{3}H-leucine method) has only more recently been measured in terrestrial ecosystems to elucidate the role of soil biogeochemical processes in global carbon cycles and climate change. Studying bacterial metabolism at the microaggregate scale (100-300 μm) may unmask important microscale biogeochemical relationships amongst bacterial processes and the surrounding soil. **Methods:** Biological laser printer technology was used to sample soil core sections (*ca.* one mm thick) nondestructively into *ca.* 100-300 μm microaggregates. Bacterial production was measured on collections of five aggregates each (180 samples over 5 cm depth profile) by suspending aggregates into filtered rainwater with ^{3}H-leucine and incubated for 4 h. Some aggregates samples were sacrificed to measure enzymatic activity (*e.g.* phosphatase using MUF-PO_4) fluorometrically.**Results:** Bacterial production varied by over two orders of magnitude amongst groups of five microaggregates collected over millimeter scale core slices (range, 4-149 fg C microaggregate^{-1} d^{-1}). As expected, variability amongst adjacent microaggregates groups generally decreased with depth. Corresponding enzyme activity (using fluorescent MUF substrate analogs) also generally decreased with depth and showed variation amongst adjacent samples but less than the two orders of magnitude variation seen with bacterial production (phosphatase: 1.1-6.8 fmoles microaggregate^{-1} d^{-1}). Some of this lack of variation may have been due to lesser sensitivity of fluorometric assay relative to the radioassay.**Conclusions:** Variation in bacterial production at the microaggregate scale was greater than that seen at larger scale (ca. 100 μg) sampling of the same core. Smaller sample size dramatically reduced radiotracer quench due to soil particles. This is the first demonstration of using a biological laser printer for fine scale sampling of soil core slices and subsequent measurement of bacterial metabolism.

Metabolomics on the Differential Secondary Metabolite Profiles Induced by Epigenetic Modifiers in Fungal Endophytes, a Case Study

Author Block:

V. Gonzalez-Menendez, F. Muñoz, C. Toro, I. Perez-Victoria, J. Martin, F. Reyes, O. Genilloud, **J. R. Tormo**; Fundacion MEDINA, Granada, Spain

Abstract Body:

Background: Fungal endophytes are known to produce a wide variety of secondary metabolites (SMs) involved in their adaptation and survival within higher plants. Plant-microbe interaction may influence the expression of some biosynthetic pathways, otherwise cryptic in these fungi when grown in laboratory conditions. Epigenetic small-molecule modifiers of Histone Deacetylase (HDAC) and DNA methyltransferase (DNMT) activities have been successfully used to perturb the fungal secondary biosynthetic mechanisms, which has led to the induction of the expression of silent metabolite pathways. Adding epigenetic elicitors in fungal endophyte fermentations may induce the expression of biosynthetic pathways which may occur naturally in plant-microbe interaction. **Methods:** The systematic addition of small-molecule epigenetic elicitors was evaluated by uHPLC profiling, and the most interesting cases were further analyzed by LC/MS metabolomic approaches for the characterization of the metabolites that resulted increased in production under these fermentation conditions. In addition, strains that produced differential SMs in presence of the small elicitors were studied in detail and their principal induced components purified, identified and quantified as a proof of concept of the OMICs methodology.**Results:** The effects of 7 epigenetic modifiers is described for a case study group of 13 fungal endophytes fermented during 7 and 14 days to evaluate the possible activation of silent biosynthetic pathways compared to their growth in standard conditions. Addition in both, the inoculum and the production medium, were evaluated. The effects of the elicitors during *inocula* had not been previously reported, so we intended to evaluate any potential differences in the metabolite profiles generated in these different scenarios. The increase in production titers of global SMs profiles in some of the strains was slightly higher when the elicitors were present from that inoculum stage.**Conclusions:** The described approach on the use of epigenetic modifiers in fungi ensured a successful systematic generation of new SMs. Current scale-up, purification and chemical characterization of selected strains/conditions are being carried out for the most promising new metabolites induced.

Lineage Tracking for Probing Heritable Phenotypes at Single-Cell Resolution

Author Block:

D. Cottinet[1], J. Bibette[2], J. Baudry[2], J. G. M. de Visser[3]; [1]Millidrop Instruments, Paris, France, [2]ESPCI ParisTech, Paris, France, [3]Wageningen Univ., Wageningen, Netherlands

Abstract Body:

Determining the phenotype and genotype of single cells is central to understand microbial evolution. DNA sequencing technologies allow the detection of mutants at high resolution, but similar approaches for phenotypes analysis are still lacking. We show that a drop-based millifluidic system (image top picture, Baraban 2010) enables the detection of heritable phenotypic changes in evolving bacterial populations. At time intervals cells were sampled and individually compartmentalized in 100 nL drops. Growth of their progeny through 15 generations was monitored using a fluorescent protein reporter. The amplification of heritable changes over multiple generations yields clusters of narrowly defined phenotypes reflecting variation relevant for evolution (image bottom graph). To demonstrate the utility of this approach, we follow the evolution of *Escherichia coli* populations during starvation (Zambrano 1993). Phenotypic diversity was observed to rapidly increase upon starvation with the emergence of heritable phenotypes. Mutations corresponding to each class were identified by DNA sequencing. This scalable lineage-tracking technology opens the door to large-scale phenotyping methods.

Separation and Isolation of Bacterial Cells Using Microfabricated Devices

Author Block:

E. D. Goluch, N. Tandogan; Northeastern Univ., Boston, MA

Abstract Body:

Lab-on-a-chip technology offers a promising solution for separating individual bacterial cells from complex mixtures. We developed a passive sub-microfluidic device designed specifically for automatic *in situ* separation and cultivation of species. The device contains multiple isolation chambers with size specific constrictions, and a main entrance for bacteria to enter into the device. Each isolation chamber has an access hole that is sealed with a polycarbonate membrane to facilitate chemical communication with the environment while preventing contamination. The first bacterial cell that enters the constriction becomes trapped. It divides in the constriction and its progeny eventually reach the isolation chamber. The cells proliferate in the presence of nutrients and growth factors diffusing into the isolation chamber from the environment and form a pure culture.For the preliminary studies, water samples from the Charles River in Boston, Massachusetts were collected in sterile 50 mL tubes. The devices were placed into the bottles for four weeks, and taken out to collect samples for plating and identifying the species. Our results show successful separation of species into different isolation chambers. This preliminary study showed promising results of our passive size-based isolation technique. Using a range of constriction sizes, a diverse distribution of species can be obtained in the isolation chambers.

Nanopore Technology for Full Length 16s Rrna Sequencing of Mixed Microbial Communities

Author Block:

S. T. Calus[1], U. Z. Ijaz[1], A. J. Pinto[2]; [1]Univ. of Glasgow, Glasgow, United Kingdom, [2]Northeastern Univ., Boston, MA

Abstract Body:

Current high-throughput platforms for 16S rRNA sequencing are limited by the size of the fragment that can be successfully sequenced. This amplicon length limitation not only necessitates choice of the target region of the gene can be sequenced, but also limits taxonomic resolution of the sequenced gene product. Newer platforms (e.g. Oxford Nanopore's MinION™) allow for sequencing of larger DNA fragments, albeit at a higher raw error rate. Nonetheless, the rapid developments in error correction and bioinformatics tools for high-error reads suggests that robust full length 16S rRNA sequencing should be soon be feasible.Here, we describe results of a study using MinION™ device for sequencing of full-length 16S rRNA genes from mock community constructed using 15 reference organisms from three independent experiments. Raw reads were aligned to reference sequences using four alignment algorithms, specifically designed for error prone reads followed by estimation of mismatch, insertion, and deletion rates. We also assessed the error rate as impacted by data filtering (i.e. base quality, mapping quality), error correction and read polishing approaches. Finally, we determined the effect of data processing steps on the ability to reconstruct the structure of the theoretical mock community.All 15 reference sequences were detected for all three independent sequencing runs with 2D read numbers varying between 48,279 to 11,177. All alignment algorithms mapped in excess of 98% of the 2D pass reads to the reference sequences. Assessment of aligned vs unaligned reads for each algorithm indicated that base quality was not an optimal data filtering approach. In contrast, filtering of aligned reads based on the mapping quality generated by the BWA allowed for a significant reduction in overall error rate. However, data filtering based on mapping quality also resulted in loss of significant amount of raw data (>70%). The error rates for quality-filtered data ranged from 6.5% for BWA (ont2D algorithm) to 14.7 for GraphMap (gotoh algorithm). In keeping with the consistent error rates, the relative abundance of each mock community member and multiple diversity indices, though deviating from the theoretical, were highly reproducible across the three sequencing runs.

A Microfluidic Screening Platform for Electroporation-Mediated Genetic Engineering

Author Block:

P. A. Garcia, Z. Ge, J. L. Moran, C. R. Buie; Massachusetts Inst. of Technology, Cambridge, MA

Abstract Body:

There are millions of species of bacteria on the planet, yet we can only genetically engineer a few dozen. The potential to solve many of mankind's most pressing challenges, including the needs for alternative fuels, enhancing oil recovery, and even treating cancer, could involve engineering the numerous bacteria currently beyond our reach. New tools are needed to unlock bacteria's true potential to solve many challenges of interest to mankind. In this work we have designed, fabricated, and tested a new microfluidic assay to quantify the critical electric field needed for electroporation in a single experiment.The microfluidic platform was designed with a converging microchannel that produces a linear electric field gradient when an electric pulse is applied, inducing electroporation in certain portions of the channel. The assay is performed in the presence of green nucleic acid stain (SYTOX®) that cannot permeate cell membranes unless there is membrane disruption. Electroporation-induced membrane disruption in regions of high electric field strength allows for intracellular delivery of the SYTOX® and a $\geq$ 500-fold fluorescence enhancement upon intracellular DNA binding. Optical detection of the transition zone was captured under fluorescence microscopy and correlated with computational models of the electric field distribution to determine critical electroporation conditions.The critical electric field threshold for *Corynebacterium glutamicum* ($OD_{600} \approx 0.5$ in BHI) electroporation in 0.01×PBS ($\sigma \approx 0.02$ S/m) is estimated as 4.13±0.34 kV/cm with a single exponentially decaying pulse ($t = 1.0$ ms; $\tau = 5$ ms). This technique has several advantages compared to the traditional trial-and-error experimental approach. First, the assay samples a continuum of electric field strengths in a single experiment, minimizing the experimental time required. Second, the assay uses low sample volume compared to conventional cuvettes, making it economical. Last, the optical confirmation allows for nearly real-time evaluation of electroporation conditions as opposed to waiting for next-day cultures. We envision this assay as a convenient tool to develop electroporation protocols for genetic transformation of previously intractable or difficult-to-transfect microorganisms.

A New Scalable Approach For Phenotypical Classification Of Microbial Communities

Author Block:

E. Asgari, K. Garakani, M. Mofrad; Univ. of California, Berkeley, Berkeley, CA

Abstract Body:

Background:A major challenge in microbial informatics is the classification of microbial communities of different phenotypes. Typical classifications based on community profiling involve reference alignment of billions of metagenomic sequences, which requires extensive data processing. Thus, using a reference-free method, which only requires a low fraction of data for characterization, would be extremely beneficial.**Method:**We introduce a new reference-free technique for classification based on k-mer sequence analysis of 16S rRNA. Using a random sampling component before estimation of k-mers, we reduce the processing data size dramatically (by 10^5 folds). Key steps in data extraction from each sample are shown in Figure 1. Support vector machine is used for classification of different conditions on k-mer distributions.

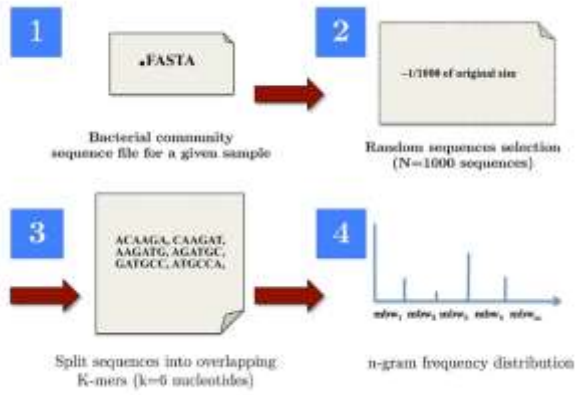

Figure 1 Key steps involved in feature extraction from each sample.**Results:**We employ this new approach to classify phenotypic microbial community differences in various settings. Specifically, we applied this approach in the classification of microbial communities across different body sites (1108 samples related to 5 major body sites), in the characterization of oral microbiomes associated with healthy and diseased individuals (20 samples, 10 healthy and 10 diseased), and in the classification of microbial communities longitudinally during the development of infants (63 samples obtain throughout 5 years). For these data sets, classification accuracies of 98.60% ± 1.8%, 100% ± 0.0%, and 99.9% ± 1.9% were obtained, respectively.**Conclusion:**Our findings support the use of the proposed reference-free data

analysis approach as a scalable approach for the rapid yet accurate analysis of 16S metagenomic data. The web tool and visualization system will be on: llp.berkeley.edu/mb.

Role of Synergistic Phage-antibiotic Combinations in Preventing Antibiotic Resistance

Author Block:

A. Jo, J. Kim, L-S. Jung, J. Ahn; Kangwon Natl. Univ., Chuncheon, Korea, Republic of

Abstract Body:

Background: The emergence of antibiotic-resistant *Staphylococcus aureus* has long been of great concern in hospitals because the nosocomial infections with methicillin-resistant *S. aureus* (MRSA) are easily transmitted between patients and furthermore become difficult to treat with common antibiotics Therefore, this study was designed to assess the role of phage-antibiotic synergy (PAS) in reducing antibiotic resistance. **Methods:** The antimicrobial activity of ciprofloxacin, phages, and combination (ciprofloxacin and phages) against *Staphylococcus aureus* was evaluated for 60 h at 37ºC as measured by disk diffusion susceptibility, biofilm-forming ability, bacterial spreading ability, and mutant frequency.**Results:** In the disk diffusion assay, the clear zone was noticeably increased to 10% in the presence of phages. The phage plaque size was increased with being close to the ciprofloxacin disk. The initial numbers of *S. aureus* treated with ciprofloxacin, phages, and combination were significantly reduced by 3.47, 4.62, and 5.75 log CFU/mL, respectively, at the early 12 h of incubation. The combination treatment was most effectively inhibited the growth of *S. aureus*, showing more than 4 log reduction in 18 h of incubation at 37ºC. Compared to the control, the most significant reduction in biofilm formation by *S. aureus* was observed at the combination treatment (3.91 log), followed by phages alone (3.13 log) and ciprofloxacin alone (1.04 log). Ciprofloxacin-treated *S. aureus* cells became resistant to both ciprofloxacin and phage, showing the mutant frequencies of 27% and 25%, respectively, while no antibiotic- and phage-resistant *S. aureus* cells were observed at the combined treatment of ciprofloxacin and phages.**Conclusions:** The most significant finding in this study was that PAS can be a potential alternative to effectively control antibiotic-resistant *S. aureus* with the least frequency of phage or antibiotic resistance. Therefore, these results provide useful information for a better understanding of PAS effect on the growth of *S. aureus* in association with mutation frequency.

Antimicrobial Activity of the Essential Oils of Ziziphora Clinopodioides Lam. from Armenia

Author Block:

N. SAHAKYAN[1], M. Petrosyan[1], A. Avetisyan[2], A. Markosian[2], S. Aloyan[2], A. Trchounian[1]; [1]Yerevan State Univ., Yerevan, Armenia, [2]Nairian, Yerevan, Armenia

Abstract Body:

The aim of this study was to analyze the chemical composition of essential oils from Z. clinopodioides (Lamiaceae) collected in Armenia and to test their biological activities. The essential oils were obtained by steam distillation in a Clevenger-type apparatus, a HP GC-MS setup was used to determine their chemical composition.The 34 names of different substances, generally terpenoids (monoterpenes) have been identified in the essential oil of Z. clinopodioides. The main component was pulegone ((R)-5-Methyl-2-(1-methylethylidine) cyclohexanone) which is used in flavoring agents, perfumery, and in aromatherapy. The concentration reached 42.1%. The concentrations of other components were 9.7 % (Isomenthone) and lower - 2.4 % (Menthone); 8.22 % (1,8- Cineol); 7.35 % (Piperitenone); 5.9 % (D- Neomenthol); 3.9 % (DL-Menthol); 3.56 % (Sabinene).According to the agar diffusion method the essential oil of Z. clinopodioides has also antimicrobial activity against Gram-positive, Gram-negative bacteria (including ampicillin- resistant E.coli dhpα-pUC18) and fungi. The highest antibacterial activity was established against St. aureus MDC 5233 (Microbial Depository Center, Armbiotechnology Scientific and Production Center, Armenia) (Laboratory control strain) (the minimal inhibitory concentration (MIC) was 3.125 µl/mL). The highest antifungal activity was established against Candida guillermondii WDCM with MIC value of 6.25 µl/mL.The obtained data indicate that essential oils can be useful natural agents for cosmetic applications and food dietary supplements.This study was done in the frame of Basic research support from State Committee on Science, Ministry of Education and Science of Armenia.

Essential Oils of Basil Plants as Antimicrobial Agents

Author Block:

M. PETROSYAN[1], A. Avetisyan[2], A. Markosian[2], N. Sahakyan[1], A. Babayan[1], S. Aloyan[2], A. Trchounian[1]; [1]Yerevan State Univ., Yerevan, Armenia, [2]Nairian, Yerevan, Armenia

Abstract Body:

The aim of the investigation was to study the antimicrobial activity of *Ocimum basilicum* var. *purpureum*, *O. basilicum* var. *thyrsiflora*, and *O. x citriodorum* essential oils. Antimicrobial activity was determined by the agar diffusion method. Gram-positive (*Bacillus subtilis* WT-A; *Staphylococcus aureus* MDC 5233) and Gram-negative (*E. coli* VKPM-M17; *Pseudomonas aeruginosa* GRP3 and ampicillin-resistant *E. coli* dhpα-pUC18) bacteria and yeasts (*Candida albicans* WT-174 and *Debariomyces hansenii* WT) were tested.The gas chromatography-mass spectrometry setup was used to reveal the chemical composition of essential oils. *O. basilicum* var. *purpureum* essential oil contained 57.3% of methyl-chavicol; *O. basilicum* var. *thyrsiflora* oil had 68.0% of linalool and the main constituents of *O. x citriodorum* oil were nerol (23.0%) and citral (20.7%).Gram-positive bacteria were more sensitive to all essential oils than Gram-negatives. The minimal inhibitory concentration (MIC) of *O. x citriodorum* essential oil was 3.125 mg/mL against *B. subtilis* and *St. aureus*. The same MIC was recorded for *O. basilicum* var. *thyrsiflora* essential oil against *St. aureus*, and *O. basilicum* var. *purpureum* essential oil against *B. subtilis*. The MIC of *O. basilicum* var. *thyrsiflora* essential oil against *B. subtilis* and the MIC of *O. basilicum* var. *purpureum* against *St. aureus* were 6.25 mg/mL. The resistant *E. coli* was also sensitive to the essential oils: the MIC values of *O. x citriodorum* and *O. basilicum* var. *purpureum* against that bacterium were 6.25 mg/ml, while *O. basilicum* var. *thyrsiflora* displayed MIC of 12.5 mg/mL. The action of the essential oils was bactericidal. Tested fungi were the most sensitive: MIC of *O. x citriodorum* against *D. hansenii* and *C. guillermondii* were 1.56 and 3.125 mg/mL, respectively.The obtained data show that basil essential oils can be useful natural agents for cosmetics, medicine and food as antimicrobial agents.This study was done in the frame of research support from Science State Committee, Ministry of Education and Science of Armenia.

Antimicrobial Mechanisms of Benzyl Alcohol and Pentanol on *Methylobacterium* Isolated from Bathrooms

Author Block:

T. Yano[1], Y. Miyahara[1], N. Morii[2], T. Okano[2], H. Kubota[1]; [1]Safety Sci. Res., Ichikai, Tochigi, Japan, [2]Household Products Res., Wakayama, Japan

Abstract Body:

The genus *Methylobacterium* tolerates various stresses including desiccation and hygiene agents such as benzalkonium chloride (BAC), and its infection is an important public health issue. We previously demonstrated that some *Methylobacterium* strains survived in 5.0% BAC after a 5-min exposure, indicating that cleaners with more immediacy and versatility are required. Fluorescence *in situ* hybridization assays of 14 pink biofilms in Japanese bathrooms have indicated that the genus *Methylobacterium* is predominant. Therefore, we searched for effective antimicrobial agents available for use in bathrooms. We isolated *Methylobacterium* strains from bathrooms, and screened agents with high antimicrobial potencies. While screening various alcohols, we found that the combined use of BAC with particular alcohols at non-lethal concentrations in terms of their solitary uses significantly reduced bacterial viability after only a 5-min exposure. These effects were also verified in biofilms on fiber-reinforced plastics, a general material of bath tubs, floors, and walls. Among the alcohols tested, Raman spectroscopic analyses showed that pentanol (PeA) and benzyl alcohol (BzA) accelerated the cellular accumulation of BAC. *In vivo* fluorescent spectroscopic assays and *in vitro* morphological assays with giant vesicles (GV) indicated that PeA rarely attacked membrane structures, while BzA increased membrane fluidity and destabilized structures. Other *in vivo* fluorescent spectroscopic assays indicated that PeA and BzA inactivated bacterial membrane proteins, including the efflux pump for BAC transportation. These results suggest that the inactivation of membrane proteins by PeA and BzA led to cellular accumulation, whereas BzA only also enhanced the penetration of BAC by membrane fluidization at non-lethal concentrations. These mechanisms may be exploited to develop a new theory that facilitates the search for the best compounds for combined use.

Transfer of Antibiotic Resistance between Bacteria within Quagga Mussels

Author Block:

A. D. KAPPELL, M. J. Walsh, K. Paavola, T. Metcalf, J. S. Maki, K. R. Hristova; Marquette Univ., Milwaukee, WI

Abstract Body:

The filter-feeding quagga mussel (*Dreissena bugensis*) has been invading the Great Lakes since the 1990's. Biological and chemical contaminants can accumulate in the tissues of filter-feeding organisms allowing the use of quagga mussels as indicators of freshwater quality and antibiotic resistant bacteria. In addition to the use of quagga mussels as indicator or sentinel organisms, the possibility of mussels as point sources and "hot spots" for the proliferation of antibiotic resistance and exchange was explored. The ability of quagga mussels to accumulate bacteria and allow exchange of antibiotic resistance in their tissue in a controlled setting was determined utilizing a selectable and differential *Escherichia coli* strain. Quagga mussels were placed in artificial lake water (ALW) containing *E. coli* CV601gfp, a strain bearing selection of kanamycin and rifampicin with constitutive expression of GFP. Mussel tissue and water were plated to quantify the presence of GFP expressing *E. coli* during exposure and post-exposure depuration. The tissue and water were also plated on media with the additional antibiotic of ampicillin, tetracycline, streptomycin, chloramphenicol, and gentamycin. Preliminary results indicate a correlation of bacteria in mussel tissue with water. The *E. coli* strain appeared to establish itself within the tissue of the mussel during depuration. After the 48 hr initial exposure and 3 hours of depuration in fresh ALW showed the remaining population of *E. coli* CV601gfp within the mussel tissue had acquired resistances to the 5 antibiotics in 4% to 18% of isolates of the 171±54 CFU/g mussel tissue. Plasmid extraction and agarose gel electrophoresis indicated the acquisition of plasmids in a number of the isolates. Additional exposure experiments in the lab and urban water ways of Milwaukee indicated a correlation between the presence of fecal indicator bacteria in mussel tissue and the waterways determined by qPCR. While these results indicate that quagga mussels could be used as an indicator for biological contamination, quagga mussels may also represent a point source of bacterial contamination and antibiotic resistance of waterways.

Targeted Amplification of Antibiotics Resistant Genes Associated with the International Space Station Environment

Author Block:

A. Checinska[1], K. G. Frey[2], C. L. Redden[2], J. Thissen[2], J. E. Allen[3], C. Jaing[3], K. Wheeler[4], **K. Venkateswaran**[1]; [1]Jet Propulsion Lab., California Institue of Technology, Pasadena, CA, [2]Naval Med. Res. Ctr.-Frederick, Fort Detrick, MD, [3]Lawrence Livermore Natl. Lab., Livermore, CA, [4]Allosource, Centennial, CO

Abstract Body:

The International Space Station (ISS) is a closed environment which is shaped by microgravity, radiation, and limited human presence. The microbial diversity associated with the ISS environmental surfaces utilizing cultivation-dependent and –independent approaches was already documented. In this report, targeted amplification technique, a novel method, was used to measure the microbial lineages that are resistant to known antibiotics.Bacterial strains isolated from ISS surfaces were tested for their resistance to nine antibiotics using conventional disc method and Vitek 2 system. Most of the *Staphylococcus aureus* strains were resistant to penicillin. Five strains were specifically resistant to erythromycin and the *ermA* gene was also detected. The nine-erythromycin sensitive *S. aureus* strains exhibited spontaneous mutation when rifampin was tested. Some of the *S. aureus* strains tolerated gentamycin and tobramycin but cefazolin, cefoxitin, ciprofloxacin and oxacillin inhibited the growth of the *S. aureus*. Whole genome sequencing (WGS) of 21 ISS strains, exhibiting resistance to various antibiotics, was carried out. The antibiotic resistant genes deduced from the WGS were compared with the resistomes generated directly from the gene pool of the environmental samples.Using a targeted amplification panel consisting of over 500 antimicrobial resistance genes, we were able to confirm the results of the phenotypic assays. Specifically, the presence of multiple β-lactamase genes was observed. The class A gene, *tem-1,* was present in multiple ISS locations from both flights. A second class A gene, *ctx-M-14,* was also found in multiple sites of ISS. In addition, presence of *mec-A* gene was confirmed in several sampling locations from both ISS flights. Finally, the existence of the *ermA* gene was established. These results suggest widespread and consistent distribution of multiple antibiotic resistance genes throughout the ISS. The resistome data generated via molecular methods will be extremely crucial in determining the microbial significance to the crew health and the ISS maintenance.

Bisthiazolidine (Btz) Inhibitors of Ndm-1: The Importance of the Thiol Substituent

Author Block:

A. J. Vila[1], M. M. Gonzalez[1], A. Rossi[1], L. I. Llarrull[1], V. Castillo[2], G. Mahler[2], M. F. Mojica[3], R. Bonomo[3], J. Spencer[4], L. Castellano[2], V. Villamil[2], C. Saiz[2]; [1]IBR - Univ. of Rosario, Rosario, Argentina, [2]Univ. of the Republic, Montevideo, Uruguay, [3]Cleveland VAMC, Cleveland, OH, [4]Univ. of Bristol, Bristol, United Kingdom

Abstract Body:

Background: Carbapenems are recognized as "last-resort" β-lactam drugs. However, the appearance of highly resistant bacteria producing metallo-β-lactamases (MBLs), such NDM-1 (New Delhi Metallo-β-lactamase-1), challenge the therapeutic primacy of carbapenems in the clinical setting. NDM-1 and other B1 MBLs are able to hydrolyze almost all β-lactam classes and are not inhibited by available serine-β-lactamase inhibitors. Clinically useful MBL inhibitors have not yet been introduced into the clinic. Recently, the synthesis and biological characterization of the first series of BTZ heterocycles against the MBLs from B1 subclass (NDM-1, VIM-2 and VIM-24) was reported. From the crystal structures between the MBLs with BTZs, we found that the thiol moiety present in the BTZ scaffold is intercalated between both Zn(II) ions and forms a stable ternary complex. Our goal is to explore the importance of the thiol interaction with NDM-1 in a novel series of derivatives. **Methods:** BTZ derivatives were synthesized wherein the thiol group was replaced with fluoroalkyl, carboxylate, sulfonic acid, tetrazole groups or methylated as a thiomethyl derivative. MBLs were purified to homogeneity. Inhibition constants were determined by following imipenem hydrolysis at 300 nm absorbance The inhibition constants were determined by data fitting to the Competitive Inhibition Model.**Results:** The inhibition assays against NDM-1 revealed that in all cases the substitution of the thiol moiety is essential for the inhibitory activity, highlighting the importance of thiol groups as the main driving force for the inhibition observed in MBLs. Instead, insertion of substituents in the bridging position did not affect the inhibition constants in the low micromolar range observed for the first series of BTZs.**Conclusions:** We report the essential nature of thiol groups in BTZs for MBL. These compounds represent a versatile and promising scaffold for the investigation and development of molecules with a diverse set of moieties capable of inhibiting MBLs.

Effect of Engineered Nanoparticles on the Operation of Wastewater Treatment Plant

Author Block:

S. Eduok, B. Martin, R. Villa, B. Jefferson, F. Coulon; Cranfield Univ., Bedfordshire, United Kingdom

Abstract Body:

The effect of mixed engineered nanoparticles (ENPs) consisting of silver oxide, (20 nm), titanium dioxide, (30 - 40 nm) and zinc oxide, (20 nm) compared with bulk metal salts and unspiked control was evaluated using 3 parallel pilot-scale wastewater treatment plants. ENPs induced 2 times higher specific oxygen uptake rate relative to the control and the heterotrophic biomass retained 98% and 80% removal rate for ammonia and COD respectively. Ammonia- and nitrite oxidizing bacteria e.g. *Nitrosomonas, Nitrobacter* and *Nitrospira* in ENP spiked sludge were inhibited with 1.4 times reduced floc size, whereas the sludge volume index was unaffected. SEM evidenced selective damage to some microbes and pyrosequencing indicated a temporal shift in microbial community structure and diversity with *Acidovorax*, *Rhodoferax, Comamonas*, *Methanocorpusculum* and *Methanosarcina* identified as nano-tolerant species in the activated sludge. Based on ether-linked isoprenoid concentration, abundance of methanogens was 1.4 times lower in ENP spiked digester, whereas pyrosequencing indicated 80% decrease in abundance and diversity of methanogens compared to the control and metal salt spiked digester. *Methanosarcina acetivorans* and *M. barkeri* were nano-tolerant with a factor of 6 and 11 times increase in relative abundance respectively. ENPs exerted 1.2 times lower hydrogen sulfide and 2.4 times higher methane production than the control and metal salt spiked digester. Exposure of wastewater microorganisms to ENPs conferred competitive advantage that enhanced growth of *Fusobacteria, Actinobacteria, Acidovorax, Rhodoferax, Comamonas M. acetivorans* and *M. barkeri* with a Trojan horse-like effect on microbial abundance and diversity.Keywords: Engineered nanoparticles, activated sludge, anaerobic digester, inhibitory effect, nanotolerant Archaea

A Chimeric Protease Inhibitor Secreted By *escherichia Coli* With The Potential For Use In Biofuel Fermentations And Therapeutic Bacterial Delivery Vectors

Author Block:

D. Quintero, D. Bermudes; California State Univ., Northridge, Northridge, CA

Abstract Body:

Naturally occurring sunflower trypsin inhibitor (SFTI) is a 14 amino acid bicyclic peptide that contains an internal disulfide bond and is cyclized by covalently binding the N-terminal and C-terminal amino acids. SFTI is a member of the Bowman-Birk family of protease inhibitors that can inhibit both trypsin and chymotrypsin. SFTI is also capable of inhibiting the tumor protease matriptase, which is expressed in a number of tumor cells and contributes to tumor cell metastasis. Although the N- to C-terminal cyclization of SFTI contributes to it's stability, SFTI lacking this covalent linkage is known to be functional. We constructed chimeric forms of SFTI with N-terminal secretion signals from the *Escherichia coli* OmpA and the *Pseudomonas aeruginosa* ToxA as well as a fusion with the C-terminus of *E. coli* YebF. Using a culture-based protease inhibitor assay, we detected small amounts of protease inhibition in the OmpA and ToxA signal sequence fusions. Co-expression of these N-terminal fusion with the ColE3 lysis protein increased the amount of protease inhibition only for the OmpA fusion. A substantially higher degree of protease inhibition was detected from the YebF fusion, which radiated more than a centimeter from a single bacterial colony. In order to assess the potential of the secreted form of SFTI to protect the ability of a cytotoxic protein to kill tumor cells, we performed a trypsin challenge on the *Pseudomonas* ToxA and its ability to kill MDA-MD-468 breast cancer cells. ToxA was able to kill greater than 90% of tumor cells based on the tetrazolium salt (MTT) reduction cytotoxicity assay, but lost substantial activity when treated with trypsin. Trypsin-challenged ToxA cytotoxicity was restored when culture supernatant of YebF:SFTI was included in the challenge. These data suggest that tumor-targeting bacterial vectors such as VNP20009 might be useful for delivering protease inhibitors with antitumor effects. Furthermore, secretion of protease inhibitors might be useful in other applications such as biofuel fermentations that may have the efficiency of exoenzymes diminished by the presence of proteases.

Publishing Title:

Linking Biosynthetic Clusters with Secondary Metabolites across Phylogenetically Diverse Soil Isolates

Author Block:

L. P. Silva[1], M. Hadjithomas[1], N. Ivanova[1], R. Lau[1], U. Karaoz[2], E. Brodie[2], N. Kyrpides[1], B. P. Bowen[1], T. Northen[1]; [1]Joint Genome Inst., Walnut Creek, CA, [2]Lawrence Berkeley Natl. Lab, Berkeley, CA

Abstract Body:

Actinobacteria are widely known for their ability to secrete bioactive secondary metabolites into their surroundings, and many of these natural products have proven critical in a diversity of applications from agriculture to human health. Given their widespread application, there is great interest in discovering new secondary metabolites as well as improving methods for predicting natural products from annotated genomes. The recent development of new HILIC stationary phases now enable characterization of polar metabolites, which are less explored than commonly detected non-polar molecules. We selected 40 phylogenetically diverse isolates (Actinobacteria and Proteobacteria) for both prediction of biosynthetic clusters and testing secondary metabolite production using LC-MS/MS. These isolates were chosen from a set of 699 isolates with known full-length 16s rRNA sequences, collected from two field sites (Hopland, CA and Moab, UT). Isolates were cultured in 1/10 R2A media in quadruplicate, and then extracted with methanol for LC-MS/MS analysis. Samples were analyzed using both pHILIC and C18 chromatographies. Mass spectrometry was performed using a QExactive mass spectrometer, in positive and negative ionization mode. Data were analyzed using Metabolite Atlas and Pactolus software. DNA was extracted from each isolate and genomes sequenced on an Illumina HiSeq 2500 platform. Genomes were assembled with SPADES, and antiSMASH was used to identify biosynthetic clusters (BCs). BCs were searched with IMG-ABC and correlated to secondary metabolites for each isolate. Approximately 500 compounds were putatively identified from each isolate using Pactolus software. The MS/MS spectra of compounds with significant differences (consumption or production) from the control media were manually validated and compared to the predicted BCs. In many cases, the metabolites identified by Pactolus were supported by the predicted BCs for each genome in IMG-ABC. However, there are numerous examples of identified metabolites without predicted BCs, and the combination of these two approaches is promising for the improvement of secondary metabolite prediction algorithms.

Assessment of Natural Compounds Against Micro-biota Isolated from Peptic Ulcer

Author Block:

A. Rehman[1], A. N. Sabri[1], S. Hasnain[2]; [1]Univ. of the Punjab, Lahore, Pakistan, [2]Women Univ. Multan, Multan, Pakistan

Abstract Body:

Background: *Helicobacter pylori* is a close relative of *Campylobacter* spp., characterized as a gram-negative, flagellated bacterium. This pathogen is capable to colonize peptic mucosa and causes peptic ulcer in human population. The elimination of *H. pylori* infection needs a long therapeutic course having multiple antibiotics administered for 7-14 days.The day by day increase in antibiotic resistance emphasizes on the establishment of novel therapeutics against *H. pylori*. The current study was designed to encompass major issues associated with H. pylori infection including detection of antimicrobial susceptibility, EPS (exo-poly-saccharide) production and formation of complex bacterial biofilms among H. pylori and associated micro-biota in gastric ulcer. In order to address issue of novel therapeutics, phytochemical based compounds were employed to eliminate pathogen in-vitro. **Methods:** Normal saline was used to crush and homogenize peptic biopsy samples which were later spread on Columbia blood agar. In microbiological medium, serum to support growth and selective antibiotics were added. All selected isolates were identified by biochemical identification scheme. The inhibitory effect of Honey and ethanolic/methanolic extracts of Black Caraway (*Nigella sativa* seeds) on isolated pathogens was observed by microtiter plate assay. The biofilm formation capacity of isolates was determined by standard motility, EPS production and adherence detection methods. **Results:** Overall 15 different microbes were isolated from 5 peptic biopsies among which one isolate was confirmed as *Helicobacter pylori*. Both honey and Black Caraway (*Nigella sativa)* were observed to have significant inhibitory effect on all isolates at potentially lower concentrations such as 2mg/ml and 1mg/ml respectively. Among all extracts the methanolic extracts of Black caraway (*Nigella sativa)* had observable significant impact on the adherence, EPS production and biofilm development. A variety of structures were found to block urease enzyme in computational studies.**Conclusions:** Natural compounds have huge potential to provide mankind with novel therapies against pathogens. Further investigation of curative potential of natural compounds and phytochemicals can lead to establishment of novel therapeutics against peptic ulcer.

Fitness Center Equipment Made with Copper-Alloys Hold Decreased Bacterial Loads Compared to Control Surfaces

Author Block:

Z. Ibrahim, P. Hooke, S. Hinsa-Leasure; Grinnell Coll., Grinnell, IA

Abstract Body:

With a rise in antibiotic resistance and an increase in community-acquired infections, it is important to find ways to decrease human exposure to pathogenic microorganisms. Athletic centers in particular, contain many high-touch surfaces and have been shown to house pathogenic bacteria including MRSA. One way to decrease exposure to pathogens in this environment is to employ antimicrobial surfaces. In 2008, the Environmental Protection Agency registered 300 different copper-alloys as antimicrobial materials. The aim of our study was to investigate the antimicrobial effects of copper-alloys on high-touch athletic center equipment including grips on barbells, kettle bells, dumbbells, and grip attachments for weight machines. We hypothesized there would be decreased bacterial loads on the 16 copper-alloy surfaces tested compared to the bacterial loads found on standard equipment. Samples were collected from the athletic center equipment at Grinnell College, by swabbing surfaces with a sterile pre-moistened wipe. Copper-alloy equipment was switched in and out of the facility on a regular basis throughout the study to decrease differences due to season or student usage. Bacteria were removed from the swabs through vortexing and plated on trypticase soy agar with 5% Sheep blood (TSAII). We found a statistically significant decrease in bacterial loads on all copper-alloy surfaces ($P<0.05$) compared to loads on standard equipment with an overall average decrease in bacterial load of just over 90%. The results support our hypothesis and previous studies conducted in hospital settings that have demonstrated the antimicrobial properties of copper-alloys. We propose the use of copper-alloy material in strategic locations will lead to a decrease in community-acquired infections from that environment. On-going and future studies aim to identity the most common bacteria, determine their antibiotic resistance profiles, and investigate possible halo effects from the copper-alloy surfaces.

Characterization of Ctx-M-151, a Novel Extended-Spectrum β-Lactamase from *Enterobacteriacae*

Author Block:

A. Yoshizumi[1], T. Saga[2], K. Aoki[1], A. Ohno[1], Y. Ishii[1], K. Tateda[1]; [1]Toho Univ., Ohta-ku, Tokyo 143-8540, Japan, [2]Akita Univ. Graduate Sch. of Med. and Faculty of Med., Akita city, Akita, Japan

Abstract Body:

Background: CTX-M extended-spectrum beta-lactamases (ESBLs) are a major cause of β-lactam resistance among Gram-negative bacteria worldwide. In our previous study, we identified the novel CTX-M gene, *bla* $_{\text{CTX-M-151}}$ on the chromosome of an unknown species belonging to *Enterobacteriaceae* isolated from piglet feces. CTX-M151 showed 68.3% sequence similarity to CTX-M-14 belonging to CTX-M group 9. In this study, we characterized the kinetic properties of CTX-M-151.**Methods:** The entire *bla* $_{\text{CTX-M-151}}$ was PCR-amplified from the total DNA extracted from the isolate. The PCR product was subcloned into a pET 9a+ expression vector and overexpressed in *Escherichia coli* BL21 (DE3)/pLysS using 1mM IPTG. CTX-M-151 was purified by cation exchange chromatography, HiTrap SP FF column. The kinetic properties of the purified CTX-M-151 were calculated for cefotaxime, ceftazidime (CAZ), cefepime, piperacillin and nitrocefin by measuring the initial hydrolysis rates using a UV2550 spectrophotometer. K_i value for clavulanic acid.(CVA) was determined using nitrocefin as the competitor substrate.**Results:** CTX-M-151 hydrolyzed all tested β-lactams except for CAZ. CTX-M-151 had K_i value for CAZ of 5784μM. Compared to CTX-M-9, CTX-M-151 showed similar hydrolytic efficiencies (k_{cat}/K_m) for nitrocefin ; 3.0 x 10^7 $M^{-1}s^{-1}$ vs. 1.8 x 10^7 $M^{-1}s^{-1}$ for CTX-M-9. The k_{cat} of CAZ for CTX-M-151 and CTX-M-9 could not be determined when 20000 μM of CAZ was used while scanning for 15 min. Using nitrocefin as a substrate demonstrated that CVA was competitive inhibitors of CTX-M-151 and CTX-M-9 with K_i values for CVA of 0.78 μM and 0.17 μM ± 10%, respectively.**Conclusions:** CTX-M-151 hydrolyzed all tested β-lactams except for CAZ. The combination of amino acid substitutions observed in CTX-M-151 result in a similar catalytic efficiency when compared to CTX-M-9for nitrocefin, cefalotin. The K_i values of CVA for CTX-M-151 was about 5 times higher than those observed for CTX-M-9.

Melipona Beecheii Honey and Its Compounds Against Virulence Factors of *Helicobacter pylori*

Author Block:

M. Lara Torres, G. Varguez Cruz, J. Ramón Sierra, E. Ortiz Vázquez, D. Magaña Ortiz, J. Ruiz Ruiz; Inst. Tecnológico de Mérida, Mérida, Mexico

Abstract Body:

Background: Helicobacter pylori is the dominant species of the human gastric microbiome, the colonization of this bacteria causes a persistent inflammatory response & plays an important carcinogenic role. Usually H. pylori infections are treated with a triple therapy, including antibiotics & proton pump inhibitors. In most cases, this treatment could fail for H. pylori eradication and cause resistance to the antibiotics employed. Research related to natural products has demonstrated significant progress in the discovery of new compounds with antimicrobial activity. In this sense, oral administration of honey to treat & protect against gastrointestinal disorders such as gastritis, duodenitis & gastric ulceration caused by bacteria & rotavirus has been reported. The goal of this study was to evaluate the effect of honey produced by Melipona beecheii on expression of virulence genes of Helicobacter pylori.**Methods:** Methods: The strain of H. pylori (ATCC 49503) was grown under microaerophilic conditions (5% O2, 10% CO2, and 85% N2) at 37 °C for 3 days. The antimicrobial activity & minimum inhibitory concentration (MIC) were determined by agar diffusion method in Brucella agar supplemented with 10% fetal bovine serum. Chromosomal DNA extraction was realized using CTAB method. The detection of presence the housekeeping & virulence genes was performed using PCR standard protocols with specific primers.**Results:** The MIC of honey against Helicobacter pylori was 10% (v/v). Chromosomal DNA extraction allowed the detection of housekeeping (hsp60 and sigma80) & virulence (vacA & ureA) genes.**Conclusions:** Honey from M. beecheii inhibits the growth of H. pylori at concentrations of 10% (v/v). The presence of phenolic compounds & proteins in honey it could be responsible of the antimicrobial effect against H. pylori; then they could be related to repression virulence of genes in the microorganism. In future studies, both components will be isolated & evaluated to test its antibacterial effect on H. pylori.

Prevalence of Antibiotic Resistant *E. coli* in Drinking Water Sources in Tamale Metropolis of Ghana

Author Block:

F. Adzitey, C. K. S. Saba; Univ. for Dev. Studies, Tamale, Ghana

Abstract Body:

Background: The use of antibiotics for therapeutic purpose is unavoidable despite concerns about multidrug resistance pathogens. The presence of antibiotic resistant *E. coli* in drinking water is a threat to public health. This study determined the prevalence of resistant *E. coli* in in drinking water samples collected from Tamale Metropolis of Ghana. **Methods**: Antibiotic susceptibility test was performed using the disc diffusion method and the results interpreted using the Clinical and Laboratory Standards Institute guidelines. Fifty six (56) *E. coli* were tested against 9 different antibiotics. **Results**: Overall, 37.90% of the *E. coli* isolates were resistant, 12.90% were intermediate and 49.21% were susceptible. Resistance to vancomycin (94.64%) and erythromycin (85.71%) was high. A relatively higher percentage of the *E. coli* isolates exhibited intermediate resistance to amoxycillin/clavulanic acid (50%). The *E. coli* isolates also exhibited 24 antibiotic resistant patterns with the pattern E-VA (erythromycin-vancomycin) and SXT-E-VA-TE (trimethoprim/sulfamethoxazole-erythromycin-vancomycin-tetracycline) being the commonest (each exhibited by nine different isolates). Multiple antibiotic index (MAR index) ranged from 0.11 to 0.56. Resistance to five (MAR index of 0.56) and four (MAR index of 0.44) different antibiotics were exhibited by 8 and 21 isolates, respectively. **Conclusions**: This study revealed that *E. coli* from drinking water sources in Tamale, Metropolis are resistant to some antibiotics. Therefore, the use of antibiotics in animal production and for human treatments in the Metropolis need to be checked and curbed to prevent more isolates from becoming resistant.

Evaluation of Bacteriological Quality of Street Vended Guinea Fowl Meat Sold in Nkalagu Motor Park, Ishielu Local Government Area of Ebonyi State, Nigeria

Author Block:

W. I. Egwurochi, D. 0. Uchendu, V. U. Olugbue, B. C. Anyaegbunam, E. I. Okonkwo; Akanu Ibiam Federal Polytechnic, Unwna-Afikpo, Ebonyi State, Nigeria

Abstract Body:

Many studies have been done on street vended meats such as bush meat but little has been done of the guinea fowl meat. This study evaluated the bacteriological quality of Street Vended Guinea fowl Meat sold in Nkalagu Motor Park in Ishielu Local Government Area of Ebonyi State, Nigeria. Guinea fowl meat samples were randomly purchased from three different hawkers at the motor park, labeled accordingly and taken to the Microbiology Laboratory of the Department of Science Laboratory Technology, Akanu Ibiam Federal Polytechnic for bacteriological analysis. Each sample was pounded in a sterile porcelain mortar. 1g of the pounded meat was homogenized in 9ml of distilled water until a serial dilution of 10^{-6} was obtained. Dilutions 10^{-6} was spread plated on MacConkey and nutrient agar plates, incubated at 37°C for 24 hours. Colony forming units were counted to determine the microbial load. Based on the colonial, morphological and biochemical characteristics, nine genera of isolates - *Staphylococcus* sp., *Salmonella* sp., *Escherichia coli*, *Bacillus* sp., *Pseudomonas* sp., *Enterobacter aerogenes*, *Streptococcus* sp., *Salmonella* sp., *Proteus* sp., were identified. From the results, there is need for observance of good personal hygiene by the sellers, potable water should be provided to avoid the use of contaminated water in the processing of these product, buyers should be prevented from touching the meats during bargain; there is need for proper covering of the products as it is being carried around in the motor park.**Results**

Microbial Evaluation and Identification of Aflatoxin Producing Fungi in Dried Stored Maize Samples Sold in Open Markets in Benin City, Nigeria

Author Block:

S. E. OMONIGHO, S. V. Obatusin; Univ. of Benin, Benin City, Benin City, Nigeria

Abstract Body:

Maize (*Zea mays*) is an annual monoecious crop and the most important cereal in the world after wheat and rice with regard to cultivation areas and total production. Despite the various improvements in the drying and storage of maize, the growth of moulds is usually a common occurrence in stored grains. The grain is vulnerable to biodeterioration by mycotoxigenic fungi which include *Aspergillus*, *Fusarium* and *Penicillium*. In this study, the microbial load of dried stored maize samples from three different open markets in Benin City was evaluated, and the aflatoxin-producing *Aspergillus* species identified. The pH and moisture contents of samples were also determined. Four fungal species; *Rhizopus* sp., *Fusarium* sp., *Aspergillus flavus*, and *Penicillium sp*., as well as three bacterial species; *Staphylococcus aureus*, *Bacillus* sp. and *Pseudomonas* sp. were isolated and identified using standard cultural and morphological techniques. The mean total bacterial count (cfu/g) ranged from $3.80 \pm 0.20 \times 10^3$ (Oba market) to $5.20 \pm 0.20 \times 10^3$ (New Benin market), while the mean total fungal count ranged from $3.70 \pm 0.29 \times 10^4$ (Oba market) to $6.47 \pm 0.38 \times 10^4$ (New Benin market). The mean pH ranged from 5.90 (Oba market) to 6.70 (New Benin market) while the mean moisture content ranged from 16.10 % (Oba market) to 18.20 % (New Benin market). *Aspergillus niger* was identified as the potential aflatoxin-producing specie, and it had 100.00 % occurrence in all samples. The study showed that stored maize samples had higher fungal load than bacteria, and were contaminated with *Aspergillus flavus*; a potential aflatoxin-producing fungus. It is then necessary to observe strict pre- and post-harvest practices in order to reduce microbial contamination of stored grains.

Mechanism for the Antibacterial Action of Theaflavin 3,3'-Di-O-Gallate on *Bacillus* Coagulans

Author Block:

J. Sato[1], A. Horiuchi[1], M. Nakayama[2], T. Sonoda[1], M. Hasumi[1], T. Miyamoto[3]; [1]Kao Corp., Ichikai, Haga, Japan, [2]Kao Corp., Sumida-ku, Tokyo, Japan, [3]Kyushu Univ., Fukuoka, Japan

Abstract Body:

Background: Tea polyphenols, such as catechins and teaflavins, have high antibacterial activity against various microorganisms including spore-forming bacteria. *Bacillus coagulans* is one of the most important targets of sterilization in beverage manufacturing, especially for tea drink, because of the high heat-resistance of the spores and high resistance against antibacterial action of catechin in vegetative cells of some strains of the bacterium. However, the antibacterial mechanism of tea polyphenols against B. coagulans has not been fully elucidated. To study the mechanism for antibacterial action of tea polyphenols, we investigated the interaction of theaflavin 3,3'-di-O-gallate (TFDG) to cell surface of *B. coagulans*. **Methods:** To examine the antibacterial effect against *B. coagulans*, minimum bactericidal concentration (MBC) of TFDG was determined in phosphate buffer for each time (1, 4, and 24 h). Changes in cell membrane fluidity were measured by using fluorescent reagent, Laurdan after the treatment of the cells with and without TFDG. Effects of TFDG on transporter of *B. coagulans* were investigated by measuring the uptake of 2-deoxyglucose. To examine the interaction between cell surface proteins and TFDG, two-dimensional electrophoresis patterns of the cellular proteins were compared between the cells treated with and without TFDG.**Results:** Viable count of *B. coagulans* decreased after the treatment with TFDG at 125 mg/L for 1h. Cell membrane fluidity and the activity of glucose transporter decreased after the treatment with TFDG. The 2D-PAGE patterns of cellular proteins of *B. coagulans* showed that some spots disappeared or showed markedly decreased intensity after the treatment with TFDG. Four cell surface proteins were identified among these proteins.**Conclusions:** TFDG showed bactericidal effect on *B. coagulans* at 125 mg/L. After the treatment with TFDG, membrane fluidity and the activity of glucose transporter of the cells decreased. Together with the changes in the 2D-PAGE pattern of the cellular proteins by the treatment with TFDG, it seems that TFDG interacts with the cytoplasmic membrane and the membrane proteins and affects their functions leading to death.

Natural Plant Products Inhibits Growth and Alters Expression of Virulence Genes in Enteroaggregative and Enterohemorrhagic *Escherichia coli*

Author Block:

A. García[1], S. Garcia[1], J. Merino[1], P. Feng[2], N. L. Heredia[1]; [1]Univ. de Nuevo León, San Nicolás, N.L., Mexico, [2]Food and Drug Admin., College Park, MD

Abstract Body:

Background: Most Escherichia coli strains are innocuous to human beings; however, some can cause diseases. Physical, chemical and therapeutic treatments have effectively controlled pathogens to some extent either in foods or human and animal infections; however, current trends also involve the use of natural antimicrobials. Although the ability of pathogenic *E. coli* to cause infections is enhanced by mechanisms that allows for colonization and persistence in different environments. little is known about the effect of natural antimicrobials on the expression of genes involved in virulence of *E. coli.* **Methods:** In this study, the effect of extracts from Mexican oregano (*Lippia berlandieri*) and Mexican logwood (*Haematoxylon brassiletto,* Hb) and their principal antimicrobial components, carvacrol and brazilin, respectively was evaluated on the growth and expression of virulence genes in enterohemorrhagic *E. coli* (EHEC) O157:H7, enteroaggregative *E. coli* (EAEC) strain 042 and Shiga toxin producing EAEC strain of O104:H4 serotype. Citral and rifaximin were used as positive controls. Minimum bactericidal concentrations (MBC) were determined in microtiter plates using various concentrations of extracts. When appropriate, the expression of *rpoS* and the virulence genes *stx2, aggR, pic,* was determined.**Results:** All of the compounds affected the survival of all three strains. The MBC ranged from 0.07 to 0.09 mg/ml for rifaximin; 0.08 to 0.1 mg/ml for carvacrol; 0.12 to 0.2 mg/ml for citral; 0.3 to 0.4 mg/ml for oregano 2.2 to 2.3 mg/ml for brazilin, and 7.2 to 8.1 mg/ml for Hb. Most compounds decreased expression of the *stx2* gene in both *E. coli* O157:H7 and *E. coli* O104:H4. The expression levels of *Pic* and *rpoS* in *E. coli* O104:H4 varied depending on compound; however, in *E. coli* 042 all compounds suppressed both genes.**Conclusions:** These antimicrobials show great potential to control pathogenic *E. coli* by affecting growth and virulence gene expression.

The Effects of Vietnamese Star Anise Fruits Essential Oil Vapour on Growth Rate of Fungi *In Vitro* and *In Vivo*

Author Block:

T. Dao[1], H. Tran[2], M. Eeckhout[3], F. Devlieghere[4]; [1]Ho Chi Minh city Univ. of Food Industry, Ho Chi Minh City, Viet Nam, [2]Cai Lan Oils & Fats Industries Company, Ho Chi Minh City, Viet Nam, [3]Lab. for Applied Mycology, Univ. Ghent, Gent City, Belgium, [4]Lab. of Food Microbiol. and Food Preservation, Univ. Ghent, Gent City, Belgium

Abstract Body:

Background: Moulds growth rapidly and can cause serious damage at post-harvest storage of agricultural products. In addition, the products can be contaminated by mycotoxins including aflatoxins, ochratoxins, and fumonisins. Therefore, it is necessary to control mould contamination of post-harvested products. One of the solutions that would be effective is the use of essential oil as natural preservative.**Methods:** In this study, the composition of Star Anise fruit (*Illicium verum* Hook.f) essential oil was identified. The main compound of *Illicium verum* Hook.f is (E)-anethole (89%). This essential oil has been considered as a gaseous biological control agent able to inhibit the growth of three strains *Aspergillus flavus*, *Penicillium digitatum* and *Penicillium italicum in vitro* and *in vivo*. The inhibition effect *in vitro* was tested in potato dextrose agar medium (PDA), *in vivo* effects were examined in Sweet orange (*Citrus sinensis*). Inhibition capacity has been evaluated through the effect on the mycelium growth**Results:** showed that at 25^0C, 0,99 a_w, 120 µl.ml^{-1} concentration of essential oil, the growth of three strains have completely inhibited development. Significant inhibition of these three strains was also observed *in vivo* although the antifungal activity of *Illicium verum* Hook.f. vaporized essential oil showed less efficacy in Sweet orange.**Conclusion:** The essential oil of Star Anise fruits is able to control the growth of three studied strains. Essential oil-based fungicides can be effectively used for bio-preservation of agricultural products.

The Anti-Noroviral Property of Curcumin in *In Vitro* and *In Vivo* Models

Author Block:

G-j. Lee[1], H. You[1], M. Yang[1], S-J. Lee[2], G. Ko[1]; [1]Seoul Natl. Univ., Seoul, Korea, Republic of, [2]Korea Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Human norovirus (HuNoV) is recognized as the leading cause of foodborne outbreak and is responsible for more than 90% of all nonbacterial gastroenteritis. Conventional intervention methods to reduce HuNoV contamination in foods and food preparation processes include physical (i.e. heating or radiation) or chemical methods (i.e. sodium hypochlorite and titanium dioxide), and have several disadvantages for direct application to foods such as potential toxicity and changes in food quality. Natural substances such as phytochemicals that possess antiviral effect on HuNoV have received attention as a potential substitute with low-toxicity and additional bioactive functions. Curcumin is a well-known phytochemical, derived from turmeric, with diverse biological functions such as antioxidant, anticancer, antiobesity, antibacterial, and antiviral activities. However, anti-noroviral property of curcumin has not been reported yet. In this study, we investigated the effectiveness of curcumin in *in vitro* and *in vivo* models.**Methods:** We firstly investigated the effect of curcumin on infectivity in aspects of inactivating viral particles using MNV-1 surrogate model and inhibiting viral replication using HG23 HuNoV replicon model. Curcumin was treated to MNV-1 (1.0×10^6 PFU/ml at 4°C at various concentrations (0.25, 0.5, 0.75, 1.0, 2.0 mg/ml) and time points (short-term, 10, 30, 60, 120 min; long-term, 1, 3, 7, and 14 day), and MNV survival in RAW264.7 cells was measured by plaque assay.**Results:** Curcumin showed anti-noroviral activity in a dose- and time-dependent manner. HuNoV replication assay was performed based on quantifying replicon level by qRT-PCR after curcumin treatment to HG23 Norwalk virus replicon bearing cells. Curcumin did not show the notable inhibitory effect on viral replication. In order to investigate *in vivo* anti-noroviral effect of curcumin, C57BL/6 mice were administered 10mg/mice/day of curcumin for 5 wks after persistent infection of MNV. Considering all the results from *in vitro* and *in vivo* study, curcumin showed the anti-noroviral properties in inactivating viral particles and inhibiting their entry to host cells.**Conclusions:** Curcumin could be a potential candidate for reducing norovirus infection in food processing industry.

Comparison of Microbiological Characteristics of Chill Tank Water and Carcasses Treated with Chlorine or Peroxyacetic Acid Antimicrobials Applied During Poultry Processing

Author Block:

J. Boulter-Bitzer; Ontario Ministry of Agriculture, Food and Rural Affairs, Guelph, ON, Canada

Abstract Body:

Presence of the pathogens *Campylobacter* and *Salmonella* on poultry carcasses post-processing is a serious problem due to the burden of health issues resulting from associated human illnesses. Immersion chilling represents a risk for microbiological cross-contamination of pathogens and spoilage organisms on carcasses. To mitigate this risk, chlorine- and acid-based antimicrobials are often used in chill tanks. Traditionally, chlorine has been used although efficacy is greatly decreased by high organic loads and pH levels above 7.0. Peroxyacetic acid (PAA), a combination of acetic acid and hydrogen peroxide, is approved as an antimicrobial for use in poultry chill tanks in North America. The effectiveness of PAA was compared to chlorine in poultry chill tanks (PAA was used in a commercial setting that traditionally had employed a chlorine antimicrobial treatment). In this trial, broiler carcasses and chill tank water were sampled for *Salmonella* spp., *Campylobacter* spp. and indicator organisms at various stages of processing over a number of processing days. In all, 150 carcasses were sampled at various stages of processing over seven processing days that were immersed in chilled either with 30 ppm of PAA or 30 ppm chlorine. PAA reduced the rate of *Salmonella*- and *Campylobacter*-positive carcasses exiting the chiller by 100% (P=0.0005) and 74% (P=0.0358) (45 min contact time), compared to chlorine. Aerobic colony counts (ACC), coliform and *E. coli* levels were also reduced on carcasses by 1.15-log (P<0.0001), 2.21-log (P<0.0001), and 2.62-log (P=0.0027), respectively, with PAA compared to chlorine treatment. The risk of cross-contamination during immersion chilling was also evaluated by examining chill tank water. Chill tank water maintained at 30 ppm PAA had significantly decreased occurrences of *Salmonella* (P=0.0158) and *Campylobacter* (P<0.0001) compared to 30 ppm chlorine use in the same chill tank as measured throughout processing days. *E. coli* levels were also significantly reduced in occurrence (P=0.0438) with PAA use as were coliform (P=0.0217) and ACC (P=0.0011), compared to chlorine use. These results suggest that PAA is a more effective antimicrobial in poultry chill tank applications than chlorine.

Determination of Antagonism between Nslab Strains and *Lactobacillus wasatchensis* Wdc04 Using the Agar-Flip Method

Author Block:

C. Oberg, M. Walker, M. Culumber, 84408-2506; Weber State Univ., Ogden, UT

Abstract Body:

Lactobacillus wasatchensis WDC04, a new obligatory heterofermentative nonstarter lactic acid bacteria (NSLAB), was recently isolated from "gassy" Cheddar cheese. Evidence indicates WDC04 may be an important cause of late gassy defect in aged cheese. One way to control WDC04 may be to incorporate other NSLAB strains into cheese that inhibit its growth. Experiments were performed to determine if inhibition occurs between common NSLABs and WDC04 utilizing the agar-flip method. A lawn of WDC04 was swabbed on MRS agar with 1.5% ribose (MRS-R) and incubated anaerobically at 25°C for 2 d or 4 d. Agar was then aseptically flipped over and individual NSLAB challenge cultures swabbed on the exposed surface. Plates were incubated anaerobically at 30°C or 37°C (for *Lb. helveticus*) for 5 d. Growth of NSLAB cultures was compared to their growth on MRS-R plates without a WDC04 lawn (controls). In a second experiment, the same procedure was utilized except the media contained 4% NaCl and pH 5.2 to mimic the cheese environment. In a third experiment, MRS-R (4% NaCl, pH 5.2) was also used but the NSLAB cultures were initially swabbed as the lawn, incubated, then WDC04 was streaked on the opposite side of agar. In the first and second experiments, *Lb. curvatus* WSU1 showed the greatest inhibition by WDC04 while *Lb. paracasei* Lila and *Lb. rhamnosus* 7469 were the least inhibited. All challenge NSLAB strains showed decreased levels of growth compared to their control plates. In both experiments, most NSLAB cultures showed more inhibition by WDC04 grown for 4 d compared to 2 d before the culture challenge. Results from the third experiment suggest some NSLAB strains can affect growth of WCD04 under cheese-like conditions with *Lb. casei* F19, *Lb. paracasei* Lila, and *Lb. rhamnosus* 7469 exhibiting inhibition. Since there was no direct contact between WDC04 and each NSLAB challenge strain, any inhibition was due to secretion of inhibitory compounds. Examining the antagonism between NSLABs and WDC04 allows for the selection of NSLAB strains that could inhibit this problematic bacterium during cheese ripening.

Inhibition of *Bacillus cereus* Growth and Toxin Related Genes by *Bacillus* sp. Isolated from Korean Traditional Fermented Soybean Paste

Author Block:

H. Choi, J. Eom, B. Seo, J. Kim, G. Song; Natl. Academy of Agricultural Sci., Wanju, Jeollabuk, Korea, Republic of

Abstract Body:

Background: *Bacillus subtilis* HJ18-4 is isolated from buckwheat *sokseongjang*, a traditional Korean traditional fermented soybean paste, and it have functions of producing several enzymes and extensive antibacterial spectrums against food-borne pathogens including Bacillus cereus**Methods:** In this study, we investigated the antibacterial efficacy and regulation of toxin gene(groEL, nheA, nheC, and entFM) expression in *B. cereus* by B. subtilis HJ18-4 with q-PCR and western blotting analysis.**Results:** As a result, The survival of B. cereus in the presence of 0.5% and 1% *B. subtilis* HJ18-4 decreased by approximately 6.87 and 5.65 log CFU/mL, respectively, when compared to coculture with *B. subtilis* KACC12680 and in the control (8.23 log CFU/mL) at 24 h postincubation. Transcript expression of toxin-related genes groEL, nheA, nheC, and entFM was significantly lower in *B. cereus* cocultured with *B. subtilis* HJ18-4 than in the control and coculture with *B. subtilis* KACC12680. We tested whether the *B. subtilis* HJ18-4 strain containing antibacterial activity against *B. cereus* in broth could have the same effect as antimicrobial in the fermented soybean product. Consistent with the result of Figure 1, the growth of *B. cereus* in fermented soybean product was inhibited by *B. subtilis* HJ18-4. The growth of *B. cereus* in coculture ratios of 5 : 5 and 1 : 9 *B. cereus* KACC10004 to *B. subtilis* HJ 18-4 was reduced by *B. subtilis* HJ18-4 inhibits *B. cereus* approximately 2.5- and 3-fold, respectively, in comparison to the control at 24 h.**Conclusions:** In conclusion, *B. subtilis* HJ18-4 is able to prevent pathogen growth on fermented soybean paste and we predict also that antibacterial substance from HJ18-4 can be candidate of novel natural food preservatives and alternative antibiotics.

Assessing the Effect of Gums on the Growth, Viability and ß-Galactosidase Activity of *Lactobacillus* spp. in Milk Drink During Refrigerated Storage

Author Block:

B. D. Karlton-Senaye[1], L. Williams[1], R. Tahergorabi[2], V. Giddings[2], S. Ibrahim[2]; [1]NCAT& SU, Kannapolis, NC, [2]NCAT& SU, Greensboro, NC

Abstract Body:

Recently, there has been a growing interest in the consumption of functional foods containing probiotic microorganisms. The composition of gums could support the growth of probiotics. Therefore, the aim of our study was to examine the growth, viability and ß-galactosidase activity of *Lactobacilli* in milk containing gums during 28 day refrigerated storage at 4°C. Our results showed that the addition of xanthan led to the highest growth of *L. rhamnosus* GGB101 (8.81±0.01logCFU/mL) and *L. rhamnosus* GGB103 (8.32±0.01 log CFU/mL) in milk. Carrageenan-maltodextrin promoted the highest growth (8.30±0.23log CFU/mL) of *L. reuteri* DSM 20016 in the medium and was found to support significant growth of *Lactobacillus* strains in both milk and medium. The population of *Lactobacillus rhamnosus* GGB101 and *Lactobacillus rhamnosus* GGB103 was maintained, whereas the population of *Lactobacillus reuteri* DSM20016 and *Lactobacillus reuteri* SD2112 significantly decreased during refrigerated storage. The highest viable number of *Lactobacillus rhamnosus* GGB103 (8.76±0.03 log CFU mL_1) was obtained in the product containing carrageenan-maltodextrin. The addition of guar-locust bean-carrageenan led to 20-fold increase in the level of b-galactosidase activity for *Lactobacillus rhamnosus* GGB101 (1208±2.12 Miller units mL_1) compared to the control (61±2.83 Miller units mL_1). Our results suggest that carrageenan-maltodextrin, xanthan and carrageenan could serve as functional ingredients for the enhanced growth, viability and ß-galactosidase activity of *Lactobacillus* to improve management of lactose intolerance and thereby promote human health.

Determination of Treatments to Reduce Late Gassy Defect in Cheese Due to *Lactobacillus wasatchensis* Wdc04 Contamination

Author Block:

I. Bowen, C. Oberg, M. Culumber; Weber State Univ., Ogden, UT

Abstract Body:

Lactobacillus wasatchensis WDC04 is a newly discovered obligately facultative lactic acid bacterium isolated from gassy Cheddar cheese. Previous research has associated WDC04 with late gassy defect in aged cheese, which causes serious commercial losses from bloated cheese packages and textual defects. Experiments were performed to determine its salt tolerance at pH 5.2 and 6.5, resistance to HTST pasteurization, and pH growth range. Understanding the growth characteristics of *Lb. wasatchensis* WDC04 could allow some manipulation of the cheese environment to control it. MRS with 1.5% ribose (MRS-R) was prepared at either pH 5.2 or 6.5 with salt concentrations ranging from 0.0%-10.0%. Two ml of the MRS-R test media was added to each well in a 24 micro-well plate and a pre-inoculated absorbance reading was taken at 600 nm. Immediately after, 100 microliters of WDC04 was inoculated into each well, and the plate incubated at 25^{o}C for 3 d (pH 6.5 MRS-R) or 2 d (MRS-R pH 5.2). Plates were then placed in a Teacon Infinite 2000 with absorbance readings (A_{600}) taken every 4 h for 24 h. Results showed WDC04 grew best at 3.0% salt (pH 6.5) and 2.0% salt (pH 5.2) but showed some growth up to 6% at either pH. Further testing was performed using a narrower salt range (5.25%-6.75%) at pH 6.5 to determine if a salt concentration used in cheese could suppress WDC04 growth. The same protocol was followed with the micro-well plate incubating for 3 d before absorbance readings were taken. Above 6.0% salt WDC04 was inhibited and ceased to grow. Using the same methodology, the pH range (2-8) for WDC04 was also determined. Results confirmed WDC04 grows best at pH 5-6 (cheese pH) but not below pH 4 or above pH 7. A heat shock experiment was performed to model HTST pasteurization. WDC04 was grown in MRS-R broth for 2 d and diluted, then heat shocked in a hot water bath at 72^{o}C for 15 sec and plated. With an initial count of 10^{8} CFU/ml, results showed a decrease of 10^{5} CFU/ml in survival of WDC04, indicating WDC04 could be contaminating the cheese by surviving pasteurization if it is at high levels in the milk. These results suggest using a higher salt/moisture ratio in cheese and increasing pre-pasteurization sanitation to remove biofilms would decrease the likelihood of *Lb. wasatchensis* WDC04 in ripening cheese, thus, reducing the possibility of late gassy defect.

The Effect of Different Fiber Sources on the Growth of *Lactobacillus acidophilus* and *Lactobacillus rhamnosus*

Author Block:

A. B. Santos, F. B. Santos, A. A. Santos, C. Gillen; Adventist Univ. of Hlth.Sci., Orlando, FL

Abstract Body:

Background: Probiotics and prebiotics have been recognized as important tools, which can be used to modulate intestinal health. The best known probiotics are those in the genera *Lactobacillus* and *Bifidobacterium*. The most common prebiotics are fibers, which have the potential to stimulate the growth of specific intestinal bacteria. Gaining insight on how fibers can affect the growth of probiotics is of great importance. Therefore, the present study aims to evaluate different sources of fibers for their capacity of functioning as prebiotics by enhancing *in vitro* bacterial growth. **Methods:** The supplementation of media with different fibers commonly used in fiber supplement products might stimulate bacterial growth. *Lactobacillus acidophilus* (ATCC® 4356™) and *Lactobacillus rhamnosus* (ATCC® 53103™) were used to prepare the bacterial inoculum, which was grown at 37°C for 48 hours in an atmosphere of 5% CO_2, yielding ca. 10^7 CFU/mL. *Lactobacillus* culture media, MRS (de Man, Rogosa and Sharpe) broth, was supplemented with four different fiber sources to evaluate the effect of these nutrients on bacterial growth. Fibers were mixed in the media at a concentration of 1% (Kuo, 2012). The fibers used were inulin, fructoligosaccharide (FOS), β-glucan, and psyllium (hulls). **Results:** Based on the results, the hypothesis that supplementation of culture media with different fibers stimulates bacterial growth was proven correct. For *L. acidophilus*, supplementation with psyllium resulted in the highest growth both at 24 and 48 h (7.7 log/mL, p < 0.05, and 7.8, p < 0.0001; respectively). *L. rhamnosus* behaved somewhat differently when compared to *L. acidophilus*. In the beginning and at the end of the experiment, the *L. rhamnosus* control growth was significantly lower than the supplemented bacteria. Supplementation with inulin and FOS increased growth of *L. rhamnosus* throughout the trial, even though psyllium produced the highest counts at 24 h (9.1 log/mL, p < 0.05). **Conclusions:** In conclusion, fiber supplementation influenced the two bacterial species differently. Therefore, the results show that the use of a single fiber supplement will not stimulate all the different bacterial species humans harbor in the intestinal tract. Finally, more research is needed to better understand the interaction between probiotic bacteria and the different prebiotics.

Survival of Lyophilized, Probiotic *Lactobacillus plantarum* and *Pediococcus acidilactici* in Refrigerated, Acidified Cucumbers

Author Block:

S. Cauley; North Carolina State Univ., Raleigh, NC

Abstract Body:

Non-pasteurized, refrigerated, acidified cucumbers represent a significant percentage of pickled cucumber products consumed in the US. Addition of probiotics would offer a non-dairy, low-calorie, health-promoting product. This study explored methods for addition of commercially available, lyophilized, probiotic cultures that would allow for high, long-term survival in this product. Cucumbers or a model system using cucumber juice (CJ) were acidified to pH 3.65 ± 0.05 with acetic acid and inoculated to ~8 $\log_{10}$ CFU/mL. Microbial counts during refrigerated storage were obtained by plating samples on MRS followed by anaerobic incubation at 30 °C for 48 h. Direct addition of 7 lyophilized probiotics, *Lactobacillus plantarum* or *Pediococcus acidilactici*, to acidified cucumbers resulted in cell death ranging from 2.3 to 5.5 $\log_{10}$ CFU/mL after 1 mo at 4 °C. Therefore, further experiments were conducted to determine the effect of sodium benzoate concentration, pre-adaptation of cultures, and modification of shelf-life temperature on survival. Sodium benzoate is a commonly used pickled cucumber preservative, known to inhibit growth of lactic acid bacteria. Although there were differences between strains in survival in the acidic pickling brine ($P < 0.05$), sodium benzoate (up to 9 mM) had no detrimental effect on survival after 2.5 h at 4 ºC ($P > 0.05$). Pre-adaptation of cells in CJ for 2 or 18 h at 4 ºC prior to inoculation demonstrated ~1 $\log_{10}$ CFU/mL improvement in survival. Acidification of the CJ pre-adaptation solution to pH 4.0 with acetic acid showed a 1 $\log_{10}$ of CFU/mL reduction in survival. Preliminary investigation of storage temperature modifications, with and without trehalose supplementation (1.5%), showed that by incubating the inoculated acidified CJ model system for 24 h at 21 ºC or 24 h at 21 ºC followed by 24 h at 14 ºC prior to storage in 4 ºC shows further improvement of survival by ~2.5 $\log_{10}$ CFU/mL. Experimentation to date demonstrates that survival can be improved by hydration in CJ prior to addition and allowing acclimation in the acidified cucumber environment at a temperature permissive of growth prior to 4 ºC storage.

Partial Characterization of β-Galactosidase Extracted from *Pediococcus* sp. as Potential Source of Probiotics for Treating Lactose Intolerance

Author Block:

R. Alpay[1], E. M. Pangan[1], M. K. Devanadera[2], M. Santiago[1]; [1]Faculty of Pharmacy, Manila, Philippines, [2]Res. Ctr. for Natural and Applied Sci., Manila, Philippines

Abstract Body:

Background: Lactose intolerance is prevalent among people especially the elderly. Lactose intolerance occurs when the body is incapable of producing β-galactosidase – the enzyme that hydrolyzes lactose. Improper digestion of lactose causes a lot of symptoms like bloating, diarrhea, and abdominal pain. This study aims characterize β-galactosidase from *Pediococcus* sp. as a potential source of probiotics for treating lactose intolerance. **Methods:** The strains used were *Pediococcus pentosaceus* K3A2-2, *Pediococcus acidilactici* K2A2-5, K2A2-1, and K2A1-1. The crude enzyme was extracted via sonication for 15 minutes in 3 minutes intervals at maximum volume. Microplate based Bradford assay was performed to measure the protein content of the crude extract and ONPG assay for the enzyme activity. The enzyme activities were measured according to three parameters: substrate, substrate concentration and pH. MRS Broth supplied with 1% glucose or lactose was used to compare which substrate gave the highest value of enzyme activity. MRS Broths at different pH (4.8, 6.8 and 8.8) and different substrate concentrations (1%, 5%, and 10%) were used to determine which value gives the highest enzyme activity.**Results:** K3A2-2 had the highest enzyme activity of $3.6x10^{-4}$ U/ml in MRS Broth supplied with 1% glucose while K2A2-5, K2A2-1, and K2A1-1 had the highest value of $4.3x10^{-4}$ U/ml, $4.9x10^{-4}$ U/ml, and $4.2x10^{-4}$ U/ml respectively in MRS Broth supplied with 1% lactose. K3A2-2, K2A2-5, K2A2-1, and K2A1-1, the highest activity of $2.4x10^{-3}$ U/ml, $2.6x10^{-3}$ U/ml, $2.4x10^{-3}$ U/ml, and $2.5x10^{-3}$ U/ml were obtained from media supplied with 10% lactose. K3A2-2 has the highest activity of $2.7x10^{-3}$ U/ml at pH 8.8 while K2A2-5, K2A2-1, and K2A1-1 had the highest activity of $5.1x10^{-3}$ U/ml at pH 4.8, $2.8x10^{-3}$ U/ml and $2.7x10^{-3}$ U/ml at pH 8.8 respectively.**Conclusion:** The best conditions for optimum production of β-galactosidase in *Pediococcus* species were 10% lactose as substrate at pH 8.8. *Pediococcus* species could be a potential source of probiotic that could help treat lactose intolerance. However, the enzyme activity is quite low thus optimization parameters such as incubation temperature and time must still be done on the bacterial strains to achieve maximum yield.

Effects of Lactulose on Growth Kinetics, Fermentation, Antioxidant Activity, and Short-Chain Fatty Acid Production of Probiotics

Author Block:

E. Puspitasari, C. K. Yeung, M. Yeung; California Polytechnic State Univ. San Luis Obispo, San Luis Obispo, CA

Abstract Body:

Prebiotics, such as fructooligosaccharide (FOS), are non-digestible oligosaccharides that selectively stimulate the growth of beneficial bacteria in the human intestine. Previous studies suggest that lactulose, a derivative of lactose, has prebiotic potential. Our study was aimed to characterize the prebiotic activities of lactulose. In addition to stimulating the growth of probiotics, we hypothesized that lactulose would enhance probiotics' antioxidant activity and short-chain fatty acid (SCFA) production, thereby alleviating gastrointestinal disorders and strengthening intestinal structure. Hence, our objectives were to determine 1) growth kinetics in aerobic condition; 2) pH and titratable acidity after fermentation; 3) antioxidant capacity; and 4) SCFA profiles of probiotics when prebiotics were given as the main carbohydrate source. Ten probiotics and two non-probiotic strains, representing genera *Lactobacillus*, *Bifidobacterium*, *Bacillus*, and *Escherichia* were assembled. Basal media containing dextrose was modified to include 2% FOS or lactulose. Except SCFA analysis, all experiments were done in at least triplicates. In aerobic condition, most strains cultured with prebiotics did not grow optimally compared to dextrose, except for two *Bifidobacterium* spp. In anaerobic condition, the non-probiotic strains were able to catabolize both prebiotics, but displayed weaker lactic acid production (0.07±0.05%) relative to *Lactobacillus* spp (0.44±0.08%) and *Bifidobacterium* spp (0.14±0.05%). All strains yielded significantly lower pH from lactulose fermentation than FOS ($p<0.01$), as seen in *Lactobacillus paracasei* (pH 4.30±0.33 vs pH 5.92±0.15) and *Bifidobacterium infantis* (pH 4.35±0.44 vs pH 5.20±0.41). Antioxidant activity of spent medium was measured with Trolox as the reference standard. Lactulose fermentation yielded 0.18±0.24 mM Trolox equivalent, whereas dextrose fermentation yielded 0.20±0.20 mM. Preliminary SCFA analysis showed that *Lactobacillus casei* and *Lactobacillus acidophilus* produced higher levels of propionate when lactulose was fermented, supporting our hypothesis. In conclusion, lactulose is a promising prebiotic ingredient that can be incorporated in functional food products.

Method Validation for Bacterial and Viral Analysis of Geoducks

Author Block:

V. A. Balta, A. L. Kossik, N. K. Beck, J. S. Meschke; Univ. of Washington, Seattle, WA

Abstract Body:

Background: The shellfish industry in Western Washington is an integral part of the State economy; with products being distributed both domestically and internationally. Oysters and geoducks are widely harvested in Washington, and ensuring growing areas with low levels of bacterial and viral contamination is essential for protecting consumers from disease. Methods for assessing viral and bacterial contamination in oysters have been established; however, similar testing procedures for geoducks have not been validated. Our study adapted viral and bacterial testing methods for oysters to better suit geoduck meat. **Methods:** To validate our methods, four trials were performed with MS2 coliphage and five trials were performed with *E. coli* CN-13 (EC) seeded into geoduck meat harvested in Washington. Each MS2 trial contained four seeding levels for which we calculated PFU/100g and percent recovery using the double agar layer method. The EC trials contained three seeding levels with the most probable number (MPN) and percent recovery calculated for each. MPN and percent recovery were assessed using the APHA's 5-tube fermentation method. Fermentation on seeded geoduck meat was first performed in Lauryl tryptose broth (LST) and then passaged into EC broth and EC-MUG medium. In addition, six unseeded field samples were processed using these methods to evaluate ability of the method to detect naturally occurring levels of *E. coli* and male-specific coliphage (MSC). **Results:** The average percent recoveries for MS2 trials ranged from 90.4% to 153.7%, with higher recoveries occurring at more concentrated seeding levels. Recoveries of over 100% are likely due to MS2 aggregation. The average percent recoveries for *EC* trials were greater than 100%, with higher recoveries also occurring at more concentrated seeding levels. Recoveries of over 100% are likely due to *EC* aggregation and potential bacterial growth in geoduck meat. All geoduck meat used in the *EC* trials was shown to have prior levels fecal coliforms but tested negative for *EC*. In unseeded geoduck, MSC levels ranged from 9.55 to 139.39 PFU/100g and *EC* levels ranged from .20 to 79.0 MPN/g. **Conclusion:** Our findings suggest that, with modifications, current oyster viral and bacterial testing methods can be applied successfully to geoduck meat. The percent recoveries indicate that both methods provide good assessment of bacterial and viral contamination in geoducks.

Evaluation of Modified Charcoal-Cefoperazone-Deoxycholate Agar Supplemented with Tazobactam for the Isolation of *Campylobacter* from Chicken Carcass Rinse

Author Block:

J. Chon[1], K. Sung[1], K. Seo[2], S. Khan[1]; [1]Natl. Ctr. for Toxicological Res., US Food and Drug Admin., Jefferson, AR, [2]Konkuk Univ., Seoul, Korea, Republic of

Abstract Body:

Tazobactam, an extended-spectrum β-lactamase (ESBL) inhibitor, is an effective supplement for quantitative isolation of *Campylobacter* from chicken cecum inhibiting ESBL-producing *E. coli*, while supporting *Campylobacter* growth (Smith et al., 2015; Int. J. Food Microbiol. 210:131-135). However, no studies have evaluated tazobactam-supplemented media for the qualitative detection of *Campylobacter* in raw chicken meat samples. We evaluated tazobactam-supplemented, modified charcoal-cefoperazone-deoxycholate agar (T-mCCDA) for the qualitative detection of *Campylobacter* in chicken carcass rinse. First, using 25 strains each of ESBL-producing *E. coli* and *Campylobacter*, we found 4 mg/L of tazobactam to be optimal for mCCDA. Smith et al. (2015) observed inhibition of ESBL-producing *E. coli* at concentrations as low as 1 mg/L tazobactam when they evaluated T-mCCDA using three ESBL-producing *E. coli* strains. However, some ESBL-producing *E. coli* strains (4 of 25, 16%) were still able to grow in the presence of 2 mg of tazobactam. Next, a total of 120 whole chickens from retails were rinsed with buffered peptone water (BPW), and 25 mL of BPW was mixed with 2× blood-free Bolton broth (25 mL) followed by incubation at 42°C for 48 h. A loopful of the culture was inoculated on normal or 4 mg/L T-mCCDA and incubated at 42°C for 48 h microaerobically. Suspected *Campylobacter* colonies were confirmed by colony PCR. The modified media (56.7%) showed a better ($p<0.05$) *Campylobacter* isolation rate than normal selective media (30.8%). Moreover, selectivity of the modified media was superior ($p<0.05$) to normal media, with only one modified media plate contaminated with non-*Campylobacter* (0.8%) compared to 83.3% of the normal plates being contaminated with non-*Campylobacter* species. This study is a follow -up of previously published investigation using mCCDA supplemented with polymyxin B (P-mCCDA) as an ESBL-inhibiting agent (Chon et al., 2012; Appl. Environ. Microbiol. 78:1624-1626). However, in this study the T-mCCDA showed higher selectivity than that observed using P-mCCDA. Our results suggested that tazobactam is a suitable supplement for mCCDA for qualitative detection of *Campylobacter* from chicken carcass rinse.

Comparison of the Liquid versus Lyophilized Inoculation Approaches in Oregano Artificially Contaminated for *Salmonella* Recovery

Author Block:

J. Jean-Gilles Beaubrun[1], **N. Addy**[2], L. Ewing[1], G. Gopinath[1], D. E. Hanes[1]; [1]US FDA, Laurel, MD, [2]US FDA, ORISE, Laurel, MD

Abstract Body:

Many studies have demonstrated the effectiveness of oregano essential oils and phenolic compounds in inhibiting the growth of pathogenic microorganisms. One of the concerns with artificial contamination is that during the inoculation process some of the phenolic compounds such as carvacrol and thymol may be released. This study was designed to evaluate two methods to inoculate oregano for use in developing methods for the isolation of *Salmonella.* Dry oregano samples (25g) were artificially contaminated with *Salmonella* serovar Montevideo using either a 10^3 cfu cell suspension for liquid inoculation or 10^3 cfu of *Salmonella* lyophilized in dry milk. Samples were aged for 2 weeks at room temperature prior to analysis. Oregano samples were pre-enriched overnight at 37^{o}C in modified Buffered Peptone water (mBPW) with 2% (vol/vol) corn oil; previous work has shown that addition of corn oil sequesters the phenolic compounds allowing recovery of *Salmonella.* Samples were transferred to selective enrichment broths, Rappaport-Vassiliadis and tetrathionate, and plated on Xylose-Lysine-Tergitol 4 agar following 24 h of pre-enrichment. Typical *Salmonella* colonies were identified as described in the FDA Bacteriological Analytical Manual (BAM), and confirmed using Vitek® 2 Compact. The results showed a significant (P= <0.050) increase in the survival of *Salmonella* from the samples inoculated with the lyophilized cells; an average of 220 CFU of *Salmonella* were recovered from liquid inoculum samples compared to 316 CFU recovered from samples inoculated with lyophilized *Salmonella.* These results suggest the artificial inoculation with lyophilized *Salmonella* increases survival in oregano and may mimic the natural contamination route of oregano and other spices. This study demonstrated that using a dry, lyophilized form of inoculation *Salmonella* increase survivability and is crucial for successfully mimicking natural contamination of oregano samples used to compare and improve detection methods.

Use of Date Palm (*Phoenix dactylifera l.*) to Develop a Medium for Cultivation of Lactic Acid Bacteria

Author Block:

A. A. Ayad[1], R. Gyawali[1], D. Gad El-Rab[2], R. Tahergorabi[1], A. Shahbazi[1], S. A. Ibrahim[1];
[1]North Carolina A&T State Univ., Greensboro, NC, [2]Natl. Res. Ctr., Giza, Egypt

Abstract Body:

Lactic acid bacteria (LAB) have many applications in food industry to develop fermented food products. The standard medium DeMan Rogosa Sharp (MRS) to grow LAB is expensive and the industry is always looking for an alternative low cost medium. There are several agricultural by-products that can be utilized to develop medium for the growth of LAB. Date fruit industry produces large amount of useless by-products. Therefore, the objective of this study was to develop date palm medium for the cultivation of LAB using date by-products. The date palm extract (DPE) was prepared by pressing fresh date fruits for one week. The extract was then mixed with deionized distilled water (DDW) at ratio 1:2 (w/v), centrifuged (4696 x *g* for 25 min) at 4°C, and then supernatant was autoclaved at 110°C for 15 min. The DPE was mixed with buffer solution prepared as MRS (Tween 80 1mL, L-Cysteine.HCL (1g), Na_2HPO_4 (2g), $NH_4C_6H_5O_7$ (2g) $C_2H_3NaO_2$ (5g), $CaCl_2$ (0.15g), K_2HPO_4 (2g), $MgSO_4.7H_2O$ (0.2g) and $MnSO_4.5H_2O$ (0.05g)) to form a date palm medium (DPM). DPM was then mixed with different concentrations of sterile phytone peptone solution (PP) (0, 0.2, 0.4, 0.6, and 0.8 %, w/v). Lactobacilli MRS was used as a standard growth medium. Three *Lactobacillus reuteri* (DSM 20016, CF2-7F, and SD 2112) strains were individually inoculated into batches of MRS, and DPMs at initial inoculum level of approximately 2.5 log CFU/ml. Inoculated media were then incubated at 37ºC for 18 h. Bacterial growth was monitored by measuring the optical density readings (O.D 610 nm) for up to 18 h. At the end of the incubation period, final populations of each individual strain were verified by enumeration on MRS agar. Our results showed that in DPM (control), bacterial population reached to 3.18±0.5 log CFU/mL. Addition of low concentration of phytone peptone did not support the bacterial growth. However, when DPM medium was supplemented with 0.8% of phytone peptone, bacterial populations reached to 6.94±0.1 log CFU/mL which was similar to the population found in standard MRS medium (7.90±0.24 log CFU/mL). These results showed that there was no significant ($P > 0.05$) difference in the growth of LAB in MRS and developed DPM medium. Therefore, our findings suggest that date by-products could be used as an alternative low cost medium to develop a growth medium for LAB.

Purification of Bile Salt Hydrolase from Philippine Cocowater Kefir Lactic Acid Bacteria

Author Block:

E. Pangan, R. Alpay, M. Devanadera, M. Santiago; Univ. of Santo Tomas, Manila City, Philippines

Abstract Body:

Bile salt hydrolase (BSH) is an enzyme produced by lactic acid bacteria that holds promise in lowering cholesterol levels, consequently decreasing the risk of cardiovascular diseases, with its presence having been correlated to hypocholesterolemic effects of food rich in probiotic bacteria, such as in kefir. In this study, lactic acid bacteria (LAB) isolates from cocowater kefir were screened for BSH activity, followed by the extraction and purification of the enzyme. The isolates were screened by observing the precipitation of deconjugated bile salts in a specific media. Purification was done via ammonium salt precipitation and size exclusion gel chromatography using Sephadex G-100. The crude and purified extracts were then assayed for protein content, using Bradford's assay, and for BSH activity. Determination of BSH activity was done by measuring the amount of glycine liberated from the deconjugation of the bile salt glycocholic acid. Four isolates, preliminary identified as bacteria isolates I002, I004, J006 and K001 upon isolation from cocowater kefir, were subjected to the purification process and the improvement of enzyme activity was analyzed. Additionally, genomic DNA extraction was performed on the four isolates for identification of the BSH-producing bacteria. The initial enzyme activities of the crude enzyme extracts from the isolates were found to be $1.33x10^{-4}$ U/mg, $1.28x10^{-4}$ U/mg, $1.25x10^{-4}$ U/mg and $1.13x10^{-4}$ U/mg, respectively. After salt precipitation, the enzyme activities increased to $4.35x10^{-4}$ U/mg, $5.41x10^{-4}$ U/mg, $4.25x10^{-4}$ U/mg and $5.20x10^{-4}$ U/mg, respectively. Finally, after gel chromatography, the eluates were assayed, and peak enzyme activities were determined to be at $7.23x10^{-4}$ U/mg from I002, $1.98x10^{-3}$ U/mg from I004, $3.55x10^{-4}$ U/mg from J006 and $2.50x10^{-4}$ U/mg from K001. From the results gathered, enzyme activity was observed to increase with every purification step for bacteria isolates I002 and I004, with the gel chromatography filtrates producing the highest enzyme activity per milligram of protein. The decrease in activity observed in isolates J006 and K001 could possibly be due to the elution conditions, thus requiring adjustments for the two isolates. Additionally, it was determined that bacteria isolate I004 expressed the highest enzyme activity, suggesting that the isolate could potentially be a good source of BSH.

Publishing Title:

Characterization of the Bacteiocin-Like Peptide (*blp*) Gene Cluster in *Streptococcus thermophiles* Strain B59671

Author Block:

J. A. Renye, Jr., G. A. Somkuti; USDA, Agricultural Res. Service, Wyndmoor, PA

Abstract Body:

Streptococcus thermophilus is a food-grade bacterium commonly used in the production of fermented dairy foods, including cheese and yogurt. Some strains have been shown to possess a *blp* gene cluster encoding for the production of antimicrobial peptides called thermophilins; however their production is largely dependent on the artificial induction of a quorum sensing (QS) system that regulates their expression. *S. thermophilus* strain B59671 has been shown to naturally produce thermophilin 110, a broad spectrum bacteriocin with anti-listerial activity, which is encoded within the *blp* locus. In this study, chromosome walking was used to sequence the *blp* gene cluster in strain B59671. Sequence analysis of the 10.7 kb gene cluster revealed 14 open readings, including two genes, *blpU* and *blpK*, that potentially encoded antimicrobial peptides. Deletion of *blpK* from the B59671 chromosome did not result in a loss of antimicrobial activity, suggesting that *blpU* encoded the bacteriocin; however, repeated attempts did not yield a *blpU* mutant. Both *blpU* and *blpK* were overexpressed in *E. coli*, and only purified BlpU was shown to have antimicrobial activity, confirming it is a functional bacteriocin. Real-time PCR analysis was used to compare the expression of *blp* components in strains B5971 and LMD-9, the latter being a sequenced strain which requires synthetic induction of the QS system to allow for thermophilin production (Fontaine *et al*., 2007). Results showed that *blpC*, which encodes the QS induction peptide, and *blpU* were expressed 22-fold and 49-fold higher in strain B59671, respectively. The lower level of BlpU expression in LMD-9 may explain why it was not previously identified as a bacteriocin in this strain. Studies are continuing to determine why the QS system is expressed at levels which allow it to function properly in strain B59671, resulting in the natural production of thermophilin 110.

Regional Similarity and Consistent Patterns of Local Variation in Beach Sand Bacterial Communities Throughout the Northern Hemisphere

Author Block:

C. Staley, M. J. Sadowsky; Univ. of Minnesota, Saint Paul, MN

Abstract Body:

Recent characterization of bacterial community structure (BCS) in beach sands has revealed patterns of biogeography similar to those observed in aquatic environments. Studies to date, however, have focused mainly on subtidal sediments from marine beaches. Here, we introduce the Beach Sands of the World investigation of bacterial diversity, using Illumina-based sequencing of the V5+V6 regions of 16S rRNA gene, at 11 beaches representing the Great Lakes, the Gulf of Mexico, and the Pacific Ocean. Alpha diversity differed significantly among regions ($P < 0.0001$), while within-region diversity was more similar. Beta diversity also differed by region ($P < 0.001$), where freshwater sands had significantly higher abundances of taxa within the *Actinobacteria*, *Betaproteobacteria*, and *Verrucomicrobia* than marine environments. In contrast, marine sands harbored greater abundances of *Gammaproteobacteria* and *Planctomycetes*, and those from the Gulf of Mexico had more *Deltaproteobacteria* and *Firmicutes*. Marine beaches had significantly different phylogenetic BCS ($P \leq 0.018$), but freshwater and Gulf beaches were more similar. Furthermore, regionally-distinct patterns in taxonomic variation were observed in backshore sands, which had BCS distinct from nearshore sands ($P < 0.001$). Sample depth minimally influenced BCS. Results of this study reveal distinct sand community structures globally, but moderate regional similarity, and suggest local variation is primarily related to distance from the shoreline. This study offers a novel comparison of bacterial communities in freshwater and marine beach sands and provides an important basis for future comparisons and analysis to elucidate factors affecting microbial ecology in this under-explored environment.

A High-Throughput Sequencing-Based Approach For Determining Sources Of Fecal Bacteria In The Lake Superior Watershed

Author Block:

C. M. Brown[1], C. Staley[1], P. Wang[1], C. L. Chun[2], M. J. Sadowsky[1]; [1]Univ. of Minnesota - Twin Cities, St. Paul, MN, [2]Univ. of Minnesota - Duluth, Duluth, MN

Abstract Body:

While several methods have been developed that aim to determine sources of fecal bacteria in freshwater systems, most techniques utilize animal or human-specific molecular markers to identify single indicator organisms (SIO) present in animal and human feces. However, developing and validating sensitive and specific SIO molecular markers to detect different sources of fecal contamination can be difficult and time-consuming. To circumvent this, a high-throughput sequencing (HTS)-based method to determine sources of fecal bacteria in a freshwater system was developed. This HTS-based method compared the total bacterial community structures (BCS) of fourteen different types of animals and wastewater effluent (n=273) to the total BCS in environmental samples (n=202) from the freshwater Lake Superior watershed, via sequencing of the 16S rRNA gene. Analysis from HTS of the 16S rRNA gene of nearly 500 fecal and environmental samples revealed that bacteria present in environmental and fecal samples are significantly different (p-value: <0.001), thus allowing phylogenetic differentiation between the bacterial taxa in the two matrices. While there were common fecal-associated phyla across fecal samples, animal-specific, or unique relative abundances of phyla allowed for differentiation between different animals (all comparisons had p-values <0.05). The statistical program SourceTracker, which calculates the amount that a source(s) contributed to contamination in a particular environment, revealed the predominant fecal pollution sources across sampled environmental sites were from fowl, and effluent from a nearby wastewater treatment plant. To corroborate SourceTracker results, host-specific SIO molecular markers were used to detect fecal contamination sources. The detection of fecal bacteria and general waterfowl by host-specific SIO molecular markers agreed with the predicted fecal contamination sources in the SourceTracker results. The results of this study may allow for an alternative method of determining sources of fecal bacteria that organizations tasked with pollution control can utilize in protecting freshwater resources.

Microbial Source Tracking in the Urbanized Tropical Watershed: Multiple Lines of Evidence to Confirm Sewage as the Cause of Water Quality Impairment

Author Block:

M. KIRS[1], V. Kisand[2], R. A. Caffaro Filho[3], M. Wong[1], V. J. Harwood[4], B. Yoneyama[1], P. Moravcik[1], R. S. Fujioka[1]; [1]Univ. of Hawaii, Honolulu, HI, [2]Univ. of Tartu, Tartu, Estonia, [3]Federal Univ. of Alagoas, Maceió, Brazil, [4]Univ. of South Florida, Tampa, FL

Abstract Body:

Indicator bacteria, which are conventionally used to evaluate recreational water quality, can originate from various non-human enteric and extra-enteric sources, hence they are not always indicative of human health risk nor do they provide information on the sources of contamination. In this study we utilized traditional (enterococci and *E. coli*) and alternative indicator organisms (*Clostridium perfringens,* coliphage), molecular markers (human-associated *Bacteroides* and human polyomaviruses), and microbial community analysis tools to evaluate human sewage-related impacts in the Manoa watershed (Hawaii). The elevated concentrations of enterococci (mean $2.8x10^3$ - $4.8x10^3$ CFU $100mL^{-1}$) and *C. perfringens* (mean $5.9x10^1$ - $1.4x10^2$ CFU $100mL^{-1}$) indicated impairment of the urbanized section. The standard threshold value triggering recreational water quality violation notifications in Hawaii was exceeded in 33 - 75% of samples from the urbanized section of Manoa Stream, but was not exceeded in samples from an upstream forested site. Indicator bacteria concentrations were correlated with rainfall measurements, while human molecular markers were not, indicating chronic sewage-related inputs of contamination. Presence of human sewage was confirmed by human-associated *Bacteroides* and human polyomavirus markers in the urbanized section of the watershed (83.3 - 100% and 41.7 - 66.7% positive samples respectively) and was further confirmed by microbial community analyses which suggested that an average 2.4 - 3.4% of the total bacterial population in this section was associated with sewage. Microbial community profiles were significantly related to rainfall (R^2=0.44, P<0.001), pH (R^2=0.31, P=0.006), salinity (R^2=0.26, P=0.038), and conductivity (R^2=0.27, P=0.031). Microbial diversity decreased in the impaired section. Leaking sewer systems, cesspools, and illegal cross-connections are implicated in the impairment. Collectively our data suggest that information derived from the analysis of microbial communities complements current marker-based microbial source tracking techniques and environmental monitoring programs.

Bacterial Community Composition and Structure in an Urban River

Author Block:

A. M. IBEKWE[1], M. Jincai[2]; [1]USDA-ARS, RIVERSIDE, CA, [2]Jilin Univ., Changchun 130021, China

Abstract Body:

Microbial communities in rivers are diverse and dynamic in composition due to different environmental factors. Here we used 454 pyrosequencing to determine the total bacterial community composition, and bacterial communities that are potentially of fecal origin, and of relevance to water quality assessment. The results were analyzed using UniFrac coupled with principal coordinate analysis (PCoA) to compare diversity, abundance, and community composition. Detrended corresponding analysis (DCA) and canonical correspondence analysis (CCA) were used to correlate bacterial composition in streams and creeks to different environmental parameters impacting bacterial communities in the sediment and surface water within the watershed. From all the sampling points, bacteria were numerically dominated by the phyla *Proteobacteria, Bacteroidetes, Acidobacteria,* and *Actinobacteria*—accounting for the majority of taxa detected. Overall results, using the β diversity measures, UniFrac, coupled with PCoA and DCA showed that bacterial composition in sediment and surface water was significantly different (P =0.001). Also, there were differences in bacterial community composition between agricultural runoff and urban runoff based on parsimony tests using 454 pyrosequencing data. Fecal indicator bacteria in surface water along different creeks and channels were significantly correlated with pH (P = 0.01), NO_2 (P = 0.03), and NH_3N (P = 0.005); and in the sediment with NO_3 (P =0.015). Our results suggest that microbial community compositions were influenced by several environmental factors, and these factors were also major drivers in fecal indicator bacterial composition in the watershed.

Metagenomic Analysis of Microbiomes in an Urban Fresh Water Lake In Seattle, Washington

Author Block:

Z. Li[1], T. Liu[2], L. Wang[3]; [1]Washington State Dept of Hlth., Shoreline, WA, [2]Washington Univ., St. Louis, MO, [3]Ohio Dept. of Agriculture, Reynoldsburg, OH

Abstract Body:

Lakes in metropolitan areas are an important part of the urban ecosystems. Urban lakes not only host recreational activities, they also play a crucial role in stormwater runoff and groundwater recharge. Microbiomes of lake water could be influenced by a variety of factors, including industrial and residential activities as well as wildlife inhabitation. In addition, many microorganisms could degrade pollutants and recycle nutrients in the lakes, which is beneficial to improve water quality. Thus, analyzing microbiomes in urban lakes could provide useful information for pollution surveillance and bioremediation. In this study, we analyzed the microbiomes from the Haller Lake located in Seattle metropolitan area, which is also in close proximity to a hazardous waste recycling facility. Water samples from the late were collected in October, 2015. Bacterial cells were collected through filtration of the lake water using 0.2 micrometer filters. Bacterial DNA was then extracted using Qiagen DNeasy Blood & Tissue Kit and sequenced using Illumina MiSeq sequencer via shotgun metagenomics method. Sequencing data was subsequently analyzed using BaseSpace and metagenomics analysis server (MG-RAST). The dominant phyla of the microbiomes in the lake water were identified as *Proteobacteria*, *Actinobacteria* and *Bacteroidetes*. Functional abundance analysis indicated the existence of several bacterial genes which are related to heavy metal resistance including Cobalt-Zinc-Cadmium resistance and copper homeostasis. In addition, several antibiotics resistance genes, such as fluoroquinolones, erythromycin and methicillin resistance genes, and multidrug resistance efflux pumps, were also detected in these microbiomes. In addition, our results also indicate that metagenomic analysis using next generation sequencing techniques could be potentially used as an indicator for urban lake water quality.

A Two Year Study on the Virome of a Singapore Reservoir

Author Block:

M. Q. X. Tay[1], L. Loh[1], S. H. Te[2], K. Y. H. Gin[2], J. R. Thompson[1]; [1]SMART, Singapore, Singapore, [2]Natl. Univ. of Singapore, Singapore, Singapore

Abstract Body:

Viruses and phage are able to shape the microbial community in different environments through "kill the winner" predation. Despite the important role phage play in freshwater systems, the field of freshwater virology is largely underdeveloped. The specific questions we have addressed in this study include (1) What is the diversity of freshwater phage in a Singapore reservoir? (2) How does the diversity of phage vary on monthly and annual frequency and at different sites within the reservoir? (3) Is there evidence that cyanophage that may associate with algal blooms? In this study we have characterized the virome of a freshwater reservior in Singapore, using next generation sequencing (NGS). NGS allows for the highthroughput sequencing of the viral community without proir knowledge of what signature genes to look out for. DNA was extracted from the virus-containing fraction (<0.22um) of 34 samples collected 10 cm below the surface monthly over 20 months. DNA was sequenced by Illumina MiSeq (250+250 paired end reads) using the Nextera XL protocol for library preparation generating 1.3 to 15 million reads per library. De novo assembly (CLC workbench) produced 188,491 contigs with N50 score of 2,466 bp and largest contig of 163,843 bp. The principle coordinate analysis read count to contig of individual libraries revealed that the temporal variability excceded spatial variability in the reservoir. A spike in the relative abundance of reads recruiting to 23 de-novo assembled contigs corresponded to a bloom of the cyanobacterium *Microcystis* and may represent novel *Microcystis*-associated phage. These results provide the first overview of viral diversity in a Singapore reservoir and motivate ongoing work to understand how phage influence the dynamics of bloom-forming algae in the reservoir.

Microbial Source Tracking by Dna Sequence Analysis of the *E. coli* Based on Partial Sequence of Beta-galactosidase Gene

Author Block:

M. Noda, K. Okuda, K. Nanba; Fukushima Univ., Fukushima, Japan

Abstract Body:

Coliforms and *E. coli* are key regulatory indicators of healthfulness of freshwater environment. In lake *Hibara* in Fukushima the number of coliforms was often beyond the environment standard (1000 MPN/100 ml) since 1989(Japanese Ministry of the Environment). The villages in the catchment of Lake *Hibara* have small population with high percentage of sewered population. As unpopulated mountainous area is wider, non-human source is suspected. Eight feces were collected from the road within the catchment. The animals might be fox, marten, bear and so on. Twenty five *E. coli* strains were isolated with BGLB and Colilert from the 8 feces. Rectum contents were collected from wild animals of other part of Fukushima-pref. including 4 wild boar, 4 masked palm civet and a raccoon dog. Thirty seven strains of *E. coli* were isolated with BGLB and Colilert from the 9 rectum contents. DNA extracts from 62 isolates were partially sequenced (240bp) for *lacZ*. The isolates *E. coli* from wild animal feces formed 7 groups and those from rectum contents formed 10 groups by *lacZ* partial sequence. In the previous study, 29 isolates of *E. coli* from the environment, the lake and tributary rivers formed 10 groups. Three groups from 14 wild animal groups (feces + rectum content) could be found from human isolates. All these three groups were also found in the isolates from the environment. Fifteen *E. coli* isolates of 29 from the environment belonged to one of the three groups that are common in wild animal and human. The result shows that partial sequence of *lacZ* does not give a clue to identify the source.

Examining Sources of Fecal Contamination in Private Groundwater Wells Across an Ontario Rural Township with Next-Generation Sequencing

Author Block:

P. Naphtali, H. Schellhorn; McMaster Univ., Hamilton, ON, Canada

Abstract Body:

Source water protection requires monitoring the presence of waterborne pathogens and fecal indicator bacteria over time, and when necessary, determining potential contamination sources. Standard methods for monitoring fecal contamination includes quantifying fecal indicators like *E. coli* using selective and differential methodology. Such assays however cannot provide conclusive identification of contamination sources. Advances in culture-independent methods, including next-generation sequencing (NGS), utilize the 16S gene as a target, enabling the characterization of entire microbial communities in many environments. With NGS, many bacterial taxa containing waterborne pathogens can be detected. Furthermore, the microbiotas of drinking water and fecal sources can be compared with one another with NGS to measure the contributions of anthropogenic inputs including sewage and agricultural runoff to water pollution. This information can complement the standard methods for quantifying fecal pollution and tracking sources of fecal contamination. To evaluate this possibility, twenty groundwater well samples, two septage samples, and manure from four farm animals were collected from a rural Ontario township between March and November 2015, and the microbial community profile determined by 16S sequencing. These sequences were then matched against the 16S Greengenes database and processed with the Quantitative Insights into Microbial Ecology (QIIME) pipeline[1]. Groundwater microbiotas are typically comprised of members within the Proteobacteria and Actinobacteria phyla, while members of the Bacteroidetes and Firmicutes phyla predominate in manure and sewage. With the substantial difference in microbiota composition, the probability of a groundwater site being polluted by a fecal contaminant increases with increased similarity between groundwater and fecal microbiotas. Sequences belonging to pathogens such as *Clostridium* are also detected in the groundwater wells, suggestive of sewage contamination. The information gained by analyzing the microbial community profiles with metagenomics, when combined with standard plate counts, can aid end-users in quantifying fecal contamination and mitigating the possibility of a waterborne outbreak.

Analysis of the Microbiome and Antibiotic Sensitivities of Fecal Bacteria in the Sparkill Creek

Author Block:

A. Panchyshyn, B. Maharaj, M. Scrudato, B. Connors; Dominican Coll. of Blauvelt, Orangeburg, NY

Abstract Body:

Microbial contamination of numerous rivers and their tributaries has been the subject of both funded and unfunded studies carried out by citizen science groups in the US. In 2010, the NYS Department of Environmental Conservation added the Sparkill Creek to its list of impaired waters due to the high concentration of fecal indicator bacteria. The source of contamination has yet to be identified, but several years of research have shown that the problem continues to exist and the levels of the indicator organism have not been diminished. This research aimed to determine the diversity of bacteria present at selected sites along the Sparkill Creek using 16S rDNA pyrosequencing, in addition to an analysis of the antibiotic resistances of the bacterial isolates. By determining the species of bacteria, it was hypothesized that the origin of contamination could be deduced and its source could be mitigated. Resistance to antibiotics, especially towards multiple drugs, poses a serious health hazard. Data show that 100% of these isolates were resistant to streptomycin and ampicillin, while 16% were resistant to vancomycin (19% showed intermediate resistance). Microbiome sequencing from three of the six sites has revealed that 36.7% of all bacteria belong to Proteobacteria, 34.8% to Bacteriodetes, and 25.6% to the Firmicutes. Success of this research is expected to help the community understand the problem before it and allow for the establishment of a healthy environment and community.

Abstract Body:

Many cities and water managers in Minnesota are implementing new stormwater and rainwater use systems, with the aim to reduce the demand for high quality potable water, to increase infiltration to groundwater, and to better manage stormwater. However, many of these water reuse systems could adversely affect public health due to the elevated presence of pathogens in storm water and rainwater. In this study, we examined rainwater collected and used for toilet flushing and stormwater used for the irrigation of athletic fields. The bacterial content of each system was investigated using cultured-based techniques for the presence of total coliforms, Enterococcus spp. and E. coli. Bacterial community composition was characterized by deep sequencing (Illumina MiSeq) of PCR-amplified 16S rRNA gene fragments. Finally, the quantities of numerous pathogens were simultaneously determined using a microfluidic qPCR technique. Both rainwater and stormwater samples had significantly higher levels of cultivable fecal indicator bacteria and genes from pathogenic organisms compared to tap water and well water samples (used as a negative controls). These results suggest that there is an elevated risk to public health associated with these creative uses of non-potable water; on-going work is being performed to quantify the extent of this increased risk.

Microbial Source Tracking of Fecal Bacteria in Surface Waters in Gunpower Creek Watershed in Kentucky

Author Block:

M. Wang[1], M. Scott[2], M. Jacobs[3], **Z. Zhou**[1]; [1]Purdue Univ., West Lafayette, IN, [2]Sanitation District No. 1 of Northern Kentucky, Frankfort, KY, [3]Boone County Conservation District, Burlington, KY

Abstract Body:

Microbial source tracking (MST) is a technique to detect dominant sources of fecal contamination in environmental waters. Fecal pollution poses a health risk to humans via pathogens and MST has been developed during the last two decades to monitor fecal pollution. As it is unrealistic to monitor all pathogens in surface waters, cultivable fecal indicator bacteria (FIB), such as *E. coli*, have been traditionally used to evaluate fecal pollution. However, FIB are not always correlated well with pathogens, and cultivable microorganisms typical only represent less than 1% of microorganisms in the total microbial community, which could result in an inaccurate estimation of fecal pollution of surface waters. Instead, molecular culture-independent and library-independent method, such as real-time PCR, can be used to trace host-specific gene markers in humans and animals in the total microbial community. In this study, we collected surface water samples from five location in Gunpower Creek Watershed in Kentucky and targeted gene markers of human, pig, cow, dog, and horse using qPCR. The results indicated that there was fecal contamination derived from pigs at all five locations, and most of the fecal contamination sources one site were from pigs (65%), but there were still othercontamination sources at Gunpowder creek. The results suggest that microbial source tracking tools could provide useful information to identify fecal pollution sources and provide guidance for better water management strategies.

Fecal Contamination Sources in Storm Water from a Ms4 Regulated Town

Author Block:

D. Rothenheber, S. Jones, E. Urquhart, J. Guimond; Univ. of New Hampshire, Durham, NH

Abstract Body:

Storm water often transports bacterial contamination to municipal separate storm sewer systems (MS4s), which is then discharged into local oceans, rivers, etc. without treatment. In the popular tourist towns of southern Maine, untreated MS4 storm water is often discharged onto recreational beaches where it flows into the ocean. Previous work in 2014 showed the fecal indicator bacteria (FIB) enterococci were consistently above regulatory limits in three storm drains at the two most popular swimming beaches. This contamination affected downstream ocean water quality and was most pronounced during wet weather. FIB provide indications of fecal contamination, however the source of the contamination can't be determined from their measurement. In this study we monitored three storm drains (n=46) and the downstream ocean (n=51) each week from late May through September 2015, to determine the seasonality of FIB contamination and dynamics of different sources that may be present. Samples were collected for enterococci enumeration and PCR-based microbial source tracking (MST) to determine general mammal (Bac32) and specific human (HF183) sources. MST PCR showed that Bac32 was detected in all storm drain samples, with 60% of those samples also showing positive detection of HF183. Downstream ocean samples were 90% positive for Bac32 with only 18% of samples positive for HF183. Significant rainfall events were sparse in 2015, with only four events over 1" in 24-48hrs. The largest rainfall (2.8") resulted in enterococci concentrations above regulatory limits in all storm drains and ocean samples, and both Bac32 and HF183 were detected in 3/3 storm drains. One storm drain also showed a significantly higher geometric mean of FIB concentration compared to others, with greater detection of human contamination. These results have provided detailed data to inform work with the EPA to eliminate storm water contamination that impairs beach water quality. Current work is being conducted to implement a qPCR method to quantify mammal and human fecal sources.

Validation of Host_Associated *Bacteroidales* Gene Marker Assays for Microbial Source Tracking in Urban Tropical Environment of Singapore

Author Block:

J-P. Nshimyimana[1], C. Cruz[2], J. Thompson[1], S. Wuertz[2]; [1]Singapore-MIT Alliance for Res. and Technology, Singapore, Singapore, [2]Singapore Ctr. for Environmental Life Sci. Engineering, Singapore, Singapore

Abstract Body:

Background: Microbial source tracking (MST) is a widely applied tool in many temperate regions of Europe and North America as well as Australia, New Zealand and Japan, but has not seen much use yet in tropical urban environments. This study applied qPCR to validate the use of host-associated *Bacteroidales* marker assays based on the 16S rRNA gene to identify human fecal pollution in the urban tropical environment of Singapore.**Methodology:** We collected a total of 285 animal and human stool as well as sewage samples. Animals tested included cats, dogs, rabbits, chicken, birds, monkeys, and wild boars. Following DNA extraction, samples were analysed by qPCR using seven assays targeting human-associated *Bacteroidales* (HF183-SYBR, HF183, BacHum, BacH and *B. thetaiotaomicron* (B. theta)), dog-associated *Bacteroidales* (BacCan), and total *Bacteroidales* (BacUni). Results were used to compare the sensitivity and specificity of assays.**Results:** The five human-associated assays (HF183-SYBR; HF183, BacHum, BacH and B. theta) and the total *Bacteroidales* assay BacUni had 100% sensitivity for sewage. The overall sensitivity for human stool samples ranged from 50 to 70% and B. theta and BacHum displayed the highest human stool sensitivity at 68.6% and 65.7%, respectively. In addition, these two assays had the highest specificity (98.6% for B. theta and 91.4% for BacHum). The HF183 assay recently recommended for MST in California, USA, had a specificity of 90% and sensitivity of 60% and 100%, respectively, for human stool and sewage samples. BacCan assay sensitivity and specificity for dog fecal samples were 80% and 97.3%, respectively.**Conclusion:** We confirmed the applicability of previously developed human-associated (B.theta and BacHum), dog-associated (BacCan) and total (BacUni) *Bacteroidales* gene markers for MST inthe tropical urban environment of Singapore. Such validation studies are needed before applying any existing host-associated *Bacteroidales* assays under new environmental conditions and at different geographical locations. Source tracking could be improved by identifying a specific human-associated gene marker for Singapore.

***lachnospiraceae* as Host-Specific Markers of Fecal Pollution**

Author Block:

S. McLellan, S. Feng; Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract Body:

Human and animal microbiome studies offer new opportunities to select alternative indicators for fecal pollution that are host specific and more informative than general indicators that are ubiquitously present in humans and animals. Although *Lachnospiraceae* is a major member of the microbial community in humans and many animals, this group has not been examined in detail for potential indicators. Using next generation sequencing data of sewage, dogs, cats, cattle, deer, pigs, and chickens, we chose V6 16S rRNA gene markers for populations of *Lachnospiraceae* that were found in sewage but not other animals. Overall, there were 14 different *Lachnospiraceae* V6 16S rRNA sequences that were potentially human indicators, which comprised 23% of all *Lachnospiraceae* in sewage samples. Most of these markers sequences where exclusively present in sewage and not in the animals we tested animals, however, several marker gene sequences appeared to be host preferred, that is they were highly abundant and present in one or two other hosts at low levels. We designed assays for Lachno 2, the second most abundant *Lachnospiraceae* (human preferred, but present in some domestic pets), Lachno 3, 11 and 12 (human specific), and Lachno 15 and 17 (found in humans, but also pigs), Combinations of these markers were tested against host sources and environmental water samples. In addition to PCR applications, direct sequencing approaches could make use of the distinctive host patterns within the family *Lachnospiraceae* for fecal pollution source identification.

Nutritional Niche of *E. coli* in Marine Sediment

Author Block:

Y. Yu, S. Lau; HongKong Univ. of Sci. and technology, Hong Kong, Hong Kong

Abstract Body:

Escherichia coli, one of the constitutive microflora in mammalian guts, was originally thought to be able to survive only in the enteric environment. Hence, the occurrence of *E. coli* in water and food has been used as an indicator of fecal contamination. However, recent reports indicate that *E. coli* can be found in many different types of external habitats (e.g. seawater, sediment and soil) independent of fecal input. Environmentally adapted *E.coli* has been reported in marine sediment. Marine sediment is suggested as a potential reservoir for the microorganism as it confers protection, nutritional entrainment and provision of surfaces for biofilms formation. Such expansion of the *E.coli* population may have a tremendous impact on both water quality monitoring and environmental management. The nutrients and physical stresses associated with a habitat are the most fundamental factors delimiting the ecological niche of a species. Heretofore, the nutritional requirement for *E.coli* to colonize external habitats remains largely unexplored. This study investigates the nutritional basis of *E.coli* to establish a niche in the marine sediment. Eight selected *E.coli* isolates from various environmental and fecal sources were cultured in a minimal medium (M9-Glucose) and in interstitial water extracted from sediment of a tidal flat in Hong Kong.RNA extracted from the culture was subjected to transcriptomic analysis for the identification genes and metabolic pathways involved in the utilization of nutrient associated with the interstitial water. Many genes that appeared to be differentially expressed in the two media were associated with B vitamins, suggesting that the vitamins may play a key role in growth of *E.coli* in interstitial water. B vitamins are crucial to amino acid synthesis and carbon resupply to the TCA cycle, and also are essential cofactors for the functioning of a variety of enzymes. Our findings have important implications to further investigations of how nutrient exploitation as a selection pressure for the establishment of *E.coli* populations in marine sediment.

Use of Boxa1r Primer and PCR to Differentiate *Escherichia coli* isolates in the Salt Marsh Periwinkle*, Littorina irrorata,* from Human and Non-Human Sources

Author Block:

M. C. Scalise, C. L. Rocha; The Citadel, Charleston, SC

Abstract Body:

Increased urban development of tidal creek systems has led to an increase in water quality degradation, namely through the presence of fecal coliform bacteria and *Escherichia coli.* Although a number of efforts have been implemented to reduce contamination of these systems, fecal input into fresh and salt water communities continues to pose a significant health risk as a result of failure to identify its non-point sources. The objective of this study was to investigate the use of repetitive extragenic palindromic polymerase chain reaction (rep-PCR) coupled with BOXA1R primer in differentiating human and non-human *E. coli* strains isolated from the Salt Marsh Periwinkle, *Littorina irrorata*. Samples of the periwinkles were collected from three different tidal creeks around Charleston, South Carolina. Two tidal creeks represented urban tidal creeks and one represented forested tidal creeks. The DNA of 48 *E.coli* isolates, obtained from homogenized periwinkle whole tissue, were subjected to PCR and analyzed by agarose gel electrophoresis. The DNA fingerprints obtained were analyzed by using the Jaccard index and the algorithm for Unweighted Pair Group Method with Arithmetic Mean (UPGMA). A dendogram constructed using Jaccard similarity coefficients separated the human isolates from the nonhuman isolates, revealing a characteristic structure of human *E. coli* populations among 53% of isolates found in one of the urban sites. Our results show that bacterial DNA isolated from the periwinkle can be sourced as human or nonhuman when rep-PCR with BOXA1R primer is performed. These results further support the use of this technique for monitoring the source of fecal pollution and, consequently, the presence of human-specific enteric pathogens in the environment.

Genomic Characterization of *Escherichia* Isolates from a Watershed

Author Block:

M. Hughes, L. Ragon, K. Lee, M. Pikaart, G. F. Peaslee, A. A. Best; Hope Coll., Holland, MI

Abstract Body:

Extensive work has characterized the extent of variation seen in isolates of *Escherichia coli* from host-associated environments around the world. These studies fall into two broad categories: global studies of the *E. coli* species through the analysis of fully sequenced genomes, and targeted studies of particular pathogen sub-types through the acquisition hundreds of draft genome sequences of clinical isolates. Both types lead to insights into the genus of *Escherichia*, however, they do not assess naturally occurring, non-host-associated populations in a systematic, in-depth manner. Thus, questions arise as to the extent of habitats for *Escherichia* strains and the extent to which there are non-host-associated reservoirs that provide opportunity for genetic exchange among diverse strains in the genus. We have a begun to perform a deep examination of *Escherichia* isolates derived from a non-host-associated environment - a watershed. The origin of *Escherichia* in watersheds include point sources associated with sewage treatment, livestock farming, animals and fowl; and non-point sources through sediment runoff from urban and agricultural environments. *Escherichia* is consistently found in aqueous environments, beach sands, and in soil, and the existence of environmental clades of *Escherichia* that fall outside of the traditional *E. coli* group is established. A limited set of the environmental clade genomes exist in public databases, yet thousands of *Escherichia* genomes from clinical, commensal, and host-associated sources are available. We have produced 56 draft genome sequences of *Escherichia* isolates as part of a longitudinal survey of microbial communities in a watershed with high sediment pollution, representing a significant increase of genomic information from non-clinical sources. We have placed each of these isolates in context with sequenced isolates using core-genome phylogenetic approaches, revealing that all of the isolates routinely obtained from this watershed are members of the traditional *E. coli* clade and represent the major subtypes. We have assessed potential for virulence and antibiotic resistance of these isolates through computational screens. These data serve as a resource for detailed examination of genome dynamics in *Escherichia* and evaluation of existing molecular identification markers used to monitor water quality in recreational bodies of water.

Role of Detection of Stool CRE Colonization in Indian Scenario -Search and Thou Shall Find

Author Block:

A. Ghafur[1], V. P. R. Lakshmi[1], R. Arjun[1], R. Raj[1], C. Ravi[1], A. Tarigopula[2]; [1]apollo speciality Hosp.,, Chennai, India, [2]apollo Hosp.s, Chennai, India

Abstract Body:

Background: Increasing prevalence of Carbapenem Resistant *Enterobacteriacea*(CRE) is a global and regional challenge. Stool screening to identify carriers of these bacteria will help augment contact isolation precautions and in selecting empirical antibiotic regimen when these patients develop sepsis. Aim of our study was to screen rectal swabs of oncology patients undergoing Bone marrow transplant, to identify CRE colonizers and to explore incidence of subsequent gram-negative bacteremia in these patients.**Methods:** We did retrospective analysis of oncology patients who had rectal swab screening for CRE over the last 6 months (July -Dec 2015). Xpert® Carba-R test was used to screen rectal swabs for the rapid detection and differentiation of the *bla*KPC, *bla*NDM, *bla*VIM, *bla*OXA-48, and *bla*IMP. Case records of these patients were analysed to identify *Enterobacteriaceae* blood stream isolates, subsequent to the rectal screening. **Results:**Stool screening was done in 43 patients. Carba R PCR was positive in 22. (NDM 15, VIM2, NDM+OXA 48 +KPC -1,NDM+VIM-2,NDM+OXA 48-2]. Of the 43 patients, 8 had blood culture positivity for *Enterobacteriaceae*, subsequent to the stool screening study.(4 carba sensitive and 4 resistant). Out of the 22 CRE colonized patients, 4 had CSE(carbapenem sensitive *Enterobacteriaceae*) infection and 3 had CRE. Of the 21 stool Carba R negative patients, only 1 patient had CRE blood stream infection. **Conclusions:** Stool/rectal swab screening for CRE colonisers, will help strengthen infection control measures. This may also guide clinicians in selecting the empirical antibiotic.

The Use of Biorad'S ßCarba Assay in Conjunction with Cepheid'S Xpert Carba-R to Confirm Suspect Carbapenemase-Producing *Enterobacteriaceae* (CPE)

Author Block:

B. M. Willey[1], X. Trimi[1], P. Rahman[1], D. N. Grohn[1], D. Boyd[2], G. Ricci[3], O. Leung[1], S. Dhunna[1], P. Lo[1], T. Mazzulli[4], **S. M. Poutanen**[4]; [1]Mount Sinai Hosp., Toronto, ON, Canada, [2]Natl. Microbiol. Lab., Winnipeg, MB, Canada, [3]William Osler Hlth.System, Brampton, ON, Canada, [4]Univ. Hlth.Network, Mount Sinai Hosp., Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background: Timely detection and confirmatory testing of CPE is important. Using a diverse collection of retrospective isolates, we verified Bio-Rad's ßCARBA assay, a rapid CPE assay based on colour changes reflecting hydrolysis of a chromogenic carbapenem in conjunction with Xpert CARBA-R assay, a research-use-only (RUO) PCR test that claims to detect IMP1, KPC, NDM, OXA48-like and VIM CPE genes.**Methods:** 259 species-diverse isolates, highly-characterized by PCR/sequencing, were used to evaluate the ßCARBA assay comprising 221 CPE (108 class A: 99 KPC, 4 SME, 2 IMI-1, 2 GES, 1 NMC-A; 80 class B: 73 NDM, 6 VIM, 1 IMP7; 26 class D; OXA48; OXA181, OXA232, OXA244; 7 class B+D: NDM+OXA181, NDM+OXA232) and 38 non-CPE (derepressed/ plasmid-mediated ampC, ESBL, ompC/ompF-mutants, ompK35/ompK36-mutants, cphA, OXA252). All 335 ßCARBA tests were inoculated with 1µL-loopful of growth from around ERT and incubated at 37ºC. Each tube was read at 30min independently by 5 blinded readers for colour-changes from yellow (negative) to orange, red or purple (positive). Consensus reads were analyzed. 228 of the above isolates (194 CPE; 34 non- CPE) were tested by the Xpert CARBA-R assay following manufacturer's instructions using isolates instead of specimens.**Results:** Overall, ßCARBA was 98.2% sensitive (95%CI: 95.8-99.3) and 100% specific (95%CI: 92.2-100) detecting 274/279 CPE in 335 tests. Detection included 100% of OXA48-like CPE (CSBA: 33/33; MHA: 21/21). False-negatives included 1/1 NMC *Enterobacter cloacae* and 1/2 GES *Klebsiella oxytoca*. The CARBA-R assay detected all KPC, NDM, VIM, and OXA48-like genes (13/13 OXA48, 1/1 OXA244, 9/9 OXA181, and 5/5 OXA232). Not surprisingly, CARBA-R was negative for SME and NMC CPE genes not claimed by the test.**Conclusions:** ßCARBA is a rapid low-complexity assay that detects CPE with high sensitivity and specificity with results in 30min using 1µL-loopful of organism. The CARBA-R RUO assay was simple to perform and provided confirmatory results within 1h for the claimed CPE genes KPC, NDM, VIM and OXA48 for which it was 100% sensitive.

The Importance of Inanimate Surfaces for the Transmission of Carbapenemase Producing *Klebsiella pneumoniae* (Cpkp) in a Tertiary Care Hospital in Izmir,Turkey

Author Block:

Z. Gulay, S. Alpcavus, A. Sari, 35340, V. Oguz, M. Bicmen; Dokuz Eylul Sch. Of Med., Izmir, Turkey

Abstract Body:

Background: Background: The prevalance of CPKp at the 9 Eylul University Hospital, increased from nil to 33.5% between 2007 and December 2015. This was mostly due to OXA-48 producers in years 2007-2014 but this situation has been changed after NDM- producing Kp was introduced in the hospital in May 2014 and most (95 %)of the carbapenem resistance is now due to this carbapenemase. Although cross transmission is usually via contaminated hands, inanimate surfaces are also implicated as potential sources. Aim: To investigate the contamination of inanimate surfaces by CPKp **Methods:** Carbapenemases produced by carbapenem resistant K.pneumoniae and their PFGE patterns are routinely investigated. Enzyme types are determined by PCR. Enviromental cultures from inanimate surfaces are performed during an outbreak or whenever the prevalance of CPKp increases in a certain hospital unit. Swabs are directly plated to selective EMB agar and also placed in enrichment broths and subcultured after overnight incubation. Species identification by Vitek 2.0 and carbapenem disk diffusion is performed from all gram negative isolates which is followed by PCR for carbapenemases and PFGE analysis.**Results:** During May 2014- December 2015, 269 enviromental sampling were done from patient rooms such as monitors, desks, ventilation units, bed rails and also from the nurse stations, dressing carts in surgical units, medication trays and the items on these mobile units. A total of 23 CPKp (21 NDM producer; 2 OXA-48 producer) was identified. These were recovered not only from the immediate patient enviroment but from common places such as medication closets, surgical carts and surgical bands. Cultures taken from the Emergency Department, Medical ICU, Surgical departments such as neurosurgery, cardovascular surgery and orthopaedics and Haemotology department were positive for NDM- Kp. The PFGE patterns were identical to the patients' hospitalized in that department almost everytime but in two occasions (emergency and haemotology units) . These two shared the most common pattern (A1a)found in the surgical units and this situation was linked to the cardiovascular surgeons who performed central line catheterization.**Conclusions:** This study shows the dissemination of NDM producing Kp in the hospital enviroment.

Antimicrobial Susceptibility and Resistomes of Carbapenem Resistant Enterobacteriaceae

Author Block:

W. C. Rutter[1], G. C. Lee[2], D. S. Burgess[1]; [1]Univ. of Kentucky, Lexington, KY, [2]Univ. of Texas Hlth.Sci. Ctr., San Antonio, TX

Abstract Body:

Background: Carbapenem resistant Enterobacteriaceae (CRE) is increasingly becoming a threat for human health. This pilot investigation sought to characterize the resistance patterns of CRE and to identify genotypic resistance mechanisms to predict resistant phenotypes.**Methods:** CRE isolates were obtained from the University of Kentucky Medical Center clinical microbiology laboratory. MICs were obtained via Phoenix II ® and E-test methods. Whole genome sequencing (WGS) was performed on 8 isolates. Multi-locus sequence type (MLST) was determined from WGS data using the *K. pneumoniae* and *E. cloacae* MLST databases. The resistome was assembled by identifying antimicrobial resistance determinants related to the phenotypically derived antibiogram.**Results:** Eighty-eight CRE isolates were obtained. *Klebsiella* (47%) and *Enterobacter* (41%) species were most common. The most active β-lactam agent was meropenem, with 30% of isolates demonstrating susceptible MICs. No isolate was susceptible to piperacillin-tazobactam, while 20% retained susceptible MICs for cefepime. Amikacin was active against 91% of isolates. Eight isolates (3 *K. pneumoniae,* 4 *E. cloacae*, and 1 *C. amalonaticus*) were selected for WGS. The *K. pneumoniae* isolates were all ST-258. One *E. cloacae isolate* was ST-484; 3 were unknown. All isolates harbored multiple genes encoding for β-lactamase genes (range 4 to 10). The most prevalent β-lactamase identified was *bla*OXA-9 (7 isolates). All *K. pneumoniae* isolates harbored *bla*KPC-3. Among *E. cloacae* isolates, 2 harbored *bla*VIM-2 and 3 harbored *bla*KPC-2. Notably, the concordance of amikacin-resistance conferring genes with susceptibility data were poorly predictive. The majority of amikacin susceptible isolates (88%) possessed genes associated with conferring aminoglycoside resistance, suggesting that expression analysis may be required. The aac(6′)-Ib-cr cassette that mediates resistance to both aminoglycosides and fluoroquinolones was identified in all 8 isolates.**Conclusions:** Despite carbapenemase production, isolates may display phenotypic susceptibility to meropenem and other β-lactams. Amikacin remains a viable option in many of these organisms. This pilot study demonstrates the potential utility of WGS to define the diversity and distribution of resistance mechanisms among CRE.

Factors Responsible for Colistin Resistance in *Klebsiella pneumoniae*

Author Block:

F. Can[1], E. Nurtop[1], N. Atac[1], S. Menekse[2], N. Lack[1], O. Kurt Azap[3], S. Simsek Yavuz[4], F. Yoruk[5], S. Karahan[1], T. Demir[1], D. Karaaslan[1], A. Azap[5], O. Ergonul[1]; [1]Koc Univ., Istanbul, Turkey, [2]Kosuyolu Hosp., Istanbul, Turkey, [3]Baskent Univ., Ankara, Turkey, [4]Istanbul Univ., Istanbul, Turkey, [5]Ankara Univ., Ankara, Turkey

Abstract Body:

Background: Alterations in *mgrb*, overexpression of *phoQ,pmrK*, and *pmrCAB*, and *mcr-1* plasmid are molecular mechanisms of colistin resistance (CR). We aimed to describe the factors contributing the CR. **Methods:** A total of 70 patients infected with CR K.pneumoniae were included. Genotyping and MLST were performed, carbapenemase type was detected. The overexpression of *phoQ*, *pmrK*, and *pmrCAB* were tested. Alterations in *mgrB* and presence of *mcr-1* were explored. **Results:** The mean age of 70 patients was 57±19 and 39% of patients were female, 80% of the patients stayed in ICU. Bacteremia was found in 28% of the patients. The mortality rate was 65%. The colistin MIC's was between 3-256 mg/l. Carbapenemase production was detected in 87% of the isolates. Rep-PCR and MLST revealed 3 large clones belonging to ST101. Intact *mgrB* gene was found in 25(36%) isolates, altered mgrB gene by IS or point mutations was detected in the 34 (49%) and 3 (4%) of the isolates, respectively. The overexpression of *pmrCAB* was shown in 4 of the isolates with intact mgrB. All of the isolates were found to be negative for *mcr-1*. Colistin was used in 40 (56%) patients and the mean duration of therapy was 17±18 days. Colistin use and length of therapy were found to be similar in isolates with intact and altered *mgrB* ($p>0.05$). **Conclusions:** Isolates with high numbers of intact *mgrB* and lack of *mcr-1* suggested that there might be unknown mechanisms that contribute to the colistin resistance. Alteration of *mgrB* was not associated with exposure to colistin.

Abstract Body:

Background: to characterize the spread of CPKP in a tertiary level hospital using ongoing active surveillance with rectal swab (SRS) cultures and analyze the presence of CPKP in the clinical samples (CS) as well as the evolution of Co-sensitive (CoS) to Co-resistant strains (CoR).**Methods:** This study was performed from Jan 1, 2012 to Dec 31 2015. In 2012, an active monitoring was conducted in the Intensive Care Dept (IC); in autumn 2013 it was extended to the Surgery Dept (SurD), and since mid-2014 to the Medical Dept (MedD). Only the first strain from each patient (pt) was included. KPC, OXA-48, VIM and NDM were detected by a validated in-house PCR and multilocus sequence typing (MLST) was used.**Results:** Among 27324 pts 714 consecutive non-replicated strains of CPKP were collected: 149 strains in 2012 (39 [26.2%] from SRS), 133 in 2013 (70 [52.6%] from SRS), 214 in 2014 (164 [76.6%] from SRS) and 218 in 2015 (142 [65,1%] from SRS). The percentage of SRS+ increased from 2012 to 2015 (chi square for trend $p<0.0001$, Figure 1). CoR were 10.7%, 25.5%, 21.9% and 15.1% ($p=0.003$) and CoR isolated from SRS were higher in 2013, 2014 and 2015 compared with 2012 (chi square for trend $p=0.03$). Among pts with a CoS strain and with a follow-up available, 12 in 2012, 18 in 2013, 20 in 2014 and 20 in 2015 switched to a CoR. ST-258, ST-512 and ST-745 were the more prevalent types.**Conclusions:** This 4-year study highlights the clinical relevance of antimicrobial resistance as well as the drug-selection pressure of colistin use. The active surveillance increased the level of CPKP isolated by SRS but the results reported in 2015 suggest the need to maintain a high attention.

Figure 1. Carbapenemase producing Klebsiella pneumoniae strains isolated from surveillance rectal swabs and from clinical samples in 2012, 2013, 2014 and 2015
IC: intensive care. CS: clinical samples. SRS: surveillance rectal swabs

Epidemiology, Clinical Characteristics & Outcomes of Carbapenemase-Producing *Enterobacteriaceae* (Cpe) Infections in a Carbapenemase-Diverse Setting

Author Block:

J. Teo[1], C. Ng[2], **Y. Cai**[1], W. Lee[1], T-P. Lim[1], T-H. Koh[1], T-T. Tan[1], A-L. Kwa[1]; [1]Singapore Gen. Hosp., SG, Singapore, [2]Natl. Univ. of Singapore, SG, Singapore

Abstract Body:

Background: CPE infections are a major global concern. Selecting an optimal therapy for these infections is a challenge due to the diversity of CPE infections. This study described the clinical characteristics, treatment & outcomes of CPE infections in Singapore. **Methods:** A retrospective cohort study of adult inpatients with clinically significant CPE infections, which had reduced susceptibility to ≥1 carbapenem, was conducted between Jan 2013 - June 2015 in a large Singapore tertiary hospital. Carbapenemase production was confirmed with PCR. MIC was assessed using CLSI broth dilution. **Results:** 80 cases (47 KPC, 7 $OXA_{48\text{-}like}$, 22 NDM, 1 IMP, 3 co-producers) were included. CPE were isolated from blood (30%), urine (25%), respiratory (24%), abdominal (18%) & wound (16%) cultures. Main CPE implicated were *Klebsiella spp.* (48%), *Enterobacter spp.* (20%), *E. coli* (15%). 21% were extensively drug-resistant (XDR). CPE was most susceptible to tigecycline (93%), polymyxin B (88%), amikacin (73%) & levofloxacin (45%). 94% had carbapenem MICs of ≥ 8 mg/L. Median (range) patient age was 66 (18 - 89) years [55% male, 50% medical patients]. Most cases had previous hospitalizations (88%) or invasive devices/procedures (85%). The median Charlson & SAPS scores were 4 (0 - 10) & 36 (12 - 69). 70 cases received treatment (39% monotherapy, 61% combination). The most common combinations were carbapenems with polymyxin B &/or tigecycline (30%), or with aminoglycosides (14%). The 30-day in-hospital all-cause mortality rate was 30%. The median time to death was 14 (1 - 152) days. Non-survivors were older ($p<0.05$), while other clinical characteristics were similar between groups, including carbapenemase type & culture source. Neither combination use, therapy type (e.g. carbapenem-based regimens) nor XDR status was associated with mortality. Mortality rates were similar in patients receiving monotherapy & combination (31% vs 29%). However, only 1/5 (20%) patients receiving therapy guided by *in vitro* combination test died. **Conclusions:** CPE infections were diverse & treated with varied non-standardized antibiotic combinations. There was no single therapy which was associated with better outcome. Combination testing-guided therapy may be considered.

A Risk Factor Study for Carbapenem Resistant *Klebsiella pneumoniae* Bloodstream Infection in an Endemic Area

Author Block:

G. Weston, E. Bellin, B. Ostrowsky; Montefiore Med. Ctr., Albert Einstein Coll. of Med., Bronx, NY

Abstract Body:

Background: Carbapenem resistant *Klebsiella pneumoniae* (CRKP) is an emerging pathogen that is endemic in New York City. This study sought to describe factors associated with CRKP bloodstream infection.**Methods:** A case control study design included patients at three hospitals in Bronx, NY. We identified 187 case patients that had a first episode of CRKP bloodstream infection between January 1, 2009 and April 30, 2014. Patients who had a blood culture drawn that did not grow CRKP and had antibiotics started within 48 hours of the blood culture were eligible for selection as control patients. We randomly selected 567 control patients. Data on comorbidities, antibiotic use, prior cultures, and other potential risk factors were electronically abstracted from the medical record using a local tool called Clinical Looking Glass. A multivariate logistic regression model for the outcome of CRKP bloodstream infection was built using a backwards stepwise process.**Results:** The patients had a median age of 65 years (IQR 54, 78). A total of 276 (37%) patients had been admitted from a skilled nursing facility (SNF). The variables in the logistic regression model for CRKP bloodstream infection are shown in the table below. A culture with a carbapenem resistant enterobacteriaceae (CRE) in the prior 6 months and admission from a SNF were most strongly associated with CRKP bloodstream infection. There was a significant interaction between admission from a SNF and having a central line during the 30 days before the blood culture (p= 0.049).**Conclusions:** A prior culture with a CRE organism was strongly associated with CRKP bloodstream infection. Admission from a SNF may alter the association of risk factors with multi drug resistant infections.

Multivariate Associations with CRKP Bloodstream Infection

Variable	Odds Ratio (95% CI)	P-Value
Culture with CRE in Prior 6 Months	7.7 (4.2, 14)	<0.001
Admission from SNF (No Central Line)	6.9 (3.8, 12)	<0.001
Admission from SNF (Central Line)	3.0 (1.7, 5.4)	<0.001
Central Line in Prior 30 Days (Not from SNF)	3.0 (1.5, 6.0)	0.001
Central Line in Prior 30 Days (From SNF)	1.3 (0.74, 2.4)	0.34
Antibiotic Received in Prior 30 Days	1.8 (1.1, 3.0)	0.02

Mechanical Ventilation in Prior 30 Days	1.8 (1.1, 2.9)	0.01
SNF*Central Line Interaction Term	-	0.049

Intra-Abdominal Infections (Iai) Caused by Carbapenem-Resistant Enterobacteriaceae (Cre): Clinical and Microbiological Characteristics & Outcomes

Author Block:

Y. Chen, **Y. Cai**, L. Loo, J. Teo, W. Lee, T-P. Lim, T. Koh, T-T. Tan, A-L. Kwa; Singapore Gen. Hosp., Singapore, Singapore

Abstract Body:

Background: Infections caused by CRE pose a major challenge. While several studies have described the characteristics of CRE infections, studies of specific infection types are limited. The objective of this study is to describe the clinical characteristics & outcomes of patients with CRE IAI.**Methods:**A retrospective cohort study was conducted in a large tertiary Singapore hospital for all inpatients with CRE IAIs (defined as resistant to at least 1 carbapenem) from January 2013 - June 2015. Patient demographics, clinical & microbiological data, & antibiotic (abx) use data were collected. The outcome measured was death from date of 1st positive culture to 30 days from end of CRE IAI treatment. Characteristics of survivor (SV) and non-survivor (NSV) subgroups were compared.**Results:**A total of 41 patients were included. The most common CRE IAI was hepatobilliary infection (59%). 24 patients (59%) had concurrent bacteremia. *K. pneumoniae* was most common (42%), followed by *E. coli* (39%). 88% were resistant to all carbapenems (meropenem MIC_{50}: 8mg/L, MIC_{90}: >=32mg/L); however, most were susceptible to polymyxin B (93%) & tigecycline (98%). Half (46%) of empirical regimens were inadequate. Post-antibiogram, almost half of the patients (42%) were prescribed abx combinations - 13 (32%) received 2-abx combination; 4 (10%) received combinations with ≥3 abx. The most common combinations were polymyxin B-based (24%). 10 (24%) patients had adequate source control. Overall, 19 patients (46%) died from CRE-IAI within 30 days treatment. Clinical response and microbiological clearance was documented in 22 (54%) & 6 (15%) patients respectively. Comparing the SV & NSV subgroups, median SOFA score was higher in the NSV subgroup [8 (5 - 13) in SV, 4 (2 - 4) in NSV, $p < 0.001$]. The proportion of patients with adequate source control is smaller in the NSV subgroup (24% in SV, 0% in NSV, $p < 0.001$). Post-antibiogram use of polymyxin B was higher in the non-survivor subgroups (53% in SV, 17% in NSV, $p = 0.017$), reflecting physicians' inclination for polymyxin B as a last-resort option in mainly in the critically-ill.**Conclusions:**CRE IAIs are associated with high mortality. Other than optimizing antibiotic choice & doses, adequate source control is a key modifiable area in improving patient survival in CRE IAIs.

Publishing Title:

Impact of Infectious Disease Consultation in Carbapenem-Resistant *Klebsiella pneumoniae* (Crkp) Infections

Author Block:

A. Jain, T. Bias; Drexel Univ. Coll. of Med., Philadelphia, PA

Abstract Body:

Background: Carbapenem-Resistant *Klebsiella pneumoniae* (CRKP) infections remain a serious public health problem given its unfavorable impact on mortality and shortage of treatment options. Infectious Disease (ID) consultation has been shown to increase adherence to evidence based treatment for select infections with implications for improved quality measures, reduced in hospital mortality and earlier discharge. Our study aimed to assess the impact of ID consultation on the management and outcomes of patients with documented CRKP infections. **Methods:** A retrospective, observational study was conducted to evaluate adult patients (age ≥ 18 years) who had a documented CRKP infection between January 2009 and September 2014. Demographics and disease specific information were collected. Patients were stratified into 3 cohorts: no ID consultation (NIDC), Early ID consultation (EIDC) and Late ID consultation (LIDC). Primary outcomes included 30-day and infection-related mortality. Secondary outcomes included microbiological cure, overall length of stay, and intensive care unit length of stay. **Results:** One hundred and four patients met criteria for inclusion; 9 in the NIDC group, 59 in the EIDC and 38 in the LIDC group. There was no statistically significant difference in 30 day all-cause mortality (19% vs. 44% vs. 33%, p= 0.122) across all groups, however a difference was observed in infection related mortality (13% vs. 41% vs. 33%, p = 0.025). In patients with Charlson Comorbidity Index (CCI) scores greater than 5, infection related mortality was still higher in the EIDC group in comparison to LIDC and NIDC groups respectively (50% vs. 13% vs 40%), emphasizing the high baseline severity of illness. Source of infection was a confounder in respect to mortality endpoints as all indications were pooled together. **Conclusions:** Interestingly ID consultation did not show improvement in mortality endpoints. Given the rise in multidrug resistance and lack of rapid diagnostic tests, ID consultation is still imperative for selection of antimicrobials, infection control measures, and adherence to guidelines.

Efficacy of Nebulized Colistin in Treatment of Patient with Nosocomial Respiratory Infections from Multidrug-Resistant Gram Negative Organisms

Author Block:

C. Quarshie, V. Sundareshan, A. Botchway; Southern Illinois Univ Sch., Springfield, IL

Abstract Body:

Background: Nebulized colistin (Polymyxin E), a bactericidal antibiotic, is used in the treatment of infections with a wide range of resistant aerobic gram negative (GN) organisms including Pseudomonas aeruginosa (P. aeruginosa), and Acinetobacter baumannii (A. baumanii). This study aims to evaluate the patterns and efficacy of use of nebulized colistin either alone or in combination with other antimicrobial agents in the treatment of respiratory infections in patients with resistant P. aeruginosa, and A. baumannii.**Methods:** We conducted a retrospective chart review of patients greater than 18 years of age diagnosed with healthcare associated pneumonia (HCAP), or ventilator associated pneumonia (VAP) secondary to MDR P.aeruginosa or A.baumanii admitted from January 2009 to January 2014 at Memorial Medical Center, Springfield, IL. The respiratory infection was diagnosed based on clinical signs, leukocytosis, and chest x ray showing infiltrate or consolidation, along with a microbiological identification of multi-drug resistant P.aeruginosa, and A. baumannii. The clinical cure rate was defined as complete resolution of all signs and symptoms of pneumonia, with improvement of chest x-ray by the 7 days. Logistic regression was used to analyze the results.**Results:** A total of 32 charts were reviewed from January 2009 to January 2014. There were 19 patients with infections with A. baumanii and there were 12 patient with P. aeruginosa who received nebulized colistin. The clinical cure rate for the P. aeruginosa was 50% and 50% for A.baumanii. The clinical cure rate of P. aeruginosa was not different from A. baumanii, OR=0.82 (CI 0.07-9.91), p = 0.88 with nebulized colistin used alone or in combination with other antibiotics. 5 patients with infection from P. aeruginosa without resolution on chest Xray and 6 patients with A. baumanii that did not show any changes in the chest Xray. There is no baseline resistance noted for P. aeruginosa and A. baumanii for colistin in our hospital. **Conclusions:** The cure rate with use of nebulized colistin was similar with P. aeruginosa and A. baumaniipatients indicating that it is equally difficult to treat infections with both organisms and when used for treatment of respiratory infections, patients should be closely monitored for clinical progress.

Incidence and Antimicrobial Resistance of Eskape Organisms in a Second Level Care Hospital in Mexico

Author Block:

M. D. Alcántar-Curiel[1], E. Toledano-Tableros[2], S. Giono-Cerezo[2], M. Jarillo-Quijada[1], J. Fernández-Vázquez[1], C. Gayosso-Vázquez[1], M. López Alvarez[3], J. Santos-Preciado[1]; [1]Univ. Natl. Autónoma de México, México D.F., Mexico, [2]Escuela Natl. de Ciencias Biológicas, IPN, México D.F., Mexico, [3]Hosp. Regional Gen. Ignacio Zaragoza, México D.F., Mexico

Abstract Body:

Background: The ESKAPE pathogens (*Enterococcus faecium, Staphylococcus aureus, Klebsiella pneumoniae-[Kpn], Acinetobacter baumannii-[Aba], Pseudomonas aeruginosa-[Psa], Enterobacter* species-*[Eclo]*) are responsible for a substantial percentage of nosocomial infections and represent the vast majority of isolates resistant to antimicrobial agents. The aim of this study was to assess the incidence and epidemiology of ESKAPE pathogens in patients who acquired a nosocomial infection at a second level care hospital in Mexico City. **Methods:** ESKAPE isolates were collected from February-July/2015. Carbapenem susceptibility was determined by disk diffusion method, using CLSI/2015 interpretative criteria. Metallo-β-lactamases-(MBL) phenotype was confirmed by modified-Hodge test and PCR assay. The ESBL and AmpC production was determined by double disc test. Clonality among *Psa* and *Aba* isolates was determined by PFGE. **Results:** Of the 1,480 specimens cultured from patients with suspected infections, only 272 isolates (18%) were positive; of these, 132 (48.5 %) were ESKAPE species isolated mainly from severely ill patients: *Psa* (32%) followed by *Aba* (28%) were the most frequent isolates. These bacteria were most frequently isolated from blood (51%) and surgical wounds (20%). Carbapenem resistance was 90% *Aba*, 87% *Psa*, 67% *Eclo* and 23% for *Kpn*. The carbapenem resistance was associated with MBL production in 84% *Aba*, 60% *Psa*, and 67% for *Kpn* and *Eclo*, but not with KPC or NDM-1 type. The cephalosporin resistance was associated with ESBL production in 85% *Kpn* and 17% *Eclo*, and with AmpC production in 53% *Psa* and 7% *Aba*. As for clonality, *Psa* showed variability and *Aba* showed dissemination of one clone. **Conclusions:** These results are worrisome because the emergence of the ESKAPE group, traditionally problematic in tertiary referral hospitals, reflects a growing problem in a second level hospital. This is undoubtedly due to the widespread use of cephalosporin and carbapenems, generally the last drugs choice for the treatment of multidrug-resistant isolates in nosocomial infections.

Phenotypic and Molecular Characterization of Beta-Lactam Resistance in Gram-Negative Bacilli from Pediatric Urology Patients

Author Block:

E. Powell, J. Schaffzin, M. Beckman, J. Muldoon, D. Haslam, **J. Mortensen**; Cincinnati Children's Hosp., Cincinnati, OH

Abstract Body:

Background: Antibiotic Stewardship Programs (ASPs) are a key partner of clinical microbiology laboratories and patient services, particularly those services that care for patients with long-term antibiotic exposure. In an effort to better understand patterns of antibiotic resistance in one such group, this study sought to determine the prevalence of beta-lactam resistance mechanisms in Gram-negative bacilli from pediatric urology patients.**Methods:** All Gram-negative bacilli isolated from the urine cultures of patients seen by the Urology service during a one-week period were identified by MALDI-ToF and antimicrobial susceptibilities were determined using VITEK2 GN-69 and XN-06 cards. DNA was isolated using the NucliSENS easyMAG extractor and the presence of various beta-lactamases—including penicillinases, AmpCs, extended spectrum beta-lactamases (ESBL), and carbapenemases—was determined using the Check-points system CT 103XL Check-MDR panel.**Results:** 39 Gram-negative bacilli were isolated: *Eschericia coli* (25), *Klebsiella pneumoniae* (3), *Pseudomonas aeruginosa* (3), *Proteus mirabilis* (3), *Enterobacter* species (2), *Serratia liquifacens* (1), *Pantoea* species (1), and *Klebsiella oxytoca* (1). The genes coding for penicillinases were detected in 14 isolates: 2 *K. pneumoniae* isolates with wild-type SHV, 11 *E. coli* isolates with wild-type TEM, and 1 *K. pneumoniae* isolate with both wild-type SHV and wild-type TEM. ACT/MIR AmpC genes were detected in both *Enterobacter* species isolates. An ESBL gene was detected in 2 *E. coli* and 1 *K. pneumoniae* and was identified as CTX-M-1, group 15-like in all three isolates. No carbapenemase genes were detected. MIC results were consistent with these genotypic findings.**Conclusion:** During this one-week period ESBLs were relatively rare (7.69%) in Gram-negative bacilli from pediatric urology patients. As part of our ASP support of clinical care, the association between antibiotic use and beta-lactamase gene prevalence will be monitored. Ongoing collaboration between ASP, the Clinical Microbiology Laboratory, and patient services will be essential to monitor for antibiotic resistance and guide appropriate and effective therapy for vulnerable patients.

Complete Sequence of an Inchi2 Plasmid Carrying Two Copies Of *Bla*$_{\text{ctx-M-2}}$ From *Escherichia coli* Sequence Type 410 Isolate

Author Block:

Q. Guo[1], C. l. McElheny[2], M. Wang[1], Y. Doi[2]; [1]Huashan Hosp., Fudan Univ., Shanghai, China, [2]Div. of Infectious Diseases, Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: CTX-M-2 is one of the common groups of extended-spectrum-β-lactamases (ESBL) in the world especially in Japan, Southern Europe and South America. The CTX-M-2-prodcing plasmid pYD786-1 was identified in an *Escherichia coli* ST410 strain isolated from the urine of an inpatient at a U.S. hospital. **Methods:** pYD786-1 was sequenced on a PacBio RSII sequencing instrument. Assembly and annotation was conducted and comparison with previously sequenced genomes. **Results:** pYD786-1 is a 227-kb IncHI2 plasmid. Its backbone is composed of replication, partition, conjugation regions and toxin-antitoxin systems as discovered in IncHI2 plasmids of *Salmonella enterica* from Hong Kong and Canada. There is also a multidrug resistance mosaic region (MRR) generated by several transposition and recombination events. The MRR is composed of a Tn*21*-derivative transposon, followed by IS*Ecp1* transposition unit and Tn*5393*::IS*1133* element. Insertion of IS*1R* truncated the *tnpR* of Tn*21* and IS*Ecp1*. Tn*21* here apparently underwent multiple insertions involving In*2*, IS*1326* and IS*1353*, thus creating a nested complex structure. Furthermore, the In*2*-derivative integron captured an IS*CR1*-*bla*$_{\text{CTX-M-2}}$ module embedded between two 3' conserved segments (3′-CS). Uniquely, however, the 3′-CS-*bla*$_{\text{CTX-M-2}}$-IS*CR1*-3′-CS module is duplicated, generating two copies of *bla*$_{\text{CTX-M-2}}$ in tandem thus forming an unusual complex class 1 integron. **Conclusions:** An IncHI2 plasmid carrying two copies of *bla*$_{\text{CTX-M-2}}$ was identified, which had undergone multiple transposition and recombination events, forming a multidrug resistance plasmid.

Distribution of β-Lactamases among Gram-Negative Pathogens from the Middle East and Turkey

Author Block:

K. Kazmierczak, S. Lob, R. Badal, D. Sahm; IHMA, Inc., Schaumburg, IL

Abstract Body:

Background: The Study for Monitoring Antimicrobial Resistance Trends (SMART) tracks *in vitro* activity of antimicrobials used to treat intra-abdominal and urinary tract infections. In this analysis, we identified β-lactamases (BL) carried by *Enterobacteriaceae* (*Ebac*) collected from patients in 5 countries in the Middle East and Turkey from 2010-2014. **Methods:** Eighteen sites each collected up to 150 consecutive, non-duplicate Gram-negative isolates per study year. Susceptibility and extended-spectrum β-lactamase (ESBL) phenotypes were determined by broth microdilution. All ertapenem (ETP) non-susceptible (NS) isolates and a randomly selected ≥50% of ESBL-phenotype positive (ESBLp+) *Escherichia coli*, *Klebsiella pneumoniae*, *K. oxytoca*, and *Proteus mirabilis* collected from each country were molecularly characterized for genes encoding ESBLs, carbapenemases (Cpases) and AmpC BL.**Results:** 5960 *Ebac* were collected in Israel, Jordan, Lebanon, Saudi Arabia, United Arab Emirates (UAE) and Turkey. The activities of tested β-lactam agents differed among countries, with 91.4% (UAE) to 97.9% (Lebanon) of collected isolates susceptible *in vitro* to ETP and 33.6% (UAE) to 76.0% (Israel) of isolates susceptible to ceftazidime. 1297 isolates (793 *E. coli*, 414 *K. pneumoniae*, 35 *Enterobacter cloacae*, and 55 isolates of 10 other species of *Ebac*) were molecularly characterized. BL types detected and overall percentages of ESBLp+ and ETP-NS isolates are shown by country (Table).

Evolution of the Carbapenem-Resistance in *Acinetobacter baumannii* Isolated in Chilean Hospitals

Author Block:

A. F. Opazo-Capurro, C. Lima, H. Bello-Toledo, M. Dominguez-Yevenes, G. Gonzalez-Rocha; Univ. of Concepcion, Concepcion, Region del Bio-Bio, Chile

Abstract Body:

Background: *A. baumannii* (Aba) is an important nosocomial pathogen, often multidrug- or pandrug-resistant, and responsible for several outbreaks worldwide. Nowadays, is commonly resistant to imipenem and meropenem, which are one of the most important remaining treatment options against this bacillus. In Chile, according to the Chilean Society for Infectious Diseases, the percentage of carbapenem-susceptible Aba isolates was nearly 30% in 2012. Due to a lack of data regarding the mechanisms of carbapenems-resistance in Chilean isolates, the aim of this study was to investigate the genetic determinants associated to this resistance. **Methods:** Seventy-seven strains collected from hospitals in 9 Chilean cities, were analyzed. They were grouped in 3 periods: 1990-99, 2000-09 and 2010-15. The isolates were identified by multiplex-PCR. Susceptibility testing to carbapenems was performed by disk diffusion. The genes encoding OXA-type carbapenemases (OTCs) were detected by multiplex-PCR. The association of *bla*$_{\text{OXA-51-like}}$ with the IS*Aba1* element was identified by standard PCR and sequencing.**Results:** All isolates (26) collected during 1990-99 were susceptible to both carbapenems. They did not harbor any OTCs genes, except for the *bla*$_{\text{OXA-51-like}}$ gene not associated to IS*Aba1*. However, 21 over 30 isolates from the second period were resistant to carbapenems; where 11 carried the *bla*$_{\text{OXA-58-like}}$ gene and 7 harbored the *bla*$_{\text{OXA-23-like}}$ gene. Finally, 21 collected during 2010-15 were resistant to both carbapenems; where 3 harbored the *bla*$_{\text{OXA-58-like}}$ gene, 11 carried the *bla*$_{\text{OXA-23-like}}$ gene and 10 were positive for the IS*Aba1-bla*$_{\text{OXA-51-like}}$ arrangement.**Conclusions:** This study shows the dynamic process of carbapenem-resistance in Aba Chilean isolates, indicating that the first OTC gene acquired was *bla*$_{\text{OXA-58-like}}$. Interestingly, this gene was rapidly replaced during the next years by the *bla*$_{\text{OXA-23-like}}$ gene and by the IS*Aba1-bla*$_{\text{OXA-51-like}}$ association. These mechanisms could confer higher carbapenem-resistance levels than *bla*$_{\text{OXA-58-like}}$, reflecting an alarming situation in the country, especially considering colistin-resistant isolates have already emerged and the potential of every single isolate of becoming resistant due to the overexpression of the intrinsic *bla*$_{\text{OXA-51-like}}$ gene.

Dissemination of Incx3 Type Plasmid Encoding Ndm-5 in *Escherichia coli* from Companion Animals in China

Author Block:

j. sun, r-s. yang, x-p. liao, y-h. liu; South China Agricultural Univ., guangzhou, China

Abstract Body:

Objectives: The emergence and worldwide spread of carbapenemase-producing *Enterobacteriaceae* has become a major public health threat. In the present study, we investigate the dissemination of carbapenemase-producing *Enterobacteriaceae* in companion animals in China.**Methods**: 174 rectal swabs were obtained from healthy or diseased dogs and cats from Harbin (20), Yangzhou (20), Chongqing (67), Wuhan (13), Chengdu (24) and Guangzhou city (30), during the July to November in 2015. Each swabs was isolated from an individual animal were direct streaked on a MacConkey agar plate containing 1 mg/L meropenem without culture. Carbapenem-non-susceptible isolates were screened the carbapenemase genes, including bla_{KPC}, bla_{IMP}, bla_{VIM}, bla_{OXA-48} and bla_{NDM} were screened and sequenced. For carbapenemase genes-positive isolates, antibiotic susceptibilities were assessed and molecular typing was performed using PFGE. Plasmid transfer to *E. coli* recipients was investigated using filter mating experiments. The genetic location of bla_{NDM} was determined by analysis of PFGE profiles of *S1* nuclease-digested genomic DNA and Southern blot hybridization. The genetic context analysis of the bla_{NDM} gene was applied by PCR mapping and primer walking.**Results**: A total of 6 bla_{NDM}-positive *E. coli* were collected from three disparate cities: Yangzhou (1), Chongqing (3), and Guangzhou (2). All isolates belonged to bla_{NDM-5}, which were resistant to carbapenems, cephalosporins, tetracycline, fluoroquinolones, and two isolates among them were also resistant to colistin. Plasmids carrying bla_{NDM-5} were successfully transferred to *E. coli* recipient EC600. *XbaI*-PFGE revealed that only two strains isolates from Guangzhou were the clonal spread. S1-PFGE and Southern blot analysis showed that bla_{NDM-5} gene was located on IncX3-type plasmids with same size ranging from 33.3 to 54.7 kb. PCR mapping and sequencing demonstrated that all isolates contained a common gene environment around bla_{NDM-5} (*IS*Aba125-*IS*5-bla_{NDM-5}-bla_{MBL}-*trpF- dsbC-IS*26).**Conclusions**: We describe the emergence of *E. coli* harboring IncX3 Type Plasmid Encoding NDM-5 from Companion Animals in China. We suggest that isolates producing New Delhi metallo-β-lactamase are currently circulating among companion animals and may act as a reservoir of gene transmission between humans and animals.

The Importance of ST258 and IncFII$_{K2}$ Plasmids among a Global Collection of *Klebsiella pneumoniae* with *bla*$_{KPCs}$

Author Block:

G. Peirano[1], P. Bradford[2], K. Kazmierczak[3], L. Chen[4], B. Kreiswirth[4], **J. Pitout**[1]; [1]Univ. of Calgary, Calgary, AB, Canada, [2]AstraZeneca Pharmaceuticals, Waltham, MA, [3]Intl. Hlth.Management Associates, Schaumburg, IL, [4]Rutgers Univ., Newark, NJ

Abstract Body:

Background: A study was designed to characterize 470 KPC-producing *K. pneumoniae* from a global surveillance study obtained from the urinary tract, skin structures, intra-abdominal, and respiratory tract specimens during the years 2012-14. **Methods:** Multilocus sequence typing was used to define STs and PCR typing was used to determine the presence of *bla*$_{KPCs}$ on IncFII$_{K2}$, IncFII$_{K1}$ and IncI$_2$ types of plasmids. **Results:** The majority of *K. pneumoniae* (58%) belonged to ST258; clade I was associated with *bla*$_{KPC-2}$ on both IncFII$_{K2}$, and IncFII$_{K1}$ plasmids and was present in Argentina, Greece, Romania and USA. ST258 clade II was associated with *bla*$_{KPC-3}$ on IncFII$_{K2}$ plasmids and was present in Italy, Germany, USA, Brazil and Israel. ST11 (18%) was present in Argentina, Brazil, Venezuela, China and Taiwan and was associated with *bla*$_{KPC-2}$ on IncFII$_{K1}$ and IncFII$_{K2}$ plasmids. The remaining *K. pneumoniae* STs (24%) had a global distribution and was associated with both *bla*$_{KPC-2}$ and *bla*$_{KPC-3}$ on IncFII$_{K1}$ plasmids. **Conclusions:** There was a strong affiliation between ST258 and IncFII$_{K2}$ (pKpQIL-like) plasmids and non-ST258 with IncFII$_{K1}$ plasmids among a global collection of *K. pneumoniae* that harbours *bla*$_{KPCs}$. This study highlights the importance of surveillance programs using molecular techniques in providing insight into characteristics and global distribution of STs and their respective plasmids.

Ges Carbapenemases in *Enterobacteriaceae* and *Pseudomonas aeruginosa* in the UK

Author Block:

K. L. Hopkins, J. Findlay, D. Meunier, D. Godoy, J. Turton, R. Hill, N. Woodford; Publ. Hlth.England, London, United Kingdom

Abstract Body:

We sought GES carbapenemases in Enterobacteriaceae and *P. aeruginosa* submitted to the national reference lab with raised carbapenem MICs in the absence of other carbapenemases, and characterised positive isolates to understand their epidemiology.MICs were determined by BSAC agar dilution. *bla*GES PCR amplicons were sequenced to define variants. For GES-positive *P. aeruginosa* isolates, MLST data were inferred from MLVA profiles. For GES-positive Enterobacteriaceae, plasmid DNA was transformed into *E. coli* DH5α and whole genomes of clinical isolates and GES transformants were sequenced. Plasmid contigs were subtracted from the DH5α genome and assembled using SPAdes. WGS data were analysed to determine bacterial identification, MLST, total plasmid *rep* types and resistance gene complements.*bla*GES alleles were found in 76 UK isolates (2 in 2012, 6 in 2013, 14 in 2014, 54 in 2015). GES-carbapenemase positive *P. aeruginosa* (n=42) had GES-5 and were submitted by 7 labs from 21 patients and 2 environmental samples. Two labs accounted for most submissions: NE-1 (n=26) and London-1 (n=10). Markers of GES-5 in *P. aeruginosa* antibiograms were MICs (mg/L) of imipenem (IPM) and meropenem (MEM) >32, IPM-EDTA ≥16, and ceftazidime (CAZ) 8-16. Typing of 34 isolates found all belonged to ST235. Most (33/34) GES-positive Enterobacteriaceae also had GES-5 (23 *K. oxytoca*, 6 *E. cloacae*, 4 *K. pneumoniae*) but 1 *Raoultella terrigena* had GES-24. These were submitted from 6 labs, from 15 patients and 12 wastewater samples; lab London-2 accounted for 18 *K. oxytoca* isolates. β-lactam MICs varied (IPM/MEM 0.5 - >32, IPM-EDTA 0.5 - >16, CAZ 8 - >256) with the underlying carbapenem resistance mechanism wrongly inferred as ESBL and impermeability in some antibiograms. MLST profiles were unique to each lab. *bla*GES-5 was located on IncQ (8.3 - 9kb), IncP-6 (25.4 kb) and untypable (76.4 kb) plasmids.GES-positive isolates are currently limited to a few scattered centres. Whilst a characteristic antibiogram and ST235 aids identification of GES-positive *P. aeruginosa*, the lack of specific antibiogram markers and strain variability makes interpretative reading less reliable for detection of GES in Enterobacteriaceae. GES enzymes are not reliably detected by carbapenemase activity assays or covered by commercial molecular assays, thereby complicating their detection.

Tracking KPC-Producing *Klebsiella pneumoniae* in a Large Healthcare Facility Using Whole Genome Sequencing

Author Block:

F. Onmus-Leone, P. T. Mc Gann, E. Snesrud, R. Maybank, A. C. Ong, R. J. Clifford, M. K. Hinkle, E. P. Lesho; WRAIR, Silver Spring, MD

Abstract Body:

Klebsiella-producing carbapenemase (KPC), encoded by bla_{KPC}, is the most common carbapenemase gene in North America. It confers resistance to all β-lactams, including carbapenems, and had become endemic in some areas of the U.S.A. In this study, we sought to unravel the epidemiology of KPC-producing *Klebsiella pneumoniae* from a large healthcare facility in the eastern U.S.A.Short and long-read whole genome sequencing (WGS) was performed on 31 bla_{KPC} -positive *K. pneumoniae* clinical samples from 17 patients using the Illumina Miseq and PacBio RSII platforms, respectively. The samples were collected between 2009 and 2015 at a 274-bed hospital that serves over 1 million beneficiaries annually.The majority of isolates (54.8%) were cultured from groin and rectal surveillance swabs, followed by urine (29%), tissue (6.4%), blood (2.4%) and respiratory (1.2%) samples. Isolates from the same patients were genetically identical, but no two patients shared the same isolate, indicating that nosocomial transmission was not a factor in the spread of KPC-producing *K. pneumoniae* in the hospital. *In silico* multi-locus sequence type (MLST) revealed six ST's circulating within the community, with ST-258 and ST-340 predominating (12 and 10 isolates respectively). Only bla_{KPC-2} (N=10) and bla_{KPC-3} (N=21) variants were identified; All ST-340 isolates carried bla_{KPC-3}, whereas one-third of ST-258 isolates carried bla_{KPC-2}. Every isolate carried from 1 to 8 plasmids representing the major incompatibility (Inc) groups, including IncA/C2, FIB, FII, H1B, L/M, R, and IncX3. However, bla_{KPC} was harbored on IncF1B or IncFII in 50% of the isolates.Epidemiological data indicates that multiple strains are circulating within the community, but there was no evidence for nosocomial transmission in the healthcare facility. The majority ofisolates belonged to ST-258 and ST-340, two prominent members of the globally distributed clonal complex 11. This diversity was reflected in the plasmids harboring bla_{KPC}, which spanned a wide range of sizes and Inc types.

Increasing B Lactam and Carbapenem Resistance in Mdr Enterobacteriaceae Isolates from Human Health Care Associated Infections in Egyptian Hospitals Between 2000-2011

Author Block:

E. Newire[1], S. F. Ahmed[2], N. Woodford[3], A. P. Roberts[1]; [1]UCL Eastman Dental Inst.. Univ. Coll. London, London, United Kingdom, [2]US. NAMRU-3, Cairo, Egypt, [3]Publ. Hlth.England, London, United Kingdom

Abstract Body:

Co-production of class-D carbapenemase OXA-48 and Extended Spectrum β-Lactamase-(ESBL) CTX-M-15 in *Escherichia coli* and *Klebsiella pneumoniae* confer broad beta-lactam resistance and is increasingly reported. The objectives of this study were to phenotypically and genotypically characterize two groups of Enterobacteriaceae isolates collected from Egypt.One hundred and sixty-nine ESBL producing Enterobacteriaceae from health care associated infections were collected from 10 Egyptian hospitals in two surveillance studies (Group 1: 65 *K. pneumoniae* collected between 2000-2003, and Group 2: 41 *E. coli* and 63 *K. pneumoniae* isolates collected from 2009-2011). ESBLs and carbapenemase production was assessed with double disc-synergy and E-test. $bla_{\text{OXA-48}}$, $bla_{\text{CTX-M-15}}$, and bla_{VIM} genes were identified by PCR and DNA sequencing.Phenotypic tests confirmed all isolates as ESBL producers with co-carriage of the Non-metallo-carbapenamse $bla_{\text{OXA-48}}$ and ESBL $bla_{\text{CTX-M-15}}$ observed in 11% (n=7) of isolates in Group 1 increasing to 92% (n=96) in group 2. Metallo-carbapenamse bla_{VIM} was detected 34% (n=22) in group 1 isolates increasing to 77% (n=80) in group 2. Additionally 8% (n=5) of isolates from group 1 and 24% (n=25) from group 2 also produced MBL. KPC was produced by 8% (n=5) of group 1 isolates increasing to 10% (n=10) in group 2.We have shown in this study that different carbapenem-hydrolysing β lacatamses of three ambler classes are carried and expressed among MDR enterobacteriaecae isolates from Egypt and their prevalence increased from 2000 to 2011.

Detection of Plasmid-borne Ndm-1 Gene in *Enterobacteriaceae* Isolated from In-patients and Out-patients Visiting Selected Health Facilities in Cross River State, Nigeria

Author Block:

A. E. Asuquo, U. I. Ulom, E. O. Ibeneme, S. J. Utsalo; Univ. of Calabar, Calabar, Nigeria

Abstract Body:

Background: *Enterobacteriacae* expressing the carbapenemase NDM-1 gene are emerging worldwide. This plasmid-mediated gene codes for resistance to carbapenems, which are regarded as the last resort for the treatment of multidrug resistant bacterial infections. This study aimed at detecting the presence of NDM-1 gene on plasmids of clinical and community enterobacterial isolates in Calabar, Nigeria. The performance of modified Hodges test (MHT) and re-modified Hodges test (rMHT) in the phenotypic detection of carbapenemase production were compared. **Methods:** A total of 79 *Enterobacteriaceae* were isolated from meropenem-supplemented agar (1µg/mL) inoculated with urine and stool samples of out-patients and in-patients attending selected health facilities. They include *Klebsiella pneumoniae* (32), *Escherichia coli* (25), *Proteus vulgaris* (13), *Proteus mirabilis* (1), *Providencia stuartii* (4) and *Serratia rubidaea* (4). The susceptibility of the isolates to antimicrobial agents was performed by the disc diffusion method. Phenotypic detection of carbapenemase production was determined using MHT and rMHT. Plasmids from isolates were analyzed by PCR using specific primers for NDM-1.**Results:** Of the 79 enterobacterial isolates, 86% (68/79) were resistant to at least one of 10 antibiotics tested and about 40% (27/68) of these were resistant to more than half of the antibiotics tested. The phenotypic test for carbapenemase production revealed that 33% (26/79) and 19% (15/79) of isolates showed correlating positive results and conflicting results respectively for MHT and rMHT. Two *Klebsiella pneumoniae* isolates from two separate urine samples harboured the NDM-1 gene; both isolates were sensitive only to tigecycline and were MHT and rMHT positive. Both patients from whom the urine specimens were obtained had previously visited India for medical treatment.**Conclusion:** To the best of our knowledge, this is the first report of the NDM-1 gene in Nigeria. It further underscores the origin of the gene and its rapid spread. This has grave public health implications for Nigeria as India remains a major medical tourism destination for Nigerians.

Higher Risk of Esbl-producing *Escherichia coli* Infection by the Large-scale Chicken Farming Style in Vietnam

Author Block:

B. T. K. Ngan[1], B. T. M. Huong[1], I. Hirai[2], S. Ueda[2], N. Q. Anh[1], L. D. Tuyen[1], Y. Yamamoto[3]; [1]Natl. Inst. of Nutrition, Hanoi, Viet Nam, [2]Univ. of the Ryukyus, Okinawa, Japan, [3]Osaka Prefectural Inst. of Publ. Hlth., Osaka, Japan

Abstract Body:

Background: CTX-M type of extended-spectrum β-lactamase (ESBL) is dominant antibiotic resistant mechanism of bacteria in nosocomial and community-acquired infections. Large-scale farm (LSF) and medium-scale family farm (MSFF) are two main poultry husbandry styles in Vietnam. In this study, we examined whether there was any difference of ESBL-producing *Escherichia coli* in the two poultry farming styles**Methods:** A total of 149 fecal swabs were collected from 24 human individuals and 38 chickens of one LSF and from 51 human and 36 chickens of 3 MSFF between June, 2013 and June, 2014 in a Vietnamese rural area. One typical *E. coli* isolate of each sample, which had been screened with 1μg/ml of cefotaxime, was subjected to antibiotic resistance test and to molecular characterization. Genetic relatedness was assessed by pulsed-field gel electrophoresis (PFGE). Genotypes of $bla_{\text{CTX-M}}$ was determined by sequencing analysis. Statistical significance was calculated by Student's *t*-test**Results:** Prevalence of ESBL-producing *E. coli* in the LSF human (100%) was significantly higher than one of the MSFF (65%). A significant difference ($p < 0.01$) was obtained in prevalence of ESBL-producing *E. coli* from chicken samples between the two farming styles (79% of the LSF and 42% of the MSFF). In isolates from human samples, $bla_{\text{CTX-M-27}}$ (56.6%) was predominant, whereas majority in isolates from chicken samples was $bla_{\text{CTX-M-14}}$ (46.9%). PFGE results suggested certain clonal distributions in the isolates from the LSF chicken**Conclusions:** Higher prevalence and antibiotics resistance of *E. coli* isolates producing ESBL were observed in both of human and chicken of the LSF. These results indicate relatively higher risk of ESBL-producing bacterial infection in large-scale farming style. Further studies are needed to elucidate transmission and distribution mechanism of ESBL-producing bacteria between chicken and human

Geographic Distribution of Carbapenem-resistant Gram-negative Infections in Adult Patients in US Hospitals

Author Block:

B. Cai[1], R. Echols[1], G. Magee[2], J. Arjona Ferreira[1], M. Ariyasu[3], T. Sawada[3], T. Nagata[3]; [1]Shionogi Inc., Florham Park, NJ, [2]Premier Res. Service, Inc., Charlotte, NC, [3]Shionogi & Co., Ltd., Osaka, Japan

Abstract Body:

Background: Carbapenem-resistant (CR) Gram-negative infections, especially KPC- producing Enterobacteriaceae, have received much attention; however, CR non-fermenters, *A. baumannii* and *P. aeruginosa,* may have a greater clinical impact. In the US, there may be regional differences in the frequency of infections due to each of these CR pathogens that need to be explored. **Methods:** Hospitalized patients with infections due to laboratory-confirmed Gram-negative pathogens from specified infection sites between 2009 and 2013 were identified from electronic health records of Premier Healthcare Database. Based on the total number of infections for each pathogen and infection site (respiratory, blood, urine, other) in each geographic region defined by one of nine US Census Bureau Divisions, the proportion of CR infections was calculated. This study describes the geographic distribution of CR *A. baumannii, P. aeruginosa, K. pneumoniae,* and *E. coli* among adult patients in US hospitals by regions. **Results:** From 2009 to 2013, 13,262 (4.5%) of 292,742 Gram-negative infections were caused by CR pathogens. Of these CR infections, 82.3% were caused by *A. baumannii* and *P. aeruginosa*, while 17.7% were caused by *K. pneumoniae* and *E. coli*. Carbapenem resistance among *A. baumannii* and *P. aeruginosa* was 44.8% and 14.2%, respectively. *P. aeruginosa* accounted for 60.3% of all CR infections while *A. baumannii* accounted for 22%.Differences among nine regions were noted: Middle Atlantic region had the highest proportion of CR infections due to *K. pneumoniae* and *E. coli* (33.1%) whereas four regions (East South Central, Mountain, New England, and West South Central) had less than 10% CR infections due to these two pathogens. Among CR infections in the New England region, 85% were caused by *P. aeruginosa*.Respiratory tract is the most common site of CR infection for *A. baumannii* (40.3%) and *P. aeruginosa* (40.1%) while urine is the most common site of CR infection for *K. pneumoniae* (48.7%) and *E. coli* (57.3%). **Conclusions:** The vast majority of CR infections in the US are caused by non-fermenters *A. baumannii* and *P. aeruginosa.* There was larger variability in CR infections due to *K. pneumoniae* and *E. coli* in different US geographic regions than non-fermenters.

Phenotypic And Multiplex Pcr Detection Of Esbl Resistant Genes In Gram Negative Bacilli Isolated From Calabar, Nigeria

Author Block:

E. O. Ibeneme[1], A-A. O. Eyo[1], E. J. Okoi[2], S. M. Obeten[2], A. E. Asuquo[1], S. J. Utsalo[1]; [1]Univ. of Calabar, Calabar, Nigeria, [2]Dr. Lawrence Henshaw Mem. Specialist Hosp., Calabar, Nigeria

Abstract Body:

Background: The occurrence and spread of plasmid-borne extended-spectrum β-lactamases (ESBLs) among Gram negative bacilli (GNB) is a growing concern worldwide.This study compared phenotypic and multiplex PCR protocols in the detection of ESBL genes carried on plasmids of Gram negative bacilli obtained from chronic cough patients attending a tuberculosis referral hospital in Calabar, Nigeria. **Methods:** A total of 180 GNB were screened for ESBL production using five ESBL indicator antibiotics (cefpodoxime, ceftriaxone, ceftazidime, cefotaxime and aztreonam) and further confirmed using the combined disc test (CDT) and double-disc synergy test (DDST). Plasmids from isolates which were positive after screening for ESBL production, were subjected to multiplex PCR using gene-specific primers to detect the presence of ESBL genes (*bla*$_{\text{TEM}}$, *bla*$_{\text{SHV}}$) and groups of CTX-M-type genes (*bla*$_{\text{CTX-M-1,2,8,9,25}}$).**Results:** Of the 180 isolates, 31% (55/180) were resistant to more than half of the antibiotics tested. A total of 136 (75.6%) isolates were resistant to at least one of the ESBL indicator antibiotics (EIAs) of which 48 (35.3%) were resistant to all five EIAs. The phenotypic methods (CDT and DDST) detected ESBL production in 11 (8.1%) and 46 (33.8%) isolates respectively compared with 87% (118/136) using multiplex PCR. About 11% (15/136) and 23% (31/136) of isolates showed correlating positive and conflicting CDT and DDST test results respectively. A total of 98 (72.1%) isolates harboured single ESBL genes: *bla*$_{\text{TEM}}$ in 94 isolates, *bla*$_{\text{CTX-M-1}}$ in 2 isolates, while one isolate each had *bla*$_{\text{CTX-M-2}}$ and *bla*$_{\text{CTX-M-9}}$. Eighteen (13.2%) isolates harboured two ESBL genes: 5 with *bla*$_{\text{TEM}}$ and *bla*$_{\text{SHV}}$, 12 with *bla*$_{\text{TEM}}$ and a *bla*$_{\text{CTX-M}}$ type, one with *bla*$_{\text{SHV}}$ and *bla*$_{\text{CTX-M-1}}$. Two (1.5%) isolates harboured all 3 ESBL gene types.**Conclusions:** Multiplex PCR enables quick and cost-effective detection of ESBL genes and eliminates the limitations of phenotypic methods.

Publishing Title:

First Report of New Delhi Metallo-β-Lactamase-4 (Ndm-4) and New Delhi Metallo-β-Lactamase-5 (Ndm-5) in Egypt

Author Block:

H. O. Khalifa, A. M. Soliman, A. M. Ahmed, T. Shimamoto, **T. Shimamoto**; Hiroshima Univ., Higashi-Hiroshima, Japan

Abstract Body:

Carbapenemase-producing Enterobacteriaceae are a serious problem worldwide. Among the newly emerging carbapenemases, New Delhi metallo-β-lactamase (NDM) is among the antimicrobial resistance factors causing greatest concern because of its rapid global spread and frequent association with other resistance genes. NDM-4 and NDM-5 differ from NDM-1 by one and two amino acid substitutions, respectively, and have stronger carbapenemase activity than NDM-1. The prevalence of both genes in the Gram-negative bacteria is unclear, especially in developing countries. We report the first detection of NDM-4- and NDM-5-producing organisms in Egypt.A total of 136 nonduplicate Gram-negative isolates were recovered from clinical samples from different hospitals in Egypt. PCR and sequencing identified one *Klebsiella pneumoniae* strain (KPE127) carrying $bla_{\text{NDM-4}}$ and two isolates (*K. pneumoniae* KPB140 and *Escherichia coli* ECW169) carrying $bla_{\text{NDM-5}}$. Interestingly, NDM-4- and NDM-5-producing *K. pneumoniae* were isolated from a 6-month-old child suffering pneumonia after the transposition of the great arteries with an atrial septostomy and intracranial hemorrhage. NDM-5-producing *E. coli* ECW169 was isolated from a wound pus swab sample from a 65-year-old patient.The three strains were resistant to different classes of antibiotics. PCR and DNA sequencing confirmed that the three isolates also carried other resistance genes.The genetic environments of the $bla_{\text{NDM-4}}$ and $bla_{\text{NDM-5}}$ genes were analyzed with PCR mapping. We identified an insertion sequence, IS*Aba125*, upstream and the bleomycin-resistance gene, ble_{MBL}, downstream. Multilocus sequence typing showed that *K. pneumoniae* KPE127 and *K. pneumoniae* KPB140 belonged to ST45, corresponding to the ST of an NDM-1-positive *K. pneumoniae* identified in Turkey. *Escherichia coli* ECW169 belonged to ST5018, unlike any other known NDM-5-producing *E. coli*.This study confirms the presence of NDM-4- and NDM-5-producing bacteria in Africa, after their recent identification in Cameroon and Algeria. The worldwide dissemination ofNDM-4 and NDM-5 producers is alarming, particularly because their carbapenemase activity exceeds that of NDM-1. Therefore, screening for NDM producers in developing countries is essential if we are to prevent their future epidemic spread.

β-Lactamases Conferring Resistance to Third Generation Cephalosporins in *Escherichia coli* from Pets in Argentina

Author Block:

V. Rumi, E. Gentilini, J. Di Conza, **G. Gutkind**; UBA, BA, Argentina

Abstract Body:

Background: The spread of antimicrobial resistance and the emergence of multidrug-resistant (MDR) pathogens increased in the last decade. The production of extended spectrum β-lactamases (ESBL) is a common cause of resistance to third generation cephalosporins (TGC) and it is considered a concern problem both in human and veterinary medicine. Genes encoding resistance to TGC are usually found in transmissible plasmids and are often associated to other resistance determinants. The aim of this study was to determine the resistance profile of *E. coli* isolated from pet and to characterize the resistance mechanisms to TGC.**Methods:** A total of 54 *E. coli* isolates were collected from clinical samples in dogs and cats. Resistance was determined by the disk diffusion method according to CLSI VET01-A4 and VET01-S2 recommendations. Screening for ESBL and plasmid AmpC β-lactamases (AmpCp) were conducted by double disk synergy tests. ESBL and AmpCp determinants were investigated by PCR. Clonal relatedness was investigated by REP/ERIC-PCR. The main phylogenetic groups in *E. coli* isolates were assessed by PCR according to Clermont *et al*.**Results:** Of the 54 strains, 31 (57%) were resistant to AMP and 20/31 (64%) isolates were also resistant to TGC. No carbapenem resistance was observed. Seven isolates were characterized as ESBL producers, while 13/20 as AmpC carriers. Most of these isolates belong to the phylogenetic group D (14/20) and to a lesser extent B2 (4/20) and B1 (2/20). In ESBL-producing isolates were detected the $bla_{\text{CTX-M-2}}$ group (4), $bla_{\text{CTX-M-1}}$ group (2) and $bla_{\text{CTX-M-9}}$ group (1) genes. Thirteen AmpC-producing strains were positive for bla_{CMY}-like genes and all of them were clustered in a single electropherotype. A significant proportion of AMP resistant strains were also resistant to quinolones [NA: 80.6% (25), CIP: 67.7% (21) and LEV: 61.3% (19)] and TMS [64.5% (20)]. Finally, 58.1% (18) isolates showed a profile of MDR. **Conclusions:** AmpCp constitute the main TGC resistance mechanism in *E. coli* isolated from pets in our region. Cefotaximases belonging to three genetically different groups were also found being CTX-M-2 group the commonest amongst *E. coli*. It is important to highlight the high level of resistance to different families of antimicrobial (commonly used in pets) associated with AMP resistance.

Characterization of Multi-Resistant *K. pneumoniae* Isolates from Romania, Region Cluj

Author Block:

M. Tompa[1], R. G. Otto[2], J. D. D. Pitout[3], G. Peirano[3], **W. H. F. Goessens**[2]; [1]Central laboratory of the Regional Inst. of Gastroenterology and Hepatology "Prof. Dr. O. Fodor", Cluj, Romania, [2]Erasmus Univ. Med. Ctr. Rotterdam, Rotterdam, Netherlands, [3]Univ. of Calgary, Calgary, AB, Canada

Abstract Body:

Background: Antimicrobial resistance is increasing worldwide and especially the increasing resistance to the last resort antibiotics i.e. carbapanems is alarming. Also in Romania a limited number of studies reported the presence of carbapenemase-producing Enterobacteriaceae. Based on these findings we prospectively collected in 2013 in the Cluj region of Romania, Enterobacteriaceae resistant to imipenem and/or meropenem. These isolates are characterized by PCR for the detection of carbapenemase-encoding genes. **Methods:** 77 *K. pneumoniae* isolates collected during 2013 at the clinic of Gastroenterology and Hepatology at Cluj were included for further characterization. The identification of the isolates was confirmed by MALDI-TOF. Susceptibility determinations were performed in the VITEK 2 system. The presence of bla_{KPC}, bla_{NDM}, $bla_{\text{OXA-48-like}}$, bla_{VIM} *and* bla_{IMP} like genes were determined by PCR.**Results:** Susceptibility determinations revealed 30 isolates with MICs for meropenem (MER) of $\geq$ 16 µg/ml and imipenem (IMP) of 2 - 8 µg/ml (group A), 27 isolates with MICs for MER and IMP of $\geq$ 16 µg/ml (group B), 2 isolates (group C) with MICs for MER of 4 µg/ml and of $\geq$ 16 µg/ml for IMP and 4 isolates (group D) with MICs for MER of 4 µg/ml and MICs of 1-2 µg/ml for IMP. The remaining 14 isolates had MICs for MER of 0.5 - 1 µg/ml and $\leq$ 0.25 µg/ml for IMP. All isolates belonging to group A, B and C were positive for the $bla_{\text{OXA-48-like}}$ gene. In group D only one isolate was $bla_{\text{oxa-48-like}}$ positive. In addition to the OXA-48 gene, two isolates of group B also harbored a NDM-gene.**Conclusion**: In the majority of the *K. pneumoniae* isolates a $bla_{\text{OXA-48-like}}$ gene was demonstrated and correlates with the reduced susceptibility to the carbapenems. The spread in the MICs for MER and IMP probably reflects the presence of additional mechanisms of resistance like efflux pumps and/or reduced permeability of the outer membrane. The present results demonstrate the further spread of the $bla_{\text{OXA-48-like}}$ gene into Eastern-Europe.

Publishing Title:

Promises and Pitfalls of Illumina Sequencing for Resistance Plasmid Tracking

Author Block:

A. E. Sheppard[1], N. Stoesser[1], R. Sebra[2], A. Kasarskis[2], A. S. Walker[1], T. E. Peto[1], D. W. Crook[1], A. J. Mathers[3]; [1]Univ. of Oxford, Oxford, United Kingdom, [2]Icahn Sch. of Med. Mount Sinai, New York, NY, [3]Univ. of Virginia, Charlottesville, VA

Abstract Body:

Antibiotic resistance is a major public health concern. In *Enterobacteriaceae*, resistance genes are often located on mobile plasmids. Traditional methods for plasmid investigation are laborious and/or provide limited resolution. Whole genome sequencing is a high throughput, cost effective tool for bacterial genomics, and is attractive for plasmid analysis. However, short read sequencing (e.g. Illumina) is not ideal for plasmid reconstruction due to repeat structures, and plasmids are generally fragmented in *de novo* assemblies. Here we explore various approaches for plasmid analysis using Illumina data, and demonstrate that naïve interpretation can be misleading.We performed whole genome Illumina sequencing on 281 carbapenem resistant *Enterobacteriaceae* isolated from a hospital bla_{KPC} outbreak over five years. This outbreak shows high levels of diversity in species, strains and plasmids carrying the bla_{KPC} resistance gene, providing an ideal framework for testing plasmid analysis methods given frequent resistance gene mobility. We use a combination of *de novo* assembly and mapping approaches to investigate methods for accurately inferring plasmid presence and structure. We also performed long read PacBio sequencing on 23 isolates, providing 97 complete, closed plasmid sequences for comparison with Illumina data, including 22 bla_{KPC} plasmids.We explore various methods for defining plasmid presence and show that due to frequent rearrangements, this is not a straightforward concept. Further, presence does not always correlate with expected plasmid structure and can be misleading for resistance plasmid tracking. For example, for four plasmids where structure could be resolved from Illumina data, bla_{KPC} was contained in the plasmid in only 1/20, 3/10, 3/5 and 45/52 isolates in which the plasmid was present. PacBio sequencing revealed similar patterns for plasmids where structure was unresolvable from Illumina data due to the presence of long repeats.We demonstrate important limitations for resistance plasmid analysis from Illumina data, and highlight how erroneous conclusions can easily be obtained through naïve interpretation. We provide suggestions for how to avoid this while maximising data potential.

Genomic Tracking of Carbapenem-Resistant *Serratia marcescens* in a Hospital Setting

Author Block:

N. Pecora[1], N. Li[1], X. Zhao[1], M. Allard[2], A. Onderdonk[1], L. Bry[1]; [1]Brigham and Women's Hosp., Boston, MA, [2]U.S. Food and Drug Admin., College Park, MD

Abstract Body:

Background: *Serratia* species are ubiquitous in the environment and can be a cause of serious nosocomial infections. Carbapenem resistance has been sporadically reported, due to both intrinsic and horizontally-acquired elements, though relatively few clinical isolates have been sequenced. In this study 11 carbapenem-resistant clinical isolates of *Serratia marcescens* collected over a 3 year period were sequenced in order to identify the underlying causes of carbapenem resistance, other resistance and virulence factors, and potential patient and hospital reservoirs. **Methods:** 11 isolates of *Serratia marcescens* were collected between 2011-2014 from 6 different patients. All strains were resistant to either imipenem or imipenem and meropenem. Sequencing was done on a Miseq (Illumina, 150-300bp reads). Assembly, beta-lactamase, transposon, and plasmid analysis were done on in-house pipelines using a combination of *de novo* (SPAdes) and reference-based (Bowtie-2) aligners. SNP analysis was done using CSI-phylogeny (cge.cbs.dtu.dk). Annotation was done with RAST (rast.nmpdr.org). Multiple alignments were done using the MAUVE aligner.**RESULTS:** The strains formed 4 clusters with 32-77000 SNPs between strains. In some cases, closely related strains occurred years apart, raising concern for an environmental hospital reservoir. Isolates had 0-2 plasmids (representing INC F, R, and L/M groups). In two clusters, carbapenem resistance was due to mobile carbapenemases (SME-4 and KPC-3). All strains harbored a chromosomal AmpC beta-lactamase as well as SHV and OXA-family enzymes. Resistance determinants to aminoglycosides, sulfonamides, and tetracyclines were present in a majority of the strains. Other virulence factors included type VI secretion systems and hemolysins.**Conclusions:** *Serratia marcescens* is an increasingly recognized nosocomial pathogen, whose combination of intrinsic and acquired resistance presents major treatment challenges. In this study, the sequencing of several clinical isolates illuminates the genomic landscape of carbapenem-resistant strains in a hospital setting. This consisted of multiple clusters of organisms, some with enzymes/mechanisms specific to *Serratia* and some with elements, such as KPC-3, likely acquired from other *Enterobacteriaceae*.

Genomic Evaluation of Nosocomial *Klebsiella pneumoniae* Carbapenemase Producing *Serratia marcescens* (KPC-Sm)

Author Block:

A. J. Mathers[1], N. Stosser[2], J. Carroll[1], J. Ainsworth[1], C. Sifri[1], D. Crook[2], A. E. Sheppard[2]; [1]Univ. of Virginia, Charlottesville, VA, [2]Oxford Univ., Oxford, United Kingdom

Abstract Body:

Background: Carbapenem resistant Enterobacteriaceae are an urgent threat to hospitalized patients. *S. marcescens* is a nosocomial pathogen with a significant degree of inherent resistance to last line drugs such as colistin. The KPC gene (bla_{KPC}) is usually carried on the transposon Tn*4401* within mobile plasmids and acquisition by *S. marcescens* results in highly antibiotic resistant strains. We investigated how KPC-Sm manages plasmid DNA and is transmitted nosocomially over extended time periods.**Methods:**KPC-producing Enterobacteriaceae were prospectively identified in a clinical lab between 8/2007-4/2015. All available isolates were Illumina sequenced and select isolates PacBio sequenced to understand population and plasmid structures in the context of an ongoing multi-species outbreak.**Results:**There were 60 KPC-Sm isolates from 36 patients from the following sources: peri-rectal surveillance (63%), respiratory (12%), blood (10%), urine (8%), and abdominal (7%). Ten (28%) patients were co-colonised/infected with another blaKPC-Gammaproteobacteria in addition to KPC-Sm. The first KPC-Sm was identified in December 2011; by 2014 KPC-Sm was the predominant species (36 KPC-Sm versus 34 KPC-*K. pneumoniae*; KPC-*Citrobacter freundii* as the next most common [n=13]). All KPC-Sm were highly genetically homogeneous (max 61 pairwise SNVs) indicating a stably circulating clone. There was a unique Tn*4401* variant found in all but one patient with KPC-Sm. This variant was only found in other species (*E. coli, Aeromonas* spp., *Enterobacter aerogenes*) in patients who also had KPC-Sm, indicating likely horizontal gene transfer from KPC-Sm. PacBio sequencing revealed a conserved 69 kb bla_{KPC} plasmid in all 4 tested isolates. Illumina data was consistent with this plasmid being present in 97% of KPC-Sm strains.**Conclusion:**We describe sustained transmission of a KPC-Sm clone with a conserved plasmid which evolved to be the predominant species within a multi-species outbreak. KPC-Sm may represent a persistent source of bla_{KPC} in nosocomial settings, as demonstrated here. Understanding the role of *S. marcescens* in the spread of drug resistance genes could be critical to combating carbapenemase producing isolates around the world.

Dissemination of *Escherichia coli* Co-Producing Ndm-5 and Mcr-1 in a Chicken Farm

Author Block:

L. Lv, J. Wang, X. Yao, Z. Zeng, **J-H. Liu**; South China Agricultural Univ., Guangzhou, China

Abstract Body:

Background: Recently, reports of carbapenemase-producing bacterium from animal sources are increasing. Until now, all these animal original carbapenemase producers were selected by plates supplied with carbapenems, detection of carbapenemase gene among randomly isolated organisms from animals have not been reported. Plasmid-mediated colistin resistance gene *mcr-1* has been emerged and caused great concern all over the world. Here we report the emergence of *E. coli* co-producing NDM-5 and MCR-1 in one chicken farm in China. **Methods:** In 2015, 21 commensal *E. coli* were recovered from healthy chickens of a farm located in Anhui province of China. MICs of various antimicrobial agents were determined by agar dilution method. The presence of carbapenemase genes and *mcr-1* were determined by PCR. The clonal relatedness of NDM-5 producers was determined by PFGE and multi-locus sequence typing (MLST). Transferability and location of of $bla_{\text{NDM-5}}$ and *mcr-1* genes were investigated by conjugation experiment, S1-PFGE, and hybridization. The genetic context of $bla_{\text{NDM-5}}$ gene was determined by PCR mapping and sequencing. **Results:** Five (23.8%) *E. coli* isolates showed reduced susceptibility to imipenem (MIC≥1 mg/L) and were positive for both $bla_{\text{NDM-5}}$ and *mcr-1*. Three of them had very similar PFGE patterns and belonged to ST10, the other two isolates were both typed as ST5442. All $bla_{\text{NDM-5}}$ genes were located on ~40kb IncX3 plasmids and can be transferred by conjugation. Analysis of the flanking regions of the $bla_{\text{NDM-5}}$ genes revealed that IS*Aba125* was located upstream of $bla_{\text{NDM-5}}$. Downstream of the $bla_{\text{NDM-5}}$ gene, the ble_{MBL}, *trpF*, and *dsbC* genes were observed. **Conclusions:** To the best of our knowledge, this is the first report of carbapenemase gene found in randomly isolated *E. coli* from food animals. The emergence and clonal spread of commensal *E. coli* carrying both $bla_{\text{NDM-5}}$ and *mcr-1* in chicken farm is alarming. Consequently, there is urgently needed to survey the occurrence of carbapenemase genes among bacteria from food animals in order to prevent their potential spread.

Antimicrobial-loaded Bone Cement Does Not Negatively Influence Sonicate Fluid Culture Positivity for the Diagnosis of Prosthetic Joint Infection

Author Block:

K-H. Park[1], K. Greenwood-Quaintance[2], A. Hanssen[2], M. Abdel[2], R. Patel[2]; [1]Chonnam Natl. Univ. Med. Sch., Gwangu Ju, Korea, Republic of, [2]Mayo Clinic, Rochester, MN

Abstract Body:

Background: Although sonication of removed implants with culture of the resultant "sonicate fluid" has high specificity and sensitivity for the diagnosis of prosthetic joint infection (PJI), the influence, if any, of antimicrobial-loaded bone cement on sonicate fluid culture positivity has not been assessed.**Methods:** We compared sonicate fluid culture results between patients with PJI who had implants with and without antimicrobial-loaded bone cement. Implants were processed according to a previously described protocol, including sonication, vortexing, and concentration. A total of 54 patients were assessed, 18 of whom had implants with antimicrobial-loaded polymethylmethacrylate.**Results:** The sensitivity of sonicate fluid culture of removed implants was 77.8% (14 of 18) in subjects with antimicrobial-loaded cemented prostheses, and 58.3% (21 of 36) in those without antimicrobial-loaded prostheses. Among the 35 sonicate culture positive cases, seven presented within 12 months after implantation, nine presented between 13 and 24 months after implantation and 19 presented beyond 24 months of implantation.**Conclusions:** Antimicrobial-loaded bone cement did not have an obvious negative impact on the microbiologic yield from removed prostheses subjected to sonication culture.

Routine Use of a Multiplex Serological Assay in the Management of Prosthetic Joint Infection

Author Block:

A-L. Roux[1], F. El Sayed[1], T. Bauer[1], B. Combourieux[2], C. Nich[2], V. Sivadon-Tardy[1], C. Lawrence[2], J-L. Herrmann[2], J-L. Gaillard[1], **M. Rottman**[2]; [1]Hosp. Ambroise Paré, APHP, Boulogne Billancourt, France, [2]Hosp. Raymond Poincare, Garches, France

Abstract Body:

The diagnosis of prosthetic joint infections (PJI) is a critical challenge for orthopedic surgeons and infectious disease specialists. The diagnosis of PJI is often delayed because non-invasive assays lack sensitivity and specificity. We evaluated in routine practice the relevance of a novel serological multiplex immunoassay detecting antibodies against staphylococci, *Propionibacterium acnes* and *Streptococcus agalactiae* to assist in the management of PJI patients. The Luminex-based assay measures serum IgG against aa array of recombinant purified antigens from *S. aureus, S. epidermidis, S. lugdunensis, S. agalactiae* and *P. acnes* selected by immunoproteomics to specifically diagnose PJI. We reviewed the cases of patients suspected of PJI who had benefited from a BJI Inoplex™ test in a French reference center for complex bone and joint infections. PJI cases were defined microbiologically (≥2 intraoperative samples yielding the same microorganism) for confrontation of microbiological and immunoassay data. Cases of probable acute hematogenous PJI (AH-PJI) eligible for debridement and implant retention (DAIR) were further studied to document the relevance of the assay in this context.32 patients were eligible for review (patients with prosthesis and signs of infection dating tested with immunoassay results). Of the 32 patients, 20 had a total hip prosthesis, 11 a total knee prosthesis and 1 an ankle prosthesis. Sensitivity and specificity for staphylococci 90% and 90%.. The review of 7 cases of AH-PJI cases showed that the immunoassay is negative in acute settings. However, in one case of *K. pneumonia* AH-PJI, BJI Inoplex™ detected an underlying infection with *S. capitis* confirmed by culture, and in one case of *S. aureus* AH-PJI, BJI Inoplex™ detected *P. acnes* that was confirmed by a PCR hybridization assay.Conclusions: This novel multiplex serological test allows the non-invasive diagnosis of staphylococcal PJI, showing a good correlation with microbiological culture. It allows the detection of occult chronic infections in patients with AH-PJI and could help identify the best candidates for DAIR. Overall it appears to be a promising tool in the management of patients with PJI.

Molecular Approaches to the Rapid and Accurate Diagnosis of Lymphadenitis, Bone and Joint Infections

Author Block:

K. Ohkusu, T. Matsumoto; Tokyo Med. Univ., Tokyo, Japan

Abstract Body:

Background: The rapid and accurate diagnosis of lymphadenitis, bone and joint infections continues to be a major challenge. The objective of this study was to evaluate molecular approaches including conventional PCR, broad-range PCR amplification followed by direct sequencing to identify genomic DNA of pathogens from patients with clinically suspected lymphadenitis, bone and joint infections. **Methods:** A prospective study was carried out from January 2005 to December 2015, during which time, 85 clinical specimens from 85 patients at 56 hospitals in Japan were analyzed. For detection of bacterial DNA, broad-range PCR of the 16S rDNA was performed using the primers 8UA and 1485B. Sequences obtained from amplified bacterial DNA were compared with those available in the GenBank and/or EzTaxon databases in identification. Specific PCR assays were also used in the study. **Results:** Eighty-five clinical specimens, including 30 pus, 23 joint fluids, 17 bone tissues, 15 lymph node tissues, were analyzed. Of the 85 specimens, 22 specimens were culture positive. In 32 patients with lymphadenitis, we detected the following pathogens from 29 patients (91%): 9 *M. bovis* BCG strains, 4 *B. henselae*, 4 *M. tuberculosis*, 2 *S. aureus* (*mecA*+), 1 *B. cepacia*, 1 *M. avium*, 1 *M. colombiense*, 1 *M. genavense*, 1 *M. haemophilum*, 1 *S. aureus*, 1 *S. aureus* (*mecA*+) & CMV & EBV, 1 *S. hominis*, 1 *S. pyogenes*, and 1 *S. pyogenes* & EBV. In 24 patients with arthritis, we detected the following pathogens from 15 patients (63%): 3 *S. aureus*, 2 *H. influenzae* type b , 2 *S. pyogenes*, 1 *M. bovis* BCG strain, 1 *M. tuberculosis*, 1 *M. wolinskyi*, 1 *N. gonorrhoeae*, 1 *N. meningitidis* Y, 1 *S. epidermidis*, 1 *Streptobacillus moniliformis*, and 1 *S. dysgalactiae* subsp. *equisimilis*. In 22 patients with osteomyelitis, we detected the following pathogens from 19 patients (83%): 15 *M. bovis* BCG strains, 1 *A. israelii*, 1 *M. kansasii*, 1 *Paecilomyces lilacinus*, and 1 *S. aureus* (*mecA*+). In 5 patients with spondylitis, we detected 3 *S. aureus*, and 1 *E. coli*. In 2 patients with discitis, we detected 1 *Helicobacter cinaedi*. **Conclusions:** We confirmed that molecular detection and identification can be a reliable approach in the diagnosis and management of lymphadenitis, bone and joint infections. This is especially true when patients have received antimicrobial therapy prior to specimen collection or when the likely agents are fastidious, slow-growing or uncultivable microorganisms.

Comparison of Initial Stream Urine Samples and Cervical Samples for Detection of Human Papillomavirus

Author Block:

Y. Yamagishi[1], K. Izumi[2], N. Miyazaki[1], H. Suematsu[1], H. Mikamo[1]; [1]Aichi Med. Univ., Aichi, Japan, [2]Izumi Ladies Clinic, Gifu, Japan

Abstract Body:

Background: Uterine cervical cancer is a treatable and preventable cancer. Medical efforts to reduce rates of cervical cancer focus on the promotion of human papillomavirus (HPV) vaccination and the promotion of routine cervical cancer screening done by cervical cytology and cervical HPV testing. Urine-based HPV testing would be simple and noninvasive approach to screen for cervical cancer. **Methods:** Two biospecimens (clinician-taken sample from cervix and initial stream urine sample) were provided from a total of 100 healthy women attending for cancer screening provided for HPV testing. We have assessed the HPV detection rates among cervical specimens, unfractionated urine specimens and pellet fraction of urine specimens using HPV test (Anyplex II HPV28 Detection test, Seegene) and also assessed HPV prevalence.**Results:** HPV prevalence was almost similar in unfractionated and pellet fractions of urine samples with 34% and 36%, respectively. Sensitivities of HPV detection for cervical samples and pellet fractions of urine samples were almost identical with 38% and 36%, respectively. HPV detection was almost similar in women detected only 1 HPV (17/38) and women detected over 2 kinds of HPV from cervical specimens (21/38), sensitivities of HPV detection were almost similar with 100% and 95%, respectively.**Conclusions:** Comparing methodologies of collection of samples for HPV detection, there have no differences between cervical specimens and pellet fractions of urine samples. These results suggest that urine could be a good noninvasive tool to monitor HPV infection in women. Additional research in a larger and general screening population would be needed.

Design and Construction of Multiplex Late Pcr Assay for Genotyping High Risk Human Papillomaviruses

Author Block:

J. Sanchez, N. Sirianni, L. Wangh; Brandeis Univ., Waltham, MA

Abstract Body:

Background: Chronic infection by one or more of 13 high-risk human papillomavirus (HR-HPV) types is the major cause of cervical cancer and several other anogenital and head-and-neck neoplasias. Cancer risk is determined by HR-HPV type or combination of co-infecting types, with some HR-HPV type combinations exhibiting synergistic effects. FDA-approved methods for HR-HPV genotyping by conventional multiplex symmetric PCR do not identify all HR-HPV types and use consensus amplification primers, which favor detection of the most abundant co-infecting HR-HPV types. We have constructed a multiplex PCR assay that detects and identifies all 13 HR-HPV types in a single closed-tube assay independent of relative HR-HPV type abundance.**Methods:**This HR-HPV assay utilizes LATE-PCR, an advanced form of asymmetric PCR. The multiplex includes HR-HPV type-specific primers/probes, as well as reagents that guarantee the specificity and temperature precision of amplification and probe hybridization. Amplification and detection are carried out in a closed-tube in a Hain Fluorocycler®96 instrument. At endpoint, detection probes hybridize to single-stranded PCR products over a wide temperature range. Each HR-HPV types is identified by a unique combination of probe fluorescent color and probe melting temperature. Targets were tested in the presence of up to 5,000 copies of human genomic DNA in according with international standards for validation of HPV assays (Int. J. Cancer, 516, 2009; J. Clin Microb. 48, 4147, 2010).**Results:**The multiplex assay detected all 13 HR-HPV types, as well as the 15 most common types of viral co-infections. Thus the assay met international HPV assay validation standards for limit of and diagnostic performance for known HR-HPV types. The assay can be run alongside a multiplex LATE-PCR STI assay under development (see Sirianni and Wangh abstract).**Conclusions:**This multiplex LATE-PCR assay promises the same or more complete information of cancer risk as more complex, non-PCR HPV genotyping assays with the added convenience being in a single closed-tube format, ease of use, potential automation, and faster results. Supported by Hain Lifescience.

Comparison of the Amplivue® Trichomonas Assay with the Affirm® Vpiii for the Detection of *Trichomonas vaginalis* in Vaginal Specimens

Author Block:

P. A. Granato, B. R. Alkins; Lab. Alliance of Central New York, Liverpool, NY

Abstract Body:

Background: *Trichomonas vaginalis* is the leading cause of vaginitis worldwide and produces an estimated 7.4 million infections in the U.S. annually. The purpose of this study was to evaluate the performance of the AmpliVue Trichomonas Assay (Quidel, San Diego, CA) with the AFFIRM VP III (BDMS, Sparks, MD) for the detection of *T. vaginalis* in vaginal specimens. **Methods:** Vaginal swab specimens from E.R. and outpatients were collected and placed in the AFFIRM VPIII Ambient Temperature Transport System and tested within 24 h of laboratory receipt. The AFFIRM assay was performed and the results were interpreted according to the manufacturer's instructions. Residual specimen from the AFFIRM transport tube was used for AmpliVue testing. The AmpliVue Trichomonas Assay is an isothermal, helicase-dependent amplification assay that was performed according to the manufacturer's instructions. All discordant results were arbitrated by using the Solana® Trichomonas Assay (Quidel) that targets a different region of DNA than the AmpliVue assay. **Results:** A total of 257 specimens were evaluated in this comparative study. One invalid AmpliVue result was obtained and that specimen was removed from the study. Of the remaining 256 specimens, 28 (10.9%) were positive by both methods. Five discordant specimens were obtained and all were positive by the AmpliVue assay but negative by the AFFIRM test. Using AFFIRM as the reference method, the AmpliVue had a sensitivity and specificity of 100% and 98% respectively. Solana arbitration testing was performed on the 5 AmpliVue positive/AFFIRM negative discordant specimens. Three specimens were confirmed as positive by the Solana test and 2 were confirmed as negative. Using Solana as the reference method, the AmpliVue and the AFFIRM tests had resolved sensitivities of 93% and 90% respectively and each had a resolved specificity of 99%. **Conclusions:** The results of this study showed that the AmpliVue Trichomonas Assay performed slightly better than the AFFIRM test when discordant results were arbitrated by an independent molecular method. The assay is easy-to-perform with a specimen time to result of less than 60 minutes and a minimum of hands-on time. The AmpliVue assay does not require specialized equipment and provides a rapid and highly reliable alternative for the molecular diagnosis of *T. vaginalis* infection.

Rapid Detection of *Trichomonas vaginalis* with the Quidel Solana Trichomonas Assay

Author Block:

L. Fleck, H. Ty, S. Caddle, H. Kong, W. Tang; Biohelix Corp., A Quidel Company, Beverly, MA

Abstract Body:

Background: *Trichomonas vaginalis* (trichomoniasis) is the most common curable, non-viral sexually transmitted disease (STD) with an estimated 7.4 million new cases occurring annually in the U.S. The Solana Trichomonas Assay is developed based on a novel helicase-dependent isothermal amplification method (HDA) and a compact fluorescence analyzer for rapid detection of *Trichomonas vaginalis* DNA from vaginal swabs and urine samples.***Methods:*** We developed a rapid DNA amplification test for the detection of *Trichomonas vaginalis.* Simple sample preparation includes heat lysis and dilution steps followed by Helicase-Dependent Amplification (HDA) and endpoint detection by fluorescent probes. A swab or neat urine specimen is transferred into either a Swab or a Urine Lysis Tube respectively. After heating the Lysis Tube for 5-minutes, the lysed specimen is transferred into a Dilution Tube. 50 µL of diluted sample is added to a Reaction Tube and then placed into the Solana instrument for 25-minutes for amplification and detection. Twelve specimens can run as a batch in less than 35 minutes.***Results:*** Analytical studies determined that the Solana Trichomonas Assay had a limit of detection (LoD) around 306 TVs/mL in swab transport media and 108 TVs/mL in urine. More than twenty *T. vaginalis* reference strains and clinical isolates were inclusive for both the swab and urine assays tested at the 1× LoD level. Both assays do not cross-react or interfere with the 47 organisms that have been evaluated. No substance interference was detected in the swab or urine assay with the 15 and 17 substances that may exist in samples. The clinical performances of Solana Trichomonas Assay are being evaluated in a multi-center clinical study and the initial results are encouraging. Compared to a composite reference method of wet-mount microscopy plus InPouch TV culture, the Solana Trichomonas Assay showed 100% sensitivity and 99.3% specificity on 165 vaginal swabs, and 100% sensitivity and 98.5% specificity on 162 urine specimens.***Conclusion:*** The Solana Trichomonas Assay provides simple and cost-effective method for rapid detection of *Trichomonas vaginalis*. It has significantly higher sensitivity than traditional wet-mount test and can be used for testing of multiple types of clinical specimens including urine and vaginal specimens.

Performance of the Bd Max™ Vaginal Panel for the Diagnosis of Vaginitis

Author Block:

C. Gaydos[1], S. Beqaj[2], B. Smith[3], J. Lebed[4], J. Schwebke[5], D. Furgerson[6], P. Nyirjesy[7], T. Davis[8], T. Spurrell[9], R. Reagan[10], K. Fife[11]; [1]Johns Hopkins Univ., Baltimore, MD, [2]Pathology Inc., Torrance, CA, [3]Planned Parenthood Gulf Coast, Houston, TX, [4]Planned Parenthood Southeastern Pennsylvania, Philadelphia, PA, [5]Univ. of Alabama at Birmingham, Birmingham, AL, [6]Planned Parenthood Mar Monte, San Jose, CA, [7]Drexel Univ. Coll. of Med., Philadelphia, PA, [8]Sidney and Lois Eskenazi Hosp., Indianapolis, IN, [9]Planned Parenthood of Southern New England, New Haven, CT, [10]Women's Hlth.Care Res. Corp., San Diego, CA, [11]Indiana Univ. – Sch. of medicine, Indianapolis, IN

Abstract Body:

Background: Vaginitis, one of the most common problems in clinical medicine, accounts for millions of office visits per year. The three main categories of vaginitis are bacterial vaginosis (BV), yeast vaginitis (candidiasis) and *T. vaginalis* vaginitis (TV). The BD MAX Vaginal Panel (not available for sale or use in the US) detects TV, BV and different Candida species (*C. albicans*, *C. tropicalis*, *C. parapsilosis*, *C. dubliniensis* as Candida group; *C. glabrata* and *C. krusei* as a separate call). The objective of this prospective clinical trial (sponsored by BD) was to evaluate the performance of the BD MAX Vaginal Panel on the BD MAX System. **Methods:** The BD MAX Vaginal Panel results obtained were compared to target specific, gold standard Reference Methods (RM) for the detection of TV (wet mount/culture), BV (Amsel/Nugent) and *Candida* (culture/sequencing). For each consented woman (N = 1686), one clinician-collected vaginal swab (BD MAX UVE Specimen Collection Kit) was tested with the BD MAX Vaginal Panel. For RM, a total of 4 swabs were collected, one for wet mount; one for InPouch™ TV Culture; one for Nugent score and yeast culture and one for Aptima® TV. **Results:** For TV, the sensitivity was 92.7% with a specificity of 99.3%. For BV, the sensitivity was 90.5% with a specificity of 86.1%. For the *Candida* group, a sensitivity/specificity of 90.9% /94.1% was observed. The specificity for *C. glabrata* and *C. krusei* were 99.7% for both. **Conclusions:** Compared to gold standard RM, the BD MAX Vaginal Panel performed with high sensitivity and specificity for the diagnosis of vaginitis/vaginosis, providing clinicians with a new tool for management of vaginitis. The assay performance supports the appropriateness of target choice and design of the BD MAX Vaginal Panel, and indicates a high clinical relevance.

Urinary Meatal Swabbing Detects More Sexually Transmitted Infections in Men Than First Catch Urine

Author Block:

M. Chernesky[1], D. Jang[1], J. Gilchrist[1], M. Arias[1], M. Smieja[1], I. Martin[2], B. Weinbaum[3], D. Getman[3]; [1]St. Joseph's Hlth.care/McMaster Univ., Hamilton, ON, Canada, [2]Natl. Microbiol. Lab., Publ. Hlth.Agency of Canada, Winnipeg, MB, Canada, [3]Hologic Inc, San Diego, CA

Abstract Body:

Background: Traditionally, sexually transmitted infections in men; such as *Chlamydia trachomatis* (CT), *Neisseria gonorrhoeae* (NG), *Trichomonas vaginalis* (TV), *Mycoplasma genitalium* (MG), and human papillomavirus (HPV) have required urethral swabs for diagnosis. With nucleic acid amplification tests, first catch urine (FCU), which is non-invasive, can be used instead of the urethral swab. . FCU sampling can be problematic because it requires accurate collection of the first 20-30 ml of urine. Gentle swabbing of the urinary meatus (UM) has been used successfully for CT and NG diagnosis, is easy to self-collect, and is comfortable.**Methods:** During 2015, 356 men (ages 16-25) consented to self-collect a FCU and a UM swab (UMS) under supervision. A subset of patients compared 2 Aptima swab types [Unisex and vaginal for UMS. The order of collection was randomized. Within 48 hours, each sample was tested for CT and NG (Aptima Combo2), TV (Aptima Trichomonas vaginalis), MG (Hologic *Mycoplasma genitalium* analyte specific reagents), and HPV (Aptima HPV test) on Tigris or Panther instruments. Confirmation of MG and TV positives was performed using alternative (Alt) laboratory derived tests. MG positives were tested for macrolide resistance phenotype by 23S sequencing.**Results:** For all organisms, the UMS identified more infections than FCU. Prevalence rates for FCU and UMS were as follows: CT 9.3% and 11.3%; NG 0.84% and 1.4%; TV 1.7% and 7.9%; MG 12.6% and 15.3%; HPV 3.4% and 5.9%, respectively. Both unisex and vaginal swab types yielded equal numbers of infections. Macrolide resistance at 2058 and 2059 positions were identified in 62.5% (21/35) patients tested.**Conclusions:** The highest prevalence rates were recorded for MG (15.3%) followed by CT (11.3%). All TV and MG positives were confirmed with Alt TMA testing. UMS detected more infections, was easy and comfortable to collect, and provides a useful sample for men.

Hlth., San Francisco, CA, [17]George Washington Univ., Washington, DC

Abstract Body:

Background: *Trichomonas vaginalis* (TV) is the etiologic agent of trichomoniasis, a common sexually transmitted infection. The Xpert® TV Assay, performed on the GeneXpert® Instrument Systems, is an *in vitro* qualitative real-time PCR test for automated detection of genomic TV DNA, providing detailed test results in 45 minutes.**Methods:** This multi-center study prospectively collected urine (UR), endocervical swabs (ES) and patient-collected vaginal swabs (PC-VS) from symptomatic and asymptomatic females. All specimens were tested with the Xpert TV Assay, the Gen-Probe® APTIMA® TV Assay, and InPouch culture. The performance was determined relative to a Patient Infected Status (PIS) algorithm- based on the result for each specimen type compared to the combined reference assays. Sequencing was performed on specimens with discrepant results.**Results:** For 1867 participants, 714 were symptomatic and 1153 asymptomatic. Average age was 33.5 yr. Relative to PIS, Xpert TV had a sensitivity and specificity on PC-VS (N = 1791) of 96.4% and 99.6%, respectively; prevalence 10.8%. Xpert TV demonstrated a sensitivity and specificity on ES (N = 1799) of 98.9% and 98.9%, respectively; prevalence 9.8%. The TV Assay demonstrated a sensitivity and specificity on UR (N = 1793) of 98.4% and 99.7%, respectively; prevalence 10.2%. There were no significant differences with respect to symptomatic status. Assay success was 99.9% (5383/5391).**Conclusions:** The Xpert® TV Assay demonstrated very high sensitivity and specificity compared to a PIS and offers a fast result that can be used to treat patients before they leave the clinic.

Publishing Title:

Validation of Simulated Body Fluid Specimens (SBFS) in Bactec Blood Culture Bottles

Author Block:

E. L. Rank, Ph.D.; Quest Diagnostics, Inc., Teterboro, NJ

Abstract Body:

Background: BD Bactec Blood Culture media (BCM) are not currently validated for the cultivation of pathogens retrieved from body fluids, but they are often submitted by physicians in that capacity. Transportation to the lab can lead to delayed vial entry time points (DVETP), which may affect recovery rates. We systematically tested the ability of Bactec BCM to grow pathogens in simulated body fluid specimens (SBFS) at various DVETPs.**Methods:** One BCM set includes 2 bottles (1 aerobic and 1 anaerobic). Fifteen isolates (8 aerobic, 5 anaerobic, 2 fastidious) and 5 pairs of isolates were each inoculated into 8 BCM sets (128 + 80 + 32 + 80 = 320 bottles, each with 1 mL suspensions of ~10^1 CFU/mL). Twenty BCM sets were negative controls. These 360 bottles were incubated at 35ºC to 37ºC up to 120 hr. Half of the bottles received SBFS and half received PBS as a control for inhibitory substances in SBFS; no inhibitory effects were observed. Of the 8 sets per isolate, 2 were incubated immediately (0 hr); 6 sets were held at room temperature (RT) to replicate DVETP. Two sets each were incubated at 12 hr, 24 hr, and 48 hr time points. Positive bottles were identified using the Vitek system.**Results:** Overall recovery rates were ≥90% for aerobes (99.2%, 127/128), anaerobes (90.0%, 36/40, with an additional 7 anaerobes recovered from aerobic bottles), and paired isolates (91.3%, 73/80); the rate for fastidious organisms was 37.5% (12/32). As the DVETP increased, the overall recovery rates decreased and the average time to recovery increased (Table). All negative controls showed no growth at 120 hrs of incubation.**Conclusions:** This study demonstrates the ability of Bactec BCM to grow pathogens in SBFS for DVETP of up to 48 hours at RT. Fastidious microorganisms were more difficult to recover, probably due to their exacting temperature requirements; at or beyond the 48 hr time point, recovery of fastidious isolates appears minimal. Despite lower recovery of fastidious isolates, it is prudent to accept all specimens up to the 48 hr DVETP for pathogen recovery.

Table: Overall Recovery % Rates and Average Time (hrs) to Recovery for DVETP

DVETP	Recovery %	Aerobes, Average Time	Anaerobes, Average Time	Fastidious, Average Time
0 hr delay	95%	4.8	7.8	16.1
12 hr delay	76.3%	5.7	9.6	17.6

24 hr delay	76.3%	10.1	16.6	33.4
48 hr delay	71.3%	16.4	14.3	0

Ascites Fluid (AF) Cultures: Evaluation of Commercial Blood Cultures versus Direct Agar Plating (Dap)

Author Block:

B. A. Forbes, K. L. Godwin, M. E. Wallace, C. D. Doern, J. L. Forbes; VCU Med. Ctr., Richmond, VA

Abstract Body:

With respect to bacteriologic culture of AF, DAP has been reported as insensitive, with European and US guidelines recommending inoculation directly into blood culture bottles at the bedside. Purchase of a new automated blood culture system (BD BACTEC^{TM} FX Microbial Detection System; BACTEC) mandated validating its use for culture of AF. For validation, 66 AF were cultured as follows: 1 drop of AF were inoculated onto sheep blood, MacConkey's, chocolate, colistin-nystatin agars and incubated aerobically, while 1 drop of AF was also inoculated on OxyPRAS Plus plated media (Oxyrase Inc; Brucella, Phenylethyl alcohol agar, Bacteroides bile esculin, and Laked kanamycin-vancomycin agar plates) and incubated anaerobically. Remaining AF was inoculated into BacTALERT® Microbial Detection System (BacTALERT; bioMerieux) Standard Anaerobic (SN) and FAN Aerobic (FA) blood culture bottles, and BACTEC Lytic Anaerobic/F non-resin media and BACTEC Plus Aerobic bottle. Cytospun Gram stains (GS; n=104) were performed on AF as well. Based on results of the validation, an additional 39 AF were also evaluated in a similar manner by inoculating 1 set of DAP and BACTEC blood culture bottles. Collective data, i.e. total number of organisms, were used as the 'gold standard'. For the validation, the sensitivity based on organisms detected for the DAP, BacTALERT and BACTEC was 86.5%, 72.7% and 82%, respectively. Comparing all data for only DAP and the BACTEC (n=105), the overall sensitivity was 83% and 82.9%, respectively. The cytospun GS was only 50% sensitive when compared to culture. GSs of all culture-negative specimens showed no organisms yet 93.6% demonstrated neutrophils; all culture-positive specimens showed few to many neutrophils. Based on organism groups, DAP missed 46% enterics while the BACTEC missed 53% anaerobes. Although both methods have equivalent sensitivities for AF cultures (83% vs. 82.9%), time-to-detection was generally faster for blood culture bottles while time-to-reporting with appropriate susceptibilities results was faster for DAP. Together, these results indicate that BACTEC bottles plus anaerobic primary plating media would be optimal for AF cultures and BACTEC appeared more sensitive than BacTALERT.

Comparison Of Body Fluid Cultures Inoculated In Blood Culture Bottles Versus Routine Media And Broth

Author Block:

A. Azar, N. D. Deschamp, R. C. Galloway, J. Liebl, K. L. Muldrew, M. A. Mahowald, **L. M. Stempak**; Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract Body:

Background: When culturing body fluid from normally sterile sites, fluid is inoculated on routine media, and additional fluid may be added to a blood culture bottle. This study assessed the accuracy of blood culture bottles for recovery of clinically significant bacterial organisms from body fluids compared to the traditional methods. **Methods:** Retrospective data from the previous three years (7/13/2012 to 6/30/2015) was reviewed for body fluid specimens in which a blood culture bottle was submitted in addition to the standard fluid for routine culture. Blood bottles (Bactec PLUS Aerobic/F, Standard Anaerobic/F and/or PEDS Plus/F) were incubated on the automated instrument (BACTEC 9000, Becton Dickinson) for 5 days or until growth was detected. For cultures using routine media, blood, chocolate, and MacConkey agars and thioglycollate broth were inoculated, incubated at 37°C in 5% CO_2 and examined daily for 3 days. Results were critically compared between the two methods for the presence of true pathogens and likely contaminants (e.g. coagulase-negative *Staphylocccus*, *Bacillus* spp., coryneform bacteria).**Results:** During the study period, 486 specimens were examined by both methods and results were compared and categorized as follows: 1. Complete concordance: 440 (90.5%). 2. Additional significant pathogens isolated solely from blood culture bottles: 30 (6.2%); 5 were likely contaminants (1%). 3. Additional pathogens isolated by the routine method: 10 (2.1%); 2 likely contaminants (0.4%). 4. No correlation (different organisms identified by each method): 6 (1.2%). On further analysis, true bacterial pathogens and contaminants were found by each method.**Conclusions:** Blood culture bottles allowed for isolation of additional significant pathogens in about 6% of cases, with only occasional contaminants. This increased sensitivity can be attributed to the larger volume of specimen inoculated into the bottle and longer incubations time. Rarely, pathogens were only isolated in routine culture on solid media. This illustrates the utility of using both detection methods for the identification of bacterial pathogens in body fluid cultures, and demonstrates that blood culture bottles are as good as, if not better than traditional methods.

Etiological Diagnosis of Bacterial Meningitis Using Filmarray Bcid Panel in Csf Samples: 6 Month Experience at Centro Hospitalario Pereira Rossell - Hospital Pediátrico, Montevideo, Uruguay

Author Block:

C. Gutierrez, M. I. Mota, A. Varela, F. Morosini, J. P. Gesuele, J. Prego, G. Algorta; Centro Hosp.ario Pereira Rossell, Montevideo, Uruguay

Abstract Body:

Bacterial meningitis has important sequelae burden and high mortality which have decreased thanks to early onset of antibiotic therapy; this however hampers the recovery of the responsible agent in cultures.In July 2015 the Film Array Blood Culture Identification (BCID) panel was introduced in our laboratory for the diagnosis of bacteremia. Here we report the off-label use of this panel in cerebrospinal fluid (CSF) samples.Biochemical and cytological findings in CSF samples of patients with clinical diagnosis of meningitis were observed from July to December 2015. To be analyzed with BCID panel the CSF had to comply with most of the following criteria: concentration of glucose <40 mg/dl, proteins >100 mg/dl, lactate >4,2 mmol/l, leukocyte count (WBC)> 1,000/µl, >75% neutrophils.6 of 232 CSF samples met the above criteria and were processed following the manufacturer's instructions for blood culture samples and analyzed with de BCID panel.**Table 1. Biochemical and cytological findings in CSF samples and FilmArray results.**

Sample	Proteins/Glucose (mg/dl)	Lactate (mmol/l)	WBC/µl (neutrophils %)	BCID panel
S1	235/37	13,36	14,400 (90%)	*S. pneumoniae*
S2	126/71	3,76	21,500 (90%)	*S. agalactiae*
S3	875/1	15,4	9,200 (90%)	*S. pneumoniae*
S4	0,96/Non detectable	8,94	1,400 (90%)	*Enterococcus* sp.
S5	320/7	11,77	3,800 (90%)	*N. meningitides*
S6	443/11	11,51	6,300 (90%)	*H. influenzae*

FilmArray detected 2 *Streptococcus pneumoniae*, 1 *Streptococcus agalactiae*, 1 *Enterococcus* sp., 1 *Neisseria meningitidis* and 1 *Haemophilus influenzae*.Gram stain examination showed neutrophils in all smears and gram positive cocci in S1 and S3 and no bacteria in S2, S4, S5 and S6.Latex agglutination test was positive only for *N.meningitidis* Y/W (S5).*E. faecalis* (S4) was

the only agent recovered from CSF cultures.For patients corresponding to S5 and S6, *N. meningitidis* W and *H. influenzae* (nontypeable) were recovered from blood culture.Unfortunately there was no more CSF sample left for further testing of the ones not confirmed by culture.Our results suggest that BCID panel may be used with CSF samples, providing rapid and accurate results.

Use Of The Biofire Meningitis/Encephalitis Panel For The Detection Of Viruses In Csf

Author Block:

D. Sayre, L. Glaser, K. Alby; Hosp. of the Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Introduction: Infectious encephalitis and meningitis are potentially life-threatening conditions caused by a host of viral, bacterial, and fungal pathogens. The clinical presentation of these conditions is often not dependent on the offending organism, leaving clinicians to utilize a broad spectrum of empiric therapies until more definitive laboratory data becomes available. The goal of this study was to establish the effectiveness and reliability of a recently approved multiplex panel for viral targets in our patient population.**Methods:** We retrospectively analyzed 32 patient samples as well as 18 patient samples known to be positive for either HSV, VZV, or enterovirus. The findings of the Biofire FilmArray ME panel were compared with conventional PCR assays and chart review.**Results:** The ME assay detected all targets previously found to be positive by standard PCR in samples obtained from outside laboratories (5 for HSV-2, 8 for VZV, 4 for enterovirus). However, additional targets were detected in three of the VZV samples (CMV, HSV-2, and *H. influenzae*), two (CMV and *H. influenzae*) of the three had sufficient residual sample for repeat testing and were negative upon repeat for the additional target. Of the 32 samples obtained from our hospital, 30 (94%) tested as negative for all viral targets. One sample (3%) tested positive for HHV-6, and one (3%) tested positive for enterovirus; no prior testing for these pathogens was previously performed but subsequent testing confirmed the observed results. Two non-viral targets were also detected. One *Cryptococcus*, confirmed by culture, and one *H. influenzae*, negative by Gram stain, culture, and chart review. Repeat testing of this sample was also negative.**Conclusions:** Overall, the ME panel demonstrated excellent sensitivity to detect multiple viral targets in CSF in a timely manner. However, a small number of the tests performed produced likely false positive bacterial results, a significant error given the severity of the disease and the aggressiveness of its therapy. This less than perfect specificity and analysis of the cost of test implementation suggest that this assay may be best utilized with some restrictions on testing and reporting by the laboratory.

Identification of Bacterial and Viral Pathogens in Previously Identified Negative Cerebrospinal Fluid Samples Using a Comprehensive Multiplex Pcr System

Author Block:

E. Lo[1], T. Lunt[2], E. Slechta[2], J. Daly[3], K. Hanson[2], A. Hemmert[1]; [1]Biofire Diagnostics, LLC, Salt Lake CIty, UT, [2]ARUP, Salt Lake CIty, UT, [3]Primary Children's Hosp., Salt Lake CIty, UT

Abstract Body:

Background: Central nervous system (CNS) infections, such as meningitis and/or encephalitis, are potentially life-threatening and require immediate and appropriate treatment. For suspected infections, cerebrospinal fluid (CSF) may be cultured for bacteria and fungi or tested by polymerase chain reaction (PCR) for viruses. The range of possible tests and test modalities makes pathogen etiology determination in CNS infection difficult and time-consuming. To aid in the identification of common causes of CNS infections, BioFire Diagnostics has developed the FilmArray™ (FA) Meningitis/Encephalitis (ME) panel recently cleared by the U.S. Food and Drug Administration (FDA) that simultaneously tests for fifteen bacteria, viruses, and fungi that may cause meningitis and/or encephalitis. Using a single-use disposable reagent pouch and, 200 µL of CSF the test is run and a result returned in about one hour.**Methods:** This study was performed to determine if a causative pathogen could be identified in previously characterized negative CSF samples. One-hundred (100) frozen, archived, de-identified patient CSF samples, previously identified to be pathogen negative by culture or specific PCR tests at Primary Children's Hospital or ARUP, were tested using the FilmArray ME panel. Any positive pathogen identification was confirmed using either a commercially available qPCR test or 16s sequencing.**Results:** For the majority of the 100 samples, no pathogen was identified. In eight of the samples, however, a virus or bacteria was discovered. Enterovirus was detected in five samples (5/100), human herpesvirus 6 in two (2/100), and *Haemophilus influenzae* in one (1/100).**Conclusions:** These data demonstrate that comprehensive molecular testing of CSF for patients suspected of meningitis or encephalitis will likely result in a higher rate of pathogen detection than selective testing for suspected etiologies. The FilmArray ME panel can provide valuable qualitative information to help clinicians make informed decisions through rapid and comprehensive identification of infectious etiologies in CNS disease.

Multi-site Assessment of an Image Analysis Device for Urine Cultures

Author Block:

J. H. Glasson[1], M. Summerford[1], D. Olden[2], L. Riley[3], S. Young[4]; [1]LBT Innovations Ltd, Adelaide, Australia, [2]Hlth.scope Pathology, Clayton, Melbourne, Australia, [3]SydPath, ST Vincents Hosp., Darlinghurst, Sydney, Australia, [4]TriCore Reference Lab., Albuquerque, NM

Abstract Body:

The reporting of growth from agar plates has traditionally relied on experienced technologists manually handling and reading those plates for the presence, quantity and characteristics of the colonies. More recently, a number of image capture devices have become available and reporting from digital images is being increasingly adopted. The Automated Plate Assessment System (APAS®, LBT Innovations, Adelaide, South Australia) is able to automatically assesses plate images for the presence, quantity and characteristics of the colonies. With a decision algorithm, it stratifies cases by the need for further action such as manual review or identification and antibiotic susceptibility testing. This multi-site study was designed to establish the diagnostic performance of this device in the screening of urine cultures. A combined total of 9977 urines submitted for routine culture to one diagnostic laboratory in the USA (TriCore Reference Laboratories) and two laboratories in Australia (Healthscope Pathology, Victoria and SydPath, NSW) were assessed. A 1µL sample of each urine was inoculated onto TSA sheep blood agar and MacConkey with CV agar (Remel, Lenexa, USA) and incubated in air at 35^{o}C for 18h. The plates were independently read by three microbiologists and the consensus results were compared with those produced by APAS®. APAS® detected colonies on blood agar with a sensitivity of 99.0% and specificity of 84.5% while on MacConkey agar, the detection sensitivity was 99.5 % and specificity 98.8%. Colony counts from the device showed agreement in 8417/9977 (84.4%) cases. Of the discrepant counts, 1267/1560 (81.2%) were higher than the consensus results. APAS® separated plates requiring further action with a sensitivity of 97.3%. In this multi-site assessment, APAS® demonstrated a comparable performance in the detection, enumeration and colonial classification of isolates when compared with conventional plate reading. The device detected the most commonly encountered organisms found in uncomplicated urinary tract infections and segregated the reports and plates for more efficient handling.

Publishing Title:

Enhanced Urine Culture Protocol Improves Detection of Clinically Relevant Microorganisms in Symptomatic Women

Author Block:

P. C. Schreckenberger, T. K. Price, E. E. Hilt, T. Dune, C. Brincat, L. Brubaker, E. R. Mueller, K. Thomas-White, S. Kliethermes, A. J. Wolfe; Loyola Univ. Med. Ctr., Maywood, IL

Abstract Body:

Background: Bacteria that are not routinely cultivated using standard urine culture protocols have been identified by new techniques in the urine of patients with and without urinary symptoms. These findings raise a concern about the accuracy of current urine culture practices. We compared results from standard urine culture to an improved urine culture protocol for detection of clinically relevant microorganisms in women with urinary symptoms. **Methods:** After institutional review board approval, we prospectively enrolled 150 urogynecologic patients and dichotomized the group based on their UTI perception, using a Y/N response to "Do you feel you have a UTI?" In addition to a standard urine culture of catheterized urine specimens, bacterial growth was assessed using 3 versions of an expanded quantitative urine culture (EQUC) protocol, which uses different media, an expansion of environmental culturing conditions, and 3 volumes of urine plated (1µL, 10µL and 100µL) instead of the 1µL used in standard culture protocols. Bacterial growth detected with EQUC was identified using MALDI-TOF MS. Microbiota diversity was assessed using the average number of unique species per urine specimen. Women were treated clinically based on results from standard urine culture alone. **Results:** The 100µL EQUC protocol detected significantly more uropathogens (174, including 95 unique species) compared to standard culture (60, including 11 unique species). The standard culture missed 67% (122/182) of the uropathogens detected using the EQUC protocols. In the YES cohort, standard culture missed 50% (55/110) of the uropathogens. Standard culture detected most *Escherichia coli* (84% - 44/50), but detected only a minority of all other uropathogens (8% - 8/100). The optimal EQUC version [100µL urine plated onto Blood (5% CO_2), CNA (5% CO_2), and MAC (O_2) with 48 hours of incubation] detected more uropathogens 84% (152/182) than standard culture 33% (60/182). **Conclusions:** Improved methods of uropathogen detection may aid clinicians in selecting treatment for women reporting UTI symptoms. The optimal form of EQUC markedly improves uropathogen detection and supports the need for an immediate reassessment of standard urine culture practices.

A Comparison of Three Commercially Available Urine Culture Collection Systems on the Stability and Overgrowth of Common Urinary Pathogens

Author Block:

S. Volhejn, **S. E. Dale**; ACM Global Central Lab., Rochester, NY

Abstract Body:

Background: Boric acid has been used for >40 years as a preservative for urine culture specimens. Many manufacturers produce urine preservative tubes, however, few comparative stability and bacterial overgrowth studies exist for common uropathogens using different devices. Given the composition differences of urine preservative tubes and potential for clinical impacts when performing quantitative urine cultures with urine collected in these devices, we compared the stability and overgrowth of common uropathogens using the Andwin Scientific Boritex®, Sarstedt Urine Monovette® and BD Vacutainer® Culture Plus C&S Urine Preservation Systems. **Methods:** Eight urinary pathogens from the American Type Culture Collection were prepared in sterile urine samples. Serial dilutions of each organism were inoculated in duplicate into the Boritex, Monovette or Vacutainer tubes. One tube of each dilution was stored either ambient (20°C -25°C) or refrigerated (2°C - 8°C). At time zero (15 minutes), 24, 48, 72 and 96 hours each dilution was plated in triplicate. Following incubation, colony forming units (CFUs) were counted and averaged to determine stability and bacterial overgrowth. **Results:** Extended stability was achieved for up to 4 days when urine was stored at 2°C to 8°C for all organisms tested in the Boritex and Vacutainer tubes. All organisms, with the exception of *S. saprophyticus*, was stable for 4 days using the Monovette. At 20°C to 25°C, the Boritex and Vacutainer tubes showed stability for 4 days for all organisms, except *P. aeruginosa* (2 days). The Monovette exhibited stability from 1 to 4 days when stored at 20°C to 25°C. The Boritex and Vacutainers were susceptible to bacterial overgrowth (> 0.5 log CFU/ml) at 20°C to 25°C with *E. coli, K. pneumoniae, P. mirabilis, S. saprophyticus* and *E. faecalis*. The Monovette contained the highest concentration of boric acid and inhibited the overgrowth of all microorganisms with the greatest efficacy. **Conclusions:** Extended stability of common uropathogens can be achieved with Boritex and Vacutainer tubes stored at 2°C to 8°C and 20°C to 25°C for up to 96 hours, however, bacterial overgrowth is observed at 20°C to 25°C. The Monovette tube showed the least stability, but the high boric acid level in these transport tubes is likely responsible for an overall reduction in bacterial overgrowth.

Comparing Results from the Iris Iq® 200 Sprint™ Analyses with Routine Urine Analyzing on an Automated Bd Kiestra System, to Validate the Prediction of the Culture Negative Urine Samples

Author Block:

L. Leerbeck, J. Iversen, A. Lund, J. Knudsen; Depart of Clin Microbiol, Hvidovre Hosp., Hvidovre, Denmark

Abstract Body:

Background: In our fully automated department of clinical microbiology, we constantly have focus on reducing the response time on the urine analyses to provide results faster and thereby improve clinical decisions. We have performed a validation test on The Iris Diagnostics iQ© 200 SPRINT™ Automated Urine Microscopy Analyzer (iQ200 SPRINT) from Beckman Coulter, and compared the results with the routine urine analysis on the BD Kiestra™ Total Lab Automation system.**Methods:** We processed 528 clinical samples both through the iQ200 SPRINT and inoculated and cultured on the BD Kiestra system. The routine urine culture analyses considered the 10(3) colony forming units/mL as significant for *Escherichia coli* and *Staphylococcus saprophyticus*, and 10(4) for other typical uro-pathogens. The data for bacteria, white blood cells and small particles counted in samples by the iQ200 SPRINT and after culture were compared. We aimed to be able to predict the culture negative samples. **Results:** Using all three of the following thresholds for iQ200 SPRINT to report negative samples: White blood cells <40/µL, bacteria <5/µL, and small particles <3500/µL, 169 sample were identified. In 101 (60%) samples no growth were seen, in 64 (38%) insignificant growth were seen, and in 2.4%, 4 samples (10(4) yeasts, 10(4) hemolytic streptococci, 10(5) *Proteus mirabilis, and* 10(4) *Proteus vulgaris)* were missed. The negative predictive value was 98%. Screening with iQ200 SPRINT could have avoided 169 of 528 (32%) cultures performed. In these 32% of cases, the clinician could have had the negative result on the day of sampling, and the laboratory did not have to perform the cultivation. We found the iQ200 SPRINT to be a fast and user friendly instrument. **Conclusions:** The validation in our laboratory revealed acceptable results with a negative predictive value of 98%. In our fully automated laboratory, is the possibility for saving space in incubators and need for photo-reading of plates highly warranted. We conclude that the iQ200 SPRINT is a valuable urine analyzer that could make us reduce response time for negative samples and save resources as fewer samples needs cultivation.

Optoelectronic Detection of Bacterial Growth in Clinical Urine Samples

Author Block:

U. Aurbach[1], M. Eiden[2], S. Lim[2], P. Rhodes[2], **H. Wisplinghoff**[3]; [1]Wisplinghoff Lab., Cologne, Germany, [2]Specific Technologies, Mountain View, CA, [3]Inst. for Med. Microbiol., Univ. of Cologne, Cologne, Germany

Abstract Body:

Background: Optoelectronic detection and identification of microorganisms based on an inexpensive, printed, disposable colorimetric sensor array (CSA) responsive to the volatiles emitted into the headspace of culture bottles during growth has been shown to have the potential to shorten time to result in blood cultures. Similarly, using sensors placed in the lids of blood agar plates, it has been possible to identify presence and species on blood agar plates.**Methods:** This study was conducted to evaluate the potential use of optoelectronic detection more broadly in clinical microbiology. Urine samples from were tested with conventional cultural methods using TSA-blood-, CPS-, and CN-agar, all with and without CSA. Urine samples included were either sterile (with and without inhibitory substances) or were inoculated with one or more of the following bacterial pathogens at concentrations of 10^2-10^6 cfu/ml: E. coli and other Enterobacteriaceae, P. aeruginosa and other non-fermenting gram-negatives, Enterococcus spp., Staphylococcus spp., Streptococcus spp. All samples were run in duplicate.**Results:** A total of 200 samples were prospectively included. Time to positivity (detection time, all positive specimens) ranged from 4.6 to 11.6 hours, sensitivity of species identification (monomicrobial cultures) at 1, 2 and 3 hours after initial detection of growth showed a high correlation to MALDI-TOF identification but varied between different pathogen /media combinations pathogens and could be improved by adaption of algorithms to the respective media.**Conclusions:** CSA-based optoelectronic detection seems to be a promising addition to the routine clinical microbiology laboratory with the potential to significantly shorten the time to positivity and / or species identification in urine and potentially other clinical specimens.

High-Resolution Seven Snp-Based Test Allows Rapid Identification of Clonotypes and Prediction of Antimicrobial Susceptibility of Extraintestinal *Escherichia coli* Directly from Clinical Specimens

Author Block:

V. Tchesnokova[1], H. Avagyan[1], M. Muradova[1], S. Chattopadhyay[1], D. Chan[1], E. Rechkina[1], F. Fang[1], J. R. Johnson[2], E. V. Sokurenko[1]; [1]Univ. of Washington, Seattle, WA, [2]Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Background: *Escherichia coli* is a highly clonal pathogen with strains belonging to a limited number of genetically related groups, often exhibiting characteristic antimicrobial resistance profiles.**Methods:** We developed a rapid method of clonotyping of extra-intestinal *E. coli* based on detection of the presence/absence of seven single-nucleotide polymorphisms (SNPs) within two genes (*fumC* and *fimH*). A reference set of 2,559 *E. coli* isolates, primarily of urinary origin, was used to evaluate the resolving power of the 7 SNP-based typing method.**Results:** A total of 54 unique SNP combinations ('septatypes') were identified in the reference strains, with clonal-group resolution power on par with traditional multi-locus sequence typing. In 72% of isolates the septatype identity predicted the sequence type identity with at least 90% (mean 97%) accuracy. Most septatypes exhibited highly distinctive antimicrobial susceptibility profiles. The 7 SNP-based test can be performed with high specificity and sensitivity using single or multiplex PCR and qPCR. In the latter format, *E. coli* presence and septatype identity was determined directly in urine specimens with bacterial loads as low as 10^2 cfu/mL within 45 minutes and, at clinically significant bacterial loads, with 100% sensitivity and specificity.**Conclusions:** The 7 SNP-based typing of *E. coli* can be used for both epidemiological studies and clinical diagnostics that could greatly improve the empirical selection of antimicrobial therapy.

A New Technique to Study Symptomatic Patients with Negative Urine or Semen Cultures

Author Block:

M. E. Ordonez Smith; Microbiol. Inst. of Colombia, Bogota, Colombia

Abstract Body:

A new technique is described in order to recover bacteria in urine or semen samples. Several urinary or prostatic symptomatic patients have negative urine or semen cultures; therefore we sought to look at a novel approach to address this diagnostic gap. All the urines (317) or semen (32) samples were processed immediately: 1. As the CLSI gold standard technique. 2. At the same time, they were done with the new technique, which consists in incubating the urine or semen samples at 37^0C for 24 hours. Each sample was smeared after 5 to 7 hours and after 24 hours, onto blood agar, and CLED agar in order to compare colony counts. This new technique gives results between 24 to 48 hours earlier than the standard method. The samples were studied from 208 symptomatic urines or semen from prostatitis (94 cases) or urinary infections (114 cases) and 109 from asymptomatic patients. Symptomatic patients had >10.000 CFU/mL after 5 to 7 hours of incubation a 40.8%, after 24 hours at 37^0C a 87.0% positive urine or semen cultures by the new method. Conversely, there were 19.5% positive cultures by the gold standard method ($p<0.05$, Table 1). This new technique not just can help to reduce costs in days of hospitalization, diagnostic tests, but it improves patients relieve in terms of urinary or prostatic symptoms. Here we show that bacteria grow better in the same urine or semen habitat (37^0C) rather than in artificial media.Keywords New technique, Urinary tract Infections, ProstatitisTABLE 1. Symptomatic patient’s samples

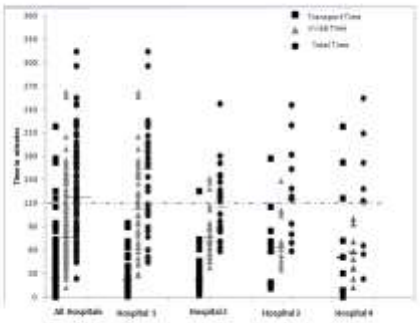
The Csf Gram Stain: Turn-Around Time Experience At One Health Care System

Author Block:

I. Agarwal, S. Das, R. B. Thomson, Jr; NorthShore Univ. Hlth.System, Evanston, IL

Abstract Body:

Bacterial meningitis is associated with high morbidity and mortality. Expedited specimen transport, rapid laboratory reporting of initial microscopic results can be crucial for initiation of appropriate therapy. In this study, we determined turn-around time (TAT) of CSF Gram stains from Emergency Department patients (ED) over a one year time period in a 4 hospital system to see if they met the proposed guidelines.Retrospective data collection of CSF Gram stain TATs from ED was done by extracting collection, laboratory receiving and reporting times from the hospital (EPIC) and laboratory (SCC) information systems. The time from sample collection to laboratory receipt was recorded as “transport time.” The time from sample receipt to result reporting was labeled “in laboratory time.” “Transport time” plus “in laboratory time” was labeled “total TAT.”Data for a total of 78 CSF specimens was collected. The overall TAT and TAT for each hospital are presented in the figure.If a 2 hour total time including a 1 hour transport and 1 hour in laboratory time is a proposed guideline recommendation, 44% specimens met the 2 hour total TAT, while 76% and 28% had a 1 hour transport time and in-lab time, respectively. When data from all 4 hospitals were combined, 2 out of 4 hospitals, met the recommended TAT for 50% of the total specimens processed. Among these, one laboratory, met the recommended in laboratory TAT for 67% of specimens and the other met the recommended total TAT for 54% of specimens.Guidelines suggesting a 2 hr TAT for CSF Gram stain reporting are not consistently achieved in our 4 hospital system. Our data show that unacceptable TATs are caused by extended transport and in-lab testing times. Plans for improvement will duplicate processes that allow some hospitals to meet acceptable TATs in hospitals that do not meet guidelines.



Scatterplot of TAT from All Hospitals and the Individual Hospitals. Horizontal dashed line represents recommended TAT of 2 hours. Median value is shown for each data set as a horizontal solid line.

Abstract Body:

Background: In this multicenter prospective cohort study it was aimed to evaluate the bacterial and viral etiology of community acquired infections of the central nervous system by standart bacteriological culture method and multiplex polymerase chain reaction method. **Methods:** A total 74 patients (aged 18-90) were hospitalized with central nervous system infections were enrolled into the prospective study between April 2012 and February 2014. Demographic information of patients were collected. Cerebrospinal fluid (CSF) samples of patients were examined for bacterial and viral pathogens by standart bacteriological culture methods, bacterial multiplex PCR (Seeplex meningitis-B ACE Detection (Streptococcus pneumoniae, Neisseria meningitidis, Haemophilus influenzae, Listeria monocytogenes, Group B streptococcus) and viral multiplex PCR (Seeplex meningitis-V1 ACE Detection kits herpes simplex virus-1 (HSV1), herpes simplex virus-2 (HSV2), varisella zoster virus (VZV), cytomegalovirus (CMV), Ebstain Barr virus (EBV) ve human herpes virus 6 (HHV6)) (Seeplex meningitis-V2 ACE Detection kits (enteroviruses)). **Results:** A total of 74 patients (24 female, 50 male, aged 43,9±17,7) fulfilled the study inclusion criteria. CSF cultures were positive in 10 patients (9 S. pneumoniae, 1 H. influenzae). Pathogens were shown by multiplex PCR in 43 patients. One type of bacteria were detected in 16 patients (13 S. pneumoniae, 2 N. meningitidis, 1 H. influenzae) and single type of virus were isolated in 14 patients (8 enterovirus, 2 HSV1, 1 HSV2, 2 VZV and 1 EBV). Besides, it is noteworthy that multipl pathogens detected such as bacteria- virus combination in 9 patients, viral-viral detections in 3 patients and two different bacterias in 1 patient in our study. **Conclusions:** These data suggest that multiplex PCR methods may increase the isolating of pathogens in central nervous system infections. Further studies are needed for the clinical significance of mixed detections.

Draft Genome Sequence of *Klebsiella pneumoniae* ST-14 Harboring *bla*$_{\text{CTX-M-15}}$, *bla*$_{\text{DHA-1}}$, *bla*$_{\text{TEM-1B}}$, *bla*$_{\text{NDM-1}}$, *bla*$_{\text{SHV-28}}$, & *bla*$_{\text{OXA-1}}$ Isolated from a Patient in Lebanon

Author Block:

S. Tokajian[1], J. A. Eisen[2], G. Jospin[2], G. Matar[3], G. F. Araj[3], D. A. Coil[2]; [1]Lebanese American Univ., Byblos Campus, Lebanon, [2]Univ. of California Davis, Davis, CA, [3]American Univ. of Beirut, Beirut, Lebanon

Abstract Body:

Extended-spectrum β-lactamase (ESBL)-producing *Klebsiella pneumoniae* constitutes one of the most common multidrug-resistant (MDR) groups of gram-negative bacteria involved in nosocomial infections worldwide. Emergence and rapid dissemination of ESBL-producing bacteria has led to the increased utilization of carbapenems, consequently leading to the occurrence of isolates with resistance genes that code for carbapenemases (1).In this study we report on the molecular characterization through whole genome sequencing of a highly drug resistant *K. pneumoniae* KGM-IMP216 isolated from a urine sample collected from a patient in Lebanon. A Nextera XT kit (Illumina, San Diego, CA, USA) was used to simultaneously fragment and adapter tag the library. The library was sequenced using the MiSeq v3 600-cycle kit (Illumina, San Diego, CA, USA) to perform 300-bp paired-end sequencing. Quality trimming and error correction of the reads resulted in 4,192,299 high-quality reads. The final draft genome sequence consisted of 77 contigs that contained 5,731,500 bases with 57% G+C content. The sequence type of *K. pneumoniae* KGM-IMP216 was ST-14. Automated annotation was performed using the RAST annotation server (2), which revealed the presence of several virulence determinants including adhesins. ResFinder additionally, revealed that the isolate harbored *bla*$_{\text{CTX-M-15}}$, *bla*$_{\text{DHA-1}}$, *bla*$_{\text{TEM-1B}}$, *bla*$_{\text{NDM-1}}$, *bla*$_{\text{SHV-28}}$, and *bla*$_{\text{OXA-1}}$ genes (3). The concomitant presence of other resistance determinants, including resistance to macrolide (*msrE* and *mphE*), phenicol, sulfonamide (*sul1* and *sul2*), tetracycline (*tetA*), trimethoprim (*drfA14*) and aminoglycoside (*aac(6')lb-cr)*, was another important finding.To the best of our knowledge we report for the first time the sequencing of *K. pneumoniae* harboring *bla*$_{\text{CTX-M-15}}$, *bla*$_{\text{DHA-1}}$, *bla*$_{\text{TEM-1B}}$, *bla*$_{\text{NDM-1}}$, *bla*$_{\text{SHV-28}}$, and *bla*$_{\text{OXA-1}}$ with the sequence type ST-14. The potential role of *K. pneumonia*e as a reservoir for ESBL and carbapenemases genes is along with the presence of key factors that favor the spread of antimicrobial resistance, a clear cause of concern.

Molecular Diversification in Epidemic Carbepenem-Resistant *K. pneumoniae* (Crkp) Clonal Group 258 (Cg258)

Author Block:

L. Chen[1], H. Xiong[2], E. G. Pamer[2], J. D. Pitout[3], M. D. Adams[4], B. N. Kreiswirth[1]; [1]PHRI-Rutgers Univ, Newark, NJ, [2]MSKCC, New York, NY, [3]Univ of Calgary, Calgary, AB, Canada, [4]JCVI, La Jolla, CA

Abstract Body:

Background: Our previous study showed that Kp ST258 is a hybrid strain distinguished into two major clades with different capsule polysaccharide (*cps*) regions. Clade I strains evolved from clade II by *cps* replacement. Our recent molecular surveillance demonstrated the emergence of novel *cps* groups in ST258. Here we use whole genome sequencing (WGS) to understand the molecular evolution in CG258.**Methods:** 39 CRKp CG258 isolates (21 ST258, 14 ST11, 2 ST437 and 2 ST340) from US, China, India, Argentina, Colombia, Brazil, and Turkey were selected for WGS using Pacific Biosciences RSII and Illumina NextSeq. The sequences were compared to other genomes from our in-house database and in the public domain. 9 CG258 isolates with different *cps* were examined in a murine pneumonia model for virulence and clearance by neutrophils and monocytes.**Results:** Among the 39 isolates, 26 KPC-2, 6 KPC-3, 3 NDM-1, 1 OXA-163 and 1 OXA-48 were identified. Core SNPs analysis clustered the 39 genomes with other CG258 from the public database, but separated CG258 from the genomes of other CGs. However, deeper analysis among the 39 CG258 genomes revealed high genetic diversity, including (1) extensive *cps* variations: 21 different *cps* types (7 in ST258, 10 in ST11, 2 in ST437 and 2 in ST340), and two truncated *cps* due to an IS insertion; (2) putative donor STs of novel *cps*: ST258 *cps-3* carries the same *cps* as one ST111, while ST258 *cps-4* harbors the same *cps* as an ST16 in our database; (3) large non-contiguous, non-*cps* chromosomal recombination regions in different ST258 strains; (4) unique genetic regions: ST258 (*cps-1* to *-7*) have unique ICE and prophage sequences in comparison to the genomes of ST11, -340 and -437; and (5) different CR genes and plasmids: ST258 are associated with KPC, while ST11 also harbor other CR genes, on different plasmids. Novel *cps* groups in ST258 mainly carry $bla_{\text{KPC-2}}$ which is located on a novel plasmid. Upon inoculation into mouse lungs, CG258 isolates differ in terms of in vivo expansion and clearance by neutrophils.**Conclusions:** Cps replacement is largely driving the molecular evolution in CG258, however, additional chromosomal recombination and plasmid acquisition also contribute to reconstructing CG258, which may create strains of novel phenotypes.

L. Villa[1], C. Feudi[1], D. Fortini[1], M. Iacono[2], J. Pires[3], C. Mammina[4], C. Bonura[4], A. Endimiani[5], **A. Carattoli**[1]; [1]Istituto Superiore Sanità, Roma, Italy, [2]Roche Diagnostic S.P.A., Monza, Italy, [3]Inst. of Infectious Diseases, BERN, Switzerland, [4]Univ. of Palermo, Palermo, Italy, [5]Univ. of Bern-Inst. of Infectious Diseases, Bern, Italy

Abstract Body:

Background: *Klebsiella pneumoniae* producing KPC(KP-KPC) of the ST258 and related variants (Clonal Group CG258) spread worldwide. Here, we report the complete genome sequencing of the emerging KP-KPC clone ST307. This clone differently by CG258 produces the ESBL CTX-M-15.**Methods:** 94 KPC-KP isolates from a surveillance study conducted in 2014 in Neonatal Intensive Care Units of Palermo, Italy, were analyzed for ESBL, carbapenemase, PMQR, and plasmid content and typed by MLST. ST307 genome was compared against ST258 reference genomes NJST258 and KPNIH1.**Results:** Multifocal dissemination of KPC-3-producing KP clones was observed, the predominant KPC-3-CG258 clone was identified in 38/94 (40%) patients, but in 27/94 (28%) the ST307 was found. ST307 also carried *aac(6')-Ib-cr* and *qnrB* genes. The complete sequence of the ST307 strain KP-48, isolated from urine, revealed that the assembled genome size was 5,687,551 bp in length. 6,080 predicted coding sequences (CDSs), 76 tRNAs, and 25 rRNAs were identified in the genome (GenBank Acc. No. LKAB00000000). Three extrachromosomal elements were identified: the two IncFIIK plasmids pKpQIL and pKN3 carrying $bla_{\text{KPC-3}}$ and $bla_{\text{CTX-M-15}}$ genes, respectively and a novel phage. The pKN3 plasmid also contained two novel virulence clusters, encoding the enzymes for glycogen synthesis and a complete urea transport system. A second phage (HK97-like) was identified, integrated in the chromosome. The wzi-173 capsular antigen allele for this strain was exacerbated from the genome sequence, defining the KN2 capsular type. Interestingly, the ST307 genome also carried a second capsular cluster, whose best match was found against *Enterobacter aerogenes* genomes. Putative VirB Type IV secretion and iron uptake proteins were identified in regions of major discordance with the ST258 genome.**Conclusions:** The ST307 clone has different resistance and virulence features than CG258. The characteristics identified in silico -the urea transport system, KN2 capsular type, and the Enterobacter-like additional capsular cluster- may favor its expansion as a persistent colonizer of the urinary tract.

Genomic and Functional Characterization of IncX3 Plasmids Harbouring *bla*$_{SHV-12}$ in *Escherichia coli* from Human and Animal Origin

Author Block:

A. Liakopoulos, A. Kant, F. Harders, M. Brouwer, D. Ceccarelli, H. Smith, D. Mevius; CVI of Wageningen Univ. and Res. Ctr., Lelystad, Netherlands

Abstract Body:

Background: Only a few IncX3 plasmids have been characterised, limiting our insight into the biology of this plasmid subtype. The aim of this study was to elucidate the biology of IncX3 plasmids encoding the *bla*$_{SHV-12}$ gene from diverse origins by sequencing and functional analysis. **Methods:** Nine epidemiologically unrelated isolates exhibiting extended-spectrum cephalosporin-resistant phenotype were included in the study. Species identification was performed using MALDI-TOF MS, while the genetic relatedness was assessed by MLST. The presence of ESBL/AmpC genes was determined by microarray analysis, PCR amplification and sequencing. Transformation experiments were performed to assess plasmid location of the ESBL/AmpC genes.Plasmids were characterized by PCR-based replicon typing, S1-PFGE, mating and stability assays. Quantification of the plasmid copy numbers and the fitness cost are currently under way. Plasmid DNA was extracted from transformants and sequenced using 150 bp paired-end libraries on an Illumina MiSeq sequencer. High quality filtered reads were assembled *de novo* and annotated.**Results:** All isolates were identified as *E. coli* belonging to five different STs and were recovered from human infections (ST69, n=1), food-producing animals (ST117, n=5; ST315, n=1) and retail meat (ST115, n=1; ST410 n=1). The *bla*$_{SHV-12}$ gene was located on non-typeable plasmids based on standard PBRT analysis (approximately 45 Kb), with stability ranging between 99 and 100% over 200 generations and transfer frequencies between $2.3*10^{-6}$ and $7.0*10^{-4}$ transconjugants per donor cell.Plasmid sequences varied in size between 43,506 and 48,414 bp, while 65 to 73 coding sequences were predicted per plasmid. All plasmids were found to belong to the IncX3 subgroup and co-carried *qnrS*1 (n=8) or *bla*$_{TEM-1}$ (n=1). Plasmid backbone shared high similarity to plasmid pIncX-SHV (JN247852), including sequences encoding replication, partitioning, conjugation/type IV secretion system, transcriptional activator and putative DNA transfer proteins.**Conclusion:** Our data underscore the potential of spreading and maintenance of these plasmids encoding for decreased susceptibility to first-line antimicrobial agents and limiting the effective treatment options for human infections.

Publishing Title:

Longitudinal Kpc-Producing *k. Pneumoniae* (Kp) Bloodstream Isolates (Bsi) Exhibit Differences In Colistin (Col) Susceptibility, Virulence, And Chromosomal And Plasmid Genes

Author Block:

M. Nguyen[1], S. Cheng[1], L. Chen[2], R. Shields[1], B. Kreiswirth[2], C. Clancy[1]; [1]Univ. of Pittsburgh, Pittsburgh, PA, [2]PHRI-Rutgers, Newark, NJ

Abstract Body:

Background: Molecular mechanisms of virulence among KPC-Kp are poorly understood. We recovered COL-susceptible (S) and -resistant (R) ST258 KPC-Kp BSIs from a patient (pt) who failed COL treatment (BSI Number 1 and Number 2, respectively). We hypothesized that genomes of the BSIs would be closely related, but virulence would be attenuated in BSI Number 2. **Methods:** We performed whole genome sequencing using Illumina MiSeq, and tested BSIs for virulence in a mouse model of intra-abdominal infection (IAI). **Results:** Genomes differ by 25 single nucleotide polymorphisms (SNPs) and 16 insertion-deletions (15 intergenic, 1 frameshift). Core genes containing non-synonymous SNPs include pmrB and ramR. PmrB encodes the sensor in a two component system that regulates lipopolysaccharide modifications; pmrB mutations have been implicated in COL R. RamR is a transcriptional repressor that controls expression of multidrug efflux genes and regulates virulence in Gram negative bacteria. In our large repository, 3 KPC-Kp from unique patients collected years apart have core genomes that are virtually identical to each of BSI Number 1 and Number 2 (0-2 SNPs). Therefore, BSI Number 2 is likely a circulating hospital strain that was acquired independently, rather than a strain that evolved from BSI Number 1 during treatment. BSI Number 2 is ~100 kb larger than strain Number 1 due to plasmid differences. BSIs Number 1 and Number 2 contain 250 kb and 350 kb that are unique, respectively. BSI Number 2 carries pKLN-IT, an $IncFII_k$-FIB-like plasmid that contains Fec-like iron (III) uptake and glutathione ABC transport systems. At high inocula, BSI Number 1 caused significantly greater mortality than BSI Number 2 during IAI. However, at lower inocula, BSI Number 2 persisted for significantly longer periods and at higher burdens within IA abcesses. **Conclusions:** A COL-R ST258 KPC-Kp BSI was less able to kill mice than a closely-related COL-S BSI, but caused more severe and persistent disease during sublethal IAI. KPC-Kp chromosomal genes (such as pmrB and ramR, which regulate multiple targets) and plasmid genes (such as those involved in iron uptake) may make unique contributions to virulence, at different stages of infection. Individual pts can be infected with multiple KPC-Kp strains, with different resistance and virulence profiles.

Comparative Genomic of Clonal Complex (Cc) 11 of Carbapenem Resistant *K. pneumoniae* (Cr-Kp) Clinical Isolates from Brazil

Author Block:

J. K. Palmeiro[1], A. L. Grazziotin[2], R. F. de Souza[3], N. M. Vidal[2], M. A. Schörner[4], T. M. Venancio[2], L. M. Dalla-Costa[1]; [1]HC-UFPR; FPP/IPPPP, Curitiba, Brazil, [2]Lab. de Química e Função de Proteínas e Peptídeos, CBB/UENF, Campos de Goytacazes, Brazil, [3]LEEP/ICB/USP, São Paulo, Brazil, [4]HU-UFSC, Florianópolis, Brazil

Abstract Body:

Background: Over the past decade CR-Kp has been recognized in health-care settings as a cause of difficult-to-treat infections associated with high mortality. Here we report a comparative genomic analysis of nosocomial Kp isolates representing different times and resistance profiles in Southern Brazil. **Methods:** A total of 51 Kp clinical isolates recovered during 2005-2012 were studied. AST was performed using agar dilution. PCR was used to detect resistance genes. PFGE was carried out to discriminate strains. Based on isolated timing, resistance profiles and genetic features, six Kp isolates were sequenced on a Illumina HiSeq 2000 platform using the RAPID method. Genomes were assembled using Velvet and SSPACE and annotated using RAST, Prokka, BLAST, ARDB and CGE servers. **Results:** In 2010, KPC-Kp (KpA2 and KpA3) caused an outbreak at our university's hospital. KpD8/KpC9 and KpB10/KpC2 were isolated before and after the outbreak, respectively. All isolates showed multidrug resistance (MDR) profiles and belonged to CC11: four ST437 (PFGE profile A and G) and two ST11 (PFGE profile L and Q). Resistance genes *bla*$_{KPC-2}$, *bla*$_{CTX-M2}$, *bla*$_{CTX-M3}$, *bla*$_{CTX-M15}$, *bla*$_{TEM-1B}$, *bla*$_{OXA-1}$, *bla*$_{OXA-2}$, aac(3')-IId, aac(6')-Ib-cr, aph(3')-Ia, ant(2")-Ia, ant(4')-Ia, aadA and *qnrB1* were variedly distributed among the isolates and presumably contributed to the diverse MDR profiles. The *bla*$_{KPC-2}$ genes were found to be located within Tn4401b and to be associated with plasmids of similar Inc groups. Such groups were markedly different from the ones found in our non-KPC isolates. KpC9 was unique because it did not have *bla*$_{KPC-2}$ but was resistant to carbapenem, thus suggesting the involvement of other resistance genes. **Conclusions:** Our isolates belong to CC11 and have *bla*$_{KPC-2}$ associated to Tn4401b. We have found the emergency of multi-resistant Kp in our samples was parallel to radical shifts in plasmid composition, thus suggesting that horizontal gene transfer was key to the evolution of the 2010 outbreak.

Single-molecule Sequencing of Pooled Conjugable Plasmids from Clinical Multidrug Resistance *Klebsiella pneumoniae* Revealed Transposons and Resistant Genes Horizontal Transfer Profile

Author Block:

Y. Jiang, Y. Wang, X. Hua, Z. Ruan, Y. Feng, P. Shen, Y. Yu; Sir Run Run Shaw Hosp., Coll. of Med., Zhejiang Univ., Hangzhou, China

Abstract Body:

Background: Plasmids play an important role in horizontal gene transfer (HGT), particularly in the dissemination of antibiotic resistance. To investigate the transposons and resistant genes HGT profile in plasmids, we designed a single-molecule real time (SMRT) sequencing assay of pooled conjugable plasmids from clinical multidrug resistance (MDR) *Klebsiella pneumoniae*.**Methods:** 53 nonduplicated MDR *K. pneumoniae* strains were obtained from affiliated hospital of Zhejiang University in China in 2009. All of these strains were confirmed harboring at least one comjugable plasmid. Plasmid conjugation was carried out by filter mating assay. The antimicrobial susceptibility were determined by K-B method. An S1 nuclease assay was performed in transconjugant strains to estimate the size of large plasmids in the presence of genomic DNA using PFGE. All conjugable plasmids from transconjugant strains were abstracted and pooled, and then they were sequenced by SMRT technique using PacBio platform.**Results:** The 53 clinical *K. pneumoniae* strains showed MDR phenotype against β-lactams, aminoglycosides, fluoroquinolones, and so on. Most of these resistance profiles could be transferred to transconjugants by plasmid conjugation. The 53 conjugable plasmids were 34kb to 355kb in size as estimate. With complete SMRT sequencing and assembling, 389 assembled fragments which have been designated as "unitigs" were acquired. All of unitigs were annotated by gene prediction and BLAST tools. 84 of 389 unitigs were deemed as plasmid fragments based on their gene annotation. There were 85 resistant genes (30 non-redundant genes) found in 84 plasmid fragments using the ResFinder tool, such as aminoglycoside resistant gene *aph(3')-Ia*, *rmtB*; β-lactamase gene bla_{SHV}, bla_{TEM}, bla_{CTX-M}, bla_{KPC}; fluoroquinolone resistant gene *qnrB4*, *qnrS1*; tetracycline resistant gene *tet*, and so on. Furthermore, 259 genes related with transposons or IS elements (96 non-redundant) were found using IS-Finder, including Tn3, Tn501, IS1, IS4, IS26, IS501, IS903 and so on. Most of HGT elements were related with resistant genes.**Conclusions:** We concluded that transposons and resistant genes were diversity in clinical MDR *K. pneumoniae* strains.

Global Analysis of Insertion Sequence (IS) Elements

Author Block:

M. D. Adams[1], B. Bishop[2], M. S. Wright[1]; [1]J. Craig Venter Inst., La Jolla, CA, [2]J. Craig Venter Inst., Rockville, MD

Abstract Body:

Background: Insertion sequence (IS) elements are active in many bacterial species and can have significant contributions to genome diversity. IS elements participate in the acquisition and spread of antimicrobial resistance genes in multidrug-resistant *Acinetobacter baumannii* and *Klebsiella pneumoniae* and have led to the sharp increase in carbapenem resistance in both species. Few studies have addressed genome-wide patterns of IS distribution using the wealth of genomic data that now exists for several pathogens. Comprehensive analysis of the IS element locations is important for understanding their evolutionary impact, but defining their insertion sites in draft genomes is challenging because typical sequencing and assembly methods do not resolve individual IS copies. **Methods:** We developed and applied a computational pipeline (ISseeker) to identify and annotate the termini of IS elements at contig edges in draft genome assemblies and applied the method to analysis of IS*Aba* and IS*Kpn* elements in all publicly available *A. baumannii* (>900) and *K. pneumoniae* (>750) genome sequences and evaluated the locations in each genome in the context of the core phylogeny for each species.**Results:** IS elements and insertion locations were more abundant and diverse in *A. baumannii* genomes than in *K. pneumoniae* genomes. In *K. pneumoniae*, IS elements associated with the bla_{KPC} gene are shared by most ST258 genomes, whereas in *A. baumannii*, the abundant IS elements are different in distinct phylogenetic groups. The location of IS elements relative to coding regions varies by the element, with some more likely to disrupt genes and others predominantly in intergenic regions. Multiple independent insertion events were found in several genomic regions, suggesting that those regions may play important roles in antimicrobial resistance or host adaptation.**Conclusions:** IS elements have played a larger role in shaping *A. baumannii* genomes than *K. pneumoniae* genomes, based on currently available sequence data.

Novel Pathogenic *Acinetobacter* Species Isolated at a Large Tertiary Care Facility

Author Block:

J. Stam[1], R. Clifford[1], E. Snesrud[1], L. Appalla[1], F. Onmus-Leone[1], P. Mc Gann[1], A. Ong[1], R. Maybank[1], Y. Kwak[1], P. Waterman[2], M. Hinkle[1], E. Lesho[1]; [1]Walter Reed Army Inst. of Res., Silver Spring, MD, [2]Armed Forces Hlth.Surveillance Ctr., Silver Spring, MD

Abstract Body:

Background: *Acinetobacter baumannii* is a serious threat to public health because of its ability to rapidly acquire drug resistance. To examine the epidemiology of multidrug resistant *A. baumannii* in a large tertiary care hospital, we performed whole genome sequencing on 1024 isolates collected from 2005 through 2011. We found that 55 isolates first identified as *A. baumannii* are members of distinct, but closely related species. Several may define novel pathogenic *Acinetobacter* species. **Methods:** All isolates identified as *A. baumannii* were provided by the hospital microbiology laboratory. Strains were reanalyzed on automated identification / antibiotic susceptibility testing platforms. Whole genomic sequencing was performed on the Illumina MiSeq or NextSeq platforms. Draft genome sequences were assembled and analyzed using a bioinformatics pipeline developed by MRSN.**Results:** The non-baumannii isolates were associated with bloodstream, sterile tissue, urinary tract, respiratory and wound infections, in addition to surveillance cultures. Seven isolates were multidrug resistant.Whole genome clustering based on core genome SNPs indicated that 55 isolates are not *A. baumannii*. The BLAST-based average nucleotide identity (ANIb) of these isolates to the *A. baumannii* reference strain ACICU ranged from 86.8% to 91.4%.The non-baumannii strains fall into three main branches. One strain, MRSN11738, is quite diverged from all others, showing only 75.9% ANIb to ACICU. Twenty-five isolates are more similar to *A. baumannii.* Three of these form one cluster, while the rest make up a cluster that includes *Acinetobacter genomosp*. 13TU. The remaining 29 strains are more similar to *A. calcoaceticus*, with ANIbs to reference strain PHEA-2 ranging from 96.1% and 96.7%. Isolates in this branch of the phylogenetic tree show more genomic diversity than those that are more similar to *A. baumannii*. These strains fall into at least 10 subgroups.**Conclusions:** Using whole genome sequencing we identified 55 healthcare associated *Acinetobacter* that are not *A. baumannii*. Isolates from several of these putative novel pathogenic species exhibit multidrug resistant phenotypes. Further characterization of these strains is ongoing.

Rapid Identification New Delhi Metallo-β-Lactamase-5 (Ndm-5) in US Hospital Populations Using Prospective Genomic Surveillance

Author Block:

X. Zhao, N. Li, N. D. Pecora, L. Bry; Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA

Abstract Body:

Background: The rapid spread of NDM-5 producing *Enterobacteriaceae* has raised serious concerns for healthcare systems. Within our hospital, multiple instances of NDM-5 have been identified in patients with international exposures. We present findings from our prospective genomic surveillance program that rapidly identified two *bla*$_{\text{NDM-5}}$-carrying *Escherichia coli* (*E.coli)* isolates using whole genome sequencing (WGS). We present the use of actionable data from genomic findings to support ongoing surveillance and support of patient care.**Method:**27 CRE isolates were collected from BWH during 2015. Species were identified by Vitek and phenotypic resistance determined by MIC and disk diffusion. WGS was performed on the Illumina MiSeq and generated paired-end reads of 250 bp with 90X average coverage. A locally developed clinical pipeline handled the assembly and analysis of resistance genes, mobile elements, and strain types, and further integrated epidemiologic data to identify local and international characteristics of strains.**Results:**Of the 27 sequenced isolates, 2 *E.coli* strains (8761 and 1465) carried *bla*$_{\text{NDM-5}}$. Epidemiologic analyses identified that 8761 was isolated from a patient who had recent hospitalizations in China and 1465 was from USA patient with hospitalizations in India. In addition to beta-lactam antibiotics, these strains were highly resistant to other drug classes. Multiple plasmids were identified in both isolates, including Inc group F, A/C2, and IncX3 plasmid which have played crucial roles in the dissemination of the *bla*$_{\text{NDM.}}$**Conclusion:** Our genomic surveillance program identified *bla*$_{\text{NDM-5}}$ positive *E.coli* isolated from two patients from different countries indicating spread of NDM carrying *E.coli* across international borders. Therefore, international cooperation between healthcare institutes will be required for robust surveillance and control of these drug resistant pathogens. With international travel, urban medical centers need to remain vigilant for the pathogens and forms of drug resistance that may spread from other locations. Clinical use of bacterial WGS provides a valuable tool to track and rapidly identify underlying causes of resistance and virulence, further supporting clinical actions taken to reduce the transmission and spread of these organisms.

The Use of Comparative Genomics to Characterize the Diversity of *Acinetobacter baumannii* in a Health Care Institution

Author Block:

L. Wallace[1], T. H. Hazen[1], S. C. Daugherty[1], S. Nagaraj[1], J. Johnson[2], A. D. Harris[2], D. A. Rasko[1]; [1]Univ. of Maryland Inst. for Genome Sci., Baltimore, MD, [2]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Despite the increasing prevalence of the nosocomial pathogen *Acinetobacter baumannii*, little is known about the genomic components which contribute to clinical presentation of this important pathogen. Whole genome comparisons of *A. baumannii* have focused on specific genomic regions associated with phenotypes in a limited number of genomes, often associated with antimicrobial resistance. In this work we describe the results of a whole genome comparative analysis of 254 surveillance isolates of *Acinetobacter* species isolates, 203 of which were identified as *A. baumannii*. These isolates were obtained as part of an infection control active surveillance program at the University of Maryland Medical Center. The collection of surveillance isolates includes both carbapenem sensitive and resistant isolates obtained from either sputum or perirectal swabs. Based on the whole genome phylogeny, the *A. baumannii* isolates belong to two major phylogenomic lineages. Results from multi-locus sequence typing indicated that one of the major phylogenetic groups of *A. baumannii* was comprised solely of strains from the international clonal lineage 2. The genomic content of the *A. baumannii* isolates was examined using Large-Scale BLAST Score Ratio analysis to identify genes that are associated with carbapenem sensitive and resistant isolates, as well as genes associated with the source of isolation. This analysis revealed a number of genes that were exclusive or present at a greater frequency among these groups, This study is the most comprehensive genomic comparison of *Acinetobacter* isolates to date and provides important information that will contribute to our understanding of the success of *A. baumannii* as a human pathogen.

Exploration Of An *acinetobacter Johnsonii* clinical Strain Genome Revealed The Presence Of Extensive Horizontal Gene Transfer (Hgt)

Author Block:

S. Montaña[1], **K. Chiem**[2], S. T. J. Schramm[2], G. M. Traglia[1], G. Parmeciano Di Noto[1], M. Almuzara[3], C. Barberis[3], M. E. Tolmasky[2], C. Vay[3], C. Quiroga[1], A. Iriarte[4], M. S. Ramírez[2]; [1]IMPaM, UBA-CONICET, Buenos Aires, Argentina, [2]CSUF, Fullerton, CA, [3]FfyB, UBA, Buenos Aires, Argentina, [4]IIBCE, Montevideo, Uruguay

Abstract Body:

Background: In recent years, *Acinetobacter* spp. such as *A. johnsonii* has been considered an emergent pathogen that can cause human infections. While most *A. johnsonii* isolates are susceptible, strains harboring a variety of β-lactamases have recently been described. Here, we present research on the genome of an Aj2199 clinical strain that was co-producing PER-2 and OXA-58. **Methods:** A draft sequence for *A. johnsonii* Aj2199 was obtained using Illumina MiSeq. SPAdes assembler was used for *de novo* assembly and RAST server to predict open reading frames (ORF). OrthoMCL method was used to identify homologous genes. Different softwares (ARG-ANNOT, ISfinder, PHAST, etc) were used to explore the genome. PCR reactions and conjugation assays were also carried out.**Results:** Assembled contigs totaled 3,803,969 base-pairs with an N50 contig size of 70,198 and has a G+C content of 41.4 %. A total of 3737 possible ORFs were predicted.Genomic comparison identified 1204 gene families in *A. johnsonii* strains, while 240 were exclusively found in Aj2199. The 240 gene families were comprised of 254 genes, of which, more than 164 of these were annotated as hypothetical proteins and 24 were mobile elements. Moreover, 46 complete insertion sequences (IS) and truncated IS as well as the presence of three intact prophages were found. The analysis of $bla_{\text{PER-2}}$ genetic context revealed the presence of the previously described context from the *Enterobacteriacea* family suggesting genetic exchange.**Conclusions:** Genomic analysis of Aj2199 showed evidence of extensive HGT events indicated by the presence of a wide variety of different mobile elements and resistance determinants in Aj2199. The data obtained from our genomic analysis strongly suggested the promiscuity of *A. johnsonii* to easily acquire exogenous DNA from other species. The detection of antimicrobial resistance determinants and mobile elements expose the potential for *A. johnsonii* to evolve into a multiresistant bacterium and will explain the further spread of these genes into other species.

Genome Sequencing Reveals Global Spread of Stable Chromosomal CTX-M-15 in *Escherichia coli* ST648

Author Block:

N. Stoesser[1], H. Phan[1], D. Eyre[1], A. Sheppard[1], P. Turner[2], R. Sebra[3], A. Kasarskis[3], C. Moore[1], D. Dance[4], P. Newton[4], R. Phetsouvanh[4], T. Peto[1], S. Walker[1], D. Crook[1]; [1]Univ. of Oxford, Headington, United Kingdom, [2]Cambodia-Oxford Med. Res. Unit, Siem Reap, Cambodia, [3]Icahn Inst. for Genomics, New York, NY, [4]Lao-Oxford-Mahosot Hosp.-Wellcome Trust Res. Unit, Vientiane, Lao People's Democratic Republic

Abstract Body:

Background:A subset of clinical clones of *E. coli* (e.g. ST131, ST73) cause a disproportionate burden of global *E. coli*-attributable disease. The association of these clones with broad-spectrum antimicrobial resistance genes is a major clinical problem.Recently, ST648 has emerged as another common lineage associated with the ESBL gene $bla_{\text{CTX-M}}$, in particular $bla_{\text{CTX-M-15}}$. We sought to identify the genetic basis for this association using whole genome sequencing.**Methods:**We identified 27 novel, non-duplicate, ST648 sequences from our Modernising Medical Microbiology (MMM) databank of >1500 *E. coli* sequences (Illumina; clinical/carriage isolates, UK/South-East Asia; 2004-2012), and 90 from data in the sequencing read archive (identified from Enterobase).Reads from both sources were mapped and *de novo* assembled, and resistance genes identified with an in-house resistance gene database/gene-finding tool. Phylogenies were created using ClonalFrameML; a time-scaled analysis was performed in BEAST on a subset of sequences for which isolation dates were available.We also performed long-read PacBio sequencing on 1 $bla_{\text{CTX-M-15}}$-positive isolate (la_12008-2) in order to confirm the chromosomal/plasmid structures and genetic context of $bla_{\text{CTX-M-15}}$.**Results:**66/117 (56%) isolates were $bla_{\text{CTX-M-15}}$-positive. Chromosomal integration of $bla_{\text{CTX-M-15}}$ was confirmed in 27/66 (41%) cases in several contexts: interrupting a fructose transporter (n=5) or *lacY* (n=1), and downstream of *nanM* (n=2) or *asd-dprA* genes (n=19). The latter context was confirmed in la_12008-2, with a 5.12Mb chromosome containing $bla_{\text{CTX-M-15}}$ in a resistance gene cassette. 18 other cases with this chromosomal context were internationally distributed (UK, Germany, Laos, Cambodia, Thailand) and clustered on the phylogeny, suggestive of stable inheritance and dispersal since 2002.**Conclusions:**Chromosomal acquisition and stable inheritance of $bla_{\text{CTX-M-15}}$ represents a significant genetic mechanism for its dissemination in the major clinical lineage *E. coli* ST648.

Genomic and Epidemiological Determinants of *Enterobacter cloacae* Transmission

Author Block:

S. E. Whitefield[1], L. L. Washer[2], C. A. Scipone[2], C. R. Dombecki[2], D. W. Newton[2], E. S. Snitkin[1]; [1]Univ. of Michigan Med. Sch., Ann Arbor, MI, [2]Univ. of Michigan Hlth.System, Ann Arbor, MI

Abstract Body:

Background: The emergence of healthcare associated carbapenem resistant *Enterobacteriaceae* (CRE) infections is concerning because carbapenems are a last line treatment for resistant gram-negative infections. Prior CRE work has focused on *Klebsiella pneumoniae*, due to widespread dissemination of *K. pneumoniae* carbapenemase (KPC)+ strains. Less is known about the genetic epidemiology of other CRE, such as *Enterobacter cloacae.* In 2015, 8 *E. cloacae* isolates were identified from clinical samples of patients who underwent a procedure in our hospital that utilized duodenoscopes with elevator channels. This type of device has been linked to previous CRE outbreaks, raising concerns that contaminated devices mediated transmission. **Methods:** We sought to determine if duodenoscopes at our institution were a vehicle for CRE transmission, through a combined epidemiological investigation and whole genome sequencing of isolates from 77 *E. cloacae* infections in our hospital since 2012. We compared genetic distances and gene content between isolates to rule out transmissions and infer factors that contribute to dissemination of *E. cloacae* strains.**Results:** Comparison of genetic distances between the 5 available isolates from patients undergoing endoscopy, definitively ruled out duodenoscope-mediated transmission among 3 patients. Of the remaining isolates with no duodenoscope exposure, 55 showed no evidence of transmission, and 17 were found in 6 putative transmission clusters. The genetically homogeneous transmission clusters are in stark contrast with the diverse population of *E. cloacae* circulating in our hospital, which spans the full diversity of all ~300 *E. cloacae* genomes in Genbank. Inspection of the largest cluster in the context of previously sequenced strains revealed that all five members carry a KPC gene, and a close genetic relationship with isolates from a recent *E. cloacae* CRE outbreak in Minnesota.**Conclusions:** Despite most CRE *E. cloacae* at our hospital not encoding carbapenemases, we find the majority of transmissions involve KPC+ strains. The observation that the most prevalent strain also recently caused an outbreak suggests an emerging lineage of CRE *E. cloacae* that is stably associated with a KPC plasmid and transmissible in hospital settings.

Prediction of Resistance Phenotypes from Microbial Genomes

Author Block:

M. FELDGARDEN, A. Badretdin, V. Brover, M. DiCuccio, D. Haft, A.Prasad, M. Shumway, W. Klimke; NCBI/NLM/NIH/DHHS, Bethesda, MD

Abstract Body:

Antimicrobial resistance (‘AMR’) is a major public health problem, especially now that multi- and totally drug-resistant clinical isolates have been observed. In the U.S., the National Strategy on Combating Antibiotic Resistant Bacteria has called for a better understanding of how bacterial genotype is related to antimicrobial resistance phenotype.To facilitate linking phenotype to genotype, NCBI has built on the existing BioSample database that provides descriptions of biological source material including isolate metadata for microbial pathogens. BioSamples are linked to sequence data providing direct links between published sequenced data, isolate metadata, and AMR phenotypes. The antibiotic resistance phenotypes are stored as an antibiogram table linked to the BioSample record. Phenotype fields include antibiotic compound, measurement data, typing method and platform, and antimicrobial susceptibility phenotypes using a standardized template with controlled vocabularies. Standardized fields streamline submissions as well as provide a structured format for researchers to comprehensively search across all records to find those relevant to their research. To date, NCBI has received 789 antibiograms.To identify AMR genes, NCBI is collaborating with external expert groups curating AMR genes to produce a high-quality reference database with up-to-date nomenclature; the database contains 4868 resistance gene proteins belonging to 1130 gene families. To identify resistance proteins in annotated genomes, we use a dual strategy of protein BLAST and hidden Markov models. To test the accuracy of this method, we assessed the correlation between our predicted AMR genotypes and resistance phenotypes in 248 clinical isolates. We found 94.3% of predicted genotypes were consistent with resistance phenotypes. The false positive and negative resistance genes resulted from limitations of currently accepted sequencing and assembly technology and software.The NCBI reference database of AMR sequences has been made available (see link at http://www.ncbi.nlm.nih.gov/pathogens). The linking of detailed antimicrobial susceptibility data to well-annotated bacterial genomes and the curated AMR gene reference set in publicly accessible databases at NCBI will be critical in the fight against antimicrobial resistance.

Identification of Pathogenicity-associated Loci in *Klebsiella pneumoniae* clinical Isolates

Author Block:

R. M. Martin, K. Rao, W. Wu, L. Zhao, D. Manthei, L. Roberts, J. Cao, P. N. Malani, M. A. Bachman; The Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Klebsiella pneumoniae is a leading cause of healthcare-associated infections (HAI) in the U.S. *K. pneumoniae* commonly colonizes hospitalized patients, and a subset of colonized patients goes on to develop extra-intestinal infections such as urinary tract infections, septicemia, and pneumonia. Though several virulence genes have been identified to date, the bacterial factors that determine whether an isolate causes disease or remains a colonizer are poorly understood. We hypothesize that horizontally-acquired genes promote extra-intestinal infection in colonized patients. To identify host factors and bacterial genes associated with *K. pneumoniae* infection, we performed a case-control study comparing infected patients meeting standard case definitions (n=39) and asymptomatic colonized patients (n=78), matched by age, sex, and sample collection date. Construction of a logistic regression model identified patient factors significantly associated with and predictive of infection (Area Under the Curve [AUC] of Receiver Operating Characteristic curve = 0.882). We then constructed a *K. pneumoniae* pan-genome, collapsed orthologous genes into "gene bins" and used read mapping from whole genome sequencing to compare the frequency of genes in each "gene bin" among colonizing and disease-causing strains. Using this Pathogenicity-Associated Locus Sequencing (PAL-Seq) method, we identified 5 gene bins associated with infection after adjustment for patient factors (P = 0.014-0.03). Incorporation of three of these gene bins improved the predictive power of our logistic regression model (Table; AUC = 0.951; P <.001). Our results suggest that genes in the accessory genome of *K. pneumoniae* are associated with HAIs and could provide a basis for novel predictive diagnostic approaches to identify colonized patients at risk of subsequent *K. pneumoniae* infection.

Table. Findings from final model of invasive *Klebsiella pneumoniae* infection

Variable	**OR (95% Confidence Interval)**	***P***

A New Automated Gram Smear Reading and Image Acquisition System for the Clinical Microbiology Laboratory

Author Block:

M. Grimaldi, **M. Oggioni**, A. Bielli, C. Lacchini, G. Lombardi, C. Vismara, G. Gesu; ASST Grande Ospedale Metropolitano Niguarda, Milano, Italy

Abstract Body:

Background: The microbiology laboratory has been automated with the implementation of different systems. Microscopy involves reading many Gram smear (GM) that are time demanding and tiresome to the eyes. The Metafer (MF) (MetaSystems) is a fully automated slide scanning and image recording platform that handles different sample types. High quality images are generated by MF with the future possibility to transfer to WASPLab^{TM} (WL)(Copan), next to same sample culture images (CI). The objective of this study was to evaluate the MF automated GM digital images acquisition in order to facilitate GM reading and results interpretation.**Methods:** WASP^{TM} (WA), prepared GM smears (N=427), 327 were sputa, broncoaspirates, bile, pus, exudate, surgical biopsies, throat, lesions, vaginal, uretrhal, wounds and abscess swabs, etc. and 100 blood cultures were used for this study. GMs were read in duplicate, one with the MF and the other with a manual microscope. Results were compared and discrepancies recorded. MF first scans the GM at 10x then reads at 63x, under oil, 9x4 field's set points on the smear and uses a scanning algorithm to recognize the presence of the sample on the slide. All samples were WA seeded on agars plates as per SOP. Gram (G) results were compared to bacteria culture.**Results:** In the 427 WA prepared smear, 327 different samples had concordant G results with both manual and automated microscopy readings. Concordant G and culture results were found in 269 samples, only 58 had discordant G and culture results due to presence of non-pathogenic bacterial flora. Both G readings and culture results of the 100 blood culture had 100% concordance. The smear pattern recognition resulted in better performance, with overall process improvement. The MF smear image acquisitions at 10x allows the assessment of smear quality, presence of cells identification and counting, while the images captured at 63x, permits a digital magnification up to 150x for better bacteria identification.**Conclusions:** The MF GM scanning and images acquisition was simple to use and reliable for reading GM prepared with the WA automation. The ability of MF to capture images and the future implementation to transfer to WL system, placing on the same screen (GM and CI), provides working time optimization, increases results reporting capabilities.

First Evaluationof the Prelud, a New Inoculation Automated System

Author Block:

p. grohs[1], L. Armand-Lefevre[2]; [1]Hosp. Européen Georges Pompidou, PARIS, France, [2]Hosp. Claude Bernard Bichat, PARIS, France

Abstract Body:

Background: The Prelud is a new inoculation automated system (I2a, Montpellier, France) designed to plate liquid specimens and swabs. It has a plating control system (PCS), a camera that detects the presence of the droplet and streaks on the medium. We evaluated here, (i) the performance of inoculation with the Prelud compared to manual method (ii) the PCS and (iii) the absence of cross contamination. **Methods:** Bacterial counts and isolated species of 277 urinary specimens, with bacteria on direct smear examination, were compared using the Prelud and the manual method inoculation. The PCS was assessed on 113 (207 media) urinary specimens. The number of different morphological and clinical relevant colonies was compared on 43 genital and 26 multi-drug resistant (MDR) bacteria positive rectal screening samples (E-swab). Quality of streaking was compared on all specimens. Microbiological cross-contamination was also evaluated. **Results:** A total of 346 specimens were processed. Among the 277 urinary samples tested, 216 (78%) showed a positive culture. Bacterial count were identical using the two methods in 142/216 (66%) samples and differed with less than 1 Log_{10} CFU/ml in 70/216. In 203/216 (94%) urinary samples, the same bacterial species were isolated with the two methods. Discrepancies concerned mostly samples (10/13) with less than 10 colonies ($<10^3$CFU/ml) on manual media *vs* no colony on Prelud media. The PCS triggered 68 alerts on 207 urinary media plated. Using the camera, 50/68 alerts were easily invalided. For 18/68 the droplet and/or the streaks could not be seen and a new medium was plated manually, most of them (13/18) concerning the Drigalski medium. No difference was observed comparing the MDR screening rectal samples. Few discrepancies (7/46 with +/- 1 colony) were observed for genital specimens, without any difference in clinical relevant colonies. No cross contamination was observed. Globally, the quality of streaking was higher with the Prelud. **Conclusions:** The Prelud is an innovative system that will improve the traceability of the inoculation step and the streaking quality of specimen. It has an important tool, the CPS, avoiding the risk of inoculation failed. Additional studies are merited to test the full potential of this instrument during the workflow of a laboratory, and to test the antibiotics susceptibility module.

Improvements in Time to Result Associated with the Bd Kiestra Inoqula

Author Block:

M. Maley, S. Neville, H. Ziochos, M. Chater, E. Treadwell, G. Parisi; Sydney South West Pathology Service, Sydney, Australia

Abstract Body:

Background: Processes in bacteriology laboratories have remained unchanged for years. Recently instruments have been introduced that automate many of the repetitive, labour intensive tasks often accompanied by claims for improved performance and efficiency. The SSWPS Microbiology lab is a large diagnostic lab operating 7 am to midnight 7 days per week. The laboratory introduced the BD Kiestra InoqulA in January 2014 to help cope with a steadily increasing workload unmatched by staff resources. This study aims to describe the impact on time to result for a range of culture based and non-culture-based tests.**Method:**Time from specimen collection to final result (TTR) was extracted from the LIS for deep wound and urine culture and for group B Streptococcus (GBS) and MRSA culture-based screening tests. Similar data was obtained for the non-culture-based tests urine pneumococcal antigen (UrPnAg) and urine and deep wound microscopy. The median TTR as well as the proportion of tests completed within a target time were determined for each month and an interrupted time series analysis was performed for the 12 months pre- and post-InoqulA implementation.**Results:**There was a reduction in median TTR and an increase in tests completed within target time for all culture based tests post-InoqulA. The effect was greatest for deep wound cultures with a reduction in median TTR from 68h 33m to 49h 13m (19h 19m reduction, $p<0.001$) and increase in proportion completed within 72hrs (58 to 84%). For MRSA screen culture there was an 8h 56m reduction in median TTR, and an increase from 35 to 61% completed within 60hrs ($p<0.001$). There was a lesser improvement for GBS screen (reduction in median TTR of 4h 27m, $p=0.33$; 42 to 55% by 48hrs) and urine culture (median TTR reduction 1h 42m, $p=0.06$, 40 to 45% completion by 24hrs). Reduction in median TTR and increased completion within target time was also noted for tests not performed by the InoqulA (UrPnAg - 2h 21m reduction, $p<0.001$; deep wound swab microscopy - 11h 20m reduction, $p<0.001$; urine micro - 45 to 60% within 6hrs, $p=0.03$).**Conclusion:**The InoqulA improved TTR for a range of culture based and non-culture based tests most likely because of a reduction in delay from specimen receipt to incubation, and from the reassignment of staff from specimen processing to specimen receipt and data entry and prioritisation of rapid diagnostic tests.

The Telegram of the 21st Century: The Digital Gram Stain

Author Block:

R. M. Martinez, B. C. Shoemaker, J. A. Riley, D. M. Wolk; Geisinger Hlth.Systems, Danville, PA

Abstract Body:

Background: Although the Gram stain is an essential clinical tool, many laboratories struggle to maintain competency for technologists, especially those who read stains infrequently. The need for a second review is common when performing Gram stains as they are often subject to variability due to inconsistent staining techniques, antibiotic pressure, as well as artifacts. Telemicroscopy utilizes technology to improve diagnostic accuracy, by providing expert consultation for technologists who are uncertain of their results.**Materials and Methods:** Geisinger Medical Laboratories is an eight hospital integrated health service organization, serving >2.6 million residents throughout 44 counties in Pennsylvania. Geisinger Medical Center serves as the full service reference laboratory for 4 limited- service laboratories (Gram stain reading, no culture work-up) and 3 partial-service laboratories (Gram stain reading, limited culture work-up). The TeleGram© program consists of infrastructure and policies to share both still and live images [Olympus BX40, BX41 microscope, Nikon cellSense software (version 1.7.1)] with the reference laboratory via Microsoft Lync/Skype [Logitech 920 camera (version 2013)]. From April 2014 through January 2016, the TeleGram© result, which is a consensus finding, was manually recorded and followed by culture review to determine patient impact. Results were imported into excel (ver. 4.3) for data analysis.**Results:** There were 65 unique consults placed by 3 remote sites (1 limited- and 2 partial-service laboratories). A change in initial interpretation was observed in 38.5% (25/65) of consults, of which, 92% (23/25) of changes positively impacted the patient, compared to culture. Overall, 84.6% (55/65) of TeleGram© results correlated with the culture result.**Conclusions:** Telemicroscopy offers an easy to use and relatively inexpensive solution to provide formal and informal second opinions to various sections of the laboratory. Gram stain consultations from remote hospital sites can improve patient care in an integrated hospital system.

Publishing Title:

Two Stepwise Molecular Approaches of Separating *Staphylococcus aureus* from Coagulase Negative Staphylococci Isolated from Clinical Samples in Ibadan South-West, Nigeria

Author Block:

C. O. Ezeamagu[1], O. E. Fagade[2], S. I. Smith[3], A. A. Ogunjobi[4]; [1]Babcock Univ., Ogun State, Nigeria, [2]Babcock Univ., Ibadan, Nigeria, [3]Nigerian Inst. For Med. Res., Yaba, Lagos, Lagos, Nigeria, [4]Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: *Staphylococcus aureus* is an important cause of nosocomial and community associated infections as well as notorious for its drug resistance potential. There are reports of inconsistencies in the presumptive diagnosis of *S. aureus* using commercial and conventional coagulase test methods. This study reports a simple, rapid, feasible, accurate and cost-effective molecular technique based on PCR-RFLP that separate and identify to species level *S. aureus* from other Coagulase Negative Staphylococci.**Methods:**Five hundred clinical samples were collected and investigated at the Microbiology Laboratory of University College Hospital, Ibadan. Specimens were streaked on mannitol salt agar and incubated for 18-24 hr. Colonies showing yellow coloration or whitish color were picked and sub-cultured on tryptone soya, blood and nutrient agars, incubated at 37^{o}C for between 18-24 hrs. Suspected staphylococcal colonies were tested for catalase, coagulase and hemolysis on blood agar. DNA was extracted using the boiling method, while *Staphylococcus* spp were identified by PCR-RFLP supplemented with specific primers. PCR products were electrophoresed on 1.5% agarose gel, and bands visualized with UV illuminator.**Results:** Fifty clinical isolates of Staphylococci were recovered from the specimens. 6 (12%) and 44 (88%) of these gave positive and negative results respectively for conventional tube coagulase test. The PCR-RFLP supplemented with species-specific primers classified these isolates into three distinct species; *S. epidermidis* (86%), *S. aureus* (12%) and *S. xylosus* (2%). However, this current technique classified the isolates into two RFLP patterns representing *S. aureus* and other Coagulase Negative Staphylococci respectively which correlated with coagulase test results.**Conclusions:Conclusion:** Since coagulase test could be sometimes misleading and inconclusive, this method could be substituted for routine laboratory program.

Development of a Phage Protein-Mediated *Staphylococcus aureus* Detection Tool

Author Block:

H. Matsui[1], J. Uchiyama[2], M. Tsuda[1], S. Matsuzaki[3], T. Nakae[1], H. Hanaki[1]; [1]Kitasato Univ., Tokyo, Japan, [2]Azabu Univ., Kanagawa, Japan, [3]Kochi Univ., Kochi, Japan

Abstract Body:

Background: Bacteriophages infect the host cells by binding on the specific cell surface receptor via the adsorption protein located at the tip of the phage tail. Therefore, the proteins have a potential utility for the development of a specific host cell detection tool. *Staphylococcus aureus* is a terrestrial bacterium that often infects children, elders and immunocompromised patients in hospitals. Thus, rapid and simple detection of this pathogen is urgent. We report here a novel method that detects *S. aureus* cells using an adsorption protein ORF16 of phage S24-1.**Methods:** The PCR-amplified *orf16* gene was cloned into an expression vector pCold II, and the recombinant ORF16 was expressed in *E.coli*. Purified rORF16 was either immobilized nitrocellurose membrane and conjugated with gold colloid particles. A chromato-strip was developed based on the principal of sandwich-type lateral flow test. The strains to be tested were pretreated with a lytic enzyme, e.g. lysostaphin. The detection limit was assessed using two strains each of MRSA and MSSA. The cross-reactivity was determined with 24 and 4 strains of bacteria and fungus, respectively. Reliability was tested using a total 50 *S. aureus* strains from clinical sources.**Results:** The size of purified rORF16 appeared as expected (~75 kDa) on SDS-PAGE. A whole operation including receptor extraction and chromatography took only 20 min. The detection limit of both MRSA and MSSA appeared ~10^6 CFU/test without noticeable variation among strains. All the strains subjected to the cross reactivity test were negative with an only exception that *Staphylococcus saprophyticus* showed false-positive reaction. All 50 clinical isolates of *S. aureus* showed positive results without exception.**Conclusions:** We developed a simple and rapid *S. aureus* detection tool using the phage tail adsorption protein. The method could be extended to the development of detection tools for other bacterial species .

Clinical Evaluation of a New Chromogenic Medium for the Isolation of *Staphylococcus aureus* in Various Samples Including Cystic Fibrosis Patients

Author Block:

V. Tafani, J. Safrani-Lahyani, S. Trouillet-Assant, M. Chiganne, F. Vincent, **F. Laurent**; Hospices Civiles de Lyon - French Natl. Reference Ctr. for Staphylococci, Lyon, France

Abstract Body:

About 20% of the population is colonized with *S. aureus* in their nose, skin or other body sites and 60% of the population can be transient carrier. Colonisation has been identified as a risk factor for *S. aureus* infection. Therefore a sensitive and rapid identification of *S.aureus* carriage could be useful to prevent the risk of healthcare-associated infection.A clinical performance evaluation was conducted for Cystic Fibrosis (CF, n=133) patients using respiratory samples, or for non-CF patients (n=271) using nasal, Ears-Nose-Throat, respiratory, genital, pus, skin (Burn Unit patients), stool specimens.Respiratory samples from CF patients were tested on chromID™ S. aureus ELITE (SAIDE) medium, chromID™ S. aureus (SAID), BBL™ CHROMagar™ Staph aureus) (BBL) and Columbia blood agar + CNA (CNA). All media were incubated at 36°C until 72 hours and 3 readings were performed after 24 h, 48 h and 72 h. Samples from non-CF patients were tested on SAIDE, SAID and CAN media and read after 20 hours.Implementation of chromID™ S. aureus ELITE in routine globally improves the sensitivity of S. aureus detection at 24h comparatively to all other media (conventional or chromogenic) whatever the samples and the patients. Of note, for CF patients, chromID™ S. aureus ELITE shows a better sensitivity at each reading time than all other media with a very high specificity.

The Investigation of *Streptococcus agalactiae* Colonization in Last Trimester Pregnants by Using Standard Culture and Molecular Methods

Author Block:

N. Kuru[1], O. Kuru[2], A. Tuten[1], **N. Gonullu**[1]; [1]Cerrahpaşa Faculty of Med. Istanbul Univ., Istanbul, Turkey, [2]Hacettepe Faculty of Med. Hacettepe Univ., Ankara, Turkey

Abstract Body:

Background: Group B streptococcus (GBS) is a leading cause of sepsis, menengitis, and death among newborns. GBS colonization in pregnant women is the most important risk factor. The most common method to diagnose the presence of GBS in pregnant women is the culture. Unfortunately, although the standard culture is a high sensitive and specific method, it takes long time. A rapid test that could accurately detect GBS carriage at the time of labour may be ideal for screening programme. Our prospective study was designed to detect GBS colonization in pregnant women at third trimester using real-time PCR and culture methods.**Methods:**Vaginal swab specimens from one hundred women between 35-37 weeks of gestation who were attending to antenatal outpatient unit of Obstetrics and Gynecology Department of Cerrahpasa Medical Faculty were taken for screening of GBS. Selective Todd-Hewitt broth medium was selected as culture media. DNA test was based on real-time PCR assay targeting cfb gene region.**Results:**In our study, rates of GBS colonization was %5 and %7 by culture and PCR methods, respectively. Sensitivity and specificity for real-time PCR were 100% and 97.9%, respectively using culture as the gold standard. When we compared GBS colonization with age groups, education levels, number of previous pregnancies, smoking habits, history of antibiotic use, and contraceptive method, there were no significant differences.**Conclusions:**Our results indicated that the PCR technique proved to be as sensitive as the culture method. We also demonstrate that the PCR is a very useful screening method and may provide a diagnostic tool for GBS detection potentially allowing a more effective intrapartum antibiotic prophylaxis and lower infant morbidity and mortality.

Publishing Title:

Development Of Immunoassays For *burkholderia Pseudomallei* Typical And Atypical lipopolysaccharide Strain Typing

Author Block:

T. Nualnoi[1], M. H. Norris[2], A. Tuanyok[2], P. J. Brett[3], M. N. Burtnick[3], P. S. Keim[4], E. W. Settles[4], C. J. Allender[4], D. P. AuCoin[1]; [1]Univ. of Nevada Sch. of Med., Reno, NV, [2]Univ. of Florida, Gainesville, FL, [3]Univ. of South Alabama, Mobile, AL, [4]Northern Arizona Univ., Flagstaff, AZ

Abstract Body:

Burkholderia pseudomallei is a Gram-negative bacillus and the causative agent of melioidosis, a severe infection prominent in Southeast Asia and northern Australia. Lipopolysaccharide (LPS) is one of the most important virulence factors used by *B. pseudomallei*. To date, four different *B. pseudomallei* LPS structures (typical LPS, atypical LPS types B and B2, and rough LPS) have been identified. It has been demonstrated *in vitro* that different LPS types may impact disease severity. However, the association between LPS types and clinical manifestations is not understood, in part because there is no effective method for distinguishing between the LPS types. This led us to develop antigen capture immunoassays for identifying LPS types of *B. pseudomallei*. To generate monoclonal antibodies (mAbs) specific to atypical LPS, mice were immunized with purified LPS type B or B2. Two mAbs, 3A2 and 5B4, were isolated from mice immunized with B2 LPS, but none were isolated from B LPS-immunized mice. Immunoblot analysis and surface plasmon resonance were exploited for mAb characterization and selection. Both 3A2 and 5B4 are cross-reactive to B LPS; however, 3A2 is preferable because of a higher affinity. The assays were further developed using capsular polysaccharide (CPS)-specific mAb 4C4 for bacterial capture, and horseradish peroxidase (HRP)-labeled 4C7 and HRP-labeled 3A2 (specific to typical and atypical LPS, respectively) for detection. The evaluations performed with 197 strains of *Burkholderia* and non-*Burkholderia* species showed that the assays are selectively reactive to pathogenic *B. pseudomallei* and *B. mallei* strains and have an accuracy of 98.5% (0 false positives and 3 false negatives) for LPS typing. The results suggest that the assays are effective and applicable for *B. pseudomallei* LPS typing and use of the assay would provide helpful information for clinicians involved in melioidosis research.

Improved Performance and Time-to-results for *Acinetobacter baumannii* / *haemolyticus* Isolates with the Updated Beckman Coulter Gram-negative Id Product

Author Block:

D. Nothaft, J. Bobolis, D. Carpenter, O. Madriaga, L. Smoot, T. Wong, **C. Beck**; Beckman Coulter Microbiol., West Sacramento, CA

Abstract Body:

Background: *Acinetobacter baumannii* has a remarkable ability to acquire antibiotic resistance, and pandrug-resistant infections have been documented globally. A predominant source of nosocomial infections, the organism survives extended periods of time in hospital environments. Thus, early and accurate identification (ID) and therapy are paramount for patient health and outbreak prevention. In this study, we report on new panel completion criteria for MicroScan's Gram-negative ID product (NID) which enhance ID performance of *Acinetobacter baumannii* / *haemolyticus* (ABH). The new criteria complete the majority of ABH isolates at 16 h with a high degree of accuracy. **Methods:** The updated MicroScan NID product was evaluated using 323 ABH isolates. Panels were inoculated and incubated following manufacturer's instructions for use. The time-to-results, measured from start of panel incubation to obtaining final results, and the percentage of correct and incorrect results were used to assess performance.**Results:** Tested on the WalkAway instrument, the majority of ABH isolates [66.9% (216/323)] completed at 16 h and all identified correctly. The remaining 107 isolates completed at 42 h and 98.1% (105/107) identified correctly. The two incorrect results were identified as *A. lwoffii*. Overall, 99.4% (321/323) of ABH isolates identified correctly, and only 0.9% (3/321) required additional tests to confirm a low-probability correct ID.A subset (n=257) was tested manually and on the autoSCAN-4 (AS-4) instrument with similar results. With the AS-4, 87.9% (226/257) completed at 16 h and all identified correctly. Manually, 94.6% (243/257) completed at 16 h and all identified correctly. Overall at 42 h, 99.6% (256/257) were identified correctly on both methods, with one isolate generating an incorrect result of *A. lwoffii*.**Conclusions:** The updated Beckman Coulter Gram-negative ID product with new panel completion criteria and updated organism database provides timely, accurate identification results for *Acinetobacter baumannii* / *haemolyticus* isolates.Beckman Coulter, the stylized logo and the Beckman Coulter product and service names mentioned herein are trademarks or registered trademarks of Beckman Coulter, Inc. in the United States and other countries.

Publishing Title:

Identifying *Burkholderia cepacia* Complex and *Pseudomonas aeruginosa* Isolates from Cystic Fibrosis Patients with the Updated Microscan Dried Gram-negative Id Product

Author Block:

C. Beck, L. Smoot, J. Bobolis, T. Wong, **D. Nothaft**; Beckman Coulter Microbiol., West Sacramento, CA

Abstract Body:

Background: MicroScan recently updated the database for the Dried Gram-negative Identification product (NID). Included in the update were the addition of 39 taxa (new to NID product), nomenclature updates, and enhanced identification of challenging species including those species isolated from cystic fibrosis (CF) patients. *Burkholderia cepacia* complex and *Pseudomonas aeruginosa* are increasingly recovered from CF patients with more advanced disease, and these pose a challenge for commercial systems due to heterogeneity within the *B. cepacia* complex and the higher prevalence of mucoid strains. Accurate identification is critical to patient care.**Materials:** To identify these isolates and expand proper patient care and management, 153 known domestic CF isolates including 32 *B. cepacia* complex and 121 *P. aeruginosa* were tested. Reference identification testing was performed following the manufacturers' instructions for use and sequencing of 16S rDNA was included for discrepant isolates. NID panels were inoculated and incubated following manufacturer's instructions for use. The percentage of correct & incorrect results were used to assess product performance.**Results:** A correct identification was obtained for 98.7% (151/153) of the isolates. An incorrect identification was obtained for 1.3% (2/153) of the isolates. The mis-identifications were within the *Pseudomonas* genus; one identified as a *P. fluorescens/putida* and the other as *P. stutzeri*.**Conclusions:** MicroScan's updated NID database accurately identifies these challenging isolates from CF patients.Beckman Coulter, the stylized logo and the Beckman Coulter product and service names mentioned herein are trademarks or registered trademarks of Beckman Coulter, Inc. in the United States and other countries.

Multicenter Evaluation Supports Accuracy of the Beckman Coulter Gram-negative Identification Product with Improved Database for Clinically Significant Bacteria

Author Block:

J. A. Hindler[1], P. C. Schreckenberger[2], J. Tjhio[2], L. Mann[3], C. Beck[4], D. Nothaft[4], D. Carpenter[4], O. Madriaga[4], L. Smoot[4], T. Wong[4], **J. Bobolis**[4]; [1]UCLA David Geffen Sch. of Med., Los Angeles, CA, [2]Loyola Univ. Med. Ctr., Maywood, IL, [3]Individual Contributer, Sacramento, CA, [4]Beckman Coulter Microbiol., West Sacramento, CA

Abstract Body:

Background: The MicroScan Gram-negative Identification (NID) organism database was revised and includes 39 new Gram-negative organisms - 22 fermentative (F) taxa and 17 non-fermentative (NF) taxa - along with updated nomenclature. A multicenter study was performed to evaluate the accuracy of the updated NID product. **Methods:** The MicroScan NID product was evaluated at two sites with 609 fresh clinical isolates comprised of 55 F and NF Gram-negative taxa. NID panels were processed in a WalkAway instrument, and the identifications were generated using the updated NID organism database. Percent correct and incorrect results were used to assess accuracy of the updated NID panel. Sequencing of 16S rDNA was included for discrepant isolates. Thirteen isolates were identified to only genus-level using the reference methods available.**Results:** A correct identification was obtained for 98.6% (414/420) of the F Gram-negatives and for 94.7% (179/189) of the NF Gram-negatives. Furthermore, the clinically significant species *A. baumannii / haemolyticus*, *E. coli*, *P. aeruginosa,* and *P. mirabilis* were correct at 100%, 97.4%, 97.8%, and 96.4% respectively. Overall, a correct species-level identification was obtained for 97.4% (593/609) of all isolates, and only 3.1% (19/593) required additional tests to confirm a low-probability correct identification. Incorrect species-level identifications were obtained for 2.5% (15/609) of the isolates, which includes the 13 isolates that had only genus-level reference identifications. A very rare biotype was obtained for 0.2% (1/609) - a single *E. aerogenes* isolate.**Conclusions:** The results of the evaluation with fresh clinical isolates show that the MicroScan Dried Gram-negative ID panel with an updated database provides accurate identification results for clinically important Gram-negative bacteria.Beckman Coulter, the stylized logo and the Beckman Coulter product and service names mentioned herein are trademarks or registered trademarks of Beckman Coulter, Inc. in the United States and other countries.

Impact of Organism Identification Method on Central Line Infection Designation

Author Block:

E. J. Gomez[1], K. Alby[2], A. L. Roberts[3], N. A. Ledeboer[4], C. D. Doern[5], **K. V. Sullivan**[1]; [1]The Children's Hosp. of Philadelphia, Philadelphia, PA, [2]The Hosp. of the Univ. of Pennsylvania, Philadelphia, PA, [3]Thomas Jefferson Univ. and Hosp., Philadelphia, PA, [4]Med. Coll. of Wisconsin, Milwaukee, WI, [5]Virginia Commonwealth Univ., Richmond, VA

Abstract Body:

Background: According to the National Healthcare Safety Network (NHSN), the assignment of central line-associated bloodstream infection (CLABSI) status requires isolation of the same commensal organism on 2 or more blood cultures (BC). The accuracy and reliability of the organism identification (ID) method in use may impact on CLABSI status and reported incidence rates. **Methods:** The Theradoc system was used to identify all CLABSI cases involving commensal organisms and meeting NHSN criteria at The Children's Hospital of Philadelphia from June 1, 2013-June 30, 2015. Routinely, first isolates undergo ID. ID of subsequently recovered isolates is referred for 72 hours. For the study, first and subsequent isolates were ID'd using Vitek 2 (V2); BD Phoenix (BDP); Micro Scan Auto Scan-4 (MSAS); Bruker Biotyper (BB); and Vitek MS (VMS). All streptococci underwent optochin susceptibility and bile solubility testing. **Results:** 13 CLABSIs involved coagulase-negative staphylococci. In 11, there was 100% concordance across all 5 ID methods in all isolates tested. In one case, 4 methods reported *S. epidermidis* in 2/2 isolates tested but BDP reported *S. schleiferi* for both isolates. In the other case, 4 methods reported *S. hominis* in 2/2 isolates tested but MSAS reported *S. epidermidis* for both. 8 cases involved viridans group streptococci. Isolates from 2 positive blood cultures were tested for each case. BB and VMS reported all isolates as *S. mitis* or *S. oralis.* BDP reported 2 cases with differing IDs (*S. acidominimus* and *S. salivarius*; *S. oralis* and *S. constellatus*). A third case yielded no ID on both isolates. V2 also reported 2 cases with differing IDs (*S. sanguinis* and *S. mitis/oralis*; *S. mitis/oralis* and *G. adiacens*). MSAS reported discordant IDs in 6/8 cases, 5 with erroneous IDs of *S. pneumoniae.* **Conclusion:** For BSI involving coagulase-negative staphylococci, the ID method did not impact on assignment of CLABSI status. For cases involving viridans group streptococci, automated biochemical methods yielded cases with differing IDs on the first and subsequent isolates recovered. Use of these methods may lead to lower reported CLABSI rates.

Ceftolozane-Tazobactam (C/T) is Effective against Most Multidrug-Resistant (Mdr) *P. aeruginosa* (*pa*) Infections, but Resistance May Emerge on Therapy

Author Block:

G. Haidar, C. J. Clancy, R. K. Shields, Y. Doi, B. A. Potoski, M. H. Nguyen; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background:KPC-producing *Enterobacter* spp. are emerging. Gentamicin (GEN) is active against the majority of carbapenem-resistant *K. pneumoniae*. The activity of GEN and other AGs against KPC-producing *Enterobacter* is not known. **Methods:** We compared the *in vitro* susceptibility of KPC-producing (KPC+) and non-producing (KPC-) *Enterobacter* isolates to aminoglycosides (GEN, tobramycin TOB, amikacin AMK). We determined the presence of KPC, ESBL and AME genes by PCR.**Results:**21 KPC+ (12 *E. aerogenes* (EA) and 9 *E. cloacae* (EC)) and 44 KPC- isolates (12 EA and 32 EC) were compared. 71% (15) and 7% (3) of KPC+ and KPC- isolates were resistant to GEN, respectively ($p<0.0001$). Corresponding rates were 67% (14) and 9% (4) for TOB ($p<0.0001$), and 9% (2) and 0% for AMK ($p=0.10$). AMEs were more common among KPC+ (95%) than KPC- isolates (20%, $p<0.0001$), as were ESBLs (41% vs. 30%, $p<.0001$). Likewise, mean and median numbers of AMEs were higher for KPC+ (4 and 5) than KPC- isolates (0.4 and 0). The most common AME genes among KPC+ isolates were: *aac(6')-Ib* (62%), *aadA2* (62%), *aac(6')-II* (57%) and *aadA1* (57%). The presence of either *aac(6')-Ib* or *aac(6')-II* was associated with resistance to all 3 AGs. The presence of any one of *aac(3)-II* and *–IV*, *aadA1* and *aadA2* was associated with resistance to GEN and TOB but not AMK. The presence of *aph(3')-Ia* was associated with GEN resistance. GEN, TOB and AMK MICs were significantly increased as the number of β lactamases (either KPC or ESBL) increased (<0.001). There was a direct correlation between presence of KPC and presence of *aac(6')-Ib* and *aph(3')-Ia*, and between presence of ESBL and *aac(6')-II* and *aph(3')-Ib* (all $p<0.01$).**Conclusion:**A significant majority of KPC+ *Enterobacter* spp. were resistant to GEN and TOB. Associations between presence of AME, KPC and ESBL genes suggest that they may be acquired on the same plasmids. The high prevalence of KPC+ isolates with *aac(6')-Ib*, known to confer resistance to GEN, TOB and AMK, suggests that these AG are unlikely to have a significant role in the treatment of KPC+ *Enterobacter* infections.

Risk Factors and Outcome of Levofloxacin-Resistant *Elizabethkingia meningoseptica* Bacteremia in Adult Patients in Taiwan

Author Block:

Y-T. Lin, Y-C. Huang, F-D. Wang; Taipei Veterans Gen. Hosp., Taipei, Taiwan

Abstract Body:

Background: *Elizabethkingia meningoseptica* is an emerging nosocomial pathogen and inherently resistant to many antimicrobial agents commonly used to treat gram-negative bacterial infections. *E. meningoseptica* bacteremia is associated with high mortality rates, and levofloxacin has been considered as a therapeutic agent based on in-vitro susceptibility. However, investigations into the risk factors and outcomes for levofloxacin-resistant *E. meningoseptica* bacteremia have never been reported. **Methods:** Adult patients with *E. meningoseptica* bacteremia were identified retrospectively in a medical center in Taiwan from January 2012 to June 2015. We compared clinical features and outcomes of patients with levofloxacin-resistant (MIC > 2 μg/mL) and levofloxacin-susceptible *E. meningoseptica* bacteremia (MIC ≤ 2 μg/mL). Risk factors for levofloxacin-resistant *E. meningoseptica* bacteremia and its mortality were analyzed by logistic regression. Antimicrobial susceptibilities were determined by E test and interpreted by the Clinical and Laboratory Standards Institute MIC breakpoints for other non-*Enterobacteriaceae* spp. **Results:** A total of 93 patients with *E. meningoseptica* bacteremia were identified and 51 patients had levofloxacin-resistant *E. meningoseptica* bacteremia. The 14-day mortality of levofloxacin-resistant *E. meningoseptica* bacteremia was significantly higher than that of levofloxacin-susceptible *E. meningoseptica* bacteremia (56.9 % vs 26.2 %; p=0.003). Levofloxacin-resistant *E. meningoseptica* bacteremia is associated with higher APACHE II score. Previous exposure to β-lactam/β-lactamase inhibitor within 30 days prior to bacteremia (OR, 2.08; 95% CI, 0.87-4.97; $p = 0.099$) and APACHE II score (OR, 1.08; 95% CI, 1.02-1.14; $p = 0.008$) were the independent risk factors for levofloxacin-resistant *E. meningoseptica* bacteremia. Regarding the risk factor for mortality, levofloxacin-resistant *E. meningoseptica* bacteremia (OR, 4.8; 95% CI, 1.77-12.96; $p = 0.002$) was found to be the independent risk factor for 14-day mortality. **Conclusion:** Levofloxacin-resistant *E. meningoseptica* bacteremia had a marked effect on patient mortality. Better surveillance and control measures are necessary to deal with invasive levofloxacin-resistant *E. meningoseptica* infections.

Ilsan Hosp., Seoul, Korea, Republic of, [5]Asan Med. Ctr., Seoul, Korea, Republic of

Abstract Body:

Background: The relationship between hematogenous vertebral osteomyelitis (HVO) and infectious endocarditis is uncertain. This study investigates the incidence and risk factors of infective endocarditis in patients with HVO, and the outcome of HVO with and without associated with infective endocarditis.**Methods:** A retrospective review was conducted of all cases of HVO from January 2015 to December 2012, occurring in 5 tertiary-care hospitals in the Republic of Korea.**Results:** A total of 345 patients with microbiologically diagnosed HVO were included. The median age was 65 years, and 181 (52.5%) were male. The most common underlying condition was diabetes (29.6%), followed by liver cirrhosis (9.3%) and malignancy (9.0%). Overall, of the 345 patients with HVO, 17 (4.9%) patients had concomitant infective endocarditis. There was no infective endocarditis in 89 patients with non-bacteremic HVO. Among remaining 256 patients with bacteremic HVO, the rates of endocarditis were 27% (8/30) for *Streptococcus*/*Enterococcus* spp., 10% (7/73) for methicillin-resistant *Staphylococcus aureus*, 2% (2/93) for methicillin-susceptible *S. aureus*, and 0% (0/54) for aerobic gram-negative bacteria. The median durations of antibiotic therapy were 67 and 69 days for the non-endocarditis and endocarditis groups, respectively (P = .58). Clinical outcomes were similar between the groups, including in-hospital mortality (11.8% vs. 8.5%; P = 0.65), recurrence (9.7% vs 13.3%; P = .65), and length of hospital stay (median 53 vs. 56 days; P = 0.65).**Conclusions:** Overall incidence of infective endocarditis was low (4.9%) in patients with microbiologically diagnosed HVO. However, bacteremic HVO due to *streptococcus*/*enterococcus* spp. and MRSA were frequently associated with infective endocarditis. For such high-risk patients, echocardiography should be performed as routine and switch to oral antibiotic therapy should be only considered after excluding infective endocarditis.

High-Level Daptomycin-Resistant (Dap-R) *Streptococcus mitis* Is Virulent in Experimental Endocarditis (Ee) and Enhances Survivability During Dap Treatment vs. Its Dap-Susceptible (Dap-S) Parental Strain

Author Block:

C. Garcia-de-la-Maria[1], J. M. Pericas[1], Y. Armero[1], A. Moreno[1], N. N. Mishra[2], M. J. Rybak[3], T. T. Tran[4], C. A. Arias[4], P. M. Sullam[5], Y. Q. Xiong[2], A. S. Bayer[2], J. M. Miro[1]; [1]Hosp. Clinic-IDIBAPS, Barcelona, Spain, [2]LA Biomed Res. Inst Torrance & Geffen Sch. of Med. at UCLA, Torrance, CA, [3]Anti-Infective Res. Lab. Wayne State, Detroit, MI, [4]UT Med. SCh., Houston, TX, [5]UCSF & VA Med. Ctr., San Francisco, CA

Abstract Body:

Background: *S. mitis* has a unique propensity to evolve rapid, durable and high-level DAP-R *in vitro* and *in vivo*. This study investigated the intrinsic fitness and DAP survivability of a DAP-R *S. mitis* strain *vs.* its DAP-S parental strain in an *in vivo* EE co-infection model.**Methods:** Strains: DAP-S 351 (DAP MIC = 0.5 ug/ml) was isolated from a clinical case of IE; its DAP-R variant (D_6-6; DAP MIC >256 ug/ml) was isolated from rabbit EE vegetations after 48 h. of DAP treatment (*AAC, 2013; 57:2319-25*). EE model: Aortic valve indwelling catheter EE model in rabbits. EE was induced by IV challenge of ~$2x10^6$ cfu/ml of a mixed DAP-S and DAP-R inoculum (1:1 ratio) 24 h post-catheterization. Studies: A) One group of animals were sacrificed 24 h. after the IV co-infection challenge; and, B) Another group was treated for 48 h. with IV DAP (6 mg/kg/d) + gentamicin (GEN, 1 mg/kg/8h). Animals were sacrificed after six drug half-lives. Target tissues were quantitatively cultured in parallel on plain and DAP-containing (8 ug/ml) plates to detect retention of the DAP-R phenotype.**Results:**

	Vegetations		**Kidney**		**Spleen**	
Study group	IR (%)	Median (IQR) log cfu/g tissue	IR (%)	Median (IQR) log cfu/g tissue	IR (%)	Median (IQR) log cfu/g tissue
Rabbits not treated with antibiotics and sacrificed at 24 h						
DAP-S strain	5/5 (100)	10.1 (9.4-10.2)[a]	5/5 (100)[b]	3.2 (2.7-4)	5/5 (100)[c]	5.3 (4.5-5.6)
DAP-R strain	4/5 (80)	6.6 (5.7-6.9)[a]	0/5 (0)[b]	0 (0-0)	0/5 (0)[c]	0 (0-0)

Rabbits treated with DAP+GEN and sacrificed after 48 h of treatment						
DAP-S strain	0/6 (0)	0 (0-0)	0/6 (0)	0 (0-0)	0/6 (0)	0 (0-0)
DAP-R strain	6/6 (100)	8.5 (6.3-9)	5/6 (83)	2.4 (2-2.5)	3/6 (50)	3.4 (2.7-3.5)
^{a}P = .009; ^{b}P = .008; ^{c}P = .008 IR, rate of animals with infected valve vegetations, kidney and spleen/total number of animals.						

In the absence of antibiotic therapy, both strains induced IE, although the DAP-S parental strain was significantly more fit in terms of target tissue seeding and proliferation. In contrast, after DAP + GEN treatment, only DAP-R strains survived in target tissues. All DAP-R variants from target tissues maintained high-level DAP-R after passage in the EE model.**Conclusions:** DAP-R variants can cause EE, with their survival amplified in the presence of DAP combination therapy. Further studies are needed to confirm that DAP + GEN therapy can effectively prevent the emergence of DAP-R variants *in vivo*.

Unravelling the Characteristics of Three Common Clonal Complexes (Ccs) of Methicillin-Susceptible *Staphylococcus aureus* (Mssa) Causing Complicated Catheter-Related Bacteremia (Crb)

Author Block:

D. Pérez-Montarelo[1], E. Viedma[1], M. Fernández de Mera[1], N. Larrosa[2], N. Fernández-Hidalgo[2], B. Almirante[2], F. Chaves[1]; [1]Hosp. Univ. 12 Octubre, Madrid, Spain, [2]Hosp. Univ. Vall d'Hebron, Barcelona, Spain

Abstract Body:

Background: Previous studies have suggested that MSSA strains causing CRB belonging to particular CCs are more prone to develop endovascular complications. Our aim was to explore the characteristics of a selection of the three most common CCs MSSA isolates producing complicated CRB using in vitro and in vivo models.**Methods:** Six CRB MSSA (CC5, CC30, CC45) with different *agr* functionality were selected. The capacity to form biofilm, to adhere to collagen, the susceptibility to antimicrobial peptides produced by neutrophils (hNP1) and the virulence in the *Galleria Mellonella* model were investigated. Three independent experiments were included in each assay. Their genomes were sequenced by NGS.**Results:** Five of the six strains were capable to form biofilm. No differences were detected among different CCs. Dysfunctional *agr* strains showed a higher biofilm formation than those with a functional *agr* (p: 0.024). The percentage of collagen binding ranged between 3.2% and 23.8%. CC45 (19.1%) and CC30 (18.9%) strains showed a higher percentage of collagen binding than CC5 (4.4%), p: 0.045. This effect could be attributed to the presence of collagen adhesion gene *cna* in both CC45 and CC30 but not in CC5. No differences in collagen binding were detected between *agr* functional (16.8%) and dysfunctional strains (8.8%), p:0.17. The percentage of bacterial survival to hNP1 varied from 49.9% to 58.9%. All CCs showed similar survival percentages (54.4% CC45, 54.6% CC30 and 54.8% CC5) and no differences were detected between strains with different *agr* functionality. The studies in *G. Mellonella* model revealed a lower larvae mean survival time in CC45 and CC5 strains than in CC30 ($p < 0.001$). Those strains with a functional *agr* showed a lower larvae mean survival time compared to the ones with a dysfunctional *agr* ($p<0.001$). In addition, strains carrying *cna* gene resulted in lower larvae mean survival time than strains without this gene (p: 0.016).**Conclusions:** Our study suggested differences in the behaviour of MSSA strains causing complicated BRC according to their genetic background. Even so, the three CCs presented characteristics that favour the virulence of these strains.

Epidemiology, Clinical Characteristics And Antimicrobial Susceptibility Profiles Of An Emerging Mdr Opportunistic Pathogen, Corynebacterium Striatum

Author Block:

A. R. McMullen, N. Anderson, M. Wallace, A. Shupe, C-A. Burnham; Washington Univ. Sch. of Med., St Louis, MO

Abstract Body:

Objective: Routine species level identification of clinically significant coryneform bacteria has revealed that *Corynebacterium striatum* is frequently isolated, especially in patients who are immunosuppressed or have an indwelling medical device. For many of these patients, long courses of antimicrobial therapy are required. Our objective was to characterize the epidemiology and antimicrobial susceptibility profiles of *C. striatum* infections.**Methods:** Between 2012 and 2015, at Barnes Jewish Hospital, a 1250 bed, tertiary care medical center, approximately 275 unique *C. striatum* isolates were recovered. Susceptibility testing was performed using gradient diffusion assays on Mueller Hinton Agar with blood. MIC values were interpreted according to CLSI guidelines (M45).**Results:** *C. striatum* was isolated from a variety of sources, including blood, LVADs, tissue and hardware/indwelling devices. The % susceptible, MIC range and MIC_{50} and MIC_{90} for antimicrobial agents tested are found in Table 1. All isolates tested were susceptible to vancomycin and linezolid. Most of the isolates were resistant to clindamycin, ciprofloxacin, and ceftriaxone. For 18 of the isolates, daptomycin susceptibility testing was performed and 16 (89%) of the isolates were susceptible. The two resistant isolates had a daptomycin MIC of >256 µg/ml.**Conclusion:** Many strains of *C. striatum* are multi-drug resistant, and antimicrobial susceptibility testing is important to guide appropriate therapy. Future studies to explore the activity of newer generation anti-Gram positive agents against this species are needed.**Table 1.** Antimicrobial susceptibly of *C. striatum* recovered from clinical specimens

Antibiotic	**% Susceptible**	**MIC range (µg/ml)**	**MIC_{50} (µg/ml)**	**MIC_{90} (µg/ml)**
Vancomycin (n = 225)	100.0	0.5 - 2.0	1.0	2.0
Linezolid (n = 50)	100.0	0.25 - 2.0	1.0	1.0
Daptomycin (n = 18)	88.9	0.064 - >256	0.25	0.25
Tetracycline (n = 224)	39.3	<0.5 - >256	>64	>256
Clindamycin (n = 183)	0.5	<0.5 - >256	>256	>256
Ciprofloxacin (n = 211)	0.0	>32	>32	>32
Ceftriaxone (n = 162)	0.0	32 - >256	>256	>256

Clinical Outcomes and Risk Factors of Ampc Producing Enterobacteriaceae

Author Block:

R. Chavada[1], D. Tong[2], G. O'Kane[1], M. Maley[3]; [1]Pathology North, Gosford Hosp., Gosford,NSW, Australia, [2]Pharmacy Dept., Gosford Hosp., Gosford, NSW, Australia, [3]SSWPS, Livperpool Hosp., Liverpool, NSW, Australia

Abstract Body:

Introduction: Blood stream infections (BSI) caused by multidrug resistant Gram negative (MDRGN) enterobacteriaceae are rising throughout the world. While the focus has shifted to carbapenem resistant enterobacteriaceae (CRE) and extended spectrum beta-lactamase (ESBL) due to limited therapeutic antimicrobial options, higher mortality and increasing healthcare costs, there is little data on outcomes in BSI caused by AmpC producing enterobacteriaceae (AmpC-E). The aim of this study was to assess the clinical outcomes and risk factors for AmpC-E BSI.**Methods:**This was a retrospective matched case control study over a period of 3 years from 2 tertiary care centres. Cases (patients with BSI due to AmpC-E) were matched with controls (standard enterobacteriaceae [SE]) in ratio of 1:2. AmpC detection was done by both phenotypic methods using a boronic acid (inhibitor) and clavulanate (inducer) and genotypic method (multiplex PCR). Clinical information was gathered from electronic medical records. Statistical analysis was done using SPSS (IBM v23.0, California).**Results:**There were 28 cases of BSI with AmpC-E which were matched to 56 cases of BSI due to SE (by age, comorbidities and site of infection). Mean age and proportion of male patients was higher in patients with AmpC-E (71.3 vs. 68.6, p=0.16 and 68% vs 61 %, p=0.32). Similarly, AmpC-E group had longer hospital stay (12.5 vs. 9.5, p=0.14), slightly higher APACHE2 score (19.5 vs 18.2, p=0.188) and more patients with healthcare associated onset (46.4% vs 30.3%, p=0.147). Indwelling urinary catheters and being on immunosuppressants were also similar in the two groups. Rates of admission to ICU (39% vs. 17.8%, p=0.33), surgery in hospital (53.5% vs. 12.5%, p=0.001) and mortality at 30 days (21.4% vs 14.2%, p=0.408) were higher in the AmpC-E group. On multivariate logistic regression analysis AmpC-E bacteraemia was significantly higher surgical setting compared to bacteraemia with SE with an OR of 8.2 (IQR 2.7-25.1, p=0.001).**Conclusion:**Incidence of AmpC-E BSI is higher in setting of recent surgery due to likely increased LOS and prolonged prior duration of antibiotics administered. Mortality and other clinical outcomes did not differ in this study.

Evaluation of Clinical Outcomes of *Pseudomonas* Infections Stratified By Carbapenem Minimum Inhibitory Concentration

Author Block:

L. L. Benitez, T. S. Patel, K. Rao, J. Nagel; Univ. of Michigan Hlth.System, Ann Arbor, MI

Abstract Body:

Background: The Clinical and Laboratory Standards Institute revised the carbapenem susceptibility breakpoint for *Pseudomonas spp.* from 4 mg/L to 2 mg/L. However, there are minimal data evaluating the impact of carbapenem MIC on clinical outcomes associated *Pseudomonas* infections.**Methods:** A single-center retrospective cohort study was conducted in adult patients with bloodstream or respiratory infections caused by Pseudomonas treated with meropenem or imipenem for greater than 48 hours. Patients infected with Pseudomonas with carbapenem MIC ≤ 2 mg/L were compared to those with carbapenem MIC ≥ 4 mg/L. All-cause 30-day mortality, hospital length of stay (LOS), and 30-day hospital readmission rates were compared between cohorts. Logistic regression was used to elucidate independent risk factors for mortality.**Results:** A total of 134 patients with bloodstream infections or respiratory infections caused by Pseudomonas were included; 82 patients had an isolate with MIC ≤ 2 mg/L. All-cause 30-day mortality (22.0% vs. 17.3%, p = 0.66) and 30-day hospital readmission (20.3% vs. 25.6%, p = 0.63) were similar between the carbapenem MIC ≤ 2 mg/L group and the carbapenem MIC ≥ 4 mg/L group, respectively. The only independent predictor for mortality was immunocompromised status (odds ratio [OR], 5.1; 95% confidence interval [95% CI], 1.2-22.2; p = 0.03). Hospital LOS was significantly longer in the carbapenem MIC ≥ 4 mg/L group (20.5 days (interquartile range [IQR], 11-49.3) vs. 16.5 days (IQR, 8-28.5), p = 0.03).**Conclusions:** Patients with bloodstream infections or respiratory infections caused by *Pseudomonas* have similar mortality rates and hospital readmission rates irrespective of carbapenem MIC. Patients infected with isolates with carbapenem MIC ≥ 4 mg/L had significantly longer hospital LOS.

The Mechanism of Resistance to Vancomycin in Slow-VISA Possibly Responsible for Recurrent MRSA Infection

Author Block:

Y. Katayama[1], Y. Aiba[2], M. Sekine[1], M. Miyazaki[3], T. Takata[4], M. Matsuo[1], T. Azechi[5], T. Hishinuma[1], H. Hanaki[6], K. Hiramatsu[7]; [1]Juntendo Univ. Faculty of Med., Tokyo, Japan, [2]Juntendo Univ. Graduate Sch. of Med., Tokyo, Japan, [3]Fukuoka Univ. Chikushi Hosp., Fukuoka, Japan, [4]Fukuoka Univ. Sch. of Med., Fukuoka, Japan, [5]Juntendo Univ. Hosp., Tokyo, Japan, [6]Kitasato Inst. for Life Sci., Kitasato Univ., Tokyo, Japan, [7]Graduate Sch. of Med., Juntendo Univ., Tokyo, Japan

Abstract Body:

Background: The Vancomycin(VAN)-intermediate *Staphylococcus aureus* (VISA) strains generally grow slowly, and form colonies on VAN-containing agar-plates after 48 hours of incubation in population analysis. However, we have found a curious group of VISA strains whose colonies appear only after 72 hours incubation. We designated them 'slow-VISA'(sVISA) (1). As compared to extant VISA strains, sVISA strains had 1) significantly prolonged doubling-times, 2) increasing resistance to VAN after prolonged incubation, 3) unstable phenotypic expression, 4) RNA polymerase subunit gene mutations are frequently detected. We investigated a characterization of sVISA in this study.**Materials and Methods:** 1)We established 26 (26/34[76.5%]) sVISA strains by selecting hVISA Mu3 with VAN 6mg/L. Whole genome sequence of the 26 sVISAs were determined and SNPs analysis were performed. 2) We detected sVISA phenotype in 214 clinical MRSA isolates obtained from blood cultures in 18 Japanese hospitals(2), using by E-test.**Results:** We found mutations in the gene(s) involved in various metabolic pathways such as purine/pyrimidine synthesis, PRPP (5P-D-ribosyl-1pyrophosphate) synthesis (*prs*), and in Embden-Meyerhof pathway. These mutations seemed to change the flow of metabolites in the cell and promote cell-wall peptidoglycan synthesis by concentrating energy and metabolites into the pathway. There were 24 sVISA-converted strains, in which the most frequent SNPs were on the transcription machinery, i.e, in *rpoB* or *rpoC* genes.**Conclusions:** The sVISA spontaneously returns to hVISA when the threat of VAN is lifted. Now, we perform metabolomic analysis among sVISA. Moreover, we detected 18 sVISA ($MIC_{VAN} > 4$ mg/L) in 214 clinical MRSA isolates. We attempt to analyze the relationship between the detection of sVISA and the clinical manifestation, medication history and prognosis of the patients.

Case Control Study of Pneumonia Patients with *Streptooccus anginosus* Group Identified from Sputum

Author Block:

J. Hirai[1], M. Hagihara[1], T. Kinjo[2], Y. Yamagishi[1], J. Fujita[2], H. Mikamo[1]; [1]Aichi Med. Univ. Hosp., Aichi, Japan, [2]Faculty of Med., Univ. of the Ryukyus, Okinawa, Japan

Abstract Body:

Background: Even though *Streptococcus anginosus* group (SAG) was previously thought to rarely cause pneumonia, they have emerged as a causative microorganism of pneumonia particularly in the elderly people, and it was reported recently that 3-4% of the cases of community-acquired pneumonia was caused by SAG. Hence, we have a policy to identify SAG as a routine culture altohgh identification of SAG from sputum is not routinely performed in most microbiology laboratories. The purpose of this study was to clarify which SAG was related to pnemonia, clinical characteristics of patients with SAG pneumonia, and radiologic features. **Methods:** We retrospectively investigated that clinical characteristics and radiological features of 27 patients with pneumonia (PWP) caused by SAG, and also compared between PWP and 37 patients without pneumonia (PWOP) detected SAG from sputum to research difference of them from September 2009 and November 2015. **Results:** In univariate analysis, PWP were statistically more likely to have bed-ridden status (p<0.01) and also had more comorbid conditions such as cerebrovascular diseases and dementia (p<0.01) than PWOP. Among PWP cases, nursing- and healthcare-associated pneumonia (NHCAP) was the most frequent cases (59.3%). *S. anginosus* was significantly higher cultured with PWP compared to PWOP (p=0.013). Polymicrobial pathogens that includes drug-resistant strains such as methicillin-resistant *Staphylococcus aureus* and *Pseudomonas aeruginosa* other than SAG detected more frequently (p=0.014) in PWP, however, surprisingly 40% cases were recovered after administering antibiotics covered only SAG. The distribution of pneumonia was the most frequently observed in bilateral lower lobe on computed tomography (CT) scans, which suggest that SAG is related to aspiration pneumonia. **Conclusions:** The present study describes that SAG must be recognized as a very important pathogen causes pneumonia especially when *S. anginosus* was detected in elderly patients with bed-ridden status. Previous article also reported that *S. anginosus* was mostly detectd in patients with respiratory infection. Therefore, our study provides an encouraging signal that SAG causes acute pneumonia and physicians and laboratory technicians need to identify SAG actively from now on.

Prevalence and Risk Factors of *Helicobacter pylori* Infection in the Northwest Region of Cameroon

Author Block:

L. E. Abongwa, M. Y. Elvis; Univ. of Bamenda, Bamenda, Cameroon

Abstract Body:

Background: *Helicobacter pylori* remain a public health problem and a major cause of peptic ulcer disease and gastric, with a prevalence of about 70% and 14-30% in developing and developed countries respectively.**Methods:** This study was carried out in Tubah District Hospital in the Northwest region to assess the prevalence and risk factors associated to *H. pylori*. This study runs from March to August 2014 with ethical clearance from the institutional ethical board. In all 400 subjects between 16-73 years were recruited. An open ended questionnaire was administered to all participants to capture information on socio-demographic data, risk **factors and Knowledge. Blood samples were collected and tested for the presence of the parasite using the Pylori test strip (dipstick). All diagnosed cases were treated using triple therapy.Results:**The prevalence of *H. pylori* in the study population was 240(60%). There was a significant difference $p<0.05$ in the prevalence of *H. pylori* among the age group, gender, occupation, educational level, monthly income and number of occupant in a house. The highest prevalences 112(82.2%), 186(75.0%), 160(66.6%), 96(40%), 152(63.3%) and 166(69.2%) was seen in the age group >34 years, female gender, students, those who attained primary education, monthly income <50,000frs CFA and > 10 occupants in a house respectively. The higher proportion 160 (61%) had poor knowledge about the disease recorded the highest prevalence 126(78.8%; $p=0.02$). A multivariate analysis showed a positive correlation between sex, age, number of house occupant, Knowledge of the disease, monthly income and occupation and the prevalence of *H. pylori.* Although no significant difference between the different treatment options most subjects 224(56%) prefer traditional herbs to synthetic drugs.**Conclusions:** Data from this study showed that gender, age, number of house occupant, knowledge, monthly income and occupation are risk factors of *H. pylori.*

Comparison of the Prevalence of Group A *Streptococcus* and *Fusobacterium necrophorum* at a Pediatric Hospital

Author Block:

T. T. Van[1], L. M. Cox[2], M. E. Cox[2], J. Dien Bard[1]; [1]Children's Hosp. Los Angeles, Los Angeles, CA, [2]Anaerobe Systems, Morgan Hill, CA

Abstract Body:

Background: *F. necrophorum*, a causative agent of Lemierre's syndrome, has recently been identified to be an important pathogen of bacterial pharyngitis with higher prevalence than group A *Streptococcus* (GAS) in adolescents and young adults. *F. necrophorum* pharyngitis is clinically indistinguishable from GAS pharyngitis and is not recoverable in routine aerobic throat culture. This study aimed to determine the prevalence of *F. necrophorum* compared to GAS to guide testing recommendations for patients with pharyngitis symptoms.**Methods:** Patients presenting to the CHLA emergency department who had a beta-streptococcus screen test ordered were enrolled prospectively in the study. For GAS, rapid antigen direct test (RADT) and culture were performed. *F. necrophorum* was detected by culture with selective and differential anaerobic medium and PCR. Medical chart abstraction was performed on all patients.**Results:** The study consisted of 196 patients, ages 1-20 years (mean: 7.8), most of whom had no significant comorbidities (95%). 11 (5.6%) were positive for GAS by RADT. Culture identified an additional 23 (13.4%) GAS and 4 group C and G streptococci. 8 (4.1%) patients had positive *F. necrophorum* by culture and PCR, ages 5-20 years (mean: 12 y). One patient was both GAS and *F. necrophorum* positive. All 8 (100%) *F. necrophorum* positive patients reported sore throat, 7 (87.5%) with fever, 7 (87.5%) with absence of cough, 1 (12.5%) with lymphadenopathy, and 4 (50%) with exudate. Comparatively, 28 (74%) of the 38 BS positive reported fever, 76% with no cough, 11% with lymphadenopathy, 32% with exudate, and 82% with sore throat. One *F. necrophorum* and 18 GAS culture positive patients were prescribed antibiotics at the time of visit.**Conclusions:** This study confirms the role of *F. necrophrorum* as a significant pathogen of pharyngitis. The prevalence of *F. necrophrorum* pharyngitis in our institution was lower than previously reported, which may be explained by the high number of patients < 10 y (67%) in our study. The vast majority of patients positive for *F. necrophrorum* did present with true signs and symptoms of pharyngitis that is indistinguishable from GAS.

***Candida spp*. Airway Colonization: A Potential Risk Factor for *Acinetobacter baumannii* Ventilator-Associated Pneumonia**

Author Block:

X. Tan[1], S. Zhu[1], D. Yan[1], W. Chen[2], R. Chen[1], J. Zou[3], J. Yan[3], X. Zhang[4], D. Farmakiotis[5], E. Mylonakis[5]; [1]Overseas Med. Ctr., Nanfang Hosp., Southern Med. Univ., Guangzhou, China, [2]The People's Hosp. of Qingyuan, Jinan Univ. Hosp., Qingyuan, China, [3]Nanfang Hosp., Southern Med. Univ., Guangzhou, China, [4]Southern Med. Univ., Guangzhou, China, [5]Div. of Infectious Diseases, Rhode Island Hosp., Warren Alpert Med. Sch. of Brown Univ., Providence, RI

Abstract Body:

This retrospective study was conducted to identify potential risk factors for *Acinetobacter baumannii (A. baumannii)* ventilator-associated pneumonia (VAP) and evaluate the association between *Candida* spp. airway colonization and *A. baumannii* VAP. Intensive care unit (ICU) patients who were on mechanical ventilation (MV) for at least 48 hours were divided into the following groups: patients with and without *Candida* spp. airway colonization; colonized patients receiving antifungal treatment or not; patients with *A. baumannii* VAP and those without VAP. Logistic regression analysis and propensity score matching were used to identify factors independently associated with *A. baumannii* VAP. Among 618 eligible patients, 264 (43%) had *Candida* spp. airway colonization and 114 (18%) developed *A. baumannii* VAP. Along with MV for ≥7 days (adjusted odds ratio [aOR] 8.9, 95% confidence intervals [95%CI] 4.9-15.8) and presence of a central venous catheter (aOR 3.2, 95%CI 1.1-9), *Candida* spp. airway colonization (aOR 2.6, 95%CI 1.6-4.3) was identified as an independent risk factor for *A. baumannii* VAP. Patients with *Candida* spp. airway colonization were more likely to develop *A. baumannii* VAP than non-colonized patients (23% *vs*. 15%, P=0.01 and 34% vs. 15%, P<0.001 in propensity score-matched subgroups). Administration of antifungal agents was not associated with *A. baumannii* VAP (29% vs. 21%, P=0.153), but with higher in-hospital mortality (53% *vs.* 39%, P=0.037). *Candida* spp. airway colonization (43%) and *A. baumannii* VAP (18%) were common in ICU patients who were on mechanical ventilation for at least 48 hours. *Candida* spp. airway colonization was an independent risk factor for subsequent *A. baumannii* VAP.

Procalcitonin as a Predictor of Bacteremia in Early Postoperative Period in Adult Cardiosurgical Patients

Author Block:

D. A. Popov, S. T. Ovseenko, T. Y. Vostrikova; Bakulev Scientific Ctr. for Cardiovascular Surgery, Moscow, Russian Federation

Abstract Body:

Background: Bacteremia is a serious post-op complication. We study the value of procalcitonin (PCT) as a predictor of bacteremia in adult patients underwent cardiac surgery. **Methods:** The retrospective 6-years study included 10158 pairs of simultaneously taken blood samples for cultivation and PCT testing from 4113 post-op patients with suspected bacteremia. Blood cultures incubation was performed using BacT/Alert 3D (bioMerieux, France). Identification of positive cultures was done by VITEK 2 compact (bioMerieux, France). PCT blood plasma concentration was determined by Vidas (bioMerieux, France). Data are presented as means and standard error of the mean (M±m) and were compared by Student`s t-test, p-values of <0.05 were considered statistically significant.**Results:** Bacteremia developed in average on day 6 of complicated post-op period (min - on day 2, max - on day 124). The whole rate of bacteremia was 20.7% (2105/10158): 972 cases (46.2%) were caused by Gram-positive cocci, 702 (33.3%) - by Gram-negative bacteria, 338 (16.1%) - by yeasts; in 93 cases (4.4%) mixed cultures were detected. Analysis included only monocultures (n=2012). Mean PCT levels were significantly higher in bacteremia cases (14,35±0.91 ng/mL) compared with negative blood cultures (7.35±0.26 ng/mL), p=0. The highest PCT levels were found in Gram-negative bacteremia (26.03±2.13 ng/mL) without significant differences between Enterobacteriaceae (30.56±4.05 ng/mL) and non-fermenters (22.79±2.21 ng/mL), p=0.07. Statistically significant differences by PCT levels between groups of bacteremia caused by Gram-negative bacteria (26.03±2.13 ng/mL) and Gram-positive cocci (7.24±0.88 ng/mL, p=0), *Candida spp.* (9.02±1.84 ng/mL, p=0) and contamination cases (9.92±2.79 ng/mL, p = 0) were found. The mean PCT levels in bacteremia caused by CNS (5.94±0.87 ng/mL), *S. aureus* (4.04±0.9 ng/mL), Enterococci (15.72±3.52 ng/mL), *Candida spp.* (9.02±1.84 ng/mL), contamination (9.92±2.79 ng/mL) and negative blood culture cases (7.35±0.26 ng/mL) were not statistically differ between each other.**Conclusions:** High PCT blood plasma levels during early post-op period in cardiosurgical patients may predict the Gram-negative bacteremia. Together with clinical data it may contribute to rational choice of empirical antibiotic therapy.

Evaluation of Vancomycin Utilization in a Pediatric Hospital Before and After 2011 Idsa Recommendations

Author Block:

S. Tremblay[1], P. Bedard[1], C. Sallaleh[2], Y. Zilber[2]; [1]CHU Ste-Justine, Montreal, QC, Canada, [2]Univ. de Montreal, Montreal, QC, Canada

Abstract Body:

Pediatric references suggest starting doses of Vancomycin between 40 and 60 mg/kg/day divided every 6 hours. In 2011, IDSA indicated that targeting trough concentrations of 15-20 mg/L should be considered in children with serious infections. At CHU Sainte-Justine(CHUSJ) , since these recommandations, the initial dosage of vancomycin is 15mg/kg/dose every 6 hours. The dosage is then adjusted to target trough concentrations of 10-20mg/L. The aim of this study was to compare use, monitoring, response and toxicity of vancomycin at CHUSJ before and after the publication of IDSA recommendations.Hospitalized children at CHUSJ between January 2006 and November 2015 with ages between 3 months and 18 years who were treated with systemic vancomycin for at least 24 hours with at least one measured serum level were included in this study. Patients were divided in two groups; group A received vancomycin between January 2006 and December 2009 and group B received this antibiotic between January 2012 and November 2015. 80 patients were chosen with Excel software, 40 patients for each time frame. Patients hospitalized in oncology or neonatal units and patients < 3 months were excluded. For each patient demographic, clinical, microbiologic and pharmacokinetic datas were collected. Descriptive statistics were performed for the studied population. Both groups were comparable. The mean daily dose of vancomycin received was higher in group B(55 mg/kg/day vs 46,6 in group A). Vancomycin was given every 6 hours in 85% of group A patients while every 6 hours in 60% and every 4 hours in 20% of group B patients. 25% of patients reached a through value of 10 mg/L in group A and 72,5% in group B. There was no differences for through value > 15 mg/L. There was no significant differences for creatinine, neutropenia, eosinophilia, Red Man syndrom and other side effects. An elevation of blood serum creatinine >25% was observed in 71.4% of patients with through >15 mg/L.The utilization of higher vancomycin dosages allowed to attain through levels >10 mg/L in a higher proportion of patients. There was no significant differences in side effects in our 2 groups except for a trend toward an elevation of blood creatinine with higher through levels. Our group was small and further studies are needed.

Abstract Body:

Background: To evaluate Cytomegalovirus (CMV), Epstein-Barr virus (EBV) and Human Herpesvirus-8 (HHV-8) DNA salivary shedding in MSM with 48 months (mo) of a persistent detectable or undetectable plasma HIV viremia (pHIV).**Methods:** Adult MSM, no oral lesions, positive CMV, EBV and HHV-8 serology provided an unstimulated saliva sample (SlSp). Viral DNA was quantified by a in-house real-time PCR. pHIV was analyzed for 24 mo prior to the first SlSp (T0) and for a 24-mo period between T0 and T1 (second SlSp); MSM were categorized as with pHIV suppressed (SS) or not suppressed (NS).**Results:** 121 MSM included (median age 44 yrs, mean CD4+ cells/mm^3 at T0 580, mean nadir value 345 cells/mm^3); HHV-8 was tested in 73 MSM. EBV and CMV shedding at T0 and T1 are reported in figure 1. No CMV and EBV shedding was more frequent in SS MSM at T0 (26.7 % vs 10 %, p=0.02); at T1 57.9% of SS were still negative but 100% of NS became positive (p=0.04). Isolated EBV detection was similar at T0 in the SS and NS group: but more NS turned EBV and CMV pos at T1 (14.3% vs 2.3 %, p=0.04). Combined CMV and EBV shedding was lost in 90% of SS at T1 versus 30% of NS MSM (p=0.01), this figure increased in NS (18% to 28%). Mean pHIV (copies/ml) was significantly higher in MSM with CMV and EBV shedding (47994) both respect those with isolated EBV (13585) and with no shedding (8425) (p=0.03). At T0 HHV8 was detected in 29 MSM, (39.7%) (17 still positive at T1); at T1 all HHV-8+/CMV+ MSM were NS respect to 36% of HHV8+/CMV- pts (p=0.01).**Conclusions:** : A persistent pHIV detectability influenced CMV, EBV and HHV-8 salivary burden both in the short and in the long period in immunocompetent MSM.

Figure 1. Different patterns of EBV DNA and CMV DNA salivary shedding in MSM with pHIV suppressed and with pHIV not suppressed at T0 and T1.

MSM with pHIV suppressed (SS, 71 pts)

T0	T1			
	EBV neg CMV neg 17 (24%)	EBV pos CMV neg 51 (71.8%)	EBV neg CMV pos 1 (1.4%)	EBV pos CMV pos 2 (2.8%)

(AHRI), ADDIS ABABA, Ethiopia, [6]HEMEN MATERNAL AND CHILDREN Hosp., ADDIS ABABA, Ethiopia

Abstract Body:

Cervical cancer is a preventable disease affecting an estimated 530,000 women each year and leading to nearly 275,000 deaths. Human papillomavirus (HPV) has been recognized as an important cause of cervical cancer and it is implicated in 99.7% of cervical squamous cell cancer cases in the world. In Ethiopia, every year 7095 women diagnosed with cervical cancer and 4732 die from the disease. Very low screening practice and inadequate screening coverage in Ethiopia makes cervical cancer as one of the major public health concern.This study was aimed to assess the prevalence and genotype distribution of High Risk Human Papilloma Virus (HR HPV) and Cervical Cytology abnormalities at selected Obstetrics and Gynecology clinics in Addis Ababa, EthiopiaInstitutional based cross sectional study design was used from 15th June to 10th October 2015. Cervical samples were collected from the os of the cervix using Abbott cervi-cyt collection material for HR HPV DNA and cyto-brush for Pap smear screening. A total of 366 participants were enrolled based on the set inclusion criteria. HR HPV DNA was analyzed using Abbott Real Time PCR and cervical cytology screening using conventional Pap smear techniques. Data entry was performed using Epi-data ver 3.1 and data analysis was performed by using STATA ver 11.0.The overall HR HPV prevalence was 13.7% (50/366), with 76% (38/50) of Other HR HPV genotypes. Abnormal cytology was observed in 13.1% (48/366) with 81.3%, 12.5%, and 6.3%, are LSIL, ASCUS and HSIL respectively.In this study, Non-16/18 genotypes contributed the largest proportion of the overall HR HPV. The highest frequency of HR HPV positives was women without cervical cytology abnormality. The HR HPV with Pap smear co-screening in women whose age is >30 shall be in place. Further evaluation between the two screening methods against a perfect reference method shall be performed.

Whole Genome Analyses Reveal Multiple Viral Pathogens in Respiratory Illness Specimens from United States Army Basic Trainees

Author Block:

J. Hang, T. J. Vento, E. A. Norby, R. G. Jarman, R. A. Kuschner, P. B. Keiser, L. N. Binn; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

Background: Human adenoviruses (AdV), in particular types 4 and 7, frequently cause acute respiratory disease (ARD) during basic military training. AdV4 and AdV7 vaccines have been proven safe and effective and have substantially reduced the ARD risk. It is important to identify other respiratory pathogens and assess their potential impact on military readiness. We investigated respiratory specimens collected from a group of basic trainees to identify their viral etiologies. **Methods:** In 2002, during a period when the adenovirus vaccines were not available, throat swabs were taken from recruits with respiratory disease at Fort Jackson, South Carolina. The swabs were inoculated into A549 cells and observed for viral cytopathic effects (cpe) and tested in neutralization assays with antisera for AdV types 3, 4, 7. Nucleic acids purified from viral culture supernatants were sequenced using Illumina MiSeq and Nextera methods. The viral genome sequences were assembled using Roche GS Data Analysis Software and applied to whole genome comparative analysis using Geneious R8.**Results:** The study enrolled 184 military recruits with febrile ARD, afebrile ARD and pneumonia. Viral culture and neutralization assays identified 86 AdV-4 isolates (46.7%) and 23 other AdVs or picorna-like cpe viruses (12.5%). Sequencing 103 cpe-positive samples confirmed these results and determined the genotypes: 78 AdV4, four AdV3, one AdV2, and 18 Coxsackie virus A-21 (CAV 21) and one enterovirus, D68. Two samples were positive for both AdV4 and CAV 21. The analyses suggest that each of these virus types originated from a single strain. The identified genotypes are phylogenetically close to but distinct from those found during other years or in other military/non-military sites.**Conclusions:** These results confirmed AdV4 is the predominant respiratory pathogen in military recruits. The genome sequence analysis shows the temporal and demographic variability of adenoviruses. CAV 21 has been a significant respiratory pathogen and needs to be evaluated for its current significance in military recruits. Next-generation sequencing enables accurate pathogen identification and provides information for improved disease surveillance and prevention.

Clinical Scoring System to Predict Life-Threatening Respiratory Syncytial Virus (Rsv) Infections in Adults

Author Block:

S. Park, Y. Jang, T. Kim, S. Hong, J. Jung, Y. Chong, S-O. Lee, S-H. Choi, Y. Kim, J. Woo, S-H. Kim; Asan Med. Ctr., Seoul, Korea, Republic of

Abstract Body:

Background: RSV is a significant cause of considerable morbidity and mortality in elderly persons as well as in young children. However, there are limited data on clinical prediction models for life-threatening RSV infection in adults, which could guide the appropriate use of antiviral agents.**Methods:** We conducted a retrospective cohort study in a tertiary referral hospital during a 2-year period. All adult patients with RSV infection confirmed by PCR on nasopharyngeal swab who visited emergency department were enrolled. Primary outcome was life-threatening RSV infection (admission to intensive care unit or need to ventilator care or in-hospital death).**Results:** A total of 227 patients were analyzed. Median age was 65 (IQR 57-74). Of these 227 patients, 216 (95%) had underlying chronic medical condition; 48 (21%) had chronic pulmonary diseases, 69 (30%) solid tumors, and 22 (10%) hematologic diseases. Life-threatening RSV infection occurred in 34 (15%) patients including 17 (8%) fatal infections. By logistic regression, lower respiratory infection (OR 4.8, 95% CI 2.0 to 11.6, *P*=0.001), fever ≥38ºC (OR 2.4, 95% CI 1.1 to 5.3, *P*=0.05), and chronic lung disease (OR 2.8, 95% CI 1.3 to 6.1, *P*=0.03) was found to be independent predictors for life-threatening RSV infection. We developed simple clinical scoring using these variables (lower respiratory tract infection= score 2, fever=score 1, chronic lung disease=score 1) to predict life-threatening RSV infection. A score of ≥2 differential life-threatening RSV from non life-threatening RSV with 82.4 sensitivity (95% CI, 65.5 - 93.2) and 51.3 specificity (95% CI, 44.0 - 58.5).**Conclusions:** Using clinical scoring based on lower respiratory infection, fever, and chronic lung disease appears to be useful for outcome prediction and risk stratification to select patients who may need early antiviral therapy.

Molecular Characterization of Circulating Strains of Influenza B Between 2014-2015 in Egypt

Author Block:

E. A. Ayoub[1], M. A. Aziz[1], N. Nabil[1], S. El Refaay[2], M. Genedy[2], A. Kandil[2], G. Defang[1]; [1]US Naval Med. Res. Unit 3, Cairo, Egypt, [2]Ministry of Hlth.and Population, Cairo, Egypt, Cairo, Egypt

Abstract Body:

Infection with influenza can result in a wide a range of clinical presentations and in some instances result in fatal disease. Monitoring genetic changes of influenza viruses is crucial for vaccine strain selection, detection of drug resistance and determination of virulence markers. Herein we analyzed the HA and NA genes of influenza B viruses circulating among influenza-like illness (ILI) patients in Egypt during winter of 2014/15.Patients were considered to have an ILI if they met the WHO criteria of fever ≥38°C and cough. Oropharyngeal swabs in viral transport media collected from seven sites within Egypt were diagnosed by real-time PCR to determine influenza subtypes. Positive influenza B samples were inoculated on MDCK cells. The supernatant was tested by PCR to confirm influenza B, and representative isolates were chosen for Sanger's sequencing.Sequence analysis of the HA gene of 40 isolates showed that all viruses were within the Influenza B/Yamagata lineage with 28 isolates clustered within clade 3 and 12 within clade 2. The two clades were differentiated by substitutions at HA1 positions 48, 108, 150, 165, 181 and 229; viruses in clade 3 encode R48, P108, I150, Y165, T181 and D229. There was no specific geographical region or time interval associated with the distribution of both clades. Clade 2 sequences had more than 99% nucleotide (nt) similarity to B/Massachuetts/02/2012, the vaccine strain for 2014/15 season in northern hemisphere. Clade 3 sequences demonstrated 97% nt similarity to the same strain and showed more than 99% nt similarity to B/Phuket/3073/2013, the vaccine strain for 2014/15 for the southern hemisphere and the 2015/16 northern hemisphere candidate vaccine, however clade 2 viruses showed 97% nt similarity to the same strain. The NA sequences showed the same pattern of the HA phylogenetic tree in which the sequences clustered within clade 2 and 3 viruses. Mutations; R152K, G109E, D198N, and G402S previously reported to be associated with resistance to NA inhibitors were not detected.Phylogenetic analysis of influenza B viruses from Egypt during 2014/15 showed no Victoria lineage viruses. Our data supports the WHO recommendation of replacing B/Massachuetts/02/2012 with B/Phuket/3073/2013 in the influenza vaccine composition for 2015/16 season.

Severe Fever with Thrombocytopenia Syndrome Associated with Hemophagocytosis Lymphohistiocytosis

Author Block:

H. Oh[1], M. Kim[1], J-O. Lee[1], H. Kim[2], E. Kim[1], P. Choe[2], W. Park[2], J. Bang[2], K. Park[2], S. Park[2], H. Kim[1], N. Kim[2], M-d. Oh[2], K-H. Song[1]; [1]Seoul Natl. Univ. Bundang Hosp., Seongnam, Korea, Republic of, [2]Seoul Natl. Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: Severe fever with thrombocytopenia syndrome (SFTS) is new emerging zoonosis. Hemophagocytic lymphohistiocytosis (HLH) is life-threatening syndrome caused by hyper-inflammation. Here we report the case of SFTS associated HLH.**Case report:** A 62-year-old man was admitted to local hospital with generalized tonic clonic seizure-like movement. He suffered from 8 days of fever and chill. Brain magnetic resonance imaging and electroencephalography were normal. First seizure spontaneously terminated and his mentality was alert during post-ictal period. His peak body temperature was 39.4℃. Initial laboratory finding revealed leukopenia ($1,900\times10^6$/L) and thrombocytopenia ($107,000\times10^6$/L). Since his mentality became confused gradually and fever persisted, he was transferred to referral hospital. Leukopenia was stationary ($2,400\times10^6$/L), but thrombocytopenia got worsened ($49,000\times10^6$/L). He had hypertriglyceridemia (627 mg/dL) and hyperferritinemia (832 ng/mL). Cerebrospinal fluid analysis showed mild elevation of protein without pleocytosis. Bone marrow examination and trans-jugular liver biopsy were performed and showed hemophagocytic histiocytes. Serological and molecular tests for possible infectious causes were negative except SFTS virus polymerase chain reaction (PCR). The PCR tests were performed by not only serum but also bone marrow and liver biopsy specimens. All of them indicated positive. Definite diagnosis was SFTS associated HLH. During 2 weeks of systemic steroid, intravenous immunoglobulin and conservative management, he was fully recovered from HLH.**Discussion:** The present case met five of eight criteria of HLH. SFTS virus PCR results were positive in all clinical specimens. We could make definite diagnosis of SFTS associated HLH. HLH can be rapidly progressing and life-threatening without adequate treatment, active investigation of possible infectious causes of HLH is crucial. We confirmed that SFTS could be one of causes of HLH. Thus, clinicians need to be aware of it, especially in endemic area.

Norovirus Infection of Children in Egypt Between 2005 and 2009 Showed Distinct Molecular Clustering Based on Time of Year and Location

Author Block:

R. Nada, I. Nakhla, S. Lizewski, I. Raafat, M. Kamel, M. Mostafa, A. Hamad, H. Mohammady; US. Naval Med. Res. Unit-3, Cairo, Egypt

Abstract Body:

Background: Noroviruses (NoVs) are a worldwide leading cause of acute viral gastroenteritis across all ages and is a major cause of acute gastroenteritis outbreaks in industrialized countries. This study investigated the prevalence and genotype distribution of noroviruses in pediatric patients presenting with diarrhea from three different regions in Egypt. It also studied the phylogeny of the predominating norovirus genotypes.**Methods:** Archived stool samples collected from 930 diarrheal patients enrolled in hospital-based, pediatric diarrhea surveillance studies between 2005 and 2009 were tested for the presence of norovirus using real-time PCR (Q-PCR) based on amplification of ORF1-ORF2 junction. Circulating norovirus genotypes for both GI and GII were identified using DNA sequencing of regions C and D of ORF2.**Results:** Noroviruses were detected in 177 (19%) patients, of which, 105 (11%) had norovirus as the sole pathogen. GII was more common (n=150; 16.1%) than GI (n=34; 3.6%). Seven patients were co-infected with noroviruses GI and GII. Both genogroups had a very high association ($p<0.0001$) with vomiting. Seasonality of norovirus infections was consistent during the five years of the study. Norovirus infections peaked in the warm months with 91% of norovirus GI and 68% of norovirus GII infections occurring between May and October. Sequence analysis of GI revealed equal distribution of GI.2 and GI.3 (15%) followed by GI.6 (12%). The other G1 genotypes were detected in smaller frequencies ranging from 6 to 9%. . GII.4 was the most abundant genotype (42%) identified in norovirus GII cases followed by GII.3 (27%) and GII.1 (7%). Other norovirus GII genotypeswere identified in lower frequencies ranging from 5% to 1%. Phylogenetic analysis of GII.3 and GII.4 norovirus strains showed clear association between time period and geographical location with norovirus clusters identified which might indicate the complexity of noroviruses epidemiology and the high infectivity of these viruses that might appear in the form of mini-outbreaks.**Conclusions:** Results of this study provide valuable information regarding the epidemiology of noroviruses infections and confirm that these viruses are responsible for a significant portion of acute gastroenteritis in outpatient children in Egypt.

Measles a Considerable Public Health Problem in Oromia Regional State of Ethiopia

Author Block:

M. Getahun, E. Assefa, Y. HaileMariyam, A. Asha, B. Beyene; Ethiopian Publ. Hlth.Inst., Addis Ababa, Ethiopia

Abstract Body:

Background: Measles is a highly contagious acute febrile rash viral infection causing large outbreaks and complications like brain damage, blindness, and deafness. Despite the availability of safe and cost effective vaccine, measles remained endemic with persistent periodic outbreaks in the Horn of Africa, being one of the five major causes of childhood illness in Ethiopia. The aim of this study was to characterize laboratory confirmed measles cases from the case based surveillance data in the highly measles affected Oromia Regional State of Ethiopia, 2008-2015. **Methods:** A suspected measles case was defined as any person presenting with fever, maculopapular rash and at least one of the three, cough, coryza or conjunctivitis or a patient in whom a clinician suspects measles. A blood sample was collected from suspected cases and information about the patient was captured by case reporting format (CRF). Samples were transported to the National Measles Laboratory where tested for Measles IgM by ELISA technique. Case based surveillance data were entered and analyzed using Epi-Info 3.5.4 software.**Results:** From 2008-2015, a total of 13,303 samples were tested for measles IgM among 15,004 cases notified with blood and CRF from Oromia Regional State. Of the tested samples, 5336 (40.1%) had confirmed measles (IgM positive) with 7608 negative and 359 equivocal result. Patients with age group 1-4 years were the most affected followed by ≥15 years.. The highest number of laboratory confirmed measles cases were detected in 2015 contributed for 20% of all years. Confirmed cases were found distributed throughout all zones of the regional state. A seasonal variation noted with the highest occurrence in the hot-dry season of the year, peak in February (figure 1).**Conclusions:** Measles infection was found increasing from year to year, mostly affecting children 1-4 years. Seasonal variation was seen reaching its peak in hot-dry season. It is highly recommended to improve routine immunization, and conduct a wide age group campaign. In addition to genotyping the circulating strain of measles, evaluating the knowledge, attitudes and practice of the parents and health care professionals about measles infection and vaccination is important.

An Under-Recognized Arbovirus in Nova Scotia, Canada: Seroprevalence of Jamestown Canyon Virus

Author Block:

G. Patriquin[1], E. Schleihauf[2], B. Johnston[3], K. Dimitrova[4], A. Mask[5], M. Traykova-Andonova[4], D. Haldane[3], M. Drebot[4], T. Cole[6], R. Lindsay[4], T. Hatchette[3]; [1]Dalhousie Univ., Halifax, NS, Canada, [2]Publ. Hlth.Agency of Canada, Halifax, NS, Canada, [3]Nova Scotia Hlth.Authority, Halifax, NS, Canada, [4]Publ. Hlth.Agency of Canada, Winnipeg, MB, Canada, [5]Publ. Hlth.Agency of Canada, Ottawa, ON, Canada, [6]Nova Scotia Dept. of Hlth.and Wellness, Halifax, NS, Canada

Abstract Body:

Background: Jamestown Canyon Virus (JCV) is a mosquito-borne arbovirus in the California serogroup (CSG) within the Bunyaviridae family. The white-tailed deer is thought to be its primary reservoir host. The virus has been described in North America, as infections ranging from asymptomatic to meningoencephalitis. Our preliminary serological data demonstrated exposure to JCV among white-tailed deer and humans. Prior data were limited to two district health authorities (DHAs) in Nova Scotia (NS).**Objective:** To determine and compare the JCV seroprevalence of each DHA in NS.**Methods:** Randomly-selected anonymized residual sera from specimens submitted for diagnostic testing in 2012 in each DHA were screened for JCV antibodies, and then confirmed using plaque reduction neutralization assay (PRNT). A PRNT titre ≥1:20 was considered positive. Additional PRNT endpoint titrations were required in some cases to discriminate between JCV and other CSG viruses. Seroprevalence estimates and 95% confidence intervals (CIs) were calculated using the Clopper-Pearson Exact method. Design weights accounted for regional oversampling in the provincial estimate (SAS v9.4; SAS Institute, Inc., Cary, NC, USA). Population estimates for 2014 were based on Statistics Canada census data.**Results:** A total of 251 samples across 9 NS DHAs were tested, with an overall seroprevalence of JCV of 21.2% (95% CI 16.1-27.0). Seroprevalence based on DHA ranged from 12.9% to 48.2%. The areas of lowest seroprevalence were in DHAs containing NS's two largest urban centres, Halifax and Sydney. DHA 1, located in southern NS had a significantly higher seroprevalence of 48.2% (CI 35.1-61.3), than all other DHAs combined (20.5% (CI 14.8-26.2)), with a p-value <0.05.**Conclusions:** The seroprevalence of JCV in NS is high and varies based on DHA. There have been no known clinical cases of JCV infection in the province, suggesting the possibility of an under-recognized zoonotic disease in NS.

Adenovirus 8 (D Strain) Associated Conjunctivitis Outbreak in a Pediatric Nursery Ward of a Tertiary Care Hospital

Author Block:

G. Satpathy, A. K. Mishra, R. Tandon; All India Inst. of Med. Sci., New Delhi, India

Abstract Body:

Objectives: The objective was to determine the microbial aetiology in a cluster of conjunctivitis cases occurring in a pediatric nursery of our hospital using classical microbiological and molecular methods and to do the molecular phylogenetic study of the causative viruses.**Methods:** Seven babies (9-66 days old) in the paediatric nursery ward developed conjunctivitis along with one of their mothers simultaneously. Conjunctival specimens were subjected to bacterial culture, direct immunofluorescence assay for *C trachomatis* antigen detection, viral culture and PCR assay for detection of conjunctivitis causing viruses (target genes: VP 1 region of EV 70 and Coxscakiae virus A 24 and 302 bp region of Adeno Virus hexon protein coding gene). Nested PCR assay was done to amplify 1004bp and 956bp internal region of Adeno Virus hexon gene, nucleotide sequencing was done and a phylogenetic tree was drawn using MEGA 4 software along with 30 different Adeno virus hexon gene sequences from gene bank and nucleotide sequences of 9 Adeno virus isolates from our laboratory from sporadic conjunctivitis cases.**Results:** Three of the babies and one of their mother were positive in diagnostic Adeno Virus PCR assay. Adeno viruses could be isolated in *Hep* 2 cells from 3 of these babies. All of them were negative for *C trachomatis* antigen detection and bacteria could be isolated from all eyes (*S epidermidis*: 6, *S aureus*: 1., *E coli:* 1). The isolated Adenoviruses demonstrated 98% sequence homology with Adeno virus 8 in the hexon gene sequences, In phylogenetic analysis they clustered with Strain D of Adeno Virus.**Conclusion:** Adeno Vorus 8 (Strain D) was concluded as the causative agent of conjunctivitis in the paediatric nursery.; this was also the causative virus in the sporadic conjunctivitis cases occurring in Delhi. Use of molecular diagnostics along with nucleotide sequencing could identify the causative virus within a short time.

Norovirus Seroprevalence in the United States, 1999-2004

Author Block:

A. E. Kirby, J. Barton, M. Sizemore, E. Anderson, C. L. Moe; Emory Univ., Atlanta, GA

Abstract Body:

Norovirus is the most common cause of foodborne gastroenteritis, however, estimates of the full burden of infection are limited. Very few cases seek medical care and testing, and epidemiologic studies focus on specific populations or severe cases. Thus, the burden of endemic norovirus causing mild or moderate disease is not known. To estimate the total burden of norovirus infection in the US, we determined the seroprevalence of antibodies to norovirus in a nationally representative sample. Banked serum specimens from adults aged 16-49 collected during the 1999-2000 and 2003-2004 cycles of the National Health and Nutrition Examination Survey were tested against a panel of norovirus virus-like particles (VLPs): GI.1 Norwalk, GI.4, GII.3, GII.4 US95/96, GII.4 Farmington Hills, GII.4 New Orleans, and GIV.1. Serum samples were diluted 1:50 for ELISA. Samples with an optical density greater than 1.0 were considered seropositive. Most samples (87.6%) were seropositive for at least one VLP, and 18.2% were seropositive for all seven VLPs. The VLPs with the highest seroprevalence were GII.4 US95/96 and GII.4 Farmington Hills, at 71.4% and 70.6%, respectively. GII.4 New Orleans, which had not yet emerged at the time of sample collection, had a seroprevalence of 65.9%. GI.1 Norwalk and GII.3 had similarly high seroprevalences, at 68.8% and 69.6%, respectively. The VLP with the lowest seroprevalence was GI.4 (44.7%). Half of all samples (49.6%) were seropositive for GIV.1. Very high titers (OD>2.5)-consistent with recent infection-were much less frequent, ranging from 4.9% to 30.9%. There were no significant findings when the results were stratified by subject age. Although this study found slightly lower seroprevalence to norovirus than previous reports, the majority of subjects had evidence of norovirus infection. This is the first nationally representative serosurvey for norovirus in the US and one of the few studies to assess prevalence of GIV.1 infection.

Norovirus and Rotavirus Coinfection in Mexican Children During 2014-2015

Author Block:

R. Infante-Ramirez[1], D. Perez-Lugo[1], J. Lopez-Franco[1], C. Delgado-Gardea[1], M. De La O-Contreras[1], G. Erosa-Dela Vega[1], M. Gonzalez-Horta[1], B. Sanchez-Ramirez[1], A. Torres Reyes[1], E. Guevara-Macias[2], F. Zavala-Diaz de la Serna[1], C. Romo-Saenz[3], J. Contreras Cordero[3]; [1]Univ. Autonoma de Chihuahua, CHIHUAHUA, Mexico, [2]Hosp. Infantil de Especialidades, CHIHUAHUA, Mexico, [3]Univ. Autonoma de Nuevo Leon, MONTERREY NL, Mexico

Abstract Body:

Severe acute diarrhea is an intestinal inflammatory type alteration caused by various infectious agents, bacteria, parasites fungi and virus; In Mexico to viral agents it is recognized as the leading cause of childhood gastroenteritis , followed by bacteria and parasites. Globally, in infants under five, Rotavirus is the most important cause of mobility and mortality. Within *Caliciviridae* family, Norovirus is the most common cause of outbreaks on non-bacterial gastroenteritis in all age patients, while in Mexico we had reported only a 3% of cases caused by this viral agent, both due to the easy dispersion by oral-fecal route. The purpose of this study was detected confection Rotavirus-Norovirus in children with acute diarrhea during 2014-2015.**Methods:** A total of 116 stool samples of children under 5, with acute diarrhea were studied. Samples were collected in Pediatric Hospital in Chihuahua, Mexico, during 2014-2015. Viral RNA was extracted by Trizol® method. Molecular detection of Rotavirus and Norovirus by two steps RT-qPCR was done. Rotavirus cDNA was synthesized for generating a fragment of 876pb of the VP4 protein amplified with primers PA1/CON2. To detect Norovirus we used specific primers JV13 and JV12, amplifying a 326 bp fragment of gen RdRp. Amplicons was analyzed by Software Kodak 1D®in 1%agarose gel. The results reveal coinfection Norovirus-Rotavirus in the children samples. The presence of the Norovirus was 18.96% (22) of the samples analyzed. Gene four of Rotavirus (VP8) was detected in 38 samples. **Conclusions:** During 2014-2015 a significant increase in norovirus strains in children with acute diarrhea, three times higher than what we had reported in previous periods was observed. Moreover Rotavirus also showed increase, so it is necessary to continue with the epidemiological surveillance.

Recurrent Respiratory Tract Infections in Children - A Prospective Cohort Study

Author Block:

L. Toivonen[1], S. Karppinen[1], L. Schuez-Havupalo[1], T. Teros-Jaakkola[1], J. Vuononvirta[2], Q. He[2], M. Waris[1], V. Peltola[1]; [1]Univ. of Turku, Turku, Finland, [2]Natl. Inst. for Hlth.and Welfare, Turku, Finland

Abstract Body:

Background: The disease burden of recurrent respiratory tract infections is unclear. We identified young children with recurrent respiratory infections in order to characterize the clinical manifestations and short-term consequences. **Methods:** In this prospective cohort study, 1089 children were followed from birth to two years of age for respiratory infections by a daily symptom diary. Background information was gathered by questionnaires. In a subgroup of 714 children, nasal swab samples taken during respiratory infections were analyzed for viruses, and nasopharyngeal swabs collected at two months of age were cultured for bacteria. The 10% of children with the highest number of annual respiratory illness days were defined to have recurrent respiratory infections.**Results:** A total of 99,587 respiratory illness days, 12,118 episodes of acute respiratory infections, and 5981 physician visits for acute respiratory infection were documented. The median number of annual respiratory illness days was 44 per child, and the 90th percentile was 98 days. Children above the 90th percentile (n = 109) had a median of 113 days with respiratory symptoms, 9.6 acute respiratory infection episodes, 6.0 physician visits, 1.8 episodes of acute otitis media, and 2.5 antibiotic treatments per child per year. Of these children, 60% were diagnosed with ≥3 episodes of acute otitis media, 33% with a wheezing illness, 73% received ≥3 antibiotic treatments, and 14% were hospitalized for an acute respiratory infection. Tympanostomy tubes were inserted to 35% and adenoidectomy was performed for 13% of these children. Older siblings, early nasopharyngeal colonization with Streptococcus pneumoniae, and an acute respiratory infection before three months of age were associated with recurrent respiratory tract infections ($P<0.0001$, $P=0.005$, and $P<0.0001$, respectively).**Conclusions:** Recurrent respiratory tract infections cause a substantial disease burden. Children with recurrent respiratory infections frequently use healthcare services and antibiotics.

Publishing Title:

Diagnostic Usefulness of CMV-Specific T Cell Immunity in Predicting CMV Infection after Kidney Transplantation

Author Block:

T. Kim, S. Park, M-C. Kim, Y. Jang, H-J. Lee, S-M. Kim, J. Jung, S. Shin, Y-H. Kim, H. Sung, Y. Chong, S-O. Lee, S-H. Choi, Y. Kim, J. Woo, D. Han, S-H. Kim; Asan Med. Ctr., Seoul, Korea, Republic of

Abstract Body:

Background: Cytomegalovirus (CMV) is one of the most important opportunistic infections in transplant recipients. Currently pretransplant serostatus for CMV IgG is the only laboratory test for stratifying the risk of CMV infection after solid organ transplant, while T cell-mediated immunity is important for controlling CMV infection. We thus evaluated the usefulness of the pretransplant CMV-specific ELISPOT assay in kidney transplant (KT) recipients for predicting CMV infections after transplant. **Methods:** All adult recipients admitted to the KT institute without donor CMV-seropositive and recipient seronegative (D+/R-) between March 2014 and March 2015 were enrolled. CMV pp65 and IE1-specific ELISPOT assays were performed before KT. The primary outcome was the incidence of CMV infection at 6 months after KT. CMV infection was defined in the presence of CMV antigenemia, CMV syndrome, or tissue-invasive CMV disease. The cut-off values for pp65 and IE1 were selected as the point on ROC curves that maximized the sum of the sensitivity and specificity. **Results:** A total of 199 transplant recipients involving 150 (75%) living-donor KT, 32 (16%) deceased-donor KT, 8 (4%) kidney-pancreas transplants, and 9 (5%) pancreas transplants were enrolled. CMV infections occurred in 73 (37%) patients. Of 199 patients, 65 (33%) had negative pp65-specific ELISPOT results (<10 spots/2.0×10^5 cells) and 134 (67%) had positive results. There was no significant difference in CMV infections between those with negative results and with positive results (43% [28/65] vs. 34% [45/134]) ($P = 0.19$). In addition, there was no difference in CMV infection between those with negative IE1-specific ELISPOT results (< 7 spots/2.0×10^5 cells, 38% [58/152]) and with positive results (32% [15/47]) ($P = 0.44$). The sensitivity, specificity, positive predictive value, and negative predictive value of the pp65-specific ELISPOT for predicting CMV infection were 38% (95% confidence interval [CI], 27%-50%), 71% (95% CI, 62%-78%), 43% (95% CI, 31%-56%), and 66% (95% CI, 58%-74%), respectively. **Conclusions:** Pretransplant CMV-specific ELISPOT results did not predict the development of subsequent CMV infections after transplant in KT recipients with moderate risk.

Post-prophylaxis Risk of Cmv Infection in Heart Transplant (Ht)

Author Block:

J. B. Doyon, A. Galar, J. M. Stempel, M. M. Givertz, F. M. Marty, S. Koo; Brigham and Women's Hosp., Boston, MA

Abstract Body:

Background: Although CMV viremia and disease are known complications of HT, the optimal prophylactic strategy is not well defined. **Methods:** We performed a cohort analysis of all HT recipients at Brigham and Women's Hospital from 1/08- 12/14 to identify risk factors for CMV infection, using Cox proportional hazards models.**Results:** The median age of our 129-patient cohort was 51 years (IQR 42, 62); 89 (69%) were male. Most common indications for HT were nonischemic (45, 35%) or ischemic (35, 27%) cardiomyopathy, or congenital heart disease (17, 13%). Median duration of CMV prophylaxis, mostly valganciclovir, was 144 days (IQR 110, 181). CMV viremia developed in 17 patients, 6 of whom also had CMV disease. CMV donor+/recipient- (D+R-) status was the only factor associated with CMV infection (HR 10.0, 95% CI 3.3, 30.9). CMV events predominantly occurred in CMV D+R- patients in the 6-month interval following discontinuation of CMV prophylaxis (Figure). There was no association between CMV infection and episodes of treated acute rejection, modeled as a time-varying covariate, humoral rejection, or the use of additional basiliximab induction in patients with renal dysfunction at the time of HT. CMV infection was associated with an increased risk of subsequent cardiac allograft vasculopathy (HR 8.8, 95% CI 2.6, 29.2), which developed in 4 patients who had CMV infection. **Conclusions:** The risk of CMV infection was higher in CMV D+R- patients with CMV events typically occurring soon after discontinuation of CMV prophylaxis through the first post-HT year. Longer CMV prophylaxis duration and increased surveillance after stopping CMV prophylaxis may be indicated to reduce the rate of CMV infections and the subsequent development of cardiac allograft vasculopathy.

Slipping Through the Cracks: Late Onset BK Viremia

Author Block:

J. Gandhi, D. DeWolfe, F. Cardarelli, M. Pavlakis, C. S. Tan; Beth Israel Deaconess Med. Ctr., Boston, MA

Abstract Body:

Introduction: Most studies indicate that viremia caused by BK virus (BKV), the step preceding BKV associated nephropathy (BKVN) in kidney transplant recipients (KTRs), occurs within one year of transplantation. In a retrospective analysis, we have found that a significant percentage of patients develop viremia after one year. Due to varying screening protocol compliance, KTRs remain at risk for BKV and subsequent allograft injury. Due to a lack of universal screening protocol and systemic screening, KTRs remain profoundly at risk for being undiagnosed with BKV and subsequent allograft injury. **Methods:** At a single center study, we screened for BK viremia in KTRs transplanted between 2003-2013, and found 50 patients with viremia. We divided patients into two groups: patients who had BK viremia diagnosed less than one year after transplant and patients who tested positive after one year. They were deemed "*early*" and "*late*" BK virus patients accordingly. We then compared the "early" and "late" BK cohorts for immunosuppression, ESRD diagnosis, patient characteristics, and graft outcomes.**Results**: 30% of our cohort presented with BK viremia after year one of transplant**.** Other than recipient age and creatinine at baseline, we found few diagnostic clues to differentiate between the onset of BK viremia between the "early" and "late" BKV patient cohorts.**Conclusions:** Screening for BKV after one year of transplant could prevent BKVN. A more formalized and prolonged screening strategy is indicated for BK virus in KTRs.

Table 1: Patient Characteristics	Early n=35	Late n=15	*P*-Value
Days to BK Viremia Diagnosis	142.9 ± 14.8	977.7 ± 141.2	0.0001
Male *n*	24	11	1.00

Immunogenicity of Standard vs. High Dose of Inactivated Influenza Vaccine in Solid Organ Transplant Recipients: A Randomized Controlled Trial

Author Block:

M. Mombelli, N. Rettby, M. Perreau, M. Pascual, G. Pantaleo, O. Manuel; CHUV, Lausanne, Switzerland

Abstract Body:

Background: Although high-dose (HD) influenza vaccine improves protection against influenza in the elderly, the effect among solid organ transplant (SOT) recipients is unknown. We assessed the immunogenicity and safety of HD vs. standard dose (SD) influenza vaccination in SOT recipients.**Methods:** SOT recipients were prospectively randomized to receive 15 µg (SD) or 30 µg (HD) of the 2014/15 influenza vaccine. Immunogenicity was evaluated using a hemagglutination inhibition assay (HIA). Vaccine response was defined as a 4-fold increase of the HIA titer for at least one of the 3 viral strains. Geometric mean titers (GMT) and seroprotection rate (SP) (HIA ≥40) were also analyzed. Follow up period was 6 months.**Results:** 39 patients (30 kidney and 9 liver transplant recipients) received the SD and 40 (33 kidney and 7 liver) the HD influenza vaccination. Baseline characteristics were similar between groups. Rate of systemic adverse events (AEs) to vaccination was similar between groups (23.1% SD and 22.5% HD) and no serious vaccine-related AEs were observed. 28% of patients in the SD group compared to 42.5% in the HD group (p=0.18) responded to vaccination at 2 weeks, with a significant difference observed for the response to influenza B (5.1% vs 22.5%; p=0.026). GMTs at 2 weeks were 97.8 and 138.5 (p=0.26) for H1N1, 147.5 and 198.9 (p=0.17) for H3N2, and 82.1 and 118.0 (p=0.04) for influenza B in SD vs. HD, respectively. Most patients were seroprotected at 6 months (79% for H1N1, 90% for H3N2, and 91% for B) without differences between groups. In univariate analysis, HD vaccine (OR 1.88; p=0.19) was positively associated whereas vaccination during the first 2 years post transplant (OR 0.33; p=0.03) was negatively associated with vaccine response. No biopsy proven rejections after vaccination were observed. Only one patient (in the HD group) developed laboratory-confirmed influenza.**Conclusions:** HD influenza vaccine was safe and well tolerated and may increase antibody responses in SOT recipients. If confirmed in a larger population, HD influenza vaccination may become an appropriate strategy to reduce the burden of influenza after SOT.

Infectious Complications after Transplantation from Donors with Circulatory Determination of Death - A Case-Control Study

Author Block:

V. Fehr, C. Benden, P. Dutkowski, I. Inci, R. Lenherr, T. Mueller, B. Müllhaupt, C. Oberkofler, O. de Rougemont, **N. Mueller**; Univ. Hosp. Zurich, Zurich, Switzerland

Abstract Body:

Background: Since re-introduction of donation after circulatory determination of death (DCD) in 2011, a total of 47 Maastricht III donors were recruited at our institution. To date little is known on the incidence of infectious disease (ID) after DCD transplantation. ID events were compared between patients with organs from DCD donors and DBD donors (Donation after Brain determination of Death). **Methods:** A case-control design matched a case DCD patient with two control DBD patients transplanted with the same organ immediately before and after the case patient. The goal of a 1:4 case-control matching could not be achieved for all patients, due to overlapping patients. ID events were systematically collected during the first year after transplant. Follow-up observation time was one year. Organs allocated to other centers were not considered. **Results:** 32 cases were matched to 89 controls (kidney (N=20), liver (N=8) lung (N=4). Incidence of proven bacterial infections (PI) (HR 2.0, 95% CI 1.3-3.2, p=0.003) was higher in recipients of a DCD organ. This difference was driven by the kidney group (2.4, 1.4-4.2, p=0.003). For lung and liver, the limited case numbers only allowed to observe a trend toward significance. Dominant pathogens were *E. coli* (27.9% of PI) for kidney recipients and *Enterococcus* spp. for liver (36.3% of all PI) as well as lung (15.3% of all PI) transplant recipients. Main sites of infection were the urinary tract in kidney (80.2%), bacteremia and liver infections (each 24%) in liver and respiratory tract infections (48.7%) in lung recipients. No difference was observed for neither viral nor fungal infections. One-year graft function did not differ between cases and controls. **Conclusions:** Causes for the higher incidence of bacterial ID events remain to be determined, but did not affect graft function or mortality at one year. Potential causes could be the higher rate of delayed graft function after DCD kidney transplantation, or the warm ischemia time of the donor predisposing for bacterial colonization of the graft.

Candiduria in Renal Transplant Recipients: Incidence, Treatment and Outcome

Author Block:

B. Denis, D. Chopin, P. Piron, M. Resche-Rigon, M-N. Peraldi, S. Bretagne, M. Gits-Muselli, I. Abboud, J-M. Molina; AP-HP, Hôpital Saint Louis, Paris, France

Abstract Body:

Background: Few studies have addressed the epidemiology and management of candiduria in renal transplant recipients (RTR); antifungal therapy is often prescribed, although the effect of treatment is uncertain. **Methods:** A single-center retrospective study between 2010-2014 in France was undertaken to assess the incidence, treatment and outcome of candiduria in RTR, with a comparison between treated and untreated patients.Candiduria was defined as a urine culture with ≥ 1000 CFU/mL of *Candida* species and clearance of candiduria as a negative urine culture within a month following candiduria diagnosis. Patients with an undisputable antifungal therapy indication at candiduria diagnosis (ie *Candida* species contamination of preservation fluid, candidemia at candiduria diagnosis and known digestive perforation during surgery) were excluded. Adequacy of treatment was evaluated using the 2009 IDSA guidelines. Candiduria clearance, severe complications and death rates were estimated by Kaplan-Meier methods and the effect of treatment by Cox models.**Results:** During the study period, 52/1223 patients (4.3%) had ≥ 1 episode of candiduria, 42 (81%) were female, 18 (35%) had diabetes, 120 candiduria episodes were recorded, leading to an incidence of 0.023 /person-year. Candiduria was asymptomatic in 51 (98%) patients. *Candida glabrata* was the most frequent pathogen identified (48% of episodes). Antifungal therapy was initiated in 14 episodes (12%), in compliance with guidelines in all cases. Candiduria clearance did not differ significantly between treated and untreated patients (HR, 0.6; 95% CI, 0.3-1.1; p=0.10). Three patients (6%) developed severe complications, in the first 2 weeks after transplantation, and 8 (15%) died. Antifungal treatment had no impact on the likelihood of severe complications or death (HR, 1.1; 95% CI, 0.3-4.8; p = 0.89).**Conclusions:** Candiduria was rare among RTR and usually asymptomatic. Treatment of asymptomatic candiduria did not impact clearance rate nor the rate of severe complications or death. However, candiduria management in the immediate post-transplant period should be extremely cautious and antifungal treatment might be beneficial during this period.

Bacteremias Following Autologous Stem Cell Transplantation for Hematologic Malignancies and Solid Tumors: Risk Factors and Outcomes

Author Block:

A. Kothari, S. P. Susanibaradaniya, M. Mohan, M. E. Saylors, K. T. Lusardi, J. R. Crescencio, M. J. Burgess, J. R. Bariola; UAMS, Little Rock, AR

Abstract Body:

Background: Autologous peripheral blood stem cell transplantation (APBSCT) is a commonly used treatment for multiple myeloma. Febrile neutropenia (FN) following APBSCT is seen in 45-83% of cases. Bacteremia occurs in 7-50% of all patients undergoing APBSCT. The Myeloma Institute at University of Arkansas for Medical Sciences conducts over 400 APBSCT procedures inpatient and outpatient each year. This retrospective cohort study characterizes the risk factors and outcomes associated with bacteremia following APBSCT. **Methods:** Retrospective chart review of patients who underwent APBSCT for hematologic or solid tumor malignancy from May 2014 to March 2015. Patients who had at least 1 positive blood culture within 60 days post-APBSCT were included in the bacteremia cohort. Others formed the non-bacteremia cohort. Cultures determined as contaminants were excluded. **Results:** During the study period, 363 APBSCTs were completed. Bacteremias were observed in 46/363 (13%) transplants. A total of 62 distinct isolates were identified in 54 episodes of bacteremia. 63% were caused by Gram positive organisms. *E. faecium* was the most common Gram positive isolate (14/39, 36 %), and the most frequent isolate overall (14/62, 23%). Vancomycin resistance was present in 93% of *E. faecium* isolates. Incidence of *Pseudomonas* spp. and *S. aureus* was 3% each (n=2), yeasts were seen in 7% (n=4) of cases. Median time between APBSCT and onset of bacteremia was 4.5 days (mean 4.3$\pm$6.6 days, 95% CI 2.3-6.2) and median time to culture clearance was 3 days (mean 3.4$\pm$1.7 days, 95% CI 2.9-3.9). Duration of neutropenia was higher in the bacteremia cohort (median days 10.0 vs 6.0, $p<0.001$). Elevated creatinine prior to transplant was a significant risk factor for bacteremia ($p=0.002$), while use of melphalan in the conditioning regimen was protective ($p<0.0001$). Bacteremia was associated with a significantly decreased survival at 3 (OR 0.15; CI 0.06, 0.38) and 6 months (OR 0.24; CI 0.11, 0.51) post-transplant. **Conclusions:** We found a high incidence of *E. faecium*, and a low incidence of MRSA and *Pseudomonas* spp. bacteremias following APBSCT in our patient population. Bacteremia was associated with decreased survival. Knowledge about local epidemiological data is important to determine empiric antibiotics for FN.

Publishing Title:

An Assessment Of *legionella* pcr Using Bronchoalveolar Samples In Hematopoietic Cell Transplantation

Author Block:

S. Sivagnanam[1], K. Kurosawa[2], C. C. S. Yeung[1], D. SenGupta[2], D. Hoogestraat[2], S. M. Butler-Wu[2], **S. A. Pergam**[1]; [1]Fred Hutchinson Cancer Res. Ctr., Seattle, WA, [2]Univ. of Washington Med. Ctr., Seattle, WA

Abstract Body:

Background: Legionellosis is associated with significant morbidity and mortality in hematopoietic cell transplant (HCT) recipients. These patients are at risk for non-*pneumophila Legionella* infections which are missed by the commonly used urinary antigen test. Furthermore, although *Legionella* culture is the gold standard diagnostic test, it is infrequently performed, time consuming and may delay treatment. We therefore assessed the utility of a real-time PCR for *Legionella* using stored bronchoalveolar lavage (BAL) samples from HCT recipients.**Methods:** We retrieved stored BAL specimens from HCT recipients who had a positive *Legionella* culture and/or Gimenez stain suggestive of *Legionella* on histopathology over a 15 year period (2000-2015) from the Seattle Cancer Care Alliance. A PCR-based assay for *Legionella* was validated using these and other stored BALs. We retrospectively reviewed medical records to determine additional microbiological/clinical diagnoses.**Results:** There were 19 *Legionella*-positive BAL specimens from 15 HCT recipients (culture positive, n=9; "possible *Legionella*" on histopathology, n=10; positive by both, n=1). The median time for finalized culture result was 12 (IQR 10, 13) days. PCR correctly identified all culture positive samples (*L. micdadei*, n=4; *L. pneumophila*, n=3; *L. wadsworthii*, n=1; *L. tusconensis*, n=1). No *Legionella* were detected from BALs known to be *Legionella* culture negative; we noted no cross-reactivity against other common and rare respiratory pathogens. All samples positive by Gimenez stain alone tested negative by PCR. Four of these had other pathogens (*Aspergillus* [n=2], respiratory syncytial virus [1] and influenza A [1] pneumonia); the etiology for the pulmonary findings for the others (n=3) were unknown.**Conclusions:** A real-time PCR for *Legionella* appeared to be as sensitive and specific as culture in detecting multiple *Legionella* species from BALs in HCT recipients. As *Legionella*-related clinical and radiological features are indistinguishable from other major post-transplant infections, the addition of a *Legionella*-specific PCR to standard BAL panels could help to more rapidly identify clinically important non-*pneumophila Legionella* species in these high-risk patients.

Publishing Title:

Oral Serum Derived Bovine Immunoglobulin for Treatment of Infectious Diarrhea Due to Norovirus & Cryptosporidiosis in Solid Organ Transplant Patients

Author Block:

M. GELFAND, K. Cleveland, M. Talwar; UTHSC, MEMPHIS, TN

Abstract Body:

Background: Diarrhea (D) is commonly seen in organ transplant patients. Current options to treat many causes of infectious D are limited. Oral immunotherapy with various immunoglobulin (Ig) preparations such as intravenous Ig and hyperimmune bovine colostrum has been previously attempted. Due to exposure of bovine herds to *Cryptosporidium* (C) as well as animal strains of norovirus (N) with possible development of antibodies against these organisms, use of oral serum derived bovine Ig (OSDBI), a medical food, might confer some efficacy in treatment of infectious D caused by N and C. **Methods** Two organ transplant recipients were evaluated for prolonged watery nonbloody D with weight loss. Neither experienced fever, abdominal pain, or nausea. Patient A had undergone a deceased donor renal transplant 6 years earlier and developed weight loss and D due to N which persisted despite symptomatic therapy and reduction of antirejection medications. After 4 months of attempts to manage D, a 6 week course of OSDBI (5 grams orally BID) was begun. Patient B presented with acute D due to C 6 weeks after following a combined kidney/pancreas transplant. D and continued weight loss persisted over the next 4 months despite reduction in immunosuppressive medications, symptomatic treatment, and 3 separate 14-day courses of nitazoxanide (1000 mg orally BID). 14 days of OSDBI (5 grams orally BID) was given. **Results** Patient A experienced resolution of D and weight gain within 7 days of beginning treatment with OSDBI. Following treatment, stool N PCR was negative. Patient B had resolution of D within 3 days of beginning OSDBI treatment and stool testing for (C) with antigen assay, PCR, and modified acid-fast smear was negative. **Conclusions** While no specific data on the antibody activity of OSDBI against C or N have been published, such activity is likely to be present in the preparation derived from large bovine herds. OSDBI, generally safe and modestly priced, may offer a therapeutic option for treatment of infectious D. *In vitro* and controlled clinical studies of OSDBI for specific antimicrobial activity will be essential in supporting further use in gastrointestinal infections.

A Case-Series Of Multi-Drug Resistant (Mdr) Fusariosis At A Large Cancer Center

Author Block:

N. Piccicacco[1], **Y. Pasikhova**[2], A. Baluch[2]; [1]Morton Plant Hosp., Clearwater, FL, [2]Moffitt Cancer Ctr., Tampa, FL

Abstract Body:

Background:*Fusarium* species display *in vitro* resistance to most antifungals with a resultant high mortality rate in immunocompromised patients. Treatment is generally empiric and without susceptibility data. Since optimal therapy and duration is currently unknown, we report 4 patients with failure to empiric fusariosis therapy to observe clinical outcomes and treatment regimens.**Methods:**Retrospective case-series of fusariosis, with antifungal susceptibility data, at an NCI designated cancer center.**Results:**We identified 4 patients with culture proven MDR *Fusarium* infections. Patients were predominately female with a median age of 44 years and BMI of 20.9 kg/m^2. 50% were HSCT recipients and the other 50% AML patients. Only 1 patient had severe neutropenia at the time of diagnosis. All received anti-mold prophylaxis prior to diagnosis. Liposomal amphotericin B (LAmB) was the most utilized antifungal, with a median dose of 6.5 mg/kg/day. Combination therapy (LAmB + voriconazole) was used in 1 patient. All patients had susceptibility testing sent secondary to clinical failure. Treatment duration was not well defined, but ranged from 8 to 18 weeks. Cases are outlined in *Table 1*.**Conclusion:**Routine mold prophylaxis in high-risk patients needs to be continuously monitored as MDR mold infections are emerging and routine susceptibility data is often not obtained.***Table 1.*** **Fusariosis Cases**

Comparison of Two Matrix-assisted Laser Desorption/Ionization Time-of-flight Mass Spectrometry (Maldi-Tof Ms) Systems Using a Formic Acid Extraction Method for the Identification of Common and Uncommon Yeast Isolates

Author Block:

H-S. Lee, J. Shin, M-J. Choi, E. Won, S-H. Kim, S-P. Suh, D-W. Ryang; Chonnam Natl. Univ. Med. Sch., Gwangju, Korea, Republic of

Abstract Body:

Background: The introduction of MALDI-TOF MS provides rapid and accurate identification (ID) of clinical isolates of fungal species. While direct on-plate formic acid extraction (FA) is simpler, Bruker Biotyper MS recommends an in-tube formic acid plus acetonitrile (FA/ACN) extraction for the ID of yeasts. We evaluated the Biotyper using the FA method for the ID of a wide spectrum of clinically relevant yeast species, in comparison with VITEK MS.**Methods:** A total of 298 clinical yeast isolates, including 158 isolates of four common *Candida* species (*C. albicans, C. tropicalis, C. glabrata,* and *C. parapsilosis*) and 140 isolates of 38 uncommon yeast species, were analyzed. In both VITEK MS and Biotyper (cutoff value of 1.7) systems, a simple FA smear was used for protein extraction, but additional FA/ACN methods were used for Biotyper. The ID results were compared to those of sequence-based ID.**Results:** For all 298 yeast isolates, 88.6% and 89.3% were correctly identified by VITEK MS and Biotyper, respectively. Both systems correctly identified 100% of 158 isolates of four common *Candida* species. However, the rates of correct ID for the 140 uncommon isolates were 75.7% and 77.1% by VITEK MS and Biotyper, respectively. For uncommon yeast isolates, Biotyper showed a higher rate of mis-ID (12.1% vs. 2.9%, $P = 0.005$) but a lower rate of no ID (0.7% vs. 11.5%, $P < 0.0001$) than VITEK MS. Especially, Biotyper often yielded incorrect ID of *Cryptococcus neoformans* [58.3% vs. 0% (Biotyper vs. VITEK), $P = 0.005$], but VITEK yielded incomplete ID of *Candida orthopsilosis* [0% vs. 100% (Biotyper vs. VITEK), $P < 0.0001$]. Using Biotyper for the ID of uncommon yeast species, either FA or FA/ACN extraction presented comparable rates of correct ID [77.1% vs. 82.9% (FA vs. FA/ACN)], incomplete ID (10.0% vs. 5.0%), mis-ID (12.1% vs. 10.7%), and no ID (0.7% vs. 1.4%).**Conclusions:** Simple FA extraction by Biotyper shows a comparable ID performance with VITEK MS for most clinical yeast isolates, except for *C. neoformans*, and both systems more accurately identify four common *Candida* species (100%) than uncommon yeast species (76-77%).

Evaluating Maldi-Tof in Derm-Fungal Infections in Clinical Microbiology

Author Block:

J. G. Thomas[1], M. Zaccagnini[2], **J. Kuzyck**[3], K. Kasarda[1]; [1]Allegheny Halth Network, Pittsburgh, PA, [2]Gannon Univ., Erie, PA, [3]Allegheny Hlth.Network, Pittsburgh, PA

Abstract Body:

Background: The integration of new methods including PCR and mass spectrometry (MS) has changed strategies/work flow in clinical microbiology, dramatically. Here, we focus on potential benefits of Matrix Assisted Laser Desorption Ionization -Time of Flight (MALDI-TOF) specifically in derm/fungal detection to facilitate rapid reporting/cost reduction, and a potential referee in selection of an MS instrument. **Methods:** The Allegheny Health Network (AHN) Epidemiology Report was used to record dermatologic fungal isolates from skin, hair and nails for 6 years (January 2009 - April 2015), provided by the 6 hospital consortium to the Core Microbiology Laboratory at AGH, representing a total of 2000 acute care beds, 77outpatient care clinics and 4 private dermatologic Groups. Fungal isolates were identified by standard culture techniques including 3 non and selective/differential media with DTM and Tap Water Media. Lab Core was used as external resource • Fu • Two fungal libraries [FDA/cleared and RUO (research use only)] were provided by each of two MS ID Systems (BD/Bruker and BMX/Vitek MS) to compare/contrast detection strengths/weaknesses with our library **Results:** Over the 6-year study, culture-positive patients yielded 1487 results, 287 patients with multiple isolates, highlighting 67 identifiable fungal/yeast isolates. • Top five species were *Trichophyton* (599), *Candida* (89*), Alternaria* (87), *Fusarium* (72) and *Penicillium* (68). • MALDI-TOF/BMX FDA cleared library matched with 14/67 species, MALDI-TOF/BD cleared with 10/67. Of top 5 species, neither cleared library matched 4, only correlating with Candida species. Of the Candida species, MALDI-TOF/BMX matched 9/11, BD 8/11. **Conclusions:** Our culture data revealed a rich and diverse derm/fungal population, some with multiple species from multiple sites . MS ID Systems with cleared FDA libraries matched culture positive isolates infrequently, primarily yeast, offering a potential differential in MS selection.

Evaluation of Rapid Microbial Identification and Susceptibility Testing from Positive Blood Cultures Using Maldi-Tof Ms After Minimal Incubation on Solid Media

Author Block:

S. L. Mitchell, K. Alby; The Univ. of Pennsylvania, The Perelman Sch. of Med., Philadelphia, PA

Abstract Body:

Bloodstream infections (BSI) are a leading cause of patient morbidity and mortality. Rapid identification of organisms from BSI is critical for initiating targeted antimicrobial therapy. Additionally, rapid identification can have positive impacts in other patient outcomes, such as decreased length of stay, reduced antibiotic usage and lower costs. Currently, the turn-around-time (TAT) from a positive blood culture to identification is approximately two days, with antimicrobial susceptibility testing (AMT) requiring an additional day. Although many methods exist for the rapid identification of organisms from positive blood cultures, they do not provide detailed or definitive susceptibility information. We therefore assessed the utility of MALDI-TOF to identify organisms from a positive blood culture bottle after only four hours of growth and whether this limited growth could yield accurate AMT results compared to overnight cultures. For identification, of 119 isolates tested, 100 (84%) were in agreement to the species level with the standard blood culture workup. Sixteen (13.4%) did not generate an identification and two (1.7%) resulted in misidentifications. Specifically, 49/57 (85.9%) Gram-negatives and 51/57 (89.5%) Gram-positives were properly identified. 1/2 (50%) anaerobic organisms and 0/4 (0%) yeast were correctly identified to the species level. Twenty-four isolates (12 Gram-positive and 12 Gram- negative) were blindly selected for AMT using Vitek 2. Twenty-one (87.5%) gave the same susceptibility profile compared to those grown overnight. Specifically, 11/12 (91.6%) Gram-negatives and 10/12 (83.3%) Gram-positives gave comparable AMT profiles. Three organism profiles were inconsistent (12.5%). Of those, one Gram-negative and one Gram-positive resulted in minor errors (8.3%) and one Gram-positive resulted in a very major error (4.2%). In conclusion, MALDI-TOF was able to accurately identify the majority of organisms after only four hours of growth resulting in identification TAT of approximately five hours and an AMT TAT of approximately one day. This study identifies a method using common commercial instruments that can provide a way to improve upon identification and detailed susceptibility information.

Evaluation of Rgm Medium for Detection and Identification of Nontuberculous Mycobacteria from Patients with Cystic Fibrosis

Author Block:

R. Plongla[1], C. L. Preece[2], J. D. Perry[2], P. H. Gilligan[1]; [1]UNC Sch. of Med., Chapel Hill, NC, [2]Northumbria Univ., Newcastle upon Tyne, United Kingdom

Abstract Body:

Overgrowth of cultures with bacteria or fungi is a challenge for isolation of nontuberculous mycobacteria (NTM) from patients with cystic fribrosis (CF). RGM medium (RGM) is a novel selective agar containing OADC supplement and 4-antimicrobial mixture, and is designed to improve detection of NTM. We evaluated the identification of NTM on this medium using MALDI-TOF MS (bioMérieux) and recovery of NTM on RGM from CF respiratory specimens.41 archived isolates (11 *M. abscessus* subsp. *abscessus*: MABS; 11 *M. abscessus* subs. *massiliense*: MABM; 5 *M. chelonae*: MCHEL; 6 *M. fortuitum* complex: MFORTG; 3 *M. immunogenum*: MIMM and 5 *M. mucogenicum*: MMUC) were grown on RGM and *Burkholderia cepacia* selective agar (BCSA). After 72-96h incubation at 30^{O}C, archived isolates were identified by MALDI-TOF MS using bM Vitek MS research use-only system (RUO) with SARAMIS v4.12 database. 116 consecutive respiratory samples (66 expectorated sputa, 44 deep pharyngeal swabs, 6 bronchoaveolar lavage fluids) from 115 CF patients were inoculated directly on RGM and BCSA and were observed after 4, 7, 10 and 14 days of incubation at 30^{O}C in air. MALDI-TOF MS or sequencing of 16s rRNA gene was used to identify the organisms.All 41 archived isolates grew on RGM but 1 MABS, 4 MFORTG and 4 MMUC did not grow on BCSA. All NTM on both media could be correctly identified by MALDI-TOF MS with $\geq$75.0% confidence value, except 1 MIMM on BCSA. Of 116 samples, 19 and 7 mycobacteria were isolated on 17 (14.7%) and 7 (6.0%) of RGM and BCSA, whereas other bacteria and fungi grew on 10 (8.6%) RGM and 38 (32.8%) BCSA (Table). 34 samples had concomitant AFB cultures (AFBC). 5 (14.7%) and 3 (8.8%) samples had 6 and 3 mycobacteria on RGM and AFBC. 10 (29.4%) LJ media were overgrown and discarded.RGM has a higher recovery rate of NTM and is more selective than BCSA. MALDI-TOF MS can be used to identify mycobacteria on RGM. There is a potential to obviate the AFBC, however studies to compare RGM with AFBC and the recovery of *M. avium-intracellurare* complex on RGM are needed.

Table: Isolates recovered on RGM, BCSA and AFBC from respiratory specimens of patients with CF

Organisms	RGM (n=116)	BCSA (n=116)	RGM (n=34)	AFBC(n=34)

Identification of *Burkholderia* and Uncommon Glucose Nonfermenters Isolated from Cystic Fibrosis Patients Using Maldi-Tof Ms

Author Block:

R. Plongla[1], T. Panagea[2], M. C. Jones[3], P. H. Gilligan[1]; [1]UNC Sch. of Med., Chapel Hill, NC, [2]Sismanogleio-A. Fleming Gen. Hosp., Athens, Greece, [3]UNC Hlth.Care, Chapel Hill, NC

Abstract Body:

With MALDI-TOF MS, Gram-negative glucose nonfermeters (GNGNF) can be identified quickly however the database is incomplete. We evaluated the performance of an updated database of bioMérieux (bM) Vitek MS *in vitro* diagnostic (IVD) system for the identification of GNGNF other than *Pseudomonas, Achromobacter, Chryseobacterium, B. gladioli* and *B. multivorans*.MALDI-TOF MS (bM, Durham, NC) was performed on 155 archived CF isolates after 24h, 48h and 72h incubation on 5% sheep blood agar (SBA), MacConkey agar (MAC) and *Burkholderia cepacia* selective agar (BCSA). Spectra were analyzed using Vitek MS research use-only system (RUO) with SARAMIS v4.12 database, bM IVD system with the current v2.0, the new v3.0 and draft v4.0 Knowledge Base (KB) database. The results were compared with identification by the *Burkholderia cepacia* Research Laboratory and Repository at the University of Michigan or 16s rRNA gene sequencing.The satisfactory results were achieved at 48.6%, 33.1%, 81.1% and 88.0% on SBA using RUO, v2.0, v3.0 and v4.0. There were the same trends on MAC (23.6% v 26.6% v 51.5% v 63.4%) and BCSA (41.1% v 28.7% v 74.7% v 84.0%). Of 1298 spectra analyzed, the incorrect identifications were 0.5%, 42.3%, 2.2% and 1.4% using RUO, v2.0, v3.0 and v4.0, which occurred on the uncommon members of *B. cepacia* complex. On v4.0, *B. cepacia*, *B. cenocepacia*, *B. vietnamiensis* and *B. contaminans* had 63.6%, 95.2%, 95.8% and 94.4% satisfactory results on SBA (Table). Identifications of *Pandoraea*, *Cupriavidus* and *Bordetella* on v4.0 were similar to v3.0 (88.9%, 66.7%, 57.1%). *Herbaspirillum* was added to the v4.0 database and had satisfactory results of 88.9%, 100% and 100% on SBA, MAC and BCSA.There is a continuing improvement to identify the uncommon GNGNF isolates especially on *B. cenocepacia* and *B. contaminans*. SBA and BCSA are preferred over MAC. The incorrect identification rate was fewer on v4.0. Improving identification of *B. cepacia*, *Cupriavidus* and *Bordetella* is still challenging.

Table: Performance of RUO SARAMIS, Vitek MS IVD v2.0, v3.0, v4.0 KB databases on selected organisms

	Satisfactory results (%)			
Organism (n)	SARAMIS	v2.0	v3.0	V4.0
B.cepacia (11)	0.0	87.9	27.3	63.6

*B.cenocepacia** (42)	44.4	0.0	87.3	95.2
*B.contaminans** (12)	0.0	0.0	91.7	94.4
*Pandoraea** (24)	68.5	0.0	88.9	88.9
Ralstonia (14)	76.2	85.7	83.3	85.7
*Herbaspirillum** (3)	55.6	0	0	88.9
Cupriavidus (6)	61.1	33.3	66.7	66.7
*Not on the current v2.0 KB database

Maldi-Tof Ms with Protein Extraction Using Naoh-Hcl Neutralization is Simple, and Cost-Effective Urine Preparation for Direct Identification of Uropathogens

Author Block:

J. Kim; Coll. of Med., Intl. St. Mary`s Hosp., Catholic Kwandong Univ., Incheon, Korea, Republic of

Abstract Body:

Background: The direct identification of bacteria in urine samples by matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) can dramatically increase the usefulness of this method, significantly reducing the time for microorganism identification. The aim of this study was to develop a rapid, simple, cost-effective and reliable protocol using very common reagents, NaOH-HCl to identify bacteria directly from urine samples on MALDI-TOF MS Bruker Biotyper (Bruker Daltonics, Leipzig, Germany) and to establish a protocol combining the conventional screening tests.**Methods:** In May and July 2015, 122 urine samples showing positivity on Gram stain were selected. After first centrifugation at 2,000 x g, the pellet was assigned for gram positive cocci (GPC) positive urine samples and the supernatant for gram negative bacteria (GNB) positive urine samples. The 0.01M NaOH-0.01M HCl neutralization method was used for the bacteria protein extraction. We evaluated the analytical performance and compared the conventional method (MicroScan, Beckman-Coulter, USA) and MALDI-TOF MS with Gram stain and screening device, Sysmex UF 1000i (UF 1000i ; bioMe´rieux, Marcy l'E´toile, France) for identification of the urinary tract pathogens. **Results:** An 84.3% (70/83) concordant rate was obtained in urine samples showing single morphotype on gram stain with bacterial counts of > 1 X 10^5 CFU/ml. Among them, *Escherichia coli* showed 90.9% (55/61) concordant rate. The MALDI-TOF MS combined with single morphotype on gram stain and UF 1000i counts ≥1 x 10^6 bacteria/mL identified this microorganism in 73.6% (67/91). In this study, the detection limit of this method was 10^7 CFU/ml both to sterile DW and sterile urine specimens.**Conclusions:** MALDI-TOF MS with protein extraction using NaOH-HCl neutralization allows a rapid, simple, cost-effective and accurate bacterial identification directly from infected urine samples especially when major uropathogens such as *E. coli* are involved. MALDI-TOF MS combined gram positive results and UF 1000i count ≥ 10^6 bacteria/mL may improve the bacterial identification efficiency in routine microbiology laboratory.

More Species, Less Time to Result - How Maldi-Tof Ms Changes Medical Microbiology

Author Block:

A. B. Pranada[1], M. Kostrzewa[2], M. Bienia[1], F. Pranada[1]; [1]MVZ Dr. Eberhard & Partner Dortmund (ÜBAG), Dortmund, Germany, [2]Bruker Daltonik GmbH, Bremen, Germany

Abstract Body:

Background: Matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry (MS) has been introduced for microorganism identification in many clinical diagnostics laboratories. High discriminatory power and speed of this technology allow more accurate and rapid results.We evaluated the impact of MALDI-TOF MS on our own clinical microbiology practice in a major independent laboratory in Germany by reviewing data obtained over a period of six years. A huge dataset for identification by MALDI-TOF MS of bacteria, filamentous fungi and mycobacteria as well as direct identification from positive blood cultures and detection of resistance markers is presented.**Materials and Methods:** A MALDI Biotyper system (Bruker Daltonik GmbH, Germany) was established in our laboratory in December 2009 as supplement to the existing conventional methods. Identification and specimen data from the LIS and the MALDI statistical system before (2009) and after (2010-2015) introduction of the new method were analyzed for changes in rapidity and reporting. **Results:** For the whole time period n=938,123 data records for reported identification results were analyzed (n=123,900 in 2009 and n=814,223 for 2010-2015). MALDI-TOF MS was performed for n=152,917 analytes. Average log(score) was 2,134 with 92.8 % successful identifications (76.7 % at high confidence level, 16.1 % at low confidence level). Log(score) values improved over time with 64.0 % of identifications at high confidence level in 2010 and 80.0% in 2015.Regarding the discriminatory power, during 2009 a total of 285 different species from 112 genera were finally reported to the clinicians. This continuously increased to 581 different species (+104 %) from 174 genera (+55 %) in 2015.For specimens with anaerobe bacteria the median time to final report decreased by 1 day after introduction of MALDI-TOF MS. **Conclusion and Outlook:** Introduction of MALDI-TOF MS into our medical microbiology laboratory has decreased the time to the final report and significantly increased the variety of microorganisms identified. In the future this may lead to a better understanding in infectious diseases and causing agents. A comprehensive dataset for MALDI-TOF MS in routine could be presented.

Optimal Turnaround Time for Direct Identification of Microorganisms by Mass Spectrometry in Blood Culture

Author Block:

A. Randazzo, J-S. Goffinet; Cliniques Sud Luxembourg, Arlon, Belgium

Abstract Body:

Background: During the past few years, several studies describing direct identification of bacteria from blood culture using mass spectrometry have been published. These methods cannot, however, be easily integrated into a laboratory workflow because of the high hands-on time they require. In this paper, we propose a new method of identification with a short hands-on time and a turnaround time smaller than 15 min once the bottle became positive and the moment we have identified the pathogen. **Materials and methods:** Blood culture bottles from adult patients were collected at the Laboratory of Clinical Biology of the Cliniques du Sud Luxembourg in Arlon (Belgium) and incubated on a BacT/Alert 3D system (Biomérieux®, Marcy-l'Etoile, France). Positive blood bottles were homogenized and 600 µL of blood were transferred to an Eppendorf tube where 600 µL of lysis buffer were added. The mix was homogenized during 5 s by vortexing. A centrifugation step of 4 min at *10,500 g* was performed and the supernatant was discarded. The pellet was then washed with the wash buffer from Vitek® MS Blood Culture Kit and a sample of the pellet was loaded in quadruplicate into wells of a Vitek® MS-DS plate. Each well was covered with a saturated matrix solution of Vitek® MS-CHCA and a matrix-assisted laser desorption ionization time-of-flight (MALDI-TOF) mass spectrometry analysis was performed. Species were identified using the software Myla 3.2.0-2 (Biomérieux®, Marcy-l'Etoile, France). **Results:** We analyzed 266 positive blood culture bottles. A total of 279 microorganisms grew in 261 cultures, while the remaining five bottles stayed sterile after 48 h of incubation in subculture. Our method reaches a probability of detection of 77,8 % (203/261) with a positive predictive value of 99,51% (202/203). We obtained 95,4 % of correct identification for the Gram-negative bacilli (145/152) and 50,9% for the Gram-positive cocci (59/116). The 5 negative cultures showed also a negative result for the rapid identification and thus were considered as false positive. **Conclusion:** We developed a new method for the identification of microorganisms using mass spectrometry, directly performed from a positive blood culture. This one has short hands-on and turnaround times and can easily take place in the workflow of a laboratory, with comparable results in performance to other known methods.

Identification of *Streptococcus pneumoniae* by Maldi-Tof Ms: Comparison of Molecular Weight Typing and the New Matching System in Bruker Database 4613 and 5627

Author Block:

E. Thidholm[1], S. Lehmann[2], O. Altun[1], **V. Ozenci**[1]; [1]Karolinska, Stockholm, Sweden, [2]Bruker, Stockholm, Sweden

Abstract Body:

Background: Identification of *S. pneumonia* with Bruker microflex mass spectrometry Bruker database 4613 have been showed to be partially successful. Analysis of the protein masses in the range 2-20 kDa showed that the alpha-hemolytic streptococci have very similar mass spectra. The aim for this study was to develop and validate a method based on specific peaks present in *S.pneumoniae* or in other alpha-hemolytic streptococci's spectra and to compare this approach with Bruker database 4613 and newly developed 5627 database. **Material/methods:** Strains of *S. pneumonia* and other alpha-hemolytic streptococci isolated from positive blood culture bottles were diagnosed by optochin susceptibility. Mass spectra from ten *S. pneumoniae* and ten other alpha-hemolytic streptococci was overlaid and analyzed to distinguish peaks, specific for *S. pneumonia* or the other alpha-hemolytic streptococci using Bruker database 4613 . The developed spectra, containing two peaks specific for the other alpha-hemolytic streptococci were defined. The two peaks were then matched to clinical isolates of 47 *S. pneumoniae* and 32 other alpha-hemolytic streptococci. **Results:** Discrimination by matching against two peaks, specific for the other alpha-hemolytic streptococci resulted in 31/32 (97%) and 45/47 (96%) correct identification result for other alpha-hemolytic streptococci and *S. pneumoniae* respectively using Bruker database 4613 . One of the two *S. pneumoniae* strains with discrepant result had both peaks while the other one had only one of the two peaks. The other alpha-hemolytic streptococcus with discrepant result showed no match on the two specific peaks. Identification of the isolates by Bruker database 5627 was successful in 30/32 (94%) and 47/47 (100%) of other alpha-hemolytic streptococci and S. pneumoniae respectively considering the four highest score values. **Conclusion:** The result showed that analysis of differences in peaks might lead to improved identification of S. pneumoniae with Bruker database 4613. In addition newly developed Bruker database 5627 is reliable in identification of S. pneumoniae.

Identification of Microorganisms Using Short-term Culture Followed by Maldi-Tof Ms

Author Block:

M. Almuhayawi, P. Lüthje, **V. Ozenci**; Karolinska, Stockholm, Sweden

Abstract Body:

Background: Polymicrobial bloodstream infections are related to high morbidity and mortality. Identification of microorganisms from polymicrobial infections by conventional microbiological methods is time-consuming and delays effective treatment of the patients. In this study, we evaluated the possibility to identify species from polymicrobial infections by MALDI-TOF MS after short-term incubation under selective conditions. **Methods:** Clinical polymicrobial blood culture (BC) bottles were analyzed after culture positivity; simulated polymicrobial samples were prepared by mixing two positive clinical monomicrobial BC bottles. Subcultures were inoculated on appropriate agar plates with antibiotic discs, i.e. linezolid and aztreonam for selection of Gram-negative and Gram-positive species, respectively. After an incubation of 6 hours, MALDI-TOF MS analysis was performed from growth around the selective discs. Results were compared with results from standard methods. **Results:** A total of 73 polymicrobial cultures were analyzed, including clinical microbiological samples (n=19) and simulated samples (n=54). In 47/73 cultures (64%), two of two bacterial species could be identified by the present method within 6 hours after BC positivity. In another 23/73 cultures (32%), at least one species was correctly identified. Only in three samples, no identification was obtained by this method. The most commonly detected pathogens, *E. coli* and *Staphylococcus spp.* could be identified in 35/38 (92%) and 42/46 (91%) of positive samples. In general, Gram-negative species were identified more often (62/65, 95%) than Gram-positive species (58/77, 75%; P<0.001). *Candida* spp. could not be identified by MALDI-TOF MS after short-term incubation. When BC medium was investigated directly, two of two bacterial species could be identified in 2/73 (3%) and one species in 41/73 (56%), mostly a Gram-positive species. **Conclusion:** In this study, we demonstrate that that short-term culture followed by MADLI-TOF MS can help to identify bacterial pathogens from polymicrobial species without the need of overnight incubation.

Evaluation of the 2415 *m/z* Peak in the MALDI-TOF Mass Spectra of *Sphylococcus aureus* to Infer Methicillin Resistance

Author Block:

D. D. Rhoads, H. Wang, S. M. Harrington, G. W. Procop, S. S. Richter; Cleveland Clinic, Cleveland, OH

Abstract Body:

Background: Methicillin resistant *S. aureus* (MRSA) isolates are *S. aureus* that express the *mecA* gene. Typically, *mecA* is a component of an SCC*mec* mobile genetic element. Some SCC*mec* types also contain the *psm-mec* gene, and MALDI-TOF mass spectrometry (MS) can detect the PSM-mec peptide at 2415 *m/z*. This MS peak has been used to infer *mecA* carriage and methicillin resistance in *S. aureus* (doi: 10.1016/j.ijmm.2014.07.005). This previous study also demonstrated that strains lacking a delta-toxin peak at 3007 and 3037 *m/z* (which implies *agr* dysfunction) never had a detectable 2415 *m/z* peak. In the current investigation, we evaluate the validity of using MS to infer *mecA* carriage in *S. aureus* clinical isolates. **Methods:** 283 consecutive blood cultures from unique patients, which grew only *S. aureus* were considered. These primary specimens were cultured March through November of 2015. Results obtained during routine clinical testing using the Verigene Gram-Positive Blood Culture Test (Nanosphere; Northbrook, IL) and VitekMS (bioMerieux; Durham, NC) were reviewed retrospectively to determine the presence or absence of three variables for each isolate: the *mecA* gene, a PSM-mec peak (2415 ± 4 *m/z*), and a delta-toxin peak (3007 ± 4 or 3037 ± 4 *m/z*). **Results:** The results are summarized in the Table. A delta-toxin peak was not prominent in 9% (25/283) of the isolates, including 2 isolates that had both *mecA* and a 2415 *m/z* peak.Table. Correlation of 2415 *m/z* and *mecA* in *S. aureus* isolates

S. aureus isolates	2415 *m/z* (no. isolates)	
	Detected	Not detected
mecA positive	53	84
mecA negative	4	142

Conclusion: In this study, a 2415 *m/z* peak detected by routine MS had low sensitivity (39%; 53/137) but high specificity (97%; 142/146) for predicting *mecA* carriage in *S. aureus* clinical isolates. Excluding isolates that lack a delta-toxin peak did not significantly improve the predictive value of the test, so it may be unnecessary or suboptimal to screen for delta-toxin before evaluating the presence or absence of the 2415 *m/z* peak. The positive predictive value

(93%; 53/57) of the 2415 *m/z* peak is high enough to consider reporting *S. aureus* isolates as MRSA using MS data alone.

Matrix-assisted Laser Desorption Ionization-time of Flight Mass Spectrometry-based Identification of *Staphylococcus aureus* and Methicillin Resistance Through Detection of a Single Peak

Author Block:

I. Budvytiene[1], H. W. Moon[2], G. Shi[3], N. Banaei[2]; [1]Stanford Hlth.Care, Palo Alto, CA, [2]Stanford Univ. Sch. of Med., Stanford, CA, [3]Bruker Daltonics, Fremont, CA

Abstract Body:

Background: Laboratory diagnosis of Methicillin-Resistant *Staphylococcus aureus* (MRSA) by culture is a two-step process which includes identification of a colony followed by phenotypic or genotypic susceptibility testing. Matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS) is increasingly used to rapidly identify *S. aureus* colonies. In this study, we evaluated the accuracy of MALDI-TOF for simultaneous detection of methicillin resistance through detection of a single SCC*mec*-associated peak.**Methods:** 235 clinical isolates of *S. aureus*, including 80 MSSA and 155 MRSA, identified by the Bruker Biotyper (Bruker Daltonics) and tested for methicillin sensitivity with mecA PCR and broth microdilution (MicroScan Walkaway, Beckman Coulter), were evaluated. The MALDI-TOF spectra was reanalyzed with the MALDI Biotyper MRSA Prototype software (Bruker Daltonics) for the presence of a peak with an identity of 2413 m/z . Multilocus sequence typing (MLST) and staphylococcal cassette chromosome mec (SCC*mec*) typing were performed by sequencing and PCR, respectively.**Results:** None of 80 MSSA isolates had the 2413 m/z peak. The 2413 m/z peak was present in 40 out of 155 MRSA isolates. The assay had a sensitivity and specificity of 25.8% and 100%, respectively. Strain typing of 50 MRSA isolates did not show a clear association between MLST type and presence of the 2413 m/z peak (ST1, 0/1; ST5, 14/19; ST8, 0/23; ST30 0/1; ST36, 1/1; ST87 0/1; ST80, 0/1; ST105, 1/1; ST254, 0/1; ST2247, 0/1;). However, MLST types that are frequently associated with SCC*mec* type II more commonly had the 2413 m/z peak (ST5, 14/19; ST36, 1/1; ST105 1/1). SCC*mec* typing is being conducted to confirm a relationship between SCC*mec* type II and MALDI detection of the 2413 m/z peak.**Conclusions:** MALDI-TOF MS can simultaneously identify *S. aureus* and methicillin resistance with a high positive predictive value. Although the sensitivity of 2413 m/z peak is low at our institution, it may be high in locales where SCC*mec* type II is prevalent.

Publishing Title:

Rapid Identification of Oxa-48 Producing *Klebsiella pneumoniae* Using Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Spectrometry (Maldi-Tof Ms)

Author Block:

B. Rodriguez-Sanchez, C. Sanchez-Carrillo, E. Cercenado, M. Marin, A. Ruiz, E. Bouza; Inst. de Investigación Sanitaria Gregorio Marañon/ Hosp. GU Gregorio Marañon, Madrid, Spain

Abstract Body:

Background: The presence of OXA-48 Carbapenem-resistant *Enterobacteriaceae* (CRE) has increased dramatically in the last years. Their rapid and accurate detection is currently one of the main challenges of the microbiology laboratory. At present, the standard for detection is based on the amplification of the responsible plasmid. Alternatively, the detection by MALDI-TOF MS, that identifies the hydrolysis products of different carbapenems, is reliable but cumbersome. In this study, a simpler, direct MALDI-TOF MS protocol was applied in order to find distinctive protein profiles in resistant and sensitive *Klebsiella pneumoniae*, correlating with the reference method.**Methods:** Overall, 183 *K. pneumoniae* isolates from clinical samples were included in this study: 79 carbapenem-sensitive and 104 hosting the OXA-48 carbapenemase. For comparison reasons, 7 VIM- and 3 KPC-expressing *K. pneumoniae* were also analysed. The reference method consisted of a real-time PCR kit (RealCycler OXVIKP, Progenie, Spain). All the isolates were directly identified by MALDI-TOF MS (Bruker Daltonics, Germany) and their protein spectra were further analysed using Flex Analysis 3.3.80 software (Bruker Daltonics).**Results:** The peak analysis showed that the protein profile of the two groups of Klebsiella isolates could be differentiated: two distinctive peaks of 3073 and 3707 m/z were present in spectra from OXA-48 *K. pneumoniae*, concordant with the real-time PCR results, and these peaks were consistently absent in the control group of Carbapenem-sensitive *K. pneumoniae* isolates. Besides, a 5377 m/z peak was also characteristic of OXA-48 *K. pneumoniae* isolates, although its intensity was more variable. The combination of these three peaks was not present in other *K. pneumoniae* isolates containing VIM or KPC carbapenemases.**Conclusions:** Although our results are preliminary, peak analysis of the CRE isolates identified by MALDI-TOF MS could provide a rapid and reliable detection of OXA-48 carbapenemases. The turnover time for this test is 10 min and does not require additional reagents to those used for the identification of the microorganism.

An Accelerated Workflow for Mbt-Astra

Author Block:

K. Sparbier, B. Wegemann, **M. Kostrzewa**; Bruker Daltonik GmbH, Bremen, Germany

Abstract Body:

Background: Antimicrobial resistance is an increasing health care problem. Since rapid identification of species has been accelerated by use MALDI-TOF MS, a gap arises until information about the resistance status is available. Recently, a semiquantitative MALDI-TOF approach, MBT-ASTRA, has been described facilitating resistance detection in two to five hours (Lange et al., 2015). The published protocol requires significant time-consuming hands-on work. Here, we describe a simplified workflow for higher throughput. **Methods:** Fresh overnight cultures of 40 *E.coli* were analyzed by Etest and the MALDI-TOF based assay. Growth of bacteria in BHI without CTX and in the presence of 20 g/ml CTX after 2 h incubation was determined using semi-quantitative MS. After growth, cell suspensions of the 80 setups were transferred to a 96-well 0.2 µm GHP filter plate (Pall Corp.) and centrifuged (3.000 x g, 5 min). Cells remaining on the filter were washed with 100 µl H_2O and 50 µl ethanol (75%). Lysis was performed directly on the filter by adding 10 µl of formic acid (70 %) and 10 µl ACN supplemented with internal standard. Lysates were recovered in a fresh microtiter plate by centrifugation. 1 µl of lysate was spotted on a MALDI target and overlaid with HCCA matrix. MS profile spectra were acquired on a microflex benchtop mass spectrometer (Bruker Daltonik GmbH). Relative protein amounts in each well were calculated using the internal standard. Ratio of the protein amounts (BHI plus CTX setup/BHI only setup) was calculated (relative growth, RG).**Results:** Etest analysis revealed 20 CTX-resistant and twenty CTX-susceptible *E.coli* strains. MBT-ASTRA were in 100% concordance with the Etest results. Employing MBT-ASTRA shortened the time until resistance information was available by several hours. The use of filter plates facilitates the parallel processing of up to 48 samples on one plate at the same time. This significantly reduced hands-on work and accelerated the workflow.**Conclusion:** Results of the MBT-ASTRA workflow were in concordance to Etest results. Time to result was about about 3.5 hours for 40 samples starting from a fresh overnight culture. The use of filter plates for sample processing significantly reduced hands-on work and accelerated sample handling.

Fluconazole and Amphotericin B: Working Together is Better Against Cryptococcus Gattii

Author Block:

N. d. Ribeiro, J. R. A. Santos, D. A. Santos; Univ.e Federal de Minas Gerais - UFMG, belo horizonte, Brazil

Abstract Body:

Background: Amphotericin B and fluconazole are the most used antifungals for the treatment of cryptococcosis caused by *Cryptococcus gattii*, a main pathogen of cryptococcosis in healthy patients. However, there is a controversy regarding the combination of amphotericin B and fluconazole for fungal infections, due potential antagonism. Here, we evaluated the interaction in vivo between fluconazole and amphotericin B against *C. gattii.* **Methods:** Six mice per group were inoculated by the intratracheal route with 1×10^6 cells of L27/01*C. gattii* strain. Fluconazole (15 or 150 mg/kg/day) and amphotericin B (0.5 mg/kg/day) alone or in combination were administered intraperitoneally (i.p.) from one day post-infection. Animals were monitored daily for the survival curve or mice were euthanized 14 or 80 days post-treatment for CFU/ g lungs or brain quantification.**Results:** All the treatments significantly prolonged the median survival of mice infected. Treatment with 150 mg/kg/day fluconazole alone or in combination with amphotericin B and 15 mg/kg/day fluconazole in combination with amphotericin B improved the median survival of mice treated with antifungals in monotherapy. Animals infected and treated with fluconazole 150 alone or in combination showed significant reduction of Log_{10} CFU/g in the lungs, but no significant reduction of fungal burden in lungs occurred in other groups. The fungal burden analysis in the brain of mice infected and treated with fluconazole 150 and amphotericin B post 80 days proved to be sterile in comparison to mice treated with fluconazole 150 alone.**Conclusions:** This study provided new insights into the fluconazole and amphotericin B combination and reinforced a success of interactions between these antifungals.

Two Voriconazole-Resistant Strains of *Aspergillus fumigatus* with *CYP51A* TR46/Y121F/T289A Genotype in China

Author Block:

W. Liu, Q. Wang, H. Zhang, Z. Wan, R. Li; Peking Univ. First Hosp., Beijing, China

Abstract Body:

Azole-resistant strains of Aspergillus fumigatus harboring TR46/Y121F/T289A mutations in CYP51A gene have been increasingly found in Europe and Asia. Here, we report 2 voriconazole(VRC)-resistant A.fumigatus strains with TR46/Y121F/T289A in CYP51A gene from an invasive aspergilosis (IA) patient in China. Three sequential strains were isolated from the sputum and BALF of a IA patient. Antifungal susceptibility testing was assayed by using the CLSI microbroth dilution method M38-A2 procedure. And CYP51A gene sequencing and microsatellite genotyping were also performed for the 3 isolates. Consequently, despite of the first isolate being susceptible, the other 2 isolates presented high-level resistance to VRC (MIC ≥8μg/ml). Sequencing analysis for the CYP51A gene showed that the TR46/Y121F/T289A mutations occurred in CYP51A gene. Microsatellite genotyping indicated that 2 resistant strains in this report showed different genotype to that being susceptible, as well as to those strains of A. fumigatus with VRC-resistance reported previously in Europe and Asia. This description for the VRC-resistant A. fumigatus with TR46/Y121F/T289A alternations in CYP51A gene indicated an urgent need for antifungal susceptibility surveillance of pathogenic Aspergillus spp. in China.

Re-Purposing of the Kinase Inhibitor Sorafenib as a Growth Inhibitor of the Fungal Pathogen Histoplasma Capsulatum

Author Block:

C. Berkes, J. Franco, M. Lawson, D. Trinh; Merrimack Coll., North Andover, MA

Abstract Body:

Background: Histoplasmosis is a respiratory disease caused by the dimorphic fungal pathogen *Histoplasma capsulatum*, which primarily affects immunocompromised individuals. New drugs to treat histoplasmosis are needed, however, efforts to identify new mechanistic classes of anti-fungal compounds have lagged, due in part to the high cost of drug development. In recent years, there has been renewed interest in the repurposing of mammalian kinase inhibitors in order to target fungal, protozoan, and even prokaryotic pathogens. MAP kinases constitute a highly conserved family of proteins present in all eukaryotes. In yeasts, the high osmolarity glycerol (Hog) MAP kinase, a direct homolog of human p38 MAP kinase, is essential for coordination of stress response upon exposure to osmotic shock, reactive oxygen and nitrogen species, temperature extremes, and other forms of cellular stress. Given that *Histoplasma capsulatum* is an intracellular pathogen that colonizes alveolar macrophages, it must be able to utilize robust stress response mechanisms in order to survive and replicate within the hostile environment of the macrophage phagosome. **Methods:** In preliminary studies, we have found that two multi-kinase inhibitors - Sorafenib and SC-1 - inhibit growth of *Histoplasma* in culture and within the context of a macrophage infection model. Here, we expand our search for kinase inhibitors that inhibit *Histoplasma* growth by screening the GlaxoSmithKline PKIS (Protein Kinase Inhibitor Set) using disc diffusion and liquid dilution assays**Results:** Liquid dilution assays show that Sorafenib and a closely related structural derivative, SC-1, inhibit growth of the G217B and G186AR strains of *Histoplasma capsulatum*, with MICs in the high nanomolar/low micromolar range. Screening of the full GSK kinase inhibitor set is currently underway.**Conclusions:** Our work has shown that re-purposing of kinase inhibitors may be an effective avenue of anti-*Histoplasma* drug identification. Future research will be aimed at building the structure-activity relationship, utilizing biochemical approaches to confirm drug targets, and investigating the effectiveness of these compounds on other dimorphic fungal pathogen species.

The Inhibition of Yeast-to-Hypha Conversion Induced by Amphotericin B in *Candida albicans* Is Dependent on Its Antifungal Effect

Author Block:

J. Argüelles; Univ. de Murcia, Murcia, Spain

Abstract Body:

The morphological transition from yeast to hypha is considered a factor of virulence in the opportunistic pathogenic fungus *Candida albicans* (Gow *et al*., 2002). It has been proposed that sub-lethal concentrations of Amphotericin B (AMB) induce a complete suppression of the capacity to issue germ-tubes, which is the first step of dimorphic conversion in *C. albicans.* Here, we have investigated the *in vitro* correlation between the fungicidal effect of AMB and its hypothetical inhibitory action on hypha formation in the *C. albicans* wild-type strain CEY.1 (CAI.4-*URA*$^{+}$). For germ-tube induction, fresh cultures were supplemented with sterile human serum (10%) and simultaneously transferred from 28 to 37ºC. AMB concentrations below or around the MIC_{90} (0.12 mg/L) added to exponential CEY.1 cells caused a weak reduction in the percentage of human serum-induced germ-tube formation at 37ºC compared with an untreated control (Guirao-Abad *et al.*, 2015). However, the dimorphic transition was drastically suppressed after addition of potentially lethal doses of AMB, which also brought about a severe degree of cell killing. These actions on cell growth and hypha formation are reversible, conditioned to the presence of the antifungal in the culture medium. In contrast, an identical experimental approach carried out with the fungistatic compound 5-fluorocytosine had no significant effect on the level of the germ-tube formation. Together, these results strongly point to a close correlation between the fungicidal action of AMB and its ability to impair morphogenetic conversion in *C. albicans*. This relationship might be relevant for therapeutical purposes, particularly in the light of the ability of *C. albicans* to develop biofilms as a main pathogenesis mechanism.

***In Vitro* Nail Penetration of Nitric Oxide Releasing Formulations for the Topical Treatment of Onychomycosis**

Author Block:

K. McHale, M. Martin, B. Johnston, Y. Zhang, R. Doxey, S. Hollenbach, N. Stasko; Novan Therapeutics, Durham, NC

Abstract Body:

Background: Onychomycosis is a common fungal infection of the nail caused primarily by dermatophytes. Topical treatments are favored over orally administered agents due to their side-effect profile and reduced risk of drug-drug interactions. However, efficacy rates for current topical therapies are hampered due to low penetration of drug across the nail plate. Nitric oxide-based topical therapies are promising due to the ability of the gaseous species to readily diffuse across the nail. Previous experiments have demonstrated the potent fungicidal effect of Novan's nitric oxide-releasing drugs in vitro. The aim of this study was to evaluate the ability of nitric oxide, released from several unique drug product formulations (gel, cream, lacquer), to penetrate the human nail and effectively kill the fungal infection. **Methods:** *In vitro* human nail penetration was evaluated (MedPharm, Guilford, UK) utilizing the ChubTur® infected human nail assay. *Tricophyton rubrum (T. rubrum)* was inoculated to the underside of human nails and allowed to establish infection for 14 days. Following the establishment of infection, the nails were mounted into modified Franz cells and topical treatments were applied to the top of the nail plate. The penetration of several unique nitric oxide-releasing formulations was evaluated by assessing the viability of *T. rubrum* after exposure via bioluminescence quantitation of ATP. **Results:** All nitric oxide-releasing topical formulations demonstrated effective fungal killing in 24 hrs, after a single treatment application. **Conclusions:** The mean reductions of viable fungal hyphae observed with various nitric oxide-releasing formulations ranged from 82% - 99 with several candidate formulations performing as well or better than 10% efinaconazole in this assay (83% mean reduction, Jublia®). The minimal difference in fungicidal effects between the various nitric oxide formulations suggests that penetration of nitric oxide gas through the nail plate was sufficient to kill the fungal infection after a single treatment application. Taken together these data demonstrate that nitric oxide-releasing treatments, with rapid penetration of the nail plate and eradication of fungal infection, are comparable to efinaconazole and represents promising novel, topical therapies for the treatment of onychomycosis.

Evaluation of Fungicidal Potential of *Nicotiana tabacum l.* and *Ocimum sanctum l.* Against *Aspergillus flavus* and *Aspergillus niger*

Author Block:

Z. Naeem, A. Maimoona, K. Jabeen, B. Khan; Lahore Coll. for Women Univ., Lahore, Lahore, Pakistan

Abstract Body:

The present study was undertaken to evaluate the antifungal activity of a locally found and ethno-botanically important plants *Ocimum sanctum* Linn. and *Nicotiana tabacum* Linn. The reason for selecting those plants is that both are rich in secondary plant metabolites. The first step was the extraction of powdered plant material in methanol of both plants in order to get their crude extracts. Extraction was carried out by means of maceration technique followed by fractionation (liquid-liquid partitioning). Qualitative phytochemical tests were carried out to confirm the absence or presence of flavanoids, glycosides, phenolics, saponins, steroids, tannins and tri-terpenes. For carrying out antifungal activity two test fungal strains belonging to genus Aspergillus were selected i.e *A. niger* and *A. flavus*. In *O. sanctum*, n-hexane fraction is most effective (100%) at conc. of 0.3% against *A. niger*. On contrary to *O. sanctum* in which maximum inhibition was given by *A. niger*, in *N. tabacum* maximum control for fungal growth has been recorded in butanol fraction at 96% at the concentration of 0.1% against *A. flavus*. Hence these plants can be used for manufacturing drugs to preserve our cereals and to treat fungal infections as both possess significant antifungal activity.

HXP124, a Plant Defensin, Represents a Novel Antifungal Therapeutic

Author Block:

N. L. van der Weerden[1], B. Hayes[2], M. Baker[1], K. Harris[2], M. Bleackley[2], **M. Anderson**[2]; [1]Hexima Limited, Melbourne, Australia, [2]La Trobe Univ., Melbourne, Australia

Abstract Body:

Background: Plant defensins with potent antifungal activity have the potential to be developed as effective and robust treatments for fungal infections in humans. The cysteine-stabilised structure of plant defensin's makes them extremely stable and able to withstand extremes of pH and temperature. Here we investigate the antifungal properties of a novel plant defensin, HXP124, against a range of clinically important fungal pathogens.**Methods:** HXP124 was recombinantly expressed using the Pichia pastoris yeast expression system and purified using a scalable two-step purification method. The activity of HXP124 against a range of fungal and bacterial pathogens was tested using the microbroth dilution method and the ability of HXP124 to kill human U937 cells was examined by monitoring the uptake of propidium iodide using FACS.**Results:** HXP124 has potent antifungal activity against a range of human fungal pathogens including Candida spp, Cryptococcus spp, dermatophytes and non-dermatophytic moulds. HXP124 is highly selective for fungal cells having no effect on mammalian cells, including red blood cells, at concentrations more than 50 times the MIC for fungus. HXP124 is also fungicidal, killing fungal cells within 1 h of exposure after the induction of reactive oxygen species and disruption of fungal membranes. Plant defensins contain four disulphide bonds which stabilise the three-dimensional structure. As such, they are stable at extremes of pH (<2) and temperature (>95°C). HXP124 can be produced recombinantly in yeast with very high yields. Its small size and positive charge makes it easy to purify and highly pure protein can be achieved with a simple two-step purification process.**Conclusions:** HXP124 is a potent antifungal molecule and an excellent candidate for the development of a novel antifungal therapeutic useful in a number of clinical settings.

Use of the Non-Essential Yeast Deletion Collection to Define the Antifungal Mechanisms of Plant Defensins

Author Block:

K. Parisi[1], M. Bleackley[1], N. van der Weerden[2], M. Anderson[1]; [1]La Trobe Univ., Melbourne, Australia, [2]Hexima Limited, Melbourne, Australia

Abstract Body:

Background: Plant defensins are potent antifungal peptides that represent a novel class of antifungal drug with excellent potential for clinical application. Plant defensins share a similar three-dimensional structure but vary significantly in sequence. This variation in sequence is thought to account for the different mechanisms of action observed for plant defensins. We have identified several novel antifungal plant defensins with high sequence variability and potentially novel mechanisms of action.**Methods:** To define the mechanism of action of each defensin we employed a *Saccharomyces cerevisiae* gene deletion library that contains 5000 unique knockout strains. Each knockout strain is identifiable by an individual barcode incorporated into the gene during deletion. A pool of this library was treated in triplicate with eight different defensins alongside an untreated control. Following defensin treatment, genomic DNA was isolated from the treated yeast. The barcoded region was amplified and sequenced using next-generation sequencing to determine the abundance of each strain. From this analysis, we determined the fitness of 5000 yeast deletion strains in the presence of a specific defensin.**Results:** We identified several strains that were sensitive or resistant to all eight defensins indicating that elements of the activity of plant defensins are conserved. These strains may represent general stress response genes. However, the clustering revealed elements that are unique to each defensin and suggests at least three different mechanisms of action. Two of the defensins we tested appear to have a conserved mechanism of action which correlates with their degree of sequence identity.**Conclusions:** Understanding how plant defensins exert their antifungal activity will assist in selection of defensins with different antifungal mechanisms which can be used in therapeutics to create broad spectrum resistance to fungi.

Effects of Aqueous and Ethanolic Extracts of *Heinsia crinita* on the Pathogenic Fungi of *Carica papaya*

Author Block:

E. Enemo, D. Anthony; Univ. of Uyo, Uyo, Nigeria

Abstract Body:

Background: The need for edible medicinal sources of antifungal agents has risen in recent times owing to the increasing resistance of pathogenic fungi to synthetic antifungal agents. Hence, this research.**Methods:** Pawpaw fruits were bought from three different markets in Uyo metropolise(Itam, Use and Akpana Ndem markets). Sterilised surgical blade was used to cut out 3mm by 3mm from the diseased area of the pawpaw fruits. This was inoculated on a Potato Dextrose Agar(PDA) media and incubated at room temperature for 5 days. Observed mixed growths were subcultured to get pure cultures. For the exact identification of the isolates further molecular methods will be employed(which is beyond the scope of this work). The fungi isolates were re-inoculated into healthy matured pawpaw fruits to test their pathogenicity. All the isolates were able to produce spoilage with EKP41 being the most pathogenic, and EKP12 being the least pathogenic. Fungi spores were obtained by growing the isolates in peptone broth. The effects of the extracts were tested on the spores using both Agar Disc Diffusion and Agar Well Diffusion methods at two levels (125mg/ml) and (50mg/ml).**Results:** Of the seven fungal samples, only EKP41 exhibited slight sensitivity to the extracts.**Conclusions:** The result confirms *Heinsia crinita's* antifungal property. Hence, the consumption of *Heinsia crinita* is recommended for curing fungal infections of pawpaw origin, especially of the EKP41 source.

***In Vitro* Anti-Dermatophyte Activities of Some Nigerian Medicinal Plants**

Author Block:

C. C. Ekwealor, C. A. Oyeka, V. N. Anakwenze, C. M. Ogbukagu; NNAMDI AZIKIWE Univ., AWKA, Nigeria

Abstract Body:

Background: Medicinal plants are plants whose parts are used in the treatment of different diseases. They are becoming popular because of their inability to cause side effects. This study is to determine the anti-dermatophyte activities of some Nigerian medicinal plants against dermatophytes recovered from rice farmers in Anambra State, Nigeria.**Methods:** Samples collected from 201 rice farmers with lesions suggestive of cutaneous mycoses were identified as *Microsporum audouinii*, *Microsporum ferruginieum*, *Trichophyton megninii*, *Trichophyton tonsurans* and *Trichophyton rubrum*. Dried leaves of *Lawsonia inermis*, *Cassia alata* and *Mitracarpus villosus* were extracted by soxhlet method using methanol as solvent. Anti-dermatophyte activities of the methanol and aqueous extracts of the leaves were studied using disc diffusion method at varying concentrations (10mg, 20mg, 40mg, 80mg). Discs impregnated with 2% DMSO and 2mg ketoconazole were used as negative and positive controls respectively. Minimum Inhibitory Concentration (MIC) and Minimum Fungicidal Concentrations (MFC) of the extracts were determined using broth dilution method.**Results:** Growth of the dermatophytes were inhibited by methanol extracts of the plants at various concentrations. The inhibition zones increased with increase in concentration of the extracts. At 10mg/disc, methanol extracts of *L. inermis* inhibited all isolates with an inhibition zone ranging from 7.8mm-16mm diameter while *C. alata* inhibited only *M. audouinii* with an inhibition zone of 8.2mm in diameter. *Mitracarpus villosus* extract showed no inhibition at this concentration. However, the highest diameter zone of inhibition (16.8mm) was observed with *L. inermis* against *T. rubrum* at 80mg/disc. All dermatophytes were susceptible to aqueous extracts of all the plants with *L. inermis* having diameter zone of inhibition of 9.0mm-14.5mm, *C. alata* 6.4mm-8.2mm and *M. villosus* 6.0mm-7.8mm. MIC was observed at ≥25mg/ml for all the plants. *L. inermis* and *C. alata* recorded an MFC of ≥50mg/ml and ≥100mg/ml respectively against the dermatophytes while no fungicidal action was recorded with *M. villosus***Conclusions:** Methanol and aqueous extracts of the plants inhibited the dermatophytes and so could be a good source for the production of plant based antifungal drugs for treatment and control of tinea infections

Candiduria and Bacteriuria in Children Attending Primary School in Amassoma Community, Niger Delta Region of Nigeria

Author Block:

O. A. Olorode, **O. A. Olorode**; Niger Delta Univ., Faculty of Pharmacy., Yenagoa Ba, Nigeria

Abstract Body:

Candiduria and Bacteriuria infections can be severe and it is associated with considerable morbidity if left untreated. Can these infections co-infect in primary school children? This study was conducted between January and October, 2015 to determine the frequency of bacteriuria and candiduria of apparently healthy children of different age groups and sex attending primary schools in Amassoma, Nigeria. Mid-Stream Urine (MSU) was examined in 142 children using selective media. The isolated organisms were characterised and identified on the basis of their cultural morphology, Gram stain and biochemical properties. Antibiotic susceptibility of isolated organisms was evaluated by standard procedure. Stastitical analysis showed no significant difference in the effectiveness of susceptible antimicrobial agents. The findings showed asymptomatic Bacteriuria and Candiduria in 91 (64.1%) and 97 (68.3%) samples respectively; the subjects who had staphylococcal co-infection with Candidiasis and other infections were 75 cases (52.8%), with female preponderance over males. Microorganisms isolated include *Staphylococcus aureus* (20.8%), *Candida glabrata* (14%), *Staphylococcus epidemidis* (13.3%), *Candida albicans* (6.8%); *Candida tropicalis* (5%), *Bacillus species* (4.3%), *Candida parapsilosis* (3.2%), *Enterococcus species* (2.2%), Klebsiella species (1.4%) other *Staphylococcus* species were (9.7%). *Staphylococcus,Bacillus and Enterococcus* species isolated were highly susceptible to Levofloxacin (97.4%), Gentamycin (93.2%), Ciprofloxacin (93.1%), Streptomycin (92.6%), moderately susceptible to Rifampicin (71.2%); least susceptible to Erythromycin (58.9%) but resistant to Chloramphenicol (85.4%). All *Candida* isolates were most susceptible to Fluconazole (87.9%) followed by Nystatin (71%), moderately susceptible to Ketoconazole (68.1%) and highly resistant to itraconazole (8.1%). Observation showed that the most infected subjects were females between ages of 5 and 12yrs.

Characterization of *Myo*-inositol Transport in *Pneumocystis* Species; A Potential New Drug Target

Author Block:

M. T. Cushion[1], M. S. Collins[1], K. Lynch[1], T. Sesterhenn[1], M. J. Linke[2]; [1]Univ. of Cincinnati Coll. of Med., Cincinnati, OH, [2]Cincinnati VA Med. Ctr., Cincinnati, OH

Abstract Body:

Background: Fungi in the genus *Pneumocystis* cause an oftentimes lethal pneumonia in humans and other mammals with compromised immune status. The niche of these fungi include patients with underlying chronic diseases such as COPD or HIV and those receiving anti-inflammatory or immunosuppressive agents. PCP is not responsive to standard antifungal therapy with few treatment alternatives besides trimethoprim-sulfamethoxazole. We recently reported *Pneumocystis* spp. were auxotrophic for *myo*-inositol, a polyol that is essential for viability, and instead uses transporters to satisfy this requirement. There is but a single such transporter (ITR1) in *P. jirovecii*, the species infecting humans, providing a potential new drug target as humans can both synthesize and transport *myo*-inositol. In the present study we characterized *myo*-inositol transport in *Pneumocystis*.**Methods:** *P. carinii* obtained from the lungs of immunosuppressed rats was used in uptake studies with *myo*-[2-^{3}H] inositol to determine the K_m, substrate specificities, and critical determinants of substrate recognition. Uptake was measure by liquid scintillation in the presence or absence of 50-100X monosaccharides and *myo*-inositol stereoisomers; with varying concentrations of proton or sodium transport inhibitors; acidic and basic pH, and *myo*-inositol biosynthesis inhibitors. Yeast *itr1/itr2* mutants were used to further evaluate function of the ITR1 from *P. carinii, P. murina,* and *P.jirovecii*. Statistical significance was measured by ANOVA with Dunnett's multiple comparison test.**Results:** The K_m was in the range of other high affinity *myo*-inositol transporters in yeast. No other hexose or pentose sugar inhibited uptake of the radioactive label besides *myo*-inositol. A similar high affinity was observed with the stereoisomers and inositol derivatives. Transport was proton but not sodium dependent. As expected, inhibitors of *myo*-inositol synthesis (e.g. lithium chloride) had no effects on uptake or viability. The ITR1 genes of the *Pneumocystis* species could complement uptake and growth of the double yeast mutants.**Conclusions:** *Pneumocystis* spp. rely on high affinity *myo*-inositol transport which offers a potential new drug target.

Type-Iii Secretion Proteins as a Broadly Protective Subunit Vaccine against *Salmonella enterica* Serovars

Author Block:

V. VISHWAKARMA, F. J. MARTINE-BASSERA, P. KUMAR, O. ARIZMENDI, M. M. PRESSNALL, W. D. PICKING, W. PICKING; Univ. OF KANSAS, LAWRENCE, KS

Abstract Body:

Salmonella enterica is an important foodborne pathogen. Infection of livestock is common and a threat to the food animal industry. Non-typhoidal *S. enterica* is the leading cause of hospitalization and death resulting from contaminated food in the US. Currently, no broadly protective vaccine is available against the many *S. enterica* serovars. We have genetically fused SPI-1 and SPI-2 tip and first translocator proteins, SipB/SipC and SseB/SseC, respectively, to produce recombinant fusion proteins S1F and S2F, respectively, for immunization of mice. S1F and S2F, alone or together, were administered intramuscularly with monophosphoryl lipid-A (MPL) and Alhydrogel as adjuvant system. Serum and bone marrow were isolated post-immunization to assess immunogenicity; cecum samples were sectioned and stained to determine cecal inflammation. Both fusions elicited a high serum IgG response alone and together. Antibody secreting cells (ASC) isolated from bone marrow of immunized mice showed moderate to high frequencies of IgG ASCs against the proteins of S1F, high frequencies to proteins in S2F, while the highest frequencies were detected in the S1S2 combination vaccinated group. Similarly, unique cytokine secretion patterns were detected in S1S2 vaccinated mice. When mice were challenged with *S.* Typhimurium or *S.* Enteritidis, the S1S2 vaccine formulation elicited the highest protection against death as well as prevention of cecal inflammation. These results demonstrate the proof of concept in a small animal model that the S1S2 subunit vaccine can provide broad coverage to protect against all *S. enterica* serovars which may be transformative to the livestock industry and improve human health.

Association of Phenotyic and Genotypic Fluoroquinolone Susceptibility Among Non-Typhoidal Salmonella Isolates From Jeddah, Ksa

Author Block:

A. Ali, R. A. Lahzah; King Abdulaziz Univ., Jeddah, Saudi Arabia

Abstract Body:

Non-typhoid Salmonella (NTS) infect 250 to 3200 per 100,000 individuals from all over the world. NTS infection is relatively high in Jeddah (ranges between 44-132) as compared to other cities of Saudi Arabia due to high influx of people from across the globe for pilgrimage. Fluoroquinolone (FQ) is the drug of choice for the treatment of NTS infections. However, miss-use of FQs has led to increase in FQ resistance. Genotypic FQ resistance has been associated with mutations in *gyrA* and *parC* genes. This study primarily explored the phenotypic FQ susceptibility among clinical NTS isolates from Jeddah, Saudi Arabia. Secondly, study also explored any correlation between phenotypic and genotypic FQ resistance.48 NTS isolates were collected from a public sector hospital in Jeddah during 2014. FQ susceptibility was determined using Clinical and Laboratory Standards Institute methodology. Presence of mutations for FQs resistance was detected in *gyrA* and *parC* genes by PCR- based gene-sequencing method.Phenotypic antibiogram revealed 38% (18/48) resistance for FQ among NTS isolates. Genotypic resistance revealed mutations in *gyrA* and *parC* genes among 39% (7/18) of FQ resistant isolates. 43% (3/7) of FQ resistant isolates showed mutations at two codons 83 (S83F, S83Y) and 87, (D87G, D87Y, D87W) of *gyrA* gene. Two resistant isolates showed triple mutations i.e. at codons 83 and 87 of *gyrA* and codon 80 (S80I and S80W*)* of *pyrC* gene. While one of each resistant isolate revealed mutation at codon 87 of *gyrA* and 57 (S57T) of *pyrC* gene. 55% (6/11) intermediate susceptible isolates for FQ revealed mutations in *gyrA* and *pyrC* genes. Of these 83% had single mutation at codon 83 of *gyrA* gene whereas, 17% (1/6) revealed double mutation at codon 83 of *gyrA* and 57 of *pyrC* gene. None of the FQ susceptible isolates showed any mutations in *gyrA* or *parC* genes.Occurrence of mutations at only four codons in *gyrA* and *parC* genes among FQ resistant isolates may assist in development of rapid molecular method for FQ resistance detection. Presence of mutations among more than fifty percent of intermediate susceptible FQ NTS isolates could also serve as a predictor for pre-resistant isolates. However, absence of mutation in about sixty percent of resistant isolates stress further investigation to explore an alternate resistance mechanism for FQ among NTS.

High Prevalence and Characterization of CTX-M-15-Producing *Salmonella enterica* Serotype Virchow in Chicken in Korea

Author Block:

S-K. Lim, D. Moon, S-R. Kim, G-C. Jang, H-S. Lee; Animal and Plant Quarantine Agency, Anyang, Korea, Republic of

Abstract Body:

Background: *Salmonella enterica* serotype Virchow (*S.* Virchow) carrying CTX-M-15 type extended-spectrum beta-lactamase (ESBL) has rapidly emerged in humans in Korea recently. Third generation cephalosporins are widely used in both human and veterinary medicine to treat important bacterial infections. The aim of this study was to investigate prevalence and characterization of ceftiofur resistant *S.* Virchow isolated from food animals and carcasses in Korea. **Methods**: *S.* Virchow strains were isolated from animal faecal and animal carcass samples in slaughterhouse during 2011-2014. Serotyping by agglutination, antimicrobial susceptibility testing by broth dilution method, identification of ESBL genes and plasmid replicon types by polymerase chain reaction and sequencing, and conjugation by filter mating of the ceftiofur resistant *S.* Virchow were performed. **Results:** From 2011 to 2014, a total of 103 ceftiofur resistant *S.* Virchow were isolated from chicken (n=42), pigs (n=3), cattle (n=1), and chicken carcasses (n=57). The percentage of ceftiofur resistant *S.* Virchow isolates dramatically increased from 0.7% (2/268) in 2011 to 20.3% (74/364) in 2014. The ceftiofur resistant *S.* Virchow isolates were recovered from 59 chicken farms, 3 pig farms and 22 slaughterhouses. All ceftiofur resistant *S.* Virchow carried the $bla_{\text{CTX-M-15}}$ gene. Among them, 18 isolates simultaneously co-carried $bla_{\text{CTX-M-15}}$ and $bla_{\text{CMY-2}}$ genes. The $bla_{\text{CTX-M-15}}$ gene was located on transferrable IncI (n=17) and IncHI1&HI2 (n=18) plasmids. Identical PFGE patterns were observed in isolates from same or different farms and slaughterhouses. **Conclusions:** These results suggested that $bla_{\text{CTX-M-15}}$ gene could be disseminate via plasmid transfer and clonal spread in chicken production system.

Detection of Plasmid-Encoded Fosfomycin Resistance Gene *Fosa3* in *Salmonella* Isolates from Food-Producing Animals

Author Block:

H-X. Jiang, W-H. Zhang, X-X. Zhang, Z-L. Zeng; South China Agricultural Univ., Guangzhou, China

Abstract Body:

The purpose of this study was to investigate the occurrence of plasmid-mediated fosfomycin-resistant genes in *Salmonella* isolates from food-producing animals and retail pork.A total of 285 non-duplicate *Salmonella* isolates obtained from retail pork (n=126), pigs (n=90) and chickens (n=69) in China during 2014-2015 were screened for the presence of plasmid-mediated fosfomycin-resistant genes (*fosA3*, *fosA and fosC2*) by PCR and sequencing. The positive isolates were further tested for the presence of other associated resistance genes (ESBLs and PMQR genes). Plasmids were characterized by conjugation, replicon type and S1-PFGE. The genetic relatedness was determined by PFGE and MLST. The genetic context was determined by PCR mapping and sequencing. In total, eight (2.8%) isolates showed resistance to fosfomycin and 5 (1.8 %) were positive for *fosA3*, no *fosC2* or *fosA* gene was detected. All of the five *fosA3*-positive isolates were recovered from chickens of two different serotypes (3were *S.Typhimurium*, 2 were *S. Indiana*). CTX-M type ESBLs were found in all five fosA3-carrying isolates (two CTX-M-27, two CTX-M-14 and one CTX-M-65), PMQR genes (*aac-(6')-Ib-cr* and /or *oqxAB*) was identified in two isolates. PFGE results showed that these *fosA3*-carrying isolates belonged to two different clonal groups. MLST analysis showed all of the five fosA3-positive isolates belonged to ST17. All fosA3 genes were located on IncN /IncA/C ~150kb plasmids with co-transfer $bla_{\text{CTX-M}}$ genes in 3 isolates. Genetic-environment analysis showed the fosA3 genes were flanked by IS26 with a genetic structure (IS26-fosA3-orf1-orf2- IS26).Our results indicated that both clonal spread of resistant strains and horizontal transmission of the plasmids contributed to the dissemination of *fosA3*-positive *Salmonella* isolates, the coexistence of $bla_{\text{CTX-M}}$ gene is also a public health concern. Close monitoring of spread tread of the *fosA3* gene is necessary.

Antimicrobial Susceptibility and Molecular Characterization of *Shigella* Clusters Associated with Men Who Have Sex with Men (MSM)

Author Block:

A. Bicknese[1], D. Campbell[2], A. Bowen[2], J. Grass[2], J. Hurd[2], J. C. Norton[3], A. McCullough[1], J. Chen[1], Z. Rigney[3], J. Concepcion-Acevedo[2], D. Wagner[1], J. Folster[2]; [1]IHRC, Atlanta, GA, [2]CDC, Atlanta, GA, [3]ORISE, Oak Ridge, TN

Abstract Body:

Shigella causes an estimated 500,000 illnesses annually in the United States, and transmission is usually fecal-oral. Shigellosis is a public health problem in the MSM-community. The National Antimicrobial Resistance Monitoring System (NARMS) at CDC tests every 20th Shigella isolated in the United States for antimicrobial resistance and tested 84 isolates from 8 MSM-associated clusters (2013-2015), identified by epidemiological and laboratory investigations.*Shigella* were speciated at State Public Health laboratories. Broth microdilution (ThermoScientific Sensititre) was performed to determine minimum inhibitory concentrations of 14 antimicrobial agents. Pulsed-field-gel-electrophoresis (PFGE) and whole genome sequencing (WGS) analysis were also performed. Seven clusters were caused by *S. sonnei* and one by *S. flexneri.* Fifteen PFGE Xbal patterns were found among the 84 isolates tested from these clusters. Resistance for up to 12 antimicrobial agents was observed, and resistance varied between clusters and even within PFGE patterns. All eight clusters had multidrug resistance (MDR, resistance in 3 or more CLSI antimicrobial classes) isolates. One cluster had 67% MDR isolates, another had 86% MDR isolates and the remaining six had 100% MDR isolates. The top three resistance patterns among MSM-associated clusters included resistance or non-susceptibility to at least one clinically important antimicrobial (ampicillin, trimethoprim/sulfamethoxazole, ciprofloxacin, or azithromycin); preliminary WGS (Illumina MiSeq) analysis using ResFinder (cge.cbs.dtu.dk) identified beta lactamase genes (primarily *bla*$_{\text{TEM}}$), trimethoprim/sulfamethoxazole resistance genes (*dfrA*1 and *sul1/2*), mutations in *gyrA*, and a macrolide resistance gene (*mphA*). Plasmids IncFIB and IncFII were identified by PlasmidFinder (cge.cbs.dtu.dk). Further studies are necessary to define risk factors for acquisition of MDR *Shigella* infections, determine how antimicrobial resistance affects transmission and success of treatment with antimicrobials, and tailor prevention strategies for at-risk groups including MSM communities.

***In Vitro* Activity of Pexiganan (Px) and 8 Comparator Antimicrobials against 230 Isolates Including 93 *Pasteurella spp* and 47 Anaerobic Bacteria Recovered from Animal Bite Wounds**

Author Block:

E. J. C. Goldstein[1], K. L. Tyrrell[2], D. M. Citron[2]; [1]R.M. Alden Res. Lab, Santa Monica, CA, [2]R.M. Alden Res. Lab, Culver City, CA

Abstract Body:

Background: Annually, &gt4 million Americans will be bitten by a dog and an additional ½ million will be bitten by a cat. While 15-20% will become infected, ~80% will use topical forms of self-administered therapy prior to seeking medical attention. Pexiganan, a 22-amino acid synthetic cationic analogue of peptide magainin II, acts by selectively damaging bacterial cell membranes. PX is in Ph3 clinical development as a topical cream (0.8%) for treatment of mild infections of diabetic foot ulcer and has potential for other skin and skin structure infections. The aim of this study was to evaluate the in vitro of typical aerobic and anaerobic bite wound isolates. **Methods:** Some of the strains were recovered during the past 3 years, although many of the unusual species were older. About 10% were from European and Canadian patients. Anaerobic isolates were tested by the agar dilution method, for all drugs except PX, which was tested using Brucella broth supplemented with vitamin K and hemin, with and without 5% lysed horse blood (CLSI M11-A8). Agar is not suitable for testing PX due to interference by the calcium concentration in agar. Aerobic organisms were tested by broth microdilution for penicillin (PCN), amoxicillin-clavulanate (A-C), piperacillin-tazobactam (P-T), meropenem (MR), clindamycin (CM), doxycycline (DX), ceftriaxone (CX), and moxifloxacin (MX). **Results:** *Pasteurella* spp. MIC_{90}s ranged from 8-32 µg/ml. The no. of isolates and MIC 90%s were as follows: *P. multocida* (31), 32 µg/ml; *P septica*, (22), *P canis (15) and P dagmatis (15)* all 16 µg/ml; and *P stomatis* (10), 8µg/m; *Bergeyella zoohelcum* (11), 16 µg/ml; *Moraxella* spp. (16), 16 µg/ml; *Neisseria zoodagmatis* (14), 2 µg/ml; *Eikenella corrodens* (32), 8 µg/ml. For anaerobes, the MIC 90%s were as follows: *Bacteroides pyogenes*, (15), 4 µg/ml; *Prevotella heparinolytica.* (12) 8 µg/ml; *Fusobacterium canifelinum* (10), 16 µg/ml; *F russii* (10), 4 µg/ml. None of the higher PX MICs was related to resistance in any of the other antimicrobial agents. **Conclusions:** PX showed a high level of activity against this diverse group of animal bite isolates. The concentration of PX in the cream is 8,000 µg/ml, more than 60 times the highest MIC obtained. PX shows great potential for early topical therapy of animal bite wounds.

Microbiological Safety of Tulathromycin on Human Gut Flora in Chemostats

Author Block:

H. Hao, S. Zhou, Z. Liu, Y. Wang, Z. Yuan; Huazhong Agricultural Univ., Wuhan, China

Abstract Body:

To evaluate microbiological safety of tulathromycin on human gut flora, low to high concentration of tulathromycin (0, 0.1, 1 and 10μg/mL) was administrated into Chemostat models. Short chain fatty acids (SCFAs), population and resistance of four dominant human interstinal bacterial was monitored daily. Colonization barrier of each community was determined by 3 successive daily challeges of *Salmonella typhimurium*. The resistance phenotype, genotype, transferability, virulence genes and pathogenicity of *Enterococus.faecalis* were determined before and after treatment with tulathromycin. Results showed that 10μg/mL tulathromycin would significantly decrease the population but increase the resistance rate of *Enterococci* and *Bacteroides fragilis*. The 100 μg/mL tulathromycin significantly decreased population of *Escherichia coli*, *Bifidobacterium* and *B.fragilis* and SCFAs, but largely increased resistant rate of *Enterococci* and selected multidrug resistant *E.faecalis*. The selected resistant *E. faecalis* always carried *ermB* gene located in transposons Tn154 and had ability of horizontal gene transfer (HGT). The *ermB* gene in selected resistant *E. faecalis* had a positive correlation with virulence gene of *esp* and *cylA*, but a negative relationship with *gelE* virulent gene. The *E. faecalis* harboring *esp* and *cylA* had higher pathogenicity. Conclusively, microbiological acceptable daily intake (mADI) of tulathromycin was calculated as 4.58μg/kg bw/day. The higher concentration of tulathromycin would disturb colonization resistance of human intestinal flora and increase antimicrobial resistance development, horizontal gene transfer and virulence of pathogens. The antimicrobial resistant pathogens with high pathogenicity may pose risk to human health.

***Dfra14* Trimethoprim Resistance Gene Associated to a Small Plasmid Is Present in Chilean *Shigella sonnei* Strains**

Author Block:

A. MIRANDA, B. ÁVILA, P. DÍAZ, L. RIVAS, K. BRAVO, J. ASTUDILLO, C. BUENO, M. ULLOA, G. HERMOSILLA, F. DEL CANTO, J. SALAZAR, **C. S. TORO**; Programa de Microbiología y Micología, ICBM - Facultad de Med., Univ. de Chile, Santiago, Chile

Abstract Body:

Background: The most common mechanism of trimethoprim (TMP)-resistance is the acquisition of dihydrofolate reductase enzyme insensitive to this drug. Previous molecular characterization of TMP-gene resistance in Chilean isolates of *S. sonnei* looking for *dfrA1* and *dfrA8*, showed solely the presence of *dfrA8* (formerly *dhfr*IIIc). However, these genetic markers were absent in *S. sonnei* strains further isolated during a nationwide outbreak in 2009.**Methods:** To identify the TMP resistance gene in these strains, a genomic DNA library from a TMP-resistant (TMP^R) *S. sonnei* representative strain for the outbreak was used to clone, select and identify a TMP-resistance marker.**Results:** The TMP^R clone was sequenced by primer walking, identifying the presence of the *dfrA14* in the *sul2-strA'-dfrA14-'strA-strB* gene arrangement, harbored in a native 6,779-bp plasmid. The same plasmid was isolated by transforming with a ~4.0 MDa plasmid from several TMP^R *S. sonnei* strains into *E. coli*. This plasmid, named pABC-3, was homologous to pCERC-1, but different due to the absence of an 11-bp repetitive unit, and present only in *dfrA14*-positive strains. The distribution of *dfrA1*, *dfrA8* and *dfrA14* TMP-resistance genes, was characterized in 126 TMP^R *S. sonnei* strains. Only one strain (0.8%) out of the 126 strains, isolated before the outbreak was negative for the three TMP resistance genes, and just 4% displayed two resistance genes. Most of the strains (95%) carried only one of the three TMP resistance gene assessed; all strains obtained during the outbreak harbored only *dfrA14*, whereas, *dfrA8* was the most abundant gene marker before outbreak and after the outbreak *dfrA1* seems have appeared in circulating strains. According PFGE, *dfrA14*-positive strains were clustered in a genetically related group including some *dfrA1*- and *dfrA8*-positive strains; meanwhile other genetic group included most of *dfrA8*-positive strains. This distribution also correlated with the isolation period, showing a dynamics of trimethoprim genetic markers prevalent in Chilean *S. sonnei* strains.**Conclusions:** To our knowledge, *dfrA14* gene associated to a small non-conjugative plasmid was detected for the first time in *Shigella*.

Identification and Characterization of *Salmonella enterica* Serotype Newport Isolates with Decreased Susceptibility to Ciprofloxacin in the United States

Author Block:

D. Campbell[1], A. Bicknese[2], A. McCullough[2], B. Karp[1], J. Folster[1]; [1]CDC, Atlanta, GA, [2]IHRC, Atlanta, GA

Abstract Body:

Nontyphoidal *Salmonella* (NTS) causes an estimated 1.2 million illnesses, 23,000 hospitalizations, and 450 deaths each year in the United States. Resistance to fluoroquinolones, which are used to treat severe NTS infections in adults, has historically been associated with chromosomal mutations in *gyrA* and *parC* (quinolone resistance determining regions; QRDRs), but plasmid-mediated quinolone resistance (PMQR) genes have recently emerged. Since 1996, the National Antimicrobial Resistance Monitoring System at the Centers for Disease Control and Prevention (NARMS-CDC) has conducted broth microdilution susceptibility testing on *Salmonella* to determine minimum inhibitory concentrations (MIC) for up to 15 drugs. Decreased susceptibility to the fluoroquinolone ciprofloxacin (DSC), defined as MIC $\geq$ 0.12 mg/L, increased from 0.4% in 1996 to 4.3% in 2014 in NTS surveillance isolates. Approximately 20% of NTS surveillance isolates with DSC were nalidixic acid susceptible, suggesting they may have PMQRs; Newport was the second most common serotype among these isolates. To investigate and characterize DSC among *Salmonella enterica* serotype Newport, we examined 38 isolates with DSC including 37 from patients (routine surveillance and outbreak) and one isolate from food (outbreak) in the United States from 1996 through 2014. Mechanisms of resistance and resistance plasmids were identified by PCR and sequencing analysis. Pulsed-field gel electrophoresis (PFGE) analysis was used to determine genetic relationships among these isolates.Twenty-seven Newport isolates (71%) contained a PMQR gene, and all had the *qnrB* gene. No additional PMQRs genes were identified. Seven isolates (18%) contained a QRDR, and these were the S83Y, S83F, or D87G *gyrA* mutations. Four isolates (11%) had no QRDR or PMQR resistance determinants detected. Several resistance plasmids were identified among PMQR-positive isolates including ColE, IncP, IncI1, and IncA/C. Also, eight PFGE patterns were found among 26 isolates that contained a PMQR gene, suggesting that multiple plasmid transmission and not clonal expansion is involved.Additional studies are needed to determine the sources of infection and to investigate DSC mechanisms among additional NTS serotypes.

Tenofovir Alafenamide (Taf) Has Wide Efficacious Range for Treatment of Hiv-1 Infection: Pharmacokinetic-Pharmacodynamic (Pk-Pd) Relationships from a Phase 3 Study

Author Block:

L. S. Ting, J. Zack, M. Yan, L. Zhong, M. S. Rhee; Gilead Sci. Inc., Foster City, CA

Abstract Body:

Background: Tenofovir alafenamide (TAF) is a novel prodrug of tenofovir (TFV) that has been coformulated with emtricitabine (F) into a fixed dose combination tablet (F/TAF) as a stand-alone N(t)RTI backbone. We conducted a randomized, double blind, active controlled study in virologically suppressed HIV-1 infected patients receiving F/TDF-containing regimens to evaluate the efficacy and safety of switching from F/TDF to F/TAF vs continuing F/TDF while remaining on the same third agent. Study drugs were taken without regard to food. **Methods:** TAF area under the curve over dosing interval (AUC_{tau}) and maximum concentration (C_{max}) were estimated from sparse PK data collected across 6 study visits using an established population PK model. The efficacy endpoint for PK-PD analysis was the proportion of subjects with HIV-1 RNA <50 copies/mL at Week 48 as defined by the FDA snapshot algorithm. The percentage of virologic success at Week 48 was summarized by exposure subgroups (i.e. quartiles of TAF AUC and C_{max}).**Results:** 663 patients were randomized (1:1) and treated. Through Wk 48, high virologic success (HIV-1 RNA <50 copies/mL) was maintained in both treatment groups: F/TAF 94.3% (312/333) vs F/TDF (307/330) 93.0% (difference +1.3%, 95% CI: -2.5% to +5.1%), demonstrating noninferiority of F/TAF to F/TDF. TAF PK exposures were available for 292 F/TAF treated subjects. Mean (% coefficient of variation) TAF AUC_{tau} was 137.2 (48.1), with a wide range of 30.3 to 466.7 ng*h/mL. The rates of virologic success were uniformly high across quartiles of TAF exposures (Table). There were no apparent trends with virologic success and TAF exposure.**Conclusions:** These data demonstrate that TAF (10 mg with boosted regimen or 25 mg with unboosted regimen) was efficacious across wide ranges of exposures in virologically suppressed HIV-1 infected patients.**Table. Percentage of Virologic Success by FDA snapshot algorithm at Week 48 Across Quartiles of TAF Exposure**

Quartile	TAF AUCtau Quartile Range (ng*h/mL)	N	Virologic Success (HIV-1 RNA < 50 copies/mL)
1	30.3 to 87.6	73	93.2%
2	87.6 to 129.5	73	95.9%
3	129.8 to 173.1	73	97.3%

4	173.8 to 466.7	73	95.9%

Combination Antiretroviral (cARV) Drug Loaded Nanoparticles (NPs) Are Efficacious in Humanized (Hu-BLT) Mice

Author Block:

S. Mandal[1], G. Kang[2], Y. Yuan[2], W. Lu[2], P. K. Prathipali[1], Q. Li[2], **C. J. Destache**[1]; [1]Creighton Univ., Omaha, NE, [2]Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract Body:

Background: The use of elvitegravir (EVG) + tenofovir alafenamide fumurate (TAF) + emtricitabine (FTC) along with cobicistat is a new formulation that has recent been approved for oral therapy. We are the first to report the use of EVG+TAF+FTC NP formulation for treatment of HIV-1 in humanized BLT mice.**Methods:** cARV-loaded nanoparticles (NPs) were formulated by oil-in-water (o-w) and water-in-oil-in-water (w-o-w) emulsion methodology. Poly(lactic-co-glycolic acid) (PLGA), a biodegradable/biocompatible polymer was used to formulate the TAF+EVG drug-loaded NPs using our standard (o-w) methodology. FTC loaded NPs were formulated using w-o-w emulsion method. Hu-BLT mice (n=12) with functional human immune reconstitution were randomly divided into treatment (Rx; n=6) and control (Ctr; n=6). Hu-BLT mice were intravaginally infected with transmitted/founder viruses (WITO.c/2474 and SUMA.c/2821) at 2.5 x 10^5 $TCID_{50}$ each. Two weeks later, baseline plasma was drawn for viral load (pVL). Rx group mice received 500 mg/kg (200 mg/kg each of TAF+EVG; 100 mg/kg FTC) cARV NPs by SubQ injection in 2 mL D5W starting 3 weeks after HIV-1 challenge. Four doses of cARV NPs were administered over 6 weeks. Ctr mice received 2 mL D5W. All mice had blood drawn for pVL using qRT-PCR every other week for 10 weeks. On the opposite week of pVL, blood was drawn for TAF+EVG+FTC trough drug levels and analyzed by LC-MS/MS.**Results:** TAF+EVG entrapment efficiency averaged 40 and 45% for each drug in the combination NPs and FTC entrapment averaged 62%. Baseline pVL averaged 1.2 x 10^4 $\pm$ 5.3 x 10^4 copies/mL for Rx mice and 1.7 x 10^5 $\pm$ 8.3 x 10^4 copies/mL for Ctr mice. At the end of the four doses, all Rx mice had non-detectable pVL (< 800 copies/mL) compared to Ctr mice 1.7 x 10^6 $\pm$ 7.9 x 10^5 copies/mL, ($p < 0.01$). Non-detectable viral load continued for an additional 3 weeks after the last cARV NP dose without re-dosing. All trough plasma drug levels were > 400 ng/mL for all ARV drugs.**Conclusions:** cARV NPs given SubQ demonstrate sustained release efficacy in this animal model of HIV-1.

Enhanced Exposure of Tenofovir-diphosphate (Tfv-Dp) in Peripheral Blood Mononuclear Cells (Pbmc) by Tenofovir Alafenamide (Taf) Compared with Tenofovir Disoproxil Fumarate (Tdf)

Author Block:

L. S. Ting, J. Zack, M. Yan, L. Zhong, J. Ling, L. Miles, M. S. Rhee; Gilead Sci. Inc., Foster City, CA

Abstract Body:

Background: TAF is a novel prodrug of tenofovir (TFV) that has been coformulated with emtricitabine (F) into a fixed dose combination tablet (F/TAF) as an N(t)RTI backbone. We conducted a randomized, double blind, active controlled study in virologically suppressed HIV-1 infected patients receiving F/TDF-containing regimens to evaluate the efficacy and safety of switching from F/TDF to F/TAF vs continuing F/TDF while remaining on the same third agent. Study drugs were taken without regard to food. **Methods:** Patients were randomized 1:1 to switch to F/TAF or continue F/TDF while remaining on the same third agent. Randomization was stratified by the third agent [boosted protease inhibitor (F/TAF 200/10 mg) vs unboosted agent (F/TAF 200/25 mg)]. A trough blood sample was collected after 4 weeks of treatment for determination of intracellular TFV-DP in PBMCs. TFV-DP concentrations in PBMCs between F/TAF and F/TDF groups were compared and 90% confidence intervals (CI) for the ratio of the geometric least-squares means (GMR) were calculated.**Results:** 663 patients were randomized (1:1) and treated. Through Wk 48, high virologic success (HIV-1 RNA <50 c/mL) was maintained in both treatment groups: F/TAF 94.3% (312/333) vs F/TDF 93.0% (307/330). Intracellular TFV-DP concentration was measured for 304 subjects receiving F/TAF and 265 subjects receiving F/TDF. TFV-DP concentrations in the F/TAF group were consistently higher than those of the F/TDF group regardless of the third agent. The mean (% coefficient of variation) TFV-DP concentration in PBMC was 192.37 (114.1) and 44.26 (139.0) pg/million cells in the F/TAF and F/TDF group, respectively. The GMR (90% CI) was 416.1% (362.4% to 477.8%), indicating TFV-DP concentrations were >4-fold higher in the TAF group compared with the TDF group, with a range of 1.7 to 9.5-fold higher in the TAF group among various third agents.**Conclusions:** TAF provided enhanced delivery of TFV into PBMCs, resulting in > 4-fold higher intracellular levels of TFV-DP when compared to TDF. These results are consistent with the high efficacy of F/TAF seen in the study and historic data on TFV-DP exposure in PBMC with TAF 25 mg as a single agent and that of TAF 10 mg administered as the single tablet regimen elvitegravir/cobicistat/F/TAF.

Abstract Body:

Background: Tenofovir alafenamide (TAF) is a novel prodrug of tenofovir (TFV) that has been coformulated with emtricitabine (F) into a fixed dose combination tablet (F/TAF) as an N(t)RTI backbone. We conducted a randomized, double blind, active controlled study in virologically suppressed HIV-1 infected patients receiving F/TDF-containing regimens to evaluate the efficacy and safety of switching from F/TDF to F/TAF vs continuing F/TDF while remaining on the same third agent. Study drugs were taken without regard to food. **Methods:** Patients were randomized 1:1 to switch to F/TAF or continue F/TDF while remaining on the same third agent. The TAF and TFV PK area under the curve over dosing interval (AUC_{tau}) and maximum concentration (C_{max}) were estimated via population PK analysis. The safety endpoints for PK-PD analysis were selected gastrointestinal (GI) adverse event (diarrhea, nausea, vomiting, abdominal pain, change in hip and spine bone mineral density (BMD), and change in selected lipid parameters. Subjects were grouped into quartile subgroups based on TAF and TFV exposures for evaluation of exposure-safety trends.**Results:** 663 patients were randomized and treated (F/TAF 333 vs F/TDF 330). Drug related serious adverse events were rare (0 vs 0.3%). Drug discontinuation due to adverse events (AEs) was low (2.1% vs 0.9%). In F/TAF-treated patients, TAF and TFV PK exposures were available for 292 and 328 subjects, respectively. No trends in GI AEs were observed across wide range of TAF exposures (Table). Similarly, no trends with TFV exposures were noted. The changes in BMD (hip and spine) and fasting lipids at Week 48 were comparable across TAF and TFV exposure quartiles, with no trends noted.**Conclusions:** These data demonstrate that TAF is well tolerated with no trends of safety signal across wide ranges of TAF exposures in virologically suppressed HIV-1 infected patients.**Table.Percentage of Subjects with Selected Adverse Events or Change from baseline at Week 48 by TAF AUC_{tau} Quartile Subgroup (N=73)**

Switch from Tdf Regimens to E/C/F/Taf Is Associated with Improved Bone Mineral Density, Decreased Serum Pth and Decreased Bone Turnover Biomarkers

Author Block:

E. T. Overton[1], P. Shalit[2], G. Crofoot[3], P. Benson[4], D. Murphy[5], Y-P. Liu[6], D. SenGupta[6], S. McCallister[6]; [1]The Univ. of Alabama at Birmingham Sch. of Med., Birmingham, AL, [2]Peter Shalit and Associates, Seattle, WA, [3]Gordon Crofoot MD, PA, Houston, TX, [4]Be Well Med. Ctr., Berkley, MI, [5]Clinique Med.e l'Actuel, Montreal, QC, Canada, [6]Gilead Sci., Inc., Foster City, CA

Abstract Body:

Background: HIV infection increases the risk of low bone mineral density (BMD) and fragility fracture; tenofovir disoproxil fumarate (TDF) is associated with decreased BMD. Tenofovir alafenamide (TAF) is a novel tenofovir (TFV) prodrug that reduces TFV plasma levels by 90% with less impact on BMD. We present an analysis of changes in BMD, parathyroid hormone (PTH), and serum bone turnover markers through 48 weeks in subjects switching to elvitegravir/cobicistat/emtricitabine/TAF (E/C/F/TAF) from TDF-containing regimens in Study 109. **Methods:** 1436 virologically suppressed adults on 1 of 4 TDF-containing regimens for ≥96 weeks were randomized (2:1) to E/C/F/TAF or to continue their prior regimen. Pre-specified secondary endpoints included percentage change (ANOVA) in hip and spine BMD, assessed by DEXA. Changes in serum bone biomarkers (PTH; bone procollagen type 1 N-terminal propeptide, P1NP; C-type collagen sequence, CTx) were assessed by Wilcoxon rank sum test.**Results:** Subjects switching to E/C/F/TAF had increased hip and spine BMD at 48 weeks compared to decreases in those remaining on TDF (p<0.001; Table). Median PTH decreased following switch to E/C/F/TAF, compared with increases in the TDF group. Bone turnover biomarkers decreased significantly in the E/C/F/TAF switch group. The changes in BMD and bone turnover results were consistent when stratified by pre-switch regimen, except serum CTx, for which there was no difference between the switch and the Atripla groups.**Conclusion:** Switching to E/C/F/TAF significantly improves spine and hip BMD, decreases PTH and decreases serum bone turnover biomarkers at 48 weeks. Long-term follow-up is needed to demonstrate changes in osteoporosis and fragility fracture risk.

Publishing Title:

Three-day Per Week Atripla® in Patients with Sustained Viral Suppression

Author Block:

E. Martínez[1], J. Rojas[1], J. L. Blanco[1], S. Sanchez[1], A. Marcos[1], M. Lonca[1], B. Torres[1], A. Gonzalez-Cordon[1], A. Romero[2], J. M. Gatell[1]; [1]Hosp. Clínic and Univ. of Barcelona, Barcelona, Spain, [2]Dept. of Epidemiology and Evaluation, IMIM (Hosp. del Mar Med. Res. Inst.), Barcelona, Spain

Abstract Body:

Background: Antiretroviral drugs contained in single tablet Atripla® could allow for longer than once-daily (OD) dosing. We hypothesized that simplifying Atripla® OD to 3-day per week would be able to maintain viral suppression and less toxic. **Methods:** HIV+ adults on Atripla® OD, with HIV-1 RNA <37 copies/mL ≥2 years, CD4 >350/mm^3 , and no prior virological failure or resistance mutations to study drugs were randomized to maintain their OD regimen or to reduce it to 3 days (Mondays, Wednesdays, and Fridays) a week (3W) (ClinicalTrials.gov: NCT01778413). Plasma HIV-1 RNA was measured at baseline, 12, and 24 weeks in both arms, and also at 1, 2, 4, 6, and 8 weeks in the 3W. Pittsburg Sleep Quality Index (PSQI), body mass index (BMI), bone mineral density (BMD), CD4 and CD8 cells, ultrasensitive HIV-1 RNA (1 copy/mL), plasma 25OH vitamin D and efavirenz levels, estimated flomerular filtration rate (CPK-EPI), fasting blood lipids and urinary proteins were measured at baseline and 24 weeks. **Results:** Sixty-one patients included: 89% men, HIV-1 RNA <1 copy/mL 72%, median age 48 years, BMI 24 kg/m^2, CD4 563/mm^3, CD4/CD8 1.1, PSQI score 4, lumbar T-score -1.3, femur T-score -1.3, plasma 25OH vitamin D 18 ng/mL, plasma efavirenz 2.1 mg/L, CPK-EPI 101 mL/min, total chol 194 mg/dL, HDL chol 47 mg/dL, triglycerides 99 mg/dL, and urine protein/creatinine 75 mg/g, albumin/creatinine 4 mg/g, and beta-2-microglobulin 194 μg/g. All patients completed the study. Out of 333 plasma samples for HIV-1 RNA measurement during the study, none had ≥37 copies/mL. At 24 weeks, total chol and femur T-score significantly increased, while PSQI, plasma efavirenz, albumin/creatinine and beta-2-microglobulin in urine significantly decreased in the 3W arm relative to OD arm (table). **Conclusions:** Three-day per week Atripla® in patients with sustained viral suppression is a feasible option that should be further confirmed in larger clinical trials.

Median (IQR) changes from baseline to 24 weeks			
	Atripla OD (n=31)	Atripla 3W (n=30)	P-value for the difference between arms

GS-9883, a Novel HIV-1 Integrase Strand Transfer Inhibitor (INSTI) with Optimized *In Vitro* Resistance Profile

Author Block:

G. Jones, J. Goldsmith, A. Mulato, K. White, D. Hansen, K. Stray, S. Yant, S. Lazerwith, H. Jin, T. Cihlar, M. Tsiang; Gilead Sci., Inc., Foster City, CA

Abstract Body:

Background: GS-9883 is a potent once-daily unboosted INSTI in clinical development combined with tenofovir alafenamide (TAF) and emtricitabine (FTC) for the treatment of HIV-infection.**Methods:** HIV-1 site-directed mutants with either NRTI, NNRTI, PI, or INSTI resistance mutations as well as a panel of 18 clonal and 47 patient-derived HIV-1 isolates with high-level INSTI resistance were profiled for susceptibility to GS-9883. *In vitro* resistant variants were selected with escalating doses of GS-9883, dolutegravir (DTG), and elvitegravir (EVG), and emergent HIV-1 variants were genotyped and phenotyped. *In vitro* resistance breakthrough studies using clinically relevant fixed doses of GS-9883, EVG and DTG were conducted in MT-2 cells and primary human CD4+ T-cells.**Results:** GS-9883 showed potent antiviral activity (EC_{50} = 1.7 to 3.2 nM) against wild-type virus and mutants resistant to NRTIs, NNRTIs, and PIs. A panel of HIV-1 site-directed mutants with up to 1520-fold change (FC) in susceptibilities to raltegravir (RAL) and EVG remained largely susceptible to GS-9883 (FC = 1 to 9). In addition, GS-9883 had an improved resistance profile (FC = 0.5 to 19; mean and median FC = 2.8 and 2.0, resp.) compared to DTG (FC = 0.64 to 63; mean and median FC = 5.8 and 3.4, resp.) against INSTI-resistant patient-derived isolates, particularly those with high-level INSTI-resistance. Both GS-9883 and DTG displayed a higher barrier to *in vitro* resistance emergence relative to EVG. HIV-1 variants selected *in vitro* by GS-9883 contained the known R263K and M50I integrase mutations and exhibited low level cross-resistance to RAL and DTG (FC = 3 to 8), and intermediate cross-resistance to EVG (FC = 15 to 26) but remained susceptible to other antiretroviral classes. In the viral breakthrough selection studies at clinically relevant concentrations, GS-9883 and DTG, but not EVG or RAL completely suppressed resistance breakthrough in both MT-2 and primary CD4+ T cells.**Conclusions:** GS-9883 is a novel potent INSTI with an *in vitro* resistance profile that is improved compared to RAL and EVG. In addition, GS-9883 was more potent than DTG against a number of patient-derived isolates with high-level INSTI resistance. Overall, these data support further development of GS-9883 as a novel antiretroviral agent.

Discovery of Gs-9883, an Hiv-1 Integrase Strand Transfer Inhibitor (Insti) with Improved Pharmacokinetics and *In Vitro* Resistance Profile

Author Block:

S. Lazerwith[1], R. Cai[1], X. Chen[1], G. Chin[1], M. Desai[1], S. Eng[1], R. Jacques[1], M. Li[1], G. Jones[1], H. Martin[1], C. McMahon[1], M. Mish[1], P. Morganelli[1], J. Mwangi[1], H-J. Pyun[1], G. Stepan[1], J. Szwarcberg[1], J. Tang[1], M. Tsiang[1], J. Wang[1], K. Wang[1], K. White[1], L. Wiser[2], J. Zack[1], H. Jin[1]; [1]Gilead Sci., Foster City, CA, [2]Fibrogen, San Francisco, CA

Abstract Body:

Background: Currently approved INSTI based treatments comprise 5 of 6 DHHS recommended regimens for HIV-1 infection. Limitations of early INSTIs include twice-daily dosing (RAL) and the need for a booster (EVG). DTG exhibits an improved resistance profile compared to RAL and EVG. However, due to dose-limiting exposure above 50 mg, it requires twice-daily dosing in some patients. GS-9883 is a potent, new INSTI with a longer half-life and an improved resistance profile. **Methods:** New INSTIs were synthesized and tested for a wide variety of properties including HIV potency (MT-4 and MT-2 cells), metabolic stability (microsomes), and protein binding (equilibrium dialysis). **Results:** Tetracyclic pyridones containing rigid, sterically-demanding ring systems were synthesized. These tetracycles are potent INSTIs and unexpectedly showed reduced PXR activation. Further work led to the optimization of potency, protein binding, metabolic stability, solubility and an improved resistance profile. This resulted in GS-9883, a potent INSTI (MT-4 EC_{50} = 2.4 nM) with a low potential for drug-drug interactions. GS-9883 shows a remarkable combination of both improved preclinical pharmacokinetics (rat MRT = 45.7 h) and an enhanced resistance profile compared to approved agents (2-fold less susceptible to G140S/Q148R vs. WT). An unusually strong relationship between plasma protein binding and in vivo clearance in preclinical species will be detailed, and the structure of GS-9883 will be disclosed.**Conclusions:** Due to its excellent preclinical PK and its in-vitro potency against many integrase-resistant strains, GS-9883 was selected for development, and is being tested in Phase III studies combined with F/TAF.

Novel Insti Gs-9883 10 Day Monotherapy in Hiv-1 Infected Subjects

Author Block:

J. Gallant[1], M. Thompson[2], T. Mills[3], E. DeJesus[4], G. Voskuhl[5], X. Wei[6], J. Zack[6], K. White[6], H. Martin[6], J. Szwarcberg[6]; [1]Southwest CARE Ctr., Santa Fe, NM, [2]AIDS Res. Consortium of Atlanta, Atlanta, GA, [3]Southern California Men's Med. Group, Los Angeles, CA, [4]Orlando Immunology Ctr., Orlando, FL, [5]AIDS Arms, Inc., Dallas, TX, [6]Gilead Sci., Foster City, CA

Abstract Body:

Background: Integrase strand transfer inhibitor (INSTI)-based regimens comprise 5 of the 6 DHHS recommended regimens for treatment of HIV-1. GS-9883 is a novel, unboosted INSTI with potent in-vitro activity against HIV-1. **Methods:** HIV-1-positive INSTI-naïve subjects were randomized to receive GS-9883 5, 25, 50, or 100 mg, or placebo once daily for 10 days. Primary endpoint was time-weighted average HIV-1 RNA change from baseline on day 11 ($DAVG_{11}$). Mean change in HIV-1 RNA, PK, and safety and laboratory data were analyzed. **Results:** 20 subjects received study treatment and completed the study. Most were male; median age was 29 years; median HIV-1 RNA was 4.32 $\log_{10}$ copies/mL. GS-9883 demonstrated a dose-dependent reduction in HIV-1 RNA, with increased exposures correlating with greater reductions in plasma HIV-1 RNA, up to 2.43 $\log_{10}$ copies/mL at Day 11 (Table). Response was durable through day 17 in the higher dose groups. PK/PD analysis suggested that near maximal efficacy was associated with GS-9883 exposures achieved at doses between 50 and 100 mg. No primary resistance mutations emerged. No serious adverse events (AEs) or clinically significant lab abnormalities were reported; there were no discontinuations due to AEs. **Conclusions:** Daily dosing of GS-9883 for 10 days at 5, 25, 50 and 100 mg was well tolerated and resulted in rapid, dose-dependent decreases in HIV-1 RNA of > 2 log at the higher doses. Based on PK/PD analyses, exposures associated with 75 mg dose of single agent GS-9883 would provide near-maximal virologic response, with a predicted $_{pa}IQ_{95}^{a}$ for wild type HIV of ~20.

	GS-9883 5 mg (n=3)	GS-9883 25 mg (n=4)	GS-9883 50 mg (n=4)	GS-9883 100 mg (n=4)
Δ HIV-1 RNA Day 11 from baseline (log10 copies/mL) Mean (SD)	-1.45 (0.097)	-2.08 (0.209)	-2.06 (0.345)	-2.43 (0.386)

Antiviral Activity of GS-9883, a Potent Next Generation HIV-1 Integrase Strand Transfer Inhibitor

Author Block:

M. Tsiang, E. Kan, L. Tsai, G. Jones, R. Phadke, G. Stepan, N. Novikov, S. Eng, G. Lee, R. Gong, E. Aguayo, S. Ahmadyar, Y. Xu, A. Niedziela-Majka, S. Yant, H. Yu, C. Voitenleitner, G. Birkus, M. Perron, J. Feng, S. Lazerwith, H. Jin, T. Cihlar; Gilead Sci., Inc., Foster City, CA

Abstract Body:

Background: GS-9883 is a potent once-daily unboosted integrase strand transfer inhibitor currently in clinical development in combination with tenofovir alafenamide (TAF) and emtricitabine (FTC) for the treatment of HIV-1 infection.**Methods:** The inhibitory activity of GS-9883 was tested against wild-type HIV-1 integrase enzyme. Antiviral potency and cytotoxicity were assessed in MT-2 and MT-4 T-cell lines and primary human CD4+ T-cells and macrophages. Inhibition of integration was assessed by qPCR of 2-LTR circles and integration junctions. A panel of 14 HIV-1 and one HIV-2 clinical isolates was used for antiviral profiling. Antiviral activity of GS-9883 was also tested against several non-HIV viruses. Cytotoxicity of GS-9883 was also tested in four non-target cell lines (Huh-7, HepG2, PC-3, MRC-5) and human primary hepatocytes. Antiviral activity of GS-9883 in pairwise combination with antiretrovirals was also assessed.**Results:** GS-9883 inhibited HIV-1 integrase enzyme strand transfer activity (IC_{50} = 7.5 ± 0.3 nM). Treatment with GS-9883 increased abortive 2-LTR circles and decreased viral-host DNA integration junctions in infected cells. GS-9883 exhibited high potency and selectivity in HIV-1 assays using lymphoblastoid T-cell lines, primary human CD4+T cells, and macrophages with EC_{50} range of 1.5 to 6.6 nM and selectivity indices of 1500 to 8700. GS-9883 was highly potent against all tested HIV-1 subtypes and HIV-2 in human PBMCs (mean EC_{50} = 0.81 nM range of <0.05 to 1.71 nM), and showed no activity against HBV, HCV, Influenza, HRV or RSV. GS-9883 had low cytotoxicity in multiple human cell lines (CC_{50} range from 35 to >44 μM) and in primary human hepatocytes (CC_{50} >100 μM). Highly synergistic *in vitro* antiviral effect was observed for combinations of GS-9883 with TAF, FTC or darunavir.**Conclusions:** GS-9883 is a novel, potent and selective HIV integrase strand transfer inhibitor. GS-9883 was highly synergistic in combinations with TAF, FTC or darunavir. These data support the clinical investigation of GS-9883 for the treatment of HIV-1 infection.

Appropriateness of Nrti Dosing During Cvvh at a Large Academic, Medical Center

Author Block:

M. M. McLaughlin[1], I. Masic[1], L. Gerzenshtein[2]; [1]Midwestern Univ., Downers Grove, IL, [2]Northwestern Med. Specialty Pharmacy, Chicago, IL

Abstract Body:

Background: HIV-infected patients may experience renal complications due to the aging process, co-morbid conditions, HIV infection itself, antiretroviral therapy, or a combination of all these factors and require renal replacement therapy. Nucleoside reverse transcriptase inhibitors (NRTIs) must be appropriately dose adjusted for continuous veno-venous hemofiltration (CVVH), due to renal elimination, as higher doses may lead to toxicity and lower doses may lead to decreased drug efficacy. This study sought to determine the percentage of patients that received appropriate doses of NRTIs during CVVH. **Methods:** Patients were considered for inclusion if they were >18 years old, HIV-infected, received an NRTI with concurrent CVVH therapy, and hospitalized from 9/1/2010 through 9/30/2013 at Northwestern Memorial Hospital. Patient demographic information, CVVH characteristics, hospital length of stay, NRTIs, dose of NRTIs, and NRTI dose adjustments were collected. A peer-reviewed dosing table based on pharmacokinetic mathematical calculations was used to determine the percentage of patients that received the appropriate NRTI dose during CVVH. **Results:** A total of 12 patients were included in this study. The median age was 51 years (interquartile range (IQR) 45-52), 11 (92%) patients were male, and 5 (42%) were Caucasian. The median CD4 count and HIV viral load were 174 cells/mm^3 (IQR 87-338) and 44 (IQR 20-48) IU/mL, respectively. Kidney injury (n=2), kidney failure (n=4), and oliguria (n=6) were the indications for CVVH. The median length of CVVH was 6 days (IQR 3-9.25) and median hospital stay was 27 days (IQR 19-31). The 12 patients were on a total of 27 NRTIs (abacavir n=2; emtricitabine n=6; lamivudine n=7; tenofovir n=10; zidovudine n=2). During CVVH therapy 10 (83%) patients had at least one NRTI dose adjustment. Overall, 11 (41%) of NRTIs were dosed correctly. Of the 16 incorrect dosing regimens, 9 (56%) doses were too high and 7 (44%) doses were too low. **Conclusion:** Over half of NRTI doses received during CVVH were incorrect based on pharmacokinetic mathematical calculations. Interventions are needed to alert ID specialists when a patient receiving NRTIs is started on CVVH to aid with appropriate dosing. Future studies with pharmacokinetic sampling are needed to further clarify appropriate dosing of NRTIs during CVVH.

An Improved Circular Consensus Algorithm to Detect Hiv-1 Drug-Resistance Associated Mutations (Drams)

Author Block:

M. L. Smith, M. P. S. Brown, N. Delany, N. L. Hepler, D. Alexander, E. E. Paxinos; PacBio, Menlo Park, CA

Abstract Body:

Scientists who require confident resolution of heterogeneous populations across complex regions have been unable to transition to short-read sequencing methods. They continue to depend on Sanger sequencing despite its cost and time inefficiencies. Here we present a new redesigned algorithm that allows the generation of circular consensus sequences (CCS) from individual SMRT® Sequencing reads. With this new algorithm, dubbed CCS2, it is possible to reach high quality across longer insert lengths at a lower cost and higher throughput than Sanger sequencing. We applied CCS2 to the characterization of the HIV-1 K103N drug-resistance associated mutation in both clonal and patient samples. This particular DRAM has previously proved to be clinically relevant, but challenging to characterize due to regional sequence context.First, a mutation was introduced into the 3rd position of amino acid position 103 (A>C substitution) of the RT gene on a pNL4-3 backbone by site-directed mutagenesis. Regions spanning ~1.3 kb were PCR amplified from both the non-mutated and mutant (K103N) plasmids, and were sequenced individually and as a 50:50 mixture. Additionally, the proviral reservoir of a subject with known dates of virologic failure of an Efavirenz-based regimen and with documented emergence of drug resistant (K103N) viremia was sequenced at several time points as a proof-of-concept study to determine the kinetics of retention and decay of K103N.Sequencing data were analyzed using the new CCS2 algorithm, which uses a fully-generative probabilistic model of our SMRT Sequencing process to polish consensus sequences to high accuracy. With CCS2, we are able to achieve a per-read empirical quality of QV30 (99.9% accuracy) at 19X coverage. A total of ~5000 1.3 kb consensus sequences with a collective empirical quality of ~QV40 (99.99%) were obtained for each sample. We demonstrate a 0% miscall rate in both unmixed control samples, and estimate a 48:52 frequency for the K103N mutation in the mixed (50:50) plasmid sample, consistent with data produced by orthogonal platforms. Additionally, the K103N escape variant was only detected in proviral samples from time points subsequent (19%) to the emergence of drug resistant viremia. This tool might be used to monitor the HIV reservoir for stable evolutionary changes throughout infection.

Renal and Bone Safety with Tenofovir Disoproxil Fumarate-Containing Single Tablet Regimens

Author Block:

E. T. Nkhoma[1], L. Rosenblatt[2], J. Myers[2], A. Villasis-Keever[2], J. Coumbis[3]; [1]Bristol-Myers Squibb, Wallingford, CT, [2]Bristol-Myers Squibb, Plainsboro, NJ, [3]Bristol-Myers Squibb, Hopewell, NJ

Abstract Body:

Objective: To estimate real-world incidence rates (IRs) of renal and bone adverse events (AEs) among patients on tenofovir disoproxil fumarate (TDF)-containing single tablet regimens (STRs). **Methods:** From U.S. health insurance data spanning 2008-2014, we identified HIV-infected patients age ≥18 years and those with ≥6 months of continuous enrolment prior to initiating efavirenz/emtricitabine/TDF (EFV/FTC/TDF), rilpivirine/FTC/TDF (RPV/FTC/TDF) or elvitegravir/cobicistat/FTC/TDF (EVG/c/FTC/TDF). We captured renal events using all renal ICD-9-CM diagnosis codes but excluding nephrolithiasis and infections. We captured bone events in one of two ways: 1) using fracture ICD-9-CM diagnosis codes; and 2) using fracture diagnosis codes or fills for bone-related medications. IRs and associated 95% confidence intervals (CIs) were estimated assuming a Poisson distribution and outcomes between STRs were compared using IR ratios (IRRs) and IR differences (IRDs). **Results;** Observed IRs for renal AEs and fracture varied by STR (Table). The IR for renal events with EFV/FTC/TDF was significantly lower than with EVG/c/FTC/TDF (IRD −3.96; 95% CI: −7.31, −1.06). The IR for fracture with EFV/FTC/TDF was significantly lower than with RPV/FTC/TDF (IRD −1.95; 95% CI: −2.66, −1.31) or than with EVG/c/FTC/TDF (IRD −1.95; 95% CI: −2.89, −1.13). There were no STR differences for the second bone outcome. IRRs showed no differences in any analysis. **Conclusion:** In this large real-world database, observed IRs for renal adverse outcomes and fracture with TDF-containing STRs were lower or similar to those for all HIV patients, with the lowest IRs observed among patients on EFV/FTC/TDF.

Ampofo[5]; [1]Sch. of BioMed. & Allied Hlth.Sci.,Univ. of Ghana, Accra, Ghana, [2]Univ. of Biology and Variability of HIV, Inst. de Salud Carlos III,, Madrid, Spain, [3]Sch. of Med. and Dentistry,Coll. of Hlth.Sci.,Univ. of Ghana,, Accra, Ghana, [4]Sch. of BioMed. & Allied Hlth.Sci.,Univ. of Ghana, Korle Bu, Accra, Ghana, [5]Noguchi Mem. Inst. for Med. Res.,Coll. of Hlth.Sci., Univ. of Ghana, Legon, Accra, Ghana

Abstract Body:

Antiretroviral therapy (ART) has been available in Ghana since 2003 for HIV-1 positive pregnant women for prevention of mother-to-child transmission (PMTCT) of HIV.For such mothers with a history of prophylaxis for PMTCT, suboptimal responses encountered made it imperative to investigate the pattern of viral mutations generated since it could adversely affect the treatment response.This study investigated HIV-1 drug resistance profiles in women in the PMTCT programme in selected centres in Ghana who were on treatment after a previous exposure to prophylaxis.Genotypic Drug Resistance Testing for HIV-1 was carried out. Subtyping was done by phylogenetic analysis.Participants who had prophylaxis before ART, those who had ART without prophylaxis and those yet to initiate PMTCT showed 32% (8), 5% (3) and 15% (4) HIV-1 drug resistance associated mutations respectively. Thirty-five percent (35%) had resistance associated mutations (RAMs) to nucleoside reverse transcriptase inhibitors (NRTIs) and non-nucleoside reverse transcriptase inhibitors (NNRTIs) and 1 (3%) had RAMs to the Protease Inhibitors. The most common NRTI mutation found was M184V; K103N and A98G were the most common NNRTI mutations seen. Thymidine Analogue Mutations (TAMs) such as M41L, D67N, K70R, L210W, T215Y/F and K219E were found in all the groups; the most common of the TAMs found was M41L and T215Y. I84V, a major resistance mutation to Protease Inhibitors (PIs), was seen. For the Reverse Transcriptase gene, 33(82%) of samples were of subtypes CRF02_AG, 2(5%) were subtype CRF01_AE, 1(3%) was subtype A, 2 (5%) were subtype B and 2 (5%) were subtype G. With the Protease gene, 32 samples (97%) were subtype CRF02_AG and 1(3%) was subtype A.The study established that in Ghana initiation of uninterrupted treatment upon diagnosis coupled with drug resistance testing would help to produce a better treatment outcome for Ghanaian HIV-1 positive mothers and pregnant women.

Correlation of Residual Viremia on Clinical Outcomes and Lipodystrophy Markers in the Kreta Study

Author Block:

J. E. McKinnon[1], J. I. Bernardino[2], J. Y. Zhou[1], F. Pulido[3], R. Delgado Vasquez[3], D. Lucic[4], J. R. Arribas[2]; [1]Henry Ford Hosp., Detroit, MI, [2]Hosp. La Paz. IdiPAZ, Madrid, Spain, [3]Hosp. Univ.rio 12 de Octubre, i+12, Madrid, Spain, [4]Abbott Molecular, Des Plaines, IL

Abstract Body:

Background: The KRETA trial enrolled lipoatrophic (LD) patients on triple nucleoside therapy who were randomized to lopinavir/ritonavir alone (MT) or to LPV/r plus abacavir/lamivudine (TT), to determine the impact of the regimens on LD. We examined the correlations between the randomized regimens and HIV residual viremia (RV) and between RV and LD markers. **Methods:** For RV quantification, we used two modified assays of the Abbot RealTime HIV assay (MA). The ultracentrifugation MA (UMA) assay spins at 170,000xg for 30 minutes to separate the viral pellet. The tabletop centrifugation (TMA) assay uses a new extraction protocol for the *m*2000sp to allow use of 3mL volumes, and a 2 hour 21,000xg centrifugation of the sample. TMA allows for handling of highly lipemic samples. Study plasma samples and data were obtained. Only patients with 4 or more 3mL plasma samples available were analyzed.**Results:** 71 patients were tested using the MA assays. RV was detected in 51 patients and 20 had undetectable samples by MA assays, with only 2 having any detectable clinical viremia (VL) during the study. RV correlated with VL ($p<0.00$), RV and median RV correlated with VL> 50c/ml ($p=0.001$, $p<0.00$). The MT arm trended to have detectable RV a median of 5.5 weeks prior to VL> 50 c/mL, more frequently detectable RV ($p=0.059$), more patients with a VL> 50c/mL ($p=0.014$), and higher RV level ($p=0.001$) than TT patients. In suppressed patients, RV levels were similar across study arms ($p=0.184$). RV detection was not impacted by age, CD4 counts, BMI, HCV status, number of prior ART regimens or duration of HIV diagnosis. Baseline and changes in Fat-Mass ratio (FMR), truncal fat and other LD markers, were not correlated with RV levels. Women had higher FMR levels than men ($p=0.021$) but gender did not impact by RV levels ($p=0.71$).**Conclusions:** RV detection using the modified Abbott assays correlated well with clinical HIV RNA levels and VL> 50 c/mL. RV detection was more prevalent and higher in patients on MT than TT regimens, but suppressed patients had similar levels. RV levels were not impacted by baseline clinical characteristics or LD markers and did not correlate with changes in LD measurements during the study.

Biofilm Formation by *Candida tropicalis* and Efficacy of Liposomal Amphotericin B for Prevention of Biofilm Development

Author Block:

Y. Yamagishi, A. Kawai, H. Mikamo; Aichi Med. Univ., Aichi, Japan

Abstract Body:

Background: There are an increasing number of cases of infection with non-*albicans Candida*. One of the major non-*albicans* fungi, *Candida tropicalis*, is likely to form biofilms, which cause a poor prognosis. This study was conducted to examine the process of biofilm formation by *C. tropicalis* and the antifungal activity of liposomal amphotericin B (LAB) against biofilm-forming strains, using time-lapse imaging. **Methods:** *C. tropicalis* was inoculated on a silicone tube and media were incubated during perfusion to reproduce biofilm formation in a catheter in clinical practice, with shaking for 90 min to promote adherence of fungi. The silicone tube was incubated at 37°C with perfusion of 5% serum with Sabouraud glucose agar and imaged by time-lapse photography. Biofilm formation was confirmed by observation of a fungi mass on the silicone tube and fluorescent staining with Fin-1 and concanavalin A.**Results:** After 14 h, *C. tropicalis* grew with gas generation, probably because of the high rate of biofilm formation and metabolic activity. After 17 h, the whole tube was covered with thick biofilms of *C. tropicalis*. LAB caused marked degeneration of *C. tropicalis* before biofilm formation and inhibited expansion of mycelia, resulting in blocking of biofilm formation. At 6 h after addition of LAB, the antifungal activity of LAB had reduced the fungi level to below that of the untreated control.**Conclusions:** This is the first study to examine the *in vitro* activity of LAB against *C. tropicalis* biofilms. The results suggest that LAB may be effective for treatment of infections caused by catheter-related non-*albicans* biofilms. This finding requires confirmation in studies including a large number of *C. tropicalis* strains.

Enhanced Activity of Carbon Nanotubes-Amphotericin B Conjugates Against Mature Biofilms of *Candida albicans*

Author Block:

Z. D. Pana[1], M. Simitsopoulou[1], R. Papi[2], C. Antachopoulos[1], D. Kyriakidis[2], E. Roilides[1]; [1]3rd Dept Pediatrics, Aristotle Univ., Thessaloniki, Greece, [2]Dept of Chemistry, Aristotle Univ., Thessaloniki, Greece

Abstract Body:

Background: Amphotericin B (AmB) is commonly used against *Candida* biofilms; however, its application is limited by its toxicity and poor solubility. *Candida* biofilms are resistant to traditional antifungal treatment therefore the need for alternative and new therapeutic approach is urgent. Multiwall carbon-nanotubes (MWNTs) are novel nanomaterials with unique physical properties that can be used to deliver therapeutic agents to the targeted site of the pathogen. Our aim was to evaluate the antifungal activity of AmB conjugated to MWNTs against *Candida albicans* mature BF vs. that by AmB alone. **Methods:** MWNTs were functionalized with poly-ethylene-glycol (PEG) and then chemically linked to AmB by sonication. The stability behavior of the MWNTs-amphotericin B conjugates was evaluated with the zeta potential. Stocks of two BF-producing *C. albicans* strains were grown in YNB medium. For mature-BF formation, 10^6 blastoconidia/mL were added to 96-well plates and incubated at 37oC for 48h. BFs were treated with AmB-PEG-CNTs or AmB at concentrations from 0.007 to 16mg/L for 24 hours. PEG-CNTs, non-functionalized CNTs, were used as controls. Percent BF damage (%BD) was assessed by XTT assay. MICs of BF were determined as the minimum antifungal concentration that caused ≥50% BF damage compared to untreated BF. **Results:** The conjugate efficiency of AmB-MWNTs was 90%, while the zeta potential (a measure of stability behaviour) was -36.1mV. At concentrations of 16mg/L, PEG-MWNTs and pure MWNTs showed minimal antifungal activity against BF of both *Candid*a strains (10.7% and 11.5% respectively), while AmB (99.1%) and AmB-PEG-MWNTs (100%) displayed high antibiofilm activity. The antibiofilm activity of AmB and AmB-PEG-MWNTs was comparable for the concentrations between 4-16mg/L, whereas in lower concentrations (<4 mg/L), AmB-PEG-MWNTs presented significantly stronger activity ($p<0.001$). The MIC50 of pure AmB was 0.25 mg/L, while the MIC50 of the AmB-PEG-MWNTs was 0.007 mg/L, respectively ($p<0.001$). **Conclusions:** AmB-PEG-MWNTs were found to inhibit BF formation to a considerable extent compared to AmB, indicating that nano-formulation of AmB might be a promising treatment for invasive candidiasis.

Effective Treatment Of Azole Resistant *candida albicans* in A Murine Ascending Urinary Tract Infection With Liposomal Amphotericin B Delivered By Bladder Lavage

Author Block:

C. Frazier, J. Olson, J. Adler-Moore; Cal Poly Univ., Pomona, CA

Abstract Body:

Background: With the frequent occurrence of urinary tract infections (UTI) in hospital ICUs and assisted-living settings, and the increasing incidence of UTI caused by azole resistant Candida spp., alternative treatments are needed. This study was done to investigate the efficacy of liposomal amphotericin B (L-AmBi) for UTI when it is caused by an azole resistant strain of *Candida albicans*. **Methods:** Mice (n=10/group) were immunosuppressed with 6mg/kg Triamcinolone d-3 and d0, sedated with ketamine/xylazine d0 and challenged transurethrally with 4.7 X 10ex6 azole resistant *C. albicans* (ATCC 62342, L-AmBI MIC = 0.78ug/mL, Fluconazole MIC = 25ug/mL) followed by daily treatment d+1 to d+5 with 7.5mg/kg L-AmBi (AmBisome) given IV, or with 0.2mg L-AmBi by bladder lavage (BLav). Controls received 5% dextrose (D5W) IV or BLav. Kidneys (Kd), bladders (Bd), livers (Lr) and spleen (Sp) were collected d+6, homogenized, and dilutions plated for mean Log_{10}CFU/g (CFU) and mean drug levels of Kd and Bd determined by an agar diffusion bioassay.**Results:** Candida was reduced to undetectable levels in the Bd with L-AmBi IV (10/10 mice) or BLav (9/10 mice) compared to high CFU in Bd of D5W mice (4.04 IV and 3.56 BLav). In Kd, L-AmBi given by IV or BLav significantly reduced the yeast burden versus controls ($p \leq 0.0079$, IV-4.56 vs 5.43; BLav-4.79 vs 5.98). There was no infection in the control livers or spleens. L-AmBi Kd drug levels were 252ug/mL IV and 24ug/mL BLav. L-AmBi Bd drug levels were 41ug/mL IV and 21ug/mL BLav.**Conclusions:** L-AmBi was significantly effective against azole resistant *C. albicans* UTI whether given as IV or bladder lavage with inhibitory drug levels in the kidneys and bladders. With the markedly decreased toxicity of L-AmBi compared to amphotericin B deoxycholate, L-AmBi is a promising alternative polyene treatment for azole resistant *C. albicans* UTI.

Selective Photoinactivation of Histoplasma Capsulatum

Author Block:

W. Melo[1], L. Regasini[2], M. Giannini[1], A. Fusco[1]; [1]Univ.e Estadual Paulista, Araraquara, Brazil, [2]Univ.e Estadual Paulista, São Jose do Rio Preto, Brazil

Abstract Body:

Histoplasmosis is a fungal infection caused by the dimorphic fungus *Histoplasma capsulatum.* This disease is considered a endemic mycosis that may present asymptomatic infections and disseminated severe form depending of patient immunity. Histoplasmosis treatment can be performed with itraconazole and fluconazole, and in the disseminated forms with amphotericin B. However, it is well-known that amphotericin B presents a high toxicity that may cause, especially, nephrotoxicity and hepatotoxicity. In addition, the development of azole-resistant histoplasmosis has been observed in patients. So, it became necessary new procedures to treat histoplasmosis, and antimicrobial photodynamic therapy (aPDT) seems to be a potential candidate. aPDT involves the synergistic combination of a photosensitizer (PS), molecular oxygen and visible light of appropriate wavelength in order to produce highly reactive oxygen species which lead to the oxidation of several cell components and to cell inactivation. In this study we have investigated a selective photoinactivation of *H. capsulatum* using chalcone water-soluble derivatives as PS. Yeast and cells (NOK, HaCat and MRC-5) were incubated with the same chalcone derivatives concentrations (0.25 - 62.5 μg mL^{-1}) and incubation time (15 and 30 minutes) followed by irradiation with doses of light (12 and 24 J cm^{-2}). The best conditions to kill *H. capsulatum* selectively were 1.95 μg mL^{-1} of PS concentration incubated by 15 min and irradiated with blue LED (450 nm) with 24 J cm^{-2}. This condition promoted a reduction of 95% in the *H. capsulatum* survival without affecting significantly the cells that present a survival index around 95% for NOK, HaCat and MRC-5. It can be concluded that chalcone derivatives have good potential for aPDT application against *H. capsulatum*.**Financial support:** FAPESP and CAPES

Absent *In Vitro* Interaction between Chloroquine and Antifungals Against *Aspergillus fumigatus*

Author Block:

S. Seyedmousavi[1], H. van der Lee[2], P. Verweij[2], A. Warris[3]; [1]Erasmus Univ. Med. Ctr., Rotterdam, Netherlands, [2]Radboud Univ. Med. Ctr., Nijmegen, Netherlands, [3]Univ. of Aberdeen, Aberdeen, United Kingdom

Abstract Body:

Background: The efficacy of voriconazole, the recommended first choice drug to treat infections caused by *Aspergillus fumigatus*, might be hampered by the emergence of azole resistance. Therefore, it is important to explore alternative treatment strategies. The antimalarial drug chloroquine in combination with antifungals has shown to have a direct antifungal effect on both azole-susceptible and azole-resistant *Candida albicans* isolates. We therefore investigated whether chloroquine potentiate synergistic activity in combination with antifungals for the treatment of *Aspergillus fumigatus*. **Methods:** The *in vitro* interaction between chloroquine and voriconazole or amphotericin B or caspofungin was determined against voriconazole-susceptible and voriconazole-resistant clinical *A. fumigatus* isolates using a checkerboard microdilution method with spectrophotometric analysis and a viability-based XTT {2,3-bis(2-methoxy-4-nitro-5-sulfophenyl)-5-[(phenylamino) carbonyl]-2H-tetrazolium hydroxide} assay within 2 h of exposure after 24 and 48 h of incubation at 35°C to 37°C. **Results:** Our studies showed that presence of chloroquine had no growth-inhibitory antifungal activities against clinical *A. fumigatus* isolates, either voriconazole-susceptible or resistant. In addition, no obvious interactions were found *in vitro* for all the combinations tested. **Conclusions:** In conclusion, chloroquine, alone or in combination with different classes of antifungal agents, did not show any *in vitro* inhibitory antifungal activity against *A. fumigatus*. Our previous observation that chloroquine increases the antifungal activity of neutrophils may however suggests that chloroquine exerts different effects in vivo and its role in the treatment of *Aspergillus* infections remains to be further assessed.

Antifungal Activities and Mode of Action of Amphiphilic Tobramycin Analogues and Their Synergistic Interactions with Azoles Against *Candida albicans*

Author Block:

S. Shrestha; Univ. of Kentucky, Lexington, KY

Abstract Body:

Background: Invasive fungal infections, such as candidiasis, have become a major cause of morbidity and mortality, especially among immunocompromised patients worldwide. Azoles are widely used antifungals to treat these infections in humans. But the increasing frequency of cross-resistance against azoles requires improved therapeutic strategies. Previously, it was shown that amphiphilic tobramycin analogues with the linear alkyl chain of **C_4-C_{14}** exhibited chain-length dependent antibacterial activities but their antifungal profile is unexplored. Besides, combination therapy has become popular in clinical practice as a potential strategy to fight resistant fungal isolates. The aim of this study was to investigate the antifungal properties and mechanism of action of novel amphiphilic tobramycin analogues and their synergistic interactions with four azoles against *C. albicans*. **Methods:** The MICs of TOB analogues against yeast cells were determined as described in CLSI document M27-A3. The fungal membrane-disruptive action of these analogues was studied by using the membrane-impermeable dye propidium iodide. Checkerboard assays were used to assess synergistic, indifferent and antagonistic effects, with **C_{12}** and **C_{14}** used in combination with four azoles by calculating fractional inhibitory concentration indices. Time kill curve assays were performed by colony counting at different time points.**Results:** **C_{12}** and **C_{14}** showed broad-spectrum antifungal activities against yeast and filamentous fungi. with the MIC values ranged from 1.95 to 31.2 μg/mL and 1.95 to 7.8 μg/mL, respectively. Our data suggests that the fungicidal mechanism of action of **C_{12}** and **C_{14}** appears to involve the perturbation of fungal membranes. Strikingly, majority of *C. albicans* strains were synergistically inhibited by **C_{12}** and **C_{14}** when combined with all four azoles (FLC, ITC, POS and VOR) except in few cases. Finally, synergism between **C_{12}** / **C_{14}** and POS were confirmed by time-kill assay.**Conclusions:** In conclusion, **C_{12}** and **C_{14}** showed broad-spectrum antifungal activities against yeasts and filamentous fungi that appear to target fungal plasma membrane. They also showed potent antifungal synergism with azoles which suggest the possibility of combining **C_{12}** or **C_{14}** with azoles to treat invasive fungal infections at lower administration doses or with a higher efficiency.

Screening of Lake Actinomycetes for the Production of Antifungal and Antialgal Compounds

Author Block:

S. Aslam, I. Sajid; Univ. of the Punjab, Lahore, Pakistan, Lahore, Pakistan

Abstract Body:

Background: Although chemical synthesis and engineered synthetic compounds are accelerated in the production process, nature still has an edge for its versatile pharmaceuticals especially from the wetland sediments. The lake sediments for isolating actinobacteria have not been extensively investigated although its ubiquitous presence and diversity remains inexhaustible than its terrestrial counterparts. The present study was designed to screen the lake actinomycetes for the production of antifungal and antialgal compounds.**Methods:** A total of forty strains of actinomycetes were isolated from the water and sediment samples of a saline Kallar Kahar lake of Pakistan. The identified strains were cultivated on small scale as shaking cultures and crude extracts were obtained by ethyl acetate extraction. These crude extracts were screened against *Candida albicans, Candida tropicalis, Chlorella vulgaris* by agar well diffusion method. In chemical screening the crude extracts were analyzed by TLC and HPLC-UV analysis.**Results:** The results revealed that majority of the isolated strains (90%) belong to the genus *Streptomyces* and some of the strains were of *Micromonospora*. Many lake actinomycete isolates showing remarkable antifungal and antialgal activity. However the strains $KL_3$6, KL_{11}7, $KL_3$7, KL_{10}3, $KL_5$1, $KL_7$1, $KL_8$3 and $KL_9$1 exhibited appreciable zones of inhibition of 15mm, 16mm, 17mm, 18mm, 21mm, 23mm, 23mm, 23mm respectively against *Candida tropicalis* while the isolates $KL_2$3, $KL_1$4, $KL_2$12, $KL_7$1, $KL_9$1, KL_{11}2, KL_{11}7, $KL_5$1, $KL_2$9, KL_{10}3 and $KL_3$6 exhibited maximum activity against *Candida albicans*. Approximately 80% of the isolated strains were observed to exhibit the potential antialgal activity against *Chlorella vulgaris*. Among the isolated strains $KL_3$6, $KL_3$7, $KL_4$1, $KL_5$9, $KL_5$2, KL_{11}6 and $KL_9$8 showed maximum zone of inhibition of 16mm, 18mm, 17mm, 19mm, 21mm, 17mm, 15mm respectively. On the other hand, $KL_8$4, $KL_9$4, $KL_4$3, $KL_5$1 and $KL_3$8 gave no zone of inhibition against *Chlorella vulgaris*. In thin layer chromatographic analysis and HPLC-UV analysis, crude extracts of the isolates also showed an impressive chemical diversity of lake actinomycetes.**Conclusions:** Lake actinomycetes are a potential source of antifungal and antialgal compounds which can be exploited for further purification of unique secondary metabolites in drug discovery.

Antifungal Effect of Soxhlet Extract of *Thymus vulgaris* Leaves on Fungal Isolates from Barbering Equipment

Author Block:

L. C. CHIDI-ONUORAH, C. A. OYEKA; NNAMDI AZIKIWE Univ., AWKA, Nigeria

Abstract Body:

Background: With the aim of ascertaining the efficacy of some plants known to have antifungal properties on fungal organisms and developing new antimicrobial agents, this study was carried out and involved twenty (20) barbershops.**Methods:**Two hundred (200) samples were collected from barbering equipment pre and post sterilization. The equipment included electric clippers, brushes, combs and scissors. The work tops were also sampled. Samples were inoculated onto Sabouraud Dextrose Agar (Micromaster Thane, Maharashta, India) incorporated with 0.5mg/ml of chloramphenicol and incubated at room temperature for 5 - 7days. Subcultures were carried out to purify the isolate. Isolates were identified microscopically and macroscopically. Soxhlet and crude extracts of *Moringa oleifera* seeds and leaves, peels of *Citrus sinensis* (orange) and *C. limon* (lemon) and leaves of *Thymus vulgaris* (thyme) were obtained and the mean zone of inhibition of the isolates to extracts determined at 500mg/ml. The mean minimum inhibitory concentration (MIC) and minimum fungicidal concentration (MFC) values of the effective extracts were also determined.**Results:**A total of one hundred (100) fungal isolates belonging to six (6) genera were recovered. These included *Trichophyton schoenleinii* (20), *Microsporum ferrugineum* (14), *Aspergillus nidulans* (8), *Scedosporium apiospermum* (4), *Rhizopus microsporus* (6), *A. glaucus* (6), *M. nanum* (15), *A. niger* (12), *A. versicolor* (10), *C. albicans* (5). All extracts with the exception of orange peel Soxhlet (OPS), thyme Soxhlet (TS) and thyme crude (TC) extracts were ineffective on the isolates. The MIC and MFC values ranged from 62.5 to 500mg/ml and 250 to >500mg/ml respectively.The antifungal effect of the extracts to the isolates was significantly different ($p < 0.05$). Maximum mean zone of inhibition of 38mm was shown by TS which also had the highest effectiveness of 52%.**Conclusion:**Soxhlet extract of leaves of *Thymus vulgaris* has shown to be a good antifungal agent as it had the highest effectiveness on the isolates.**Key words: *Thymus vulgaris*, antifungal, barbering equipment**

Revealing Molecular Mechanisms of Fluconazole (Flc) Resistance in *Candida tropicalis* (Ct) Through Whole Genome Sequencing (Wgs) and Rna-Seq

Author Block:

J. M. Rybak[1], C. M. Dickens[2], P. D. Rogers[1]; [1]Univ. of Tennessee, Memphis, TN, [2]Univ. of Texas A & M, College Station, TX

Abstract Body:

Background: *Candida* spp. are the most common cause of invasive fungal infections in North America and remain associated with mortality rates as high as 40%. Rising rates of resistance to FLC, the most commonly utilized antifungal, remains of clear concern. While much is known about the molecular mechanisms contributing to FLC resistance in *Candida albicans* (Ca), relatively little is known with regards to *Candida tropicalis* (Ct), where rates of FLC resistance are higher. We utilized WGS and RNA-seq to identify novel mutations and altered gene expression in genes related to fluconazole susceptibility.**Methods:** 13 clinical isolates of Ct with reduced susceptibility to FLC (MIC≥1mg/L) and 5 susceptible control clinical isolates were obtained from the University of Iowa repository. FLC MICs for each isolate were determined using Clinical Laboratory and Standards Institute methodology. RNA and genomic DNA were isolated from cultures of each isolate in mid-log growth phase. WGS and RNA-seq was performed using the Ion Proton System and aligned to the Ct MYA-3404 reference genome. RNA-seq analysis was performed using edgeR, and gene expression was compared to a composite of the 5 control isolates.**Results:** MIC ranged from 0.5 to ≥256mg/L. 12 isolates were observed to be FLC resistant (MIC 8 to ≥256mg/L). WGS revealed numerous novel mutations in several ergosterol biosynthetic genes including *ERG3* and *ERG11*, as well as transcription factor genes *UPC2, TAC1*, and *MRR1*. RNA-seq results were consistent with increased transcription factor activity in Ct isolates with potential gain- of- function mutations in *UPC2, TAC1*, and *MRR1*. Overexpression of genes associated with reduced FLC susceptibility in Ca, *ERG11* (>3 fold), *CDR1* (≥10 fold), and *MDR1* (20 fold) was observed in FLC resistant Ct isolates. Overexpression (>10 fold) of the efflux pump genes *SNQ2* and *CDR11*, not previously reported in Ca, was also observed in FLC resistant isolates.**Conclusions:** These data reveal potential molecular mechanisms of FLC resistance in Ct which parallel mechanisms previously identified in Ca. Additional mechanisms of resistance such as greatly increased expression of the efflux pump genes *SNQ2* and *CDR11* were also identified. Further research is needed to definitively identify mechanisms of FLC resistance among Ct.

Metal Chelation as a Powerful Strategy to Probe Cellular Circuitry Governing *C. albicans* Drug Resistance and Morphogenesis

Author Block:

E. J. Polvi, L. E. Cowen; Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Fungal pathogens have evolved diverse strategies to sense host relevant cues and coordinate cellular responses, which enable virulence and drug resistance. Defining circuitry controlling drug resistance and virulence opens new opportunities for chemical diversity in therapeutic drugs, as the cognate inhibitors are not typically explored by conventional screening approaches. This has great potential to address the pressing need for new strategies to treat invasive fungal infections, which have a staggering impact on human health. To explore this approach, we focused on a leading fungal pathogen of humans, *Candida albicans*, and performed a screen of 1,280 pharmacologically active compounds to identify those that abrogate resistance to the echinocandins, which are the newest class of antifungal and target synthesis of the fungal cell wall. We identified 13 compounds that abolished echinocandin resistance of a clinical isolate, with the broad spectrum chelator DTPA having the most potent synergistic activity. Depletion of metals individually revealed that DTPA modulates echinocandin resistance via chelation of magnesium. Whole genome sequencing of mutants resistant to the combination of DTPA and echinocandin identified mutations in the histidine kinase gene, *NIK1*. Furthermore, *NIK1* mutations are sufficient to confer resistance to the combination. Functional analyses demonstrated that DTPA activates the mitogen-activated protein kinase Hog1, and that *NIK1* mutations block activation of Hog1 in response to both echinocandin and DTPA. This suggests that DTPA may modulate Hog1 signaling through Nik1, in order to enhance the efficacy of echinocandins. We found that DTPA not only abrogates drug resistance but also modulates morphogenesis, a key virulence trait that is normally regulated by environmental cues. DTPA induced filamentation via depletion of zinc, in a manner that is contingent upon Ras1-protein kinase A (PKA) signaling, as well as the transcription factors Brg1 and Rob1. Thus, we establish a new mechanism by which metal chelation modulates morphogenetic circuitry and echinocandin resistance, and illuminate a new facet to metal homeostasis at the host-pathogen interface.

The Influence of Ergosterol Biosynthesis Inhibition on the Mycelial Growth in *Aspergillus flavus*

Author Block:

E. Mizusawa, K. Hashimoto, H. Maki, A. Naito; Shionogi & Co., Ltd., Toyonaka, Japan

Abstract Body:

Background: Invasive aspergillosis (IA) contributes to significant mortality in immunosuppressed patients. Azoles, known as Cyp51 inhibitors, are used to treat IA. The majority of IA is caused by *Aspergillus fumigatus*, followed by *Aspergillus flavus*. The effect of these inhibitors on ergosterol biosynthesis pathway has been studied mostly in *A. fumigatus*, whereas little has been reported in *A. flavus*. In this study, we compared the influence of Cyp51 inhibition by voriconazole (VRCZ) on the mycelial growth in *A. fumigatus* and *A. flavus*. **Methods:** *A. fumigatus* and *A. flavus* were grown by shaking overnight in YNB broth at 35°C, then VRCZ and 2-^{13}C-acetate were added to the cultures. After incubation at 35°C for 16 hr, mycelia pellets were harvested by vacuum filtration. Sterols were extracted by n-heptane from the cell pellets. From them, ergosterol, eburicol and abnormal C_{14}-methylated sterols such as obtusifoliol were individually analyzed by liquid chromatography-mass spectrometry. *De novo* synthesized sterols were detected as the [^{13}C] labeled sterols. Growth rates were estimated by the ratios of the dry weight of mycelia against drug free control. **Results:** The MICs of VRCZ against the species were both 0.5 µg/mL. In both species, VRCZ-treated cells showed dose-dependent decreases in growth rates and ergosterol biosynthesis rates until almost complete inhibitions. There was little difference between the 80% inhibition concentration of growth rate [$IC_{80\ grow}$] and that of ergosterol biosynthesis rate [$IC_{80\ erg}$] in *A. fumigatus* ($IC_{80\ grow}$: 0.25 µg/mL, $IC_{80\ erg}$: 0.25 µg/mL). In contrast, $IC_{80\ grow}$ was 4 times higher than $IC_{80\ erg}$ ($IC_{80\ grow}$: 0.5 µg/mL, $IC_{80\ erg}$: 0.13 µg/mL) in *A. flavus*. VRCZ treatment showed the accumulation of eburicol and abnormal sterols, and abnormal sterols accumulation per mg-mycelia was similar in both species. In *A. fumigatus*, the total ergosterol amount per mg-mycelia was not decreased at the $IC_{80\ erg}$, where the mycelial growth was not observed. On the other hand, in *A. flavus*, it was decreased to the half of the control at the $IC_{80\ erg}$ of VRCZ, where the mycelial growth was observed. **Conclusions:** *In vitro* VRCZ exposure revealed that the contribution of ergosterol biosynthesis inhibition on the mycelial growth in *A. flavus* is less than that in *A. fumigatus*. The ergosterol metabolisms may be different between these two species.

Differential Contribution of ROS Production to the Fungicidal Action of Amphotericin B and Micafungin in *Candida albicans*

Author Block:

J. Argüelles; Univ. de Murcia, Murcia, Spain

Abstract Body:

As well acting according to the well established mechanism, recent evidence suggests that the lethal effect of some clinical antifungals depends on previously unknown targets. In this study, we have examined the hypothetical role played by the intracellular formation of ROS in the fungicidal action carried out by Amphotericin B (AMB) and Micafungin (MF) on the opportunistic yeast *Candida albicans*, which remains the most prevalent fungal pathogen. The clinical MIC_{90} for MF and AMB were 0.016 and 0.12 mg/L, respectively. The ROS levels were measured by flow cytometry with dihydrofluorescein diacetate and the level of survival was assessed by counting viable cells. Whereas AMB (0.5-1.0 x MIC) induced a marked production of ROS in parallel with a severe degree of cell killing in the *C. albicans* SC5314 strain, the fungicidal effect of MF was still effective with only a slight degree of ROS generation. Preincubation with rotenone or thiourea suppressed the generation of ROS and caused a marked increase of cell viability regardless of the antifungal supplied. Simultaneous measurement of a set of well established antioxidant enzymes (catalase, glutathione reductase and superoxide dismutase) revealed a strong AMB-induced activation of the three activities, whereas MF only had a weak stimulating effect. Likewise, AMB but not MF promoted a conspicuous intracellular synthesis of trehalose, the non-reducing disaccharide which acts as a specific protector against oxidative stress in *C. albicans*. Taken together, our results strongly point to that the induction of an internal oxidative stress in *C. albicans* through the release of ROS is a contributory factor to the antifungal action of polyenes (AMB) but not echinocandins (MF). HXP124 as a Novel Treatment for Onychomycosis

Author Block:

B. Hayes[1], M. Bleackley[1], M. Baker[1], P. Quimbar[1], M. Anderson[1], N. van der Weerden[2]; [1]La Trobe Univ., Melbourne, Australia, [2]Hexima Ltd., Melbourne, Australia

Abstract Body:

Background: Onychomycosis, or fungal infection of the nail, affects about 14% of the population. These infections are long-term, hard to treat, can be painful and have a cosmetic impact to the patient. Treatment options include systemic and topical therapies. Although effective, systemic therapies commonly have adverse effects, such as liver toxicity. Current topical have low cure rates due to poor nail penetration, and as a result typically require long treatment times. We are developing a novel topical treatment for onychomycosis infections, using a naturally occurring cationic peptide from plants. This molecule, HXP124, belongs to a family of innate immunity peptides called plant defensins, which have potent antifungal activity against a wide range of fungal pathogens. In this study, we evaluated the suitability of HXP124 in the treatment of onychomycosis by assessing its activity against the causative fungal pathogens and analysing its ability to penetrate human nails.**Method:** The antifungal activity of HXP124 was tested against fungal pathogens commonly associated with onychomycosis (*T. rubrum, T. interdigitale* and *C. albicans*) using an *in vitro* antifungal susceptibility assay. The ability of HXP124 to penetrate human cadaver toenails was assessed in an *in vitro* system using Franz cell nail adapters and In-Line cells (PermeGear) using a method modified from Hui et al, (2002). In brief, human nails were hydrated on PBS-soaked kimwipe, screwed tightly into a nail adapter and PBS-soaked cotton wool placed underneath. HXP124 was added to the top surface of the nail every 24H and penetration was assessed by analysing the contents of the cotton wool by RP-HPLC.**Results:** HXP124 has antifungal activity against fungal species most commonly associated with onychomycosis, and this activity is comparable to the activity of currently available topical treatments. HXP124 efficiently penetrates cadaver toenails with up to 60% passing through within 24 h.**Conclusions:** The plant defensin HXP124 has potent activity against the causative agents of onychomycosis and has the potential to be a novel topical onychomycosis treatment with superior nail penetration compared to current therapies.

Abstract Body:

Background: Growing numbers of infections caused by antibiotic resistant fungi require increasing efforts to develop new treatment and prevention strategies.**Methods:** In this study, we assessed the physicochemical properties and fungicidal activity of magnetic nanoparticles (MNP) coated with selected ceragenins CSA-13 and CSA-131 (MNP@CSA-13; MNP@CSA-131) against different *Candida* spp., including fluconazole-resistant strains. Fourier transform infrared spectroscopy (FTIR), thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) were employed to confirm the chemical structure of the obtained nanoparticles. To determine the candidacidal ability of tested agents, MIC/MFC/MBIC measurements were performed in the presence of DNase I, 50 % human blood plasma or pus. Biofilm mass was evaluated using crystal violet (CV) staining, and the morphology of the treated cells was assessed using atomic force microscopy (AFM).**Results:** Ceragenins in the presence of DNase I demonstrated an increased ability to kill DNA-induced *Candida* biofilms. Microscopy studies show that treatment with the tested nanosystems causes *Candida* cells to undergo extensive surface changes, indicating surface membrane damage.**Conclusion:** Magnetic nanoparticles functionalized by antimicrobial cationic lipids might serve as drug carriers in drug delivery system for topical application.

Molecular Characterization of *CYP*51 Gene Coding for Cytochrome P450 14α-Sterol Demethylase from a Posaconazole-Resistant, Voriconazole-Susceptible *Scedosporium apiospermum* Isolated from a Cystic Fibrosis Patient

Author Block:

E. Manavathu[1], S. Wakade[1], A. Rao[1], J-P. Bouchara[2], J. Vazquez[1]; [1]Med. Coll. of Georgia/Augusta Univ., Augusta, GA, [2]Univ. of Angers, Angers, France

Abstract Body:

Background: *Scedosporium apiospermum* (*Sa*) complex rank second among the filamentous fungi colonizing the airways of cystic fibrosis (CF) patients. Clinical isolates of *Sa* show varying degree of susceptibility to antifungal drugs. *Sa* IHEM 14462 (*Sa*14462) isolated from a CF patient showed high level resistance (MIC 16µg/ml) to posaconazole (PCZ), but remained susceptible (MIC 0.5 µg/ml) to voriconazole (VCZ). On the other hand, *Sa* ATCC MYA-3634 (*Sa*3634) was susceptible to PCZ and VCZ. Since azole resistance in fungi is largely due to drug target mutation(s), we characterized *CYP51* coding for the target enzyme P450 14α-sterol demethylase from *Sa*14462 and *Sa*3634.**Methods:** Genomic DNA was purified from *Sa*14462 and *Sa*3634, and a 2.4-kb DNA fragment containing *CYP51* was amplified by PCR. The DNA sequence of the protein coding and non-coding strands of the amplicon was determined. The DNA and the deduced amino acid sequences were analyzed using Analytical Tools available from NCBI and EMBL.**Results:** The protein coding sequence of *Sa CYP*51 gene was contained in a 1751-bp DNA fragment with a 75-bp and a 92-bp introns located at the 5'-end. The *Sa* Cyp51 protein consists of 528 amino acid (aa) residues. Amino acid alignment of *Sa* Cyp51 with those from five other fungi showed six highly conserved regions (CR). A comparison of the deduced Cyp51 aa sequences of *Sa*3634 and *Sa*14462 revealed 98.5% identity and the latter showed I34V, K74R, D416E, I434L, E439D (conservative), G152A, V485A (semi-conservative) and D446A (non-conservative) aa substitutions within or close to the CRs. The D446A change is located in the heme binding region which could affect the inhibitory effect of triazole(s) on the enzyme molecule.**Conclusions:** In vitro antifungal drug susceptibility studies showed that *Sa*14462 is highly resistant to PCZ, while remaining susceptible to VCZ, whereas *Sa*3634 is highly susceptible to both PCZ and VCZ. Characterization of Cyp51 from *Sa*14462 and *Sa*3634 showed several aa changes, including D446A at the critical heme binding region of the enzyme. One or more of these aa changes could be at least partly responsible for the differential susceptibility of *Sa*14462 to the triazoles PCZ and VCZ.

***In Vitro* Activity of Cefepime-Zidebactam [WCK 5222, A Combination of Cefepime with the Dual-action Bicyclo-Acyl Hydrazide β-Lactam Enhancer Zidebactam (WCK 5107)]**

Author Block:

M. R. Jacobs[1], S. Bajaksouzian[1], K. M. Papp-Wallace[2], R. A. Bonomo[2]; [1]CWRU,UHCMC, Cleveland, OH, [2]Cleveland VAMC, CWRU, Cleveland, OH

Abstract Body:

Background: Zidebactam (ZID) is a β-lactam enhancer inhibiting PBP2 of Gram negative species as well as a broad-spectrum β-lactamase inhibitor with activity against class A and C enzymes. These activities are targeted at overcoming resistance to β-lactams, including carbapenems. ZID with cefepime (FEP) is currently being studied in a Phase 1 clinical trial. **Methods:** In vitro susceptibilities of FEP-ZID, ZID (Wockhardt Research Center, India) and comparator agents piperacillin-tazobactam (PIP-TAZO), ceftazidime (TAZ), ceftazidime-avibactam (TAZ-AVI), cefepime (FEP), imipenem (IMI), meropenem (MER) were tested by CLSI broth microdilution. ZID was tested alone and combined with FEP at fixed concentrations of 4 and 8 mg/L. Isolates tested were from a genetically well-characterized collection of strains that included Enterobacteriaceae and non-fermenters expressing i) class A wild-type and ESBLs (CTX-M, SHV and TEM types), ii) KPC, OXA 23/24, NDM, VIM and L1 β -lactamases and iii) OMP deletions (Omp35, -36 and OprD). PIP-TAZO resistant ESBL-producing Enterobacteriaceae were specifically selected for inclusion in this study.**Results:** PIP-TAZO, FEP and CAZ were only active against the NSBL group, while IMI and MER were active against the NSBL and 92% of the ESBL isolates. TAZ-AVI was active against these groups as well as KPC and OMP. ZID alone was active at 4 mg/L against 30.7% of the isolates, including 51% of the strains containing *bla*$_{NDM}$. None of the agents tested showed good activity against *bla*$_{OXA}$ containing strains. FEP-ZID was active against all NSBL, ESBL, OMP and KPC containing isolates as well as 87.7% of *bla*$_{NDM}$, 80-100% of *bla*$_{L1}$ strains and 50% of *bla*$_{VIM}$. Overall, FEP-ZID inhibited the highest percentage of strains.**Conclusions:**In this study FEP-ZID demonstrated activity against all KPC and most NDM isolates with a broad spectrum of activity especially against NDM and some VIM producing strains.

Percent of isolates inhibited by resistance mechanism at breakpoints shown									
Agent	PIP-TAZO	FEP	IMI	MERO	TAZ	TAZ-AVI	ZID	FEP-ZID (ZID at 4 mg/L)	FEP-ZID (ZID at 8 mg/L)
Breakpoint MIC (mg/L)	16	8	4	4	8	8	4	8	8

WCK 5107 (Zidebactam, ZID): A Pan Gram-Negative β-Lactam Enhancer Augmenting β-Lactam Pharmacodynamics in Wild Type and Carbapenemase Producers (CP)

Author Block:

S. R. Palwe, P. R. Joshi, H. N. Khande, S. S. Biniwale, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: ZID is a β-lactam (BL) enhancer with pan Gram-negative high affinity PBP2 binding and Class A and C βlactamase inhibition. We describe β-lactam enhancer-based approach leading to enhanced potency and cidality against strains expressing ZID non-inhibitable carbapenamases as well as those lacking significant β-lactamase expression. **Methods:** Microscopy was performed to observe PBP-binding-dependent specific morphological changes induced by ZID and other BLs. MICs were determined as per CLSI recommendation for 12 ZID-resistant (ZID-R) β-lactamase-negative (BLN, confirmed by nitrocefin assay) Enterics (Proteus -9, *K. pneumoniae* (KP)-3). Time-kill studies comparing BL-BLIs [clavulanic acid (CLA) and tazobactam (TAZ)] and BL-ZID combinations involving six PBP3 binding BLs [cefepime (FEP), piperacillin (PIP), ceftriaxone (CRO), ceftazidime (CAZ), aztreonam (ATM) and sulbactam (SUL)] were undertaken employing nine BLN Gram-negatives (E. coli (EC)-7, Enterobacter-2) and 1 wild type strain each of *P. aeruginosa* (PA) and *A. baumannii* (AB). Time-kill studies were undertaken with CP Gram-negatives [EC (NDM), KP (NDM), PA (VIM-10) and AB (OXA 23 and 25)]. Time-kill studies were conducted in CA-MHB with starting inoculum of 10^6-10^7 CFU/mL and periodic viable count enumeration.**Results:** ZID (0.12-16 µg/mL) efficiently induced spheroplast formation indicating effective PBP2 binding. For 12/12 ZID-R (>16 µg/mL) BLN strains, MICs of FEP lowered by 4-32x and 8-64x with the addition of ZID at 0.25 and 0.5 µg/mL, respectively. Such lowering of FEP MICs was not brought about by CLA and TAZ (2x lowering in 3/12 strains). In time-kill studies, employing BLN/WT strains neither standalone BLs (1x MIC) nor ZID (2-4µg/mL) provided any cidal effect. However, unlike BL-BLIs, BLs (0.25x MIC)-ZID (2 µg/mL) combination, induced rapid 2->3 log kill. For CP strains, standalone BLs (4-16 µg/mL) or ZID (2-8 µg/mL) did not provide killing. However, ZID combination with FEP or ATM brought about 1.78->3 $\log_{10}$ kill in EC, KP and PA while its combination with FEP or SUL was effective against AB.**Conclusion:** ZID enhances the antibacterial effects of PBP3 binding BLs owing to complementary PBP binding in BLN/WT strains and broadens the therapeutic coverage of BLs to CP pathogens.

Publishing Title:

Activity of Combinations of Cefepime with Zidebactam (WCK 5107), a Novel Triple-Action Diazabicyclooctane

Author Block:

D. M. Livermore[1], S. Mushtaq[2], M. Warner[2], A. Vickers[2], N. Woodford[2]; [1]Univ. of East Anglia, Norwich, United Kingdom, [2]Publ. Hlth.England, London, United Kingdom

Abstract Body:

Background. Diazabicyclooctanes (DBOs) inhibit Class A, C and some Class D β-lactamases. A few, e.g. OP0595/RG6080, also bind PBP2, giving direct antibacterial activity together with a β-lactamase–inhibition-independent 'enhancement' of the activity of β-lactams binding to other PBPs. We characterised the behaviour of a novel acyl hydrazide-DBO, zidebactam. **Methods**. CLSI agar dilution MICs of cefepime were determined with zidebactam (0.06-8 mg/L) in a chequerboard format for bacteria with known resistance genotypes and phenotypes. **Results**. MICs of zidebactam alone were ≤1 mg/L (mostly 0.12-0.5 mg/L) for 49/50 *E. coli*, 39/55 *Klebsiella*, 43/45 *Citrobacter* and *Enterobacter*, but were >32 mg/L for 19/19 Proteeae, 7/10 *Serratia* and for 14/150 *E. coli*, *Klebsiella* and *Enterobacter/Citrobacter*. At subinhibitory concentrations, zidebactam potentiated cefepime strongly against Enterobacteriaceae with class A, C and OXA-48 enzymes. Overall, 33/33 ESBL Enterobacteriaceae (6 with zidebactam MICs >32 mg/L) were susceptible to cefepime + zidebactam 1+1 mg/L, as were 35/35 AmpC producers (7 with zidebactam MICs >32 mg/L), 29/30 with KPC enzymes (2 with zidebactam MICs >32 mg/L), 15/15 with OXA-48 (3 with zidebactam MICs >32 mg/L) and 30/35 with MBLs (7 with zidebactam MICs >32 mg/L). Among 8 MBL Enterobacteriaceae with zidebactam MICs ≥16 mg/L, 4 showed strong enhancer-effect cefepime-zidebactam synergy whereas 4 -one *E. coli* and 3 *P. rettgeri* - did not. MICs of zidebactam for 36/50 *P. aeruginosa* were 4-16 mg/L whereas all MICs for *A. baumannii* and *S. maltophilia* exceeded 32 mg/L; synergy with cefepime was frequent for AmpC-derepressed *P. aeruginosa* and for cystic fibrosis isolates that were resistant to meropenem, cefepime and multiple other antibiotics but rare for those with efflux or MBLs; synergy was frequent also for *S. maltophilia*, but absent for *A. baumannii* regardless of resistance type. **Conclusion**. Zidebactam represents a second, triple action DBO, after OP0595, with β-lactamase-inhibitory activity, direct antibacterial activity and a potential to enhance cefepime activity independently of β-lactamase inhibition. MICs of zidebactam were lower than those previously found for OP0595 for Enterobacteriaceae and *P. aeruginosa*,

Wck 5222 [Cefepime (FEP)-WCK 5107 (Zidebactam, Zid)]: *In Vitro* and *In Vivo* Coverage of OXA-Carbapenemases Expressing-*Acinetobacter* (OXA-Ab)

Author Block:

P. R. Joshi, H. N. Khande, S. S. Takalkar, A. M. Kulkarni, S. R. Palwe, S. S. Biniwale, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: Though preferred, β-lactam-based therapies for OXA-AB are currently ineffective due to unavailability of β-lactam inhibitors (BLIs) inhibiting OXA carbapenemases. ZID is a novel β-lactam enhancer with selective, high-affinity pan Gram-negative (including AB) PBP2 binding, and its combination with FEP provides a novel approach in tackling these pathogens. Herein, we describe potent FEP-ZID activity against AB through a range of *in vitro* and *in vivo* studies.**Method:***Acinetobacter* PBP IC_{50}s for FEP and ZID were determined by Bocillin FL competition assay. The OXA-carbapenemase inhibition (IC_{50}) by ZID was assessed by nitrocefin as substrate. MICs of FEP-ZID for 208 Indian OXA-AB strains were determined as per CLSI recommended agar dilution method. Time-kill studies employing reference OXA-AB (AB NCTC 13301 and AB NCTC 13303) were conducted in CA-MHB (starting inoculums: 6.5-6.8 log_{10} CFU/mL). *In vivo* ED_{90} doses were determined through systemic infection studies. Mice were intraperitonially infected with OXA-AB (AB NCTC 13301 and AB NCTC 13303, 6.5-6.69 log_{10} CFU/mouse) and treatment was initiated 1h post-infection (BID, 3h apart for 1 day) and survival was monitored till 7 days.**Results:**ZID showed potent PBP2 affinity (IC_{50}: 0.01 µg/mL) while FEP showed complementary dual binding to PBP1a, 1c (IC_{50}: 0.05, 0.84 µg/mL) and PBP3 (IC_{50}: 0.08µg/mL). OXA IC_{50} of ZID for OXA-23, 24, 25, 26, and 27 was ≥2.0 µM. $MIC_{50/90}$ for standalone FEP or ZID were 64/128, >1024 µg/mL. Addition of ZID to FEP (1:1) lowered the $MIC_{50/90}$ to 16/32 µg/mL [$MIC_{50/90}$: imipenem (IPM) and meropenem -16/64 µg/mL; ceftazidime (CAZ)-avibactam (AVI) -64/128 µg/mL]. FEP-ZID (sub-MIC concentrations, 8-16 + 4-8 µg/mL) time-kill studies showed 2 log_{10} kill while standalone FEP, ZID, IPM and CAZ-AVI failed to show any cidality. *In vivo* systemic infection studies employing OXA-AB strains (FEP-ZID MICs, 16-32 µg/mL), provided FEP-ZID ED_{50} of (FEP) 50–100 mg/kg - (ZID) 12.21–28.60 mg/kg and ED_{90} of (FEP) 50–100 mg/kg - (ZID) 25.28–53.42 mg/kg. Even at higher doses, FEP and IPM even at higher doses failed to provide protection.**Conclusion:**Despite high MICs, FEP-ZID combination provided therapeutically promising activity against OXA-AB through β-lactam enhancer mechanism.

WCK 5222 [Cefepime (Fep)-WCK 5107 (Zidebactam, Zid)]: Thigh and Lung Pk/Pd Studies against Higher MIC OXA Carbapenemase-Expressing *A. baumannii* (Ab)

Author Block:

S. S. Takalkar, R. P. Chavan, A. M. Patel, K. V. Umarkar, J. S. Satav, A. P. Udaykar, A. M. Kulkarni , V. S. Zope, S. S. Bhagwat, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: FEP-ZID combination is based on β-lactam enhancer, ZID, a pan Gram-negative PBP2 binder, irrespective of associated β-lactamases. In combination with FEP, ZID evokes a strong cidal response against AB. *In vivo* thigh and lung PK/PD studies in neutropenic mouse were undertaken for identifying the efficacy driving ZID threshold concentrations (C_T) and associated FEP exposures for three OXA-23 carbapenemase-expressing AB strains with FEP-ZID (1:1) MICs of 16-64 µg/mL.**Methods:** Mouse PK data was obtained by administering subcutaneous q2h doses of FEP-ZID (2:1) ranging from 12.5/6.25-200/100 mg/kg. Serum was collected over 24h and assayed by LC-MS/MS. Neutropenic mice were infected intra-nasally or intramuscularly in thigh (10^7 CFU), to achieve bacterial burden of 6.13-7.02 $\log_{10}$ CFU/thigh at the initiation of treatment (2h post-infection). 27h post-infection bacterial lung/thigh load were determined. To arrive at the optimal dosing regimen and ZID C_T, total daily doses (100-550 mg/kg) and multiple regimens (q2h, q4h, q6h, q12h and q24h) were employed in combination with FEP doses (50 and 75 mg/kg, q2h). Imipenem (IPM) was administered 20 mg/kg, q2h. Exposure-response analysis to arrive at ZID C_T was undertaken using non-linear regression using Graph Pad 6.0.**Results:** Standalone FEP, ZID and IPM did not provide bactericidal effect in lung and thigh infection studies. In lung infection caused by AB SL46 (FEP-ZID MICs 64 µg/mL), combination of FEP 50 mg/kg q2h and ZID 8.33-45.83 mg/kg q2h provided 2.91-3.41 log kill from the base line. In thigh AB 13301 infection (FEP-ZID MICs 16 µg/mL), AB SL 71 and SL46 (FEP-ZID MICs 64 µg/mL), combination of FEP 50 mg/kg q2h and ZID 16.66-91.66 mg/kg q4h provided 1.15-1.31 log kill. Against AB 13301, FEP 75 mg/kg q2h in combination with ZID 8.33-45.83 mg/kg q2h, provided 1.14-2.74 log kill. The lowest total ZID dose of 100 mg/kg (AUC_{0-24} 90-100 µg.h/mL) provided effective eradication. Dosing regimen q2h and q4h were more efficacious. For three CHDL OXA-producers, exposure-response analysis showed that ZID C_T in combination with FEP was 2-8 µg/mL.**Conclusions:** FEP-ZID showed therapeutically promising PK/PD for high MIC carbapenemase-expressing AB.

WCK 5222 [Cefepime (FEP)-WCK 5107 (Zidebactam, ZID)]: Activity against ESBL, Class C, and KPC-Expressing Enterics and *Pseudomonas* (PA) Expressing AmpC (PA AmpC) or OXA β-Lactamases (PA OXA)

Author Block:

H. N. Khande, P. R. Joshi, S. R. Palwe, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background:β-lactam-β-lactamase inhibitor (BL-BLI) combinations rely on β-lactamase inhibition and restoration of BL activity. However, FEP-ZID confers activity by dual mechanism of action based on ZID's PBP2 binding and β-lactamase inhibition. The *in vitro* and *in vivo* activity of FEP-ZID was explored by multi-pronged analysis to measure the additional benefits conferred by β-lactam enhancer, ZID.**Method:**β-lactamase inhibition was determined by nitrocefin assay. MICs were determined against 194 enterics [ESBL (96), Class C (76), KPC (22)] and 225 *Pseudomonas* (PA) [AmpC (153), OXA (72)] strains as per the reference CLSI agar dilution method. Time-kill studies employed initial inoculum 6.0–7.0 $\log_{10}$ CFU/mL. Mutant prevention concentration (MPC) were determined for KPC and Class C enteric strains (MHA, inoculum: 10^9–10^{10} CFU/plate, 48h of incubation).**Results:**IC_{50} of ZID against ESBL and KPC enzymes ranged from 0.16–1.21 µM and against Class C IC_{50} was 0.01–0.21 µM. For PA AmpC and PA OXA, ZID IC_{50} was 0.16–0.21 µM and 0.76–0.82 µM, respectively. For enterics, FEP-ZID MIC_{90}s were 4–16 times lower than ceftazidime (CAZ)-avibactam (AVI) and >16 times lower than ceftolozane-tazobactam (CXA-201). For PA AmpC, CXA 201 was 1–2 times more active than FEP-ZID and CAZ-AVI, however for PA OXA, FEP-ZID was more active (table). In time-kill studies, at comparable concentrations [FEP-ZID and CAZ-AVI (4+4 µg/mL)], FEP-ZID brought about 1–2 $\log_{10}$ additional kill over CAZ-AVI within 2–4h for ESBL and Class C enterics. Unlike CXA 201 and CAZ-AVI, FEP-ZID (all at 8+8 µg/mL) showed >2 $\log_{10}$ kill for PA OXA. For KPC and Class C enteric strains, FEP-ZID MPCs were 4 +1 µg/mL and for CAZ-AVI MPCs were 4–8 + 4 µg/mL. CXA 201 did not attain MPC.**Conclusion:**WCK 5222 through its dual action imparts *in vitro* features superior than existing BL-BLIs against ESBL and carbapenem-resistant organisms.

Organisms, β-lactamase	$MIC_{50/90}$ (µg/mL)					
	FEP	ZID	FEP-ZID (1:1)	CAZ-AVI	CXA-201	Imipenem

WCK 5222 [Cefepime (Fep)-WCK 5107 (Zidebactam, ZID)]: Lung Pk/Pd Studies for Carbapenamase-Expressing *K. pneumoniae* (KP) and *P. aeruginosa* (Pa)

Author Block:

S. S. Takalkar, R. P. Chavan, A. M. Patel, K. V. Umarkar, J. S. Satav, A. P. Udaykar, A. M. Kulkarni , J. U. Shaikh, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 5222 is based on β-lactam enhancer - ZID, a pan Gram-negative PBP2 binder, irrespective of associated β-lactamases. In combination with FEP, ZID evokes a strong cidal response against carbapenemase-producers. *In vivo* PK/PD studies aimed at identifying the efficacy driving ZID threshold concentrations (C_T) and associated FEP exposures were undertaken employing KP strains expressing KPC (FEP-ZID MIC 0.5 µg/mL) and NDM (FEP-ZID MIC 8 µg/mL) and PA expressing VIM (FEP-ZID MIC 16 µg/mL).**Methods:** Mouse PK data for subcutaneous FEP-ZID (2:1) q2h doses (12.5/6.25–200/100 mg/kg) were determined. Serum was collected over 24h and assayed by LC-MS/MS. Neutropenic mice were infected intra-nasally (10^7–10^8 CFU), with bacterial burden at the initiation of treatment (2h post-infection) in the range of 5.6–7.11 $\log_{10}$ CFU/lung. 27h post-infection bacterial lung load was enumerated. For determination of optimal dosing regimen and ZID C_T, total daily doses (100–550 mg/kg) and regimens (q2h, q4h, q6h, q12h and q24h) were employed in combination with FEP (50 and 75 mg/kg, q2h). Imipenem (IPM) was administered 20 mg/kg, q2h. Exposure-response analysis to arrive at ZID C_T was undertaken using nonlinear regression using Graph Pad 6.0.**Results:** Standalone FEP, ZID and IPM did not provide bactericidal effect. Combination of FEP 50 mg/kg q2h and ZID 8.33–45.83 mg/kg q2h provided 0.94–3.97 log kill for the three strains studied. Similarly, higher FEP dose of 75 mg/kg q2h in combination with ZID, provided 1.66–4.0 log kill. Thus, lowest total ZID dose of 100 mg/kg ($AUC_{0–24}$: 90–100 µg.h/mL) provided effective eradication of all the three carbapenamase-producing strains. Dosing regimen q2h was more efficacious. For three carbapenemases-producers, exposure-response analysis showed that in combination with FEP, ZID C_T was 1–8 µg/mL.**Conclusion:** FEP-ZID showed therapeutically promising PK/PD for carbapenemase-expressing KP and PA.

WCK 5222 [(Cefepime (FEP)-WCK 5107 (Zidebactam, ZID)]: *In Vitro* and *In Vivo* Activity against Indian Metallo-β-Lactamase (MBL)-Producing *Enterobacteriaceae* (ENT) and *Pseudomonas* (PA)

Author Block:

S. S. Takalkar, A. M. Kulkarni, P. R. Joshi, H. N. Khande, J. S. Satav, S. S. Bhagwat, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background:MBL-expressing pathogens are currently untreatable by β-lactam (BL)-based antibacterial agents, necessitating the use of compromised therapies such as colistin and tigecycline. FEP-ZID exerts its antibacterial activity against MBL ENT and PA isolates by virtue of complementary PBP binding of the two constituents. Here, we describe the *in vitro* and *in vivo* activity of FEP-ZID against MBL ENT and PA.**Method:**MICs of FEP-ZID (1:1 and 2:1**)** were determined by reference CLSI agar dilution method against 106 MBL enterics (*E. coli* (EC)-39, *K. pneumoniae* (KP)-57, *Citrobacter*-2, *Enterobacter*-1, Proteae-6 and unidentified strain-1) and 91 PA isolates. *In vitro* cidal activity of FEP-ZID was established through time-kill studies (starting inoculum: 10^6-10^7 CFU/mL). $ED_{50/90}$ doses of FEP-ZID were determined through systemic infection employing eight strains (6 ENT: EC S30, EC S35, EC S33, KP B88, KP 13443, PA13437 and PA 32). Mice were intraperitonially infected with 6.5-6.69 $\log_{10}$ CFU/mouse and treatment was initiated 1h post-infection (BID/TID for 1 day).**Results:**Standalone ZID $MIC_{50/90}$ was 0.25/2 µg/mL. FEP-ZID (1:1 and 2:1) was highly active against MBL enterics with $MIC_{50/90}$ of 0.25/1 and 0.5/2 µg/mL, respectively. Meropenem (MEM), and ceftazidime (CAZ)-avibactam (AVI) $MIC_{50/90}$ for enterics were >32 µg/mL. FEP-ZID inhibited 73.62% and 96.7% of the PA MBL strains at ≤ 8 and ≤ 16 µg/mL, respectively. $MIC_{50/90}$ for FEP and MEM were 128/>256 µg/mL and for CAZ-AVI >128/>256 µg/mL. Time-kill studies showed that, unlike standalone agents, FEP-ZID at 8+8 µg/mL caused 1.5–>3 $\log_{10}$ CFU kill, while MEM and CAZ-AVI showed no cidal activity. *In vivo* systemic infection efficacy studies for enteric MBL provided ED_{90} of FEP 50–100 mg/kg + ZID 7.12–50.57 mg/kg. Similarly for PA MBL strains, ED_{90} was achieved at FEP 50 mg/kg + ZID 21.20–25.28 mg/kg. Carbapenems and CAZ-AVI failed to protect animals at significantly higher doses.**Conclusion:**WCK 5222 demonstrates promising *in vitro* and *in vivo* activity against MBL ENT and PA strains based on ZID's β-lactam enhancer action.

Publishing Title:

WCK 5222 (Cefepime-Zidebactam) Antimicrobial Activity Tested against *Enterobacteriaceae* Clinical Isolates Collected Worldwide (2015)

Author Block:

H. S. Sader, M. Castanheira, R. K. Flamm, D. J. Farrell, R. N. Jones; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: Zidebactam (ZID), a bicyclo-acyl hydrazide, is a β-lactam-enhancer with a dual mechanism of action involving selective and high binding affinity to Gram-negative PBP2 and β-lactamase inhibition. We evaluated the *in vitro* activity of cefepime (FEP) combined with ZID against contemporary clinical isolates of Enterobacteriaceae (ENT).**Methods:** 1,404 isolates from USA (452), Europe (645), Asia-Pacific (257) and Latin America (50) were collected in 2015 by the SENTRY Antimicrobial Surveillance Program and susceptibility (S) tested by a reference broth microdilution method against FEP-ZID (1:1 and 2:1 ratios) and comparator agents.**Results**: FEP-ZID was the most active compound with $MIC_{50/90}$ of ≤0.03/0.12 and 0.06/0.25 μg/mL, and highest MIC values of 4 (1:1 ratio) and 8 μg/mL (2:1). Amikacin ($MIC_{50/90}$, 2/4 μg/mL; 98.1% S) and meropenem (MEM; $MIC_{50/90}$, 0.03/0.06 μg/mL; 97.4% S; Table) were also very active. FEP-ZID was active against all ENT species ($MIC_{50/90}$, ≤0.03-0.06/0.12-0.5 μg/mL [1:1 ratio]) and retained potent activity against MEM-non-S *K. pneumoniae* (KPN; $MIC_{50/90}$, 0.5/2 μg/mL; highest MIC, 4 μg/mL [1:1]) and ceftazidime-non-S *Enterobacter* spp. ($MIC_{50/90}$, 0.12/0.5 μg/mL; highest MIC, 1 μg/mL [1:1]). FEP-ZID activity was consistent among geographic regions and only 2 isolates showed MIC values of >2 μg/mL for FEP-ZID (1:1 ratio), 2 KPN (Russia and Taiwan), both with a MIC of 4 μg/mL. S rates for MEM among KPN was lower in the USA (86.0%) compared to the other regions (94.4-97.0%).**Conclusion:** FEP-ZID (WCK 5222) was very active against this worldwide collection of ENT, including isolates resistant to broad-spectrum cephalosporins and/or carbapenems. These results support the further clinical development of WCK 5222.

***In Vitro* activity of WCK 5222 (Cefepime-Zidebactam) Tested against Clinical Isolates of Antimicrobial-Resistant Gram-Negative Bacilli**

Author Block:

H. S. Sader, R. K. Flamm, D. J. Farrell, M. Castanheira, R. N. Jones; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: Zidebactam (ZID) is a bicyclo-acyl hydrazide with a dual mechanism of action: selective binding to Gram-negative PBP2 and β-lactamase inhibition. We evaluated the *in vitro* activity of cefepime (FEP) combined with ZID against contemporary clinical isolates of Enterobacteriaceae (ENT) and *P. aeruginosa* (PSA) with various resistant (R) phenotypes.**Methods:** Isolates were collected from 55 medical centers from 19 countries worldwide in 2015 by the SENTRY Antimicrobial Surveillance Program. Susceptibility testing was performed in a central laboratory by a reference broth microdilution method against FEP-ZID (1:1 and 2:1 ratios) and comparator agents.**Results:** FEP-ZID (1:1 ratio) was very active against all R subsets (see Table). The highest FEP-ZID (1:1) MIC values among ENT was only 4 μg/mL; thus, 100.0% of strains would be considered susceptible (S) when the CLSI high dose FEP breakpoint (≤8 μg/mL) is applied. Further, 93.8-100.0% of ENT were inhibited at FEP-ZID (1:1) MIC of ≤2 μg/mL (low dose FEP breakpoint, CLSI). MIC values for FEP-ZID at a 2:1 ratio were slightly higher (less than one doubling dilution overall) compared to the 1:1 ratio. Among ESBL-phenotype *E. coli* (EC) / *Klebsiella* spp. (KSP), meropenem (MEM) and amikacin (AMK) were active against 98.3/80.5% and 98.3/83.7%, respectively. Only 78.7-84.6% of multidrug-R (MDR) ENT were S to MEM, AMK or colistin (COL). Carbapenem-R ENT (CRE) and extensively drug R (XDR) ENT exhibited low S to AMK (71.9 and 77.8% S, respectively), COL (87.5 and 72.2% S, respectively) and all antimicrobials tested except for FEP-ZID. COL and the FEP-ZID combinations were the most active compounds tested against MDR and XDR PSA. ZID tested alone was also active *in vitro* against MDR and XDR PSA ($MIC_{50/90}$, 8/16 μg/mL for both); whereas only 59.6 and 50.0% of strains were S to AMK, respectively.**Conclusion:** FEP-ZID (WCK 5222) showed potent *in vitro* activity against R subsets of Gram-negative bacilli with high rates of R to most antimicrobial agents currently available for clinical use.

WCK 5222 (Cefepime-Zidebactam) Antimicrobial Activity Tested against Gram-Negative Organisms Producing Clinically Relevant β-Lactamases

Author Block:

H. S. Sader, P. R. Rhomberg, R. N. Jones, M. Castanheira; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: Zidebactam (ZID) is a β-lactam enhancer with dual mechanism of action involving binding to Gram-negative (GN) PBP2 and β-lactamase (BL) inhibition. Cefepime (FEP) combined with ZID is under clinical development.**Methods:** 193 clinical GN strains producing the most clinically relevant BL types plus 71 wild type (WT) strains were tested for susceptibility (S) by a reference broth microdilution method against FEP-ZID (1:1 and 2:1 ratios tested at 0.06-128 μg/mL), FEP and ZID. BL encoding genes were evaluated by a microarray-based assay.**Results:** FEP-ZID (1:1) was very active against Enterobacteriaceae (ENT) producing CTX-M-15 (21; $MIC_{50/90}$, 0.25/1 μg/mL), SHV (20; $MIC_{50/90}$, 0.12/0.25 μg/mL), other extended-spectrum BLs (ESBLs; 20, including GES-18; OXA-1/30, OXY-, PER-, TEM- and VEB-like; $MIC_{50/90}$, 0.25/1 μg/mL), plasmidic AmpC (10; $MIC_{50/90}$, ≤0.06/≤0.06 μg/mL), derepressed AmpC (23; $MIC_{50/90}$, 0.12/0.5 μg/mL), KPC (35; $MIC_{50/90}$, 0.25/1 μg/mL), metallo-BL (MBL; 20 including VIM, IMP and NDM; $MIC_{50/90}$, 0.5/8 μg/mL; Table). WT ENT had $MIC_{50/90}$ values of ≤0.06/≤0.06, ≤0.06/0.12 and 0.25/>128 μg/mL for FED-ZID (1:1), FEP and ZID, respectively. FEP-ZID was also active against *P. aeruginosa* (PSA) producing derepressed AmpC (21; $MIC_{50/90}$, 4/8 μg/mL) and MBL (12 [VIM and IMP]; $MIC_{50/90}$, 4/8 μg/mL). FEP-ZID 1:1 ratio was slightly (2-fold) more active than FEP-ZID 2:1 ratio when tested against BL-producing ENT and PSA; and ZID alone exhibited potent *in vitro* activity against some ENT and PSA, including BL-producing strains. FEP-ZID 1:1 ratio ($MIC_{50/90}$, 32/32 μg/mL) showed only moderate activity against OXA-23/24-producing *Acinetobacter* spp., but it was >4-fold more active than FEP or ZID tested alone.**Conclusion:** FEP-ZID (1:1 and 2:1 ratios) showed potent in vitro activities against ENT and PSA producing various clinically relevant BLs, including ESBLs, KPCs, AmpC and MBLs for which limited treatment options are currently available. These *in vitro* results support further clinical development of FEP-ZID (WCK 5222).

Publishing Title:

Cefepime (FEP) and Zidebactam (ZID) Mediated Dual Pbp Engagement at Sub-Mic Concentrations Drive Cidality against Diverse β-Lactamase Expressing Gram-Negatives

Author Block:

S. R. Palwe, S. S. Biniwale, H. N. Khande, P. R. Joshi, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: β-lactams induce morphological changes based on their preferential binding to Gram-negative PBPs thereby causing elongation (PBP3 binders) or spheroplastation (PBP2 binders). Multiple PBP binders with preferential PBP2 affinity - such as carbapenems, are rapidly cidal. However, amidst carbapenemases, they lose their spheroplast inducing activity and therefore cidality. ZID is a pan β-lactamase stable, spheroplasting agent for pan Gram-negatives. Herein, we describe the functional basis of cidal synergy exerted by FEP-ZID combination against pathogens expressing various β-lactamases including carbapenemases.**Methods**: Microscopic observation inducing morphological changes were performed to identify minimum elongation concentration (MEC) and minimum spheroplast forming concentrations (MSC) required for elongation and spheroplastation respectively. Time-kill studies were undertaken by employing log phase cultures (10^6-10^7 CFU/mL) in CA-MHB. Strains and associated β-lactamases employed in the study are listed in the table. The viable counts were enumerated periodically by plating aliquots of serially diluted culture exposed to FEP, ZID and FEP-ZID.**Results**: MICs of FEP and ZID were in the range of 0.03-256 µg/mL and 0.25->256 µg/mL, respectively. Elongation and spheroplastation were attained at sub-MIC concentrations. MEC and MSC for FEP and ZID, were 0.015-16 µg/mL and 0.12-8 µg/mL, respectively. Time-kill studies (n=13) **i**nvolving combinations of ZID at its MSC and FEP at its MEC brought about 0.31->3 and 1.29->3 $\log_{10}$ CFU/mL kill at 4 and 6h, respectively.**Conclusion:** Combination of MEC and MSC, the functional attributes of PBP2 and PBP3, confers cidality to FEP-ZID combination even in the presence of carbapenamases.

WCK 5107 (Zidebactam, ZID) and WCK 5222 [Cefepime (FEP)-ZID]: Repeated-Dose Toxicity in Rat and Dog

Author Block:

M. B. Nandanwar, A. J. Kansagara, S. Satale, M. I. Patel, S. R. Gupta, R. P. Chavan, A. M. Patel, R. D. Yeole, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background:ZID is a Gram-negative antibacterial agent acting both as a pan Gram-negative β-lactam enhancer and a β-lactamase inhibitor. In order to establish the toxicity, 28-day repeated-dose toxicity studies were performed with both ZID and FEP-ZID in Wistar rats and Beagle dogs.**Method:**ZID was administered intravenously (i.v.) at 200, 400 and 800 mg/kg/day in rat and at 200, 300 and 750 mg/kg/day in dog. FEP-ZID was administered at 300+150 and 300+300 mg/kg/day in dogs (i.v.). Control group included standalone i.v. FEP administration at 300 mg/kg/day in the dog study. In parallel, corresponding recovery groups were also maintained for 14 days for control, ZID (800 mg/kg/day) in rat, ZID (750 mg/kg/day) and FEP-ZID (300+300 mg/kg/day) in dog. In both rat and dog, the doses were equally divided and administered twice-daily. For toxicokinetic profiling, blood was sampled at multiple time points (on 1, 14 and 28 days) in both rat and dog. Clinical signs, body weight, food consumption, ophthalmoscopy, clinical pathology, ECG, organ weight, gross and histopathology evaluations were performed.**Results:**No major or significant changes were observed in both rat and dog studies even at the highest doses tested for ZID and FEP-ZID. In rat, a mild increase in AST and ALT values was observed at 400 and 800 mg/kg/day doses with no changes in bilirubin levels. Histopathological investigations did not reveal any changes either in liver or any other vital organ. The mild elevation of AST and ALT values were fully normalized during the 14 day recovery period. In dog, mild increase in AST (males) was observed at all doses of ZID on day 29 with no histopathological alterations in liver. This AST level was normalized by the end of 14-day reversal period. ZID stand-alone or in combination with FEP elicited reaction at injection site. No Observable Adverse Effect Level (NOAEL) of WCK 5107 in rat and dog was found to be 800 and 750 mg/kg/day, respectively. The highest AUC achieved at NOAEL doses in rat and dog were 1948 and 1962 μg.h/mL, respectively. For WCK 5222, 300+300 mg/kg/day dose was estimated as NOAEL in dog and the AUC achieved was 850 μg.h/mL (FEP) + 1660 μg.h/mL (ZID).**Conclusions:**Both WCK 5107 and WCK 5222 showed a promising safety profile in rat and dog.

WCK 5107 [Zidebactam, (ZID)] and WCK 5222 [Cefepime (FEP)-Zidebactam (ZID)] Intravenous Pharmacokinetics (PK) in Beagle Dogs

Author Block:

R. P. Chavan, A. M. Patel, V. S. Zope, J. U. Shaikh, A. D. Patil, R. D. Yeole, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: ZID is a novel β-lactam enhancer currently undergoing Phase I study in combination with FEP. ZID is a bicyclo-acyl hydrazide with a pan Gram-negative PBP2 binding as well as potent β-lactamase inhibition. **Methods:** Intravenous PK of standalone ZID, FEP and FEP-ZID (2:1) was evaluated in beagle dogs to investigate PK interactions. The doses were administered as 0.25h constant infusion. Other BLIs- avibactam (AVI) and relebactam (REL) were also studied. Plasma concentrations were determined by validated LC/MS-MS method. PK parameters were calculated by non-compartmental analysis (Phoenix WinNonlin).**Results:** Standalone ZID at 15 and 30 mg/kg, yielded plasma C_{max} of 61.2 and 138.5 µg/mL, and AUC of 78.6 and 200.4 µg.h/mL, respectively. ZID (15 and 30 mg/kg) administered as FEP-ZID provided plasma C_{max} of 76.6 and 99.4 µg/mL, and AUC of 100.5 and 157.9 µg.h/mL, respectively. Standalone FEP at 30, and 60 mg/kg, yielded plasma C_{max} of 137.6 and 251.6 µg/mL, and AUC of 181.6 and 358.5 µg.h/mL, respectively whereas FEP (30 and 60 mg/kg) in FEP-ZID yielded plasma C_{max} of 134.9 and 208.8 µg/mL, and AUC of 174.3 and 327.0 µg.h/mL, respectively. Plasma elimination half-life of FEP and ZID was in the range of 1.0 to1.5h and 1.3 to 1.7h, respectively. AVI and REL at 15, 30 mg/kg, achieved plasma C_{max} of 33.28, 100.12 µg/mL and 79.57, 141.91 µg/mL, respectively. Similarly, plasma AUCs of AVI and REL (both at 15, 30 mg/kg) were 35.83, 79.11 µg.h/mL and 98.35, 188.55 µg.h/mL, respectively. Elimination half-life of AVI and REL was observed to be 1.0 and 1.5h, respectively.**Conclusions:**No PK interaction between WCK 5107 and WCK 5222 was observed. WCK 5107 showed higher exposures than AVI and comparable to REL.

Ceftazidime-Avibactam (CAZ-AVI) Activity Tested against Eleven *Enterobacteriaceae* (ENT) Species Producing KPC Enzymes

Author Block:

M. Castanheira, R. E. Mendes, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: KPC enzymes are usually detected in *K. pneumoniae* (KPN); however other ENT species often carry these carbapenemases. We evaluated the activity of CAZ-AVI and comparators tested against KPC-producing ENT belonging to 11 bacterial species.**Methods:** 662 KPC-producing ENT clinical isolates collected worldwide from 2009-2014 were susceptibility (S) tested by reference broth microdilution methods using CAZ-AVI (AVI at fixed 4 µg/ml) and comparators. CLSI, US-FDA (tigecycline [TIG] and CAZ-AVI) and EUCAST interpretative criteria were applied. KPC and metallo-β-lactamase (MBL) genes were detected by PCR/sequencing.**Results:** Overall, CAZ-AVI inhibited 98.8% of the isolates at the breakpoint recently established by the US-FDA. Among other antimicrobial agents, TIG (97.4 and 90.8% S by US-FDA and EUCAST criteria, respectively) and colistin (COL; 82.1% S [EUCAST]) were the only agents with S rates >80.0%. Amikacin inhibited 56.2 and 40.2% of the isolates according to CLSI and EUCAST S criteria, respectively. Isolates displaying elevated CAZ-AVI (>8 µg/ml) were one *E. cloacae* (ECL; Poland) and seven KPN isolates from China, Greece, USA (one each) and Italy (n=4). These 8 isolates co-produced MBL: five VIM-1-producers and one each of IMP-4, VIM-4 and VIM-26. KPN isolates displayed higher resistance rates for comparators; CAZ-AVI, TIG and COL were the agents with higher S rates (98.7, 97.5/91.1 and 81.9% S, respectively). KPC-producing ECL isolates had higher S rates to amikacin (95.2/85.7% S) compared to KPN and CAZ-AVI displayed the highest S rates (97.6% S). CAZ-AVI was active against all isolates belonging to other ENT species (100.0% S; Table).**Conclusions:** CAZ-AVI was very active against this large collection of KPC-producing isolates, inhibiting >97.0% of the isolates at the US-FDA breakpoint criteria. Eight isolates in this collection displaying CAZ-AVI MIC values >8 µg/ml and co-produced MBLs that are not inhibited by AVI.

KPC-producing species(no. tested)	% susceptible CLSI (US-FDA for CAZ-AVI and tigecycline)/EUCAST

Meropenem/Vaborbactam (MER/VAB) Tested Against Contemporary *Enterobacteriaceae* (ENT) Isolates from USA Hospitals

Author Block:

M. Castanheira, M. D. Huband, R. K. Flamm, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: Carbapenem-resistant ENT (CRE) have been detected in various USA hospitals and most of these isolates produce KPC enzymes. We evaluated the activity of MER/VAB (formerly RPX7009), that has enhanced activity against KPC-producing isolates, and comparators tested against Enterobacteriaceae (ENT) isolates collected during 2015 in 29 USA hospitals.**Methods:** 3995 ENT clinical isolates consecutively collected were susceptibility (S) tested by reference broth microdilution methods for MER ± VAB (at fixed 8 µg/ml) and comparators. CRE was defined as an isolate non-S (CLSI criteria) to imipenem and/or meropenem. CLSI, US-FDA (tigecycline) and EUCAST interpretative criteria were applied.**Results:** MER/VAB ($MIC_{50/90}$, 0.03/0.06 µg/ml) was very active against ENT isolates and 99.8% of the isolates were inhibited at ≤1 µg/ml (MER S CLSI breakpoint) and only one isolate (*K. pneumoniae* [KPN] from Texas) had a MER/VAB MIC >4 µg/ml. MER alone inhibited 98.4% of the isolates at the same concentration. Among 839 KPN tested, 94.9% were S to MER and 98.2% of the isolates were inhibited by MER/VAB at ≤1 µg/ml. MER/VAB was very active against other ENT species and inhibited all 1621 *E. coli* and 121 *C. freundii* at ≤0.06 µg/ml and all 371 *E. cloacae*, 232 *P. mirabilis* and 68 *M. morgannii* isolates tested at ≤0.12 µg/ml. One *S. marcescens* displayed a MER/VAB MIC result at 0.5 µg/ml but the other 180 isolates tested had MIC results at ≤0.12 µg/ml and 97.8% were S to MER using the CLSI criteria. MER/VAB was very active against ESBL-phenotype isolates (n=387 [9.7% overall]; $MIC_{50/90}$, 0.03/0.06 µg/ml) and CRE isolates (n=59 [1.5% overall]; $MIC_{50/90}$, 0.06/2 µg/ml) that included 38 KPN and six other species. MER alone inhibited 87.9% of the ESBL, but only 3.4% of CRE isolates using CLSI breakpoints. CRE isolates were resistant to β-lactams (S rates ranged from 0.0 to 3.4%) and more resistant to other antimicrobial classes when compared to overall ENT isolates. Minocycline, colistin and tigecycline displayed the highest S rates (81.4, 82.4 and 100.0% S by CLSI, EUCAST and US-FDA criteria) against CRE.**Conclusions:** MER/VAB was very active against ENT isolates recently collected in USA hospitals and the advantage of this combination over MER alone was demonstrated in CRE isolates that are less susceptible to other clinically available antimicrobials.

Sanishvili[4]; [1]Univ. of South Florida, Tampa, FL, [2]Univ. of California San Francisco, San Francisco, CA, [3]Clermont Univ´., Clermont-Ferrand, France, [4]Advanced Photon Source, Argonne, IL

Abstract Body:

Beta-lactamases are the main resistance mechanism against beta-lactam antibiotics in Gram-negative bacteria. Inhibitor discovery against these enzymes has mainly focused on covalent ligands, while the development of novel chemotypes remains challenging. Using a fragment-based structural approach, we recently uncovered a tetrazole-based non-covalent inhibitor displaying a Ki of 89 nM against CTX-M-9 Class A beta-lactamase, one of the most common clinically observed extended spectrum beta-lactamase. Here we demonstrate that this compound is able to inhibit a range of serine beta-lactamases including different CTX-M subtypes and some enzymes from other classes, reducing the MIC of cefotaxime by 2-8 fold in bacteria expressing these proteins. The same inhibitor also allowed us to capture a special short hydrogen bond (2.53 Angstrom) between the catalytic Ser70 and the purported general base Lys73, where the hydrogen is equi-distant to the two heteroatoms. This observation sheds new light on the catalytic mechanism by Class A beta-lactamases and potentially by many other enzymes as well. Additionally, through virtual screening, we have developed new tetrazole-based inhibitors displaying activity against both KPC-2 and NDM-1, two of the most problematic carbapenemases, in biochemical testing. These studies demonstrate that tetrazole-based compounds can provide new scaffolds in developing novel beta-lactamase inhibitors as well as unique chemical probes in studying the catalytic mechanisms of these proteins.

Easy Detection of Bacterial Tolerance to Antibiotics in Clinical Isolates by a Modified Disk-Diffusion Assay

Author Block:

O. Gefen[1], **J. Strahilevitz**[2], N. Q. Balaban[1]; [1]Hebrew Univ., Jerusalem, Israel, [2]Hadassah Med. Ctr., Jerusalem, Israel

Abstract Body:

Background: Antibiotic drug tolerance - the ability to survive longer under bactericidal treatments - is a potentially clinically significant phenomenon that is overlooked because time-kill assays are too labor intensive to perform routinely in clinical microbiology labs. We developed the TDtest, a simple modification of the standard disk-diffusion assay, that allows the semi-quantitative evaluation of survival rate and killing dynamics. **Methods:** The TDtest consists of a regular disk-diffusion test modified by the replacement of the antibiotic disk with a nutrient-rich disk, and incubation for additional 7 hours. Tolerant bacteria were detected by the growth of colonies within the inhibition zone. Tolerance levels were categorized according to the ratio of surviving colonies to the number of plated cells within the zone of inhibition; low tolerance ($<10^{-5}$), medium tolerance (10^{-5} to 10^{-3}) and high tolerance ($>10^{-3}$). Tolerance detected by the TDtest was correlated with time-kill curves.**Results:** Time-kill curves showed a 2 to 3-log increased survival to ampicillin for the previously defined *tolerance by lag E.coli* mutants (*metG* and *vapB*) versus *wt E.coli* K-12 after 10 hours incubation. With the TDtest, the level of tolerance to ampicillin of *metG* and *vapB* mutants and *wt E.coli* K-12 was high, high, and low, respectively. Using the TDtest, we were able to detect similar differences in the levels of antibiotic tolerance in clinical isolates of *E.coli*. Furthermore, the TDtest identified antibiotics that effectively eliminate ampicillin tolerant bacteria, as further confirmed by time-kill curves.**Conclusions:** The additional information on drug susceptibility provided by the TDtest should enable the tailoring of better treatment regimens for antibiotic tolerant pathogenic bacteria.

Identification of Novel Fluoroquinolones, Wfq-101 and Its Analogues, Circumventing Bacterial Efflux Pumps

Author Block:

D. Kazamori, T. Kinoshita, A. Sasaki, S. Inoue, T. Hirano, H. Amano, Y. Kuramoto, A. Yazaki; Wakunaga Pharmaceutical Co., Ltd., Hiroshima, Japan

Abstract Body:

Background: Spread of drug-resistant bacteria has been a serious and global concern. Over-expression of efflux pumps is one of the major resistant mechanisms in Gram-negative bacteria. In this study, we evaluated antibacterial activity of novel fluoroquinolones of WFQ-101 and its analogues against Gram-negative bacteria, focusing on the impact of the bacterial efflux pumps.**Methods:** Clinical isolates of bacteria were collected from hospitals, universities, and bacteria suppliers. MICs were determined according to standard agar dilution method described by the Japanese Society of Chemotherapy. The effect of efflux pumps on the antibacterial activities was evaluated by comparing the MIC values with and without efflux pump inhibitor of PAβN.**Results:** WFQ-101 and its most potent analogue of WFQ-228 displayed highly potent antibacterial activities against clinical isolates of *P. aeruginosa* (133 strains) and *E. coli* (111 strains); MIC_{90} values of WFQ-101, WFQ-228, and levofloxacin were 8, 2, and 64 mg/L for *P. aeruginosa* and 4, 2, 32 mg/L for *E. coli*, respectively. Compared to levofloxacin, WFQ-228 exerted 32 and 16 times more potent activities against *P. aeruginosa* and *E. coli*, respectively. In addition, the mean MIC value of WFQ-101 was only 3.2-fold decreased against *P. aeruginosa* (3 strains) by co-treatment with PAβN, whereas that of levofloxacin was drastically decreased (26-fold). Furthermore, the treatment of PAβN had little impact on the antibacterial activities of WFQ-101 analogues.**Conclusions:** WFQ-101 analogues demonstrated the superior antibacterial activities against quinolone-resistant Gram-negative bacteria, including *P. aeruginosa* and *E. coli*. This high potency of the compounds would be attributed to the distinct property being poor substrates for efflux pumps of Gram-negative bacteria. These findings indicate that this series of compounds could overcome the drug resistance conferred by the over-expression of bacterial efflux pumps.

***In Vitro* Activity of WCK 771, a Benzoquinolizine Fluoroquinolone (Levonadifloxacin) When Tested against Contemporary Gram-Positive and -Negative Bacteria from a Global Surveillance Program**

Author Block:

R. K. Flamm, H. S. Sader, D. J. Farrell, P. R. Rhomberg, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: Intravenous (WCK 771) and oral (WCK 2349) formulations of the anti-MRSA fluoroquinolone, levonadifloxacin (LND) are in clinical development and were awarded QIDP status. LND has a broad spectrum of activity including fluoroquinolone- and methicillin-resistant *Staphylococcus aureus* (MRSA). In this study, LND was tested against Gram-positive and -negative clinical isolates collected in medical centers worldwide as part of the 2014 SENTRY Antimicrobial Surveillance Program.**Methods: 4,276 isolates from United States, 4,264 (Europe), 1,975 (Asia-Pacific), and 1,959 (Latin America) were susceptibility (S) tested against LND and multiple comparators by reference broth microdilution (CLSI).Results:** 96.8% of *S. aureus* (SA) isolates were inhibited at a LND concentration of ≤2 µg/mL (n=4,077; MIC_{50}/MIC_{90}, 0.015/1 µg/mL). MICs for LND were elevated for MRSA (MIC_{50}/MIC_{90}, 0.5/2 µg/mL) compared to MSSA (MIC_{50}/MIC_{90}, 0.015/0.015 µg/mL) and for levofloxacin (LEV)-R (MIC_{50}/MIC_{90}, 0.5/4 µg/mL) compared to LEV-S (MIC_{50}/MIC_{90}, 0.015/0.015 µg/mL) isolates. However 91.5 and 88.8% of MRSA and LEV-R SA were inhibited at LND MICs ≤2 µg/mL, respectively. All SA were S to vancomycin, tigecycline, and linezolid. Daptomycin S was 99.9% and LEV S 71.7% (MRSA LEV S, 30.8%). The MIC_{50}/MIC_{90} for LND against *Streptococcus agalactiae* (n=353) and *S. pyogenes* (n=352) was 0.25/0.5 µg/mL; against viridans group streptococci (n=438) the MIC_{50}/ MIC_{90}, was 0.5/1 µg/mL. Against enterococci (n=535), LND MICs were elevated for *E. faecium* (MIC_{50}/MIC_{90}, >8/>8 µg/mL) compared to *E. faecalis* (MIC_{50}/MIC_{90}, 0.25/8 µg/mL). LND MIC_{50}/MIC_{90} values were 0.015/0.03 µg/mL for *Haemophilus influenzae* (n=1,002) and 0.015/0.015 µg/mL for *Moraxella catarrhalis* (n=504). Against *S. pneumoniae* the MIC_{50}/MIC_{90} for LND was 0.25/0.5 µg/mL and for LEV 1/1 µg/mL (n=1,196). The LND MIC_{50}/MIC_{90} against 3,000 Enterobacteriaceae was 0.5/>8 µg/mL with 73.2% of isolates inhibited at ≤4 µg/mL (LEV-S, 78.1/76.9% [CLSI/EUCAST]) and for *Pseudomonas aeruginosa* was 2/>8 µg/mL and 67.4% inhibited at ≤4 µg/mL (LEV-S, 71.2/62.7% [CLSI/EUCAST]).**Conclusions:** WCK 771 activity, including potent activity against MRSA supports the potential value of further development studies to define its clinical use.

***In Vitro* Activity of Delafloxacin (DLX) When Tested against Contemporary Bacterial Pathogens from the USA (2014)**

Author Block:

R. K. Flamm, D. J. Farrell, H. S. Sader, P. R. Rhomberg, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: DLX is an anionic fluoroquinolone in clinical development (oral and intravenous routes) for the treatment of acute bacterial skin and skin structure infections and community acquired bacterial pneumonia. In this study, DLX was tested against clinical isolates collected in USA medical centers as part of the 2014 SENTRY Antimicrobial Surveillance Program.**Methods:** A total of 4,410 USA clinical isolates were tested for susceptibility (S) to DLX and comparators by reference broth microdilution.**Results:** DLX was the most potent ($MIC_{50/90}$, ≤0.004/0.03 μg/mL) agent tested against methicillin-susceptible *Staphylococcus aureus* (MSSA) and based on MIC_{90} was eight- and 128-fold more potent than ceftaroline (CPT) and levofloxacin (LEV). Tigecycline ($MIC_{50/90}$, 0.06/0.06 μg/mL), DLX ($MIC_{50/90}$, 0.06/0.5 μg/mL), trimethoprim-sulfamethoxazole (SXT, $MIC_{50/90}$, ≤0.5/≤0.5 μg/mL), and daptomycin ($MIC_{50/90}$, 0.25/0.5 μg/mL) were the most potent agents tested against MRSA. MRSA exhibited high levels of resistance (R) against LEV (68.4%) and erythromycin (82.9%). DLX ($MIC_{50/90}$, 0.06/1 μg/mL), linezolid ($MIC_{50/90}$, 1/1 μg/mL) and SXT ($MIC_{50/90}$, ≤0.5/≤0.5 μg/mL) were the most active agents against *Enterococcus faecalis.* Against *S. pneumoniae* ($MIC_{50/90}$, 0.008/0.015 μg/mL), DLX was eight-fold more active than CPT ($MIC_{50/90}$, ≤0.015/0.12 μg/mL; 99.7% S), 16-fold more active than moxifloxacin ($MIC_{50/90}$, ≤0.12/0.25 μg/mL; 98.3% S), and 64-fold more active than LEV ($MIC_{50/90}$, 1/1 μg/mL; 98.3% S). All DLX MIC values for *S. pyogenes* were ≤0.015 μg/mL and for *S. dysgalactiae* ≤0.03 μg/mL. For *S. agalactiae*, 98.0% of isolates were ≤0.03 μg/mL; the highest MIC was only 0.5 μg/mL. Against Enterobacteriaceae, the DLX $MIC_{50/90}$ was 0.06/2 μg/mL with 82.3% of isolates at ≤1 μg/mL. Ciprofloxacin (CIP) and LEV S were 82.8 and 84.3%, respectively. DLX inhibited 75.0% of *P. aeruginosa* at ≤1 μg/mL; CIP and LEV exhibited S at 76.0 and 75.0%, respectively. DLX inhibited 59.0% of *Acinetobacter* spp. at ≤1 μg/mL. CIP S and LEV S were poor (48.0 and 50.0%, respectively).**Conclusions:** DLX offers advantages in potency and spectrum *in vitro* when compared to currently marketed fluoroquinolone agents, especially with its enhanced activity against *S. aureus* including methicillin-resistant strains, and improved potency against *S. pneumoniae* and β-hemolytic streptococci.

***In Vitro* Efficacy of Am-1977, a New Fluoroquinolone, Against *Streptococcus pneumoniae* with Fluoroquinolone Resistance-determining Regions (Qrdrs) Mutations**

Author Block:

M. Murata, K. Kosai, S. Yamauchi, D. Sasaki, N. Kaku, Y. Morinaga, K. Yanagihara; Nagasaki Univ. Hosp., Nagasaki, Japan

Abstract Body:

Background: Fluoroquinolone resistance in *Streptococcus pneumoniae* is caused by gradual accumulation of DNA gyrase (GyrA) and topoisomerase IV (ParC) mutations in the fluoroquinolone resistance-determining regions (QRDRs). In this study, we evaluated relations between QRDR mutations, drug susceptibility and frequencies of appearance of resistant strains against fluoroquinolones including AM-1977, which was a newly developed by Kyorin Pharmaceutical Co., Ltd.**Methods:** We evaluated minimum inhibitory concentrations (MICs) for seven fluoroquinolones and the presences of *gyr*A and *par*C mutations by pyrosequencing method in 34 clinical isolates. Further, we evaluated frequencies of appearance of resistant strains against levofloxacin (LVX) and AM-1977 for two strains which had wild-type *gyr*A and *par*C mutation as a first step mutation.**Results:** The MICs for LVX were 1 or 2 μg/mL in 19 strains with neither *gyr*A nor *par*C mutation, 2 μg/mL in 14 strains with either mutation and 4 μg/mL in one strain with both mutations. All strains had the MICs of 0.06 or 0.12 μg/mL for AM-1977. Table showed the frequencies of appearance of resistant strains selected by multiple concentrations of fluoroquinolones. GyrA mutation was additionally detected in resistant strains generated by exposure to 2×, 4×MIC of LVX, but not to 2×MIC of AM-1977. Those resistant strains, which were generated by LVX exposure and had both *gyr*A and *par*C mutations, had MICs of 16 or 32 μg/mL for LVX and 0.12 to 0.5 μg/mL for AM-1977.**Conclusions:** Both the MICs and the frequencies of appearance of resistant strains were lower for AM-1977 than for LVX. In addition to low MICs, AM-1977 was superior to LVX with respect to preventing resistance induction when the strains had a single step mutation and were exposed to each fluoroquinolone.

The frequencies of appearance of resistant strains selected by fluoroquinolones

Mutation in ParC	Drug	Frequency at the following drug concentration			
		2×MIC	4×MIC	8×MIC	16×MIC
Ser79Phe	LVX	1.08×10^{-7}	4.66×10^{-8}	$<1.27\times10^{-9}$	$<1.27\times10^{-9}$
	AM-1977	5.52×10^{-9}	$<1.27\times10^{-9}$	$<1.27\times10^{-9}$	$<1.27\times10^{-9}$
Asp83Tyr	LVX	1.90×10^{-7}	3.47×10^{-8}	$<2.59\times10^{-8}$	$<2.59\times10^{-8}$

	AM-1977	3.90×10^{-9}	$<2.59\times10^{-8}$	$<2.59\times10^{-8}$	$<2.59\times10^{-8}$

Mechanism for High Pulmonary Distribution of Lascufloxacin (Am-1977), a New Fluoroquinolone Antibiotic

Author Block:

K. Ohya, S. Manita; Kyorin Pharmaceutical Co., Ltd., tochigi, Japan

Abstract Body:

Background: Lascufloxacin is highly active especially against respiratory tract pathogens. Moreover, clinical pharmacological study (Phase I) revealed that the tissue-to-plasma concentration ratio (T/P) of lascufloxacin was 21 in the lung epithelial lining fluid (ELF). Generally, a high tissue distribution of drugs can be attained through higher active transport or tissue binding. In this study, therefore, several *in vitro* assays were carried out to clarify the mechanisms governing higher distribution of lascufloxacin into the alveolar compartment.**Methods:** Transcellular transport of lascufloxacin and the effects of various inhibitors on this transport were both evaluated using Calu-3 cell monolayers, known as a human lung epithelial cell model. Substrate recognition of lascufloxacin mediated by various drug transporters was assessed using each of the transporter-expressing cells.**Results:** Vectorial transport of lascufloxacin to the secretory direction was observed in the transcellular transport assay across Calu-3 cell monolayer. The concentration-dependent inhibition of lascufloxacin transport by valspodar and Ko143 resulted from involvements of P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP) in to this transport. In addition, each of the transporter-expressing cells showed that lascufloxacin is a substrate for P-gp and BCRP.**Conclusions:** This result clearly indicates that lascufloxacin is subject to P-gp- and BCRP-mediated active transport in the Calu-3 model. This transporter-dependent secretion may lead to higher lascufloxacin concentrations in ELF than those in plasma. Furthermore, we now assume that lascufloxacin might bind to some component(s) of ELF.

Table. Substrate recognition of lascufloxacin mediated by MDR1 and BCRP

Transporter	Control cells			Transporter-expressing cells			Corrected P_{app} ratio
	P_{app} ($\times 10^{-6}$cm/sec)		P_{app} ratio	P_{app} ($\times 10^{-6}$cm/sec)		P_{app} ratio	
	AP to BL	BL to AP		AP to BL	BL to AP		
MDR1	14.7	21.0	1.4	7.08	31.1	4.4	3.1
BCRP	18.1	49.0	2.7	18.6	80.9	4.3	1.6

Gepotidacin (GSK2140944) *In Vitro* Activity against Gram-Positive and Gram-Negative Bacteria (MBC/MIC, Kill Kinetics, Checkerboard, PAE/SME Tests)

Author Block:

R. K. Flamm[1], H. S. Sader[1], P. R. Rhomberg[1], N. E. Scangarella-Oman[2], D. J. Farrell[1]; [1]JMI Lab., North Liberty, IA, [2]GSK, Collegeville, PA

Abstract Body:

Background: Gepotidacin (GEP) is a novel triazaacenaphthylene antibiotic, which inhibits bacterial DNA replication and has *in vitro* activity against susceptible and drug-resistant pathogens associated with a range of conventional and biothreat infections.**Methods:** Reference *in vitro* methods were used to evaluate the MIC/MBC activity of GEP and comparators against *S. aureus* (SA), *S. pneumoniae* (SPN) and *Escherichia coli* (EC). GEP *in vitro* activity was also evaluated using time-kill kinetics (KK), broth microdilution checkerboard methods (CM) and for post-antibiotic (PAE) and sub-inhibitory (PAE-SME) effects.**Results:** MIC_{90} values for GEP against 50 SA (including MRSA) and 50 SPN (including penicillin-intermediate and -resistant) isolates were 0.5 µg/mL and for EC (n=25) was 4 µg/mL. GEP was bactericidal against the tested strains of SA, *SPN*, and EC. GEP had MBC/MIC ratios of ≤4 against 98, 98, and 88% of isolates tested, respectively. KK indicated that bactericidal activity for GEP was generally observed at 4 or 10x MIC concentrations at 24 hours. In a few instances, regrowth was observed in the presence of GEP and in the presence of levofloxacin. CM experiments demonstrated no occurrences of antagonism when testing GEP in combination with a variety of currently used antimicrobial agents including aztreonam, ceftriaxone, tetracycline and trimethoprim-sulfamethoxazole. The most common interaction when testing GEP was indifference (82.7% for Gram-positive and 82.0% for Gram-negative). The PAE for GEP against SA was short (≤0.6 hours against MRSA and MSSA) and the PAE-SME was extended in length (>8 hours; 3 isolates at ½x MIC). Against the levofloxacin-susceptible *SA* isolate tested, the PAE for levofloxacin was modest (0.1-2.4 hours) and an extended PAE-SME was observed (>9 hours at ½x MIC).**Conclusions:** GEP demonstrated bactericidal activity against the majority of Gram-positive and Gram-negative isolates tested. For the isolate and drug combinations tested, *in vitro* checkerboard studies showed that interactions were generally indifferent and no antagonism was seen. The PAE for GEP was of short to modest duration, with an extended PAE-observed in the presence of sub-MIC concentrations. These *in vitro* data indicate that further study of GEP is warranted.

Gepotidacin (GSK2140944) *In Vitro* Activity against *Neisseria gonorrhoeae* (MIC/MBC, Kill Kinetics, Checkerboard, PAE/SME Tests)

Author Block:

D. J. Farrell[1], H. S. Sader[1], P. R. Rhomberg[1], N. E. Scangarella-Oman[2], R. K. Flamm[1]; [1]JMI Lab., North Liberty, IA, [2]GSK, Collegeville, PA

Abstract Body:

Background: Gepotidacin (GEP) is a novel triazaacenaphthylene antibiotic, which inhibits bacterial DNA replication and has *in vitro* activity against susceptible and drug-resistant pathogens associated with a range of conventional and biothreat infections, including *Neisseria gonorrhoeae* (GC).**Methods**: Broth microdilution using fastidious broth was used to evaluate the MIC/MBC activity of GEP and comparator agents against 25 GC strains (including 5 ciprofloxacin [CIP] non-susceptible [NS] strains). GEP *in vitro* activity was also evaluated against 3 GC strains (including ATCC 49226 and two tetracycline [TET]- and azithromycin [AZI]-NS strains) using time-kill kinetics and checkerboard methods, and against 2 GC strains for the investigation of post-antibiotic (PAE) and sub-inhibitory (PAE-SME) effects.**Results**: The MIC_{50} and MIC_{90} for GEP against 25 GC isolates were 0.12 and 0.25 µg/mL, respectively. The highest GEP MIC value was 0.25 µg/mL. The MBC_{50} and MBC_{90} for GEP were 0.25 and 0.5 µg/mL, respectively, and the highest MBC value was 1 µg/mL (2 isolates). GEP was bactericidal when tested against GC with 25/25 of isolates exhibiting a MBC/MIC ratio of ≤4 (≤2 for 20/25 of the isolates). GEP demonstrated bactericidal activity in time-kill curves against the 3 GC strains tested. For all the combinations of GEP and comparators tested against GC, using checkerboard methods, there were no instances where antagonism occurred and only one instance where synergy occurred (with moxifloxacin; FIC index, 0.375), but this was not confirmed by *in vitro* time-kill studies. An extended PAE for GEP against the wild-type GC strain (0.5->2.5 hours) and an extended PAE-SME (>2.5 hours) occurred. The GEP PAE (0.7 hours at all exposures) and PAE-SME (1.2-2.7 hours) was shorter with the TET- and AZI-NS GC strain.**Conclusions**: Using MBC and time-kill kinetics, GEP demonstrated bactericidal activity against the *N. gonorrhoeae* isolates tested. *In vitro* checkerboard studies showed interactions were generally additive/indifferent and no antagonism was seen. The PAE for GEP was generally short to modest duration, with an extended PAE-observed in the presence of sub-MIC concentrations. These *in vitro* data indicate that further study of GEP is warranted for potential use in treating infections caused by GC.

Analysis of Agar Dilution Mic Testing Methods and Variables and *In Vitro* activity of Gepotodacin (Gsk2140944) Against *Neisseria gonorrhoeae*

Author Block:

N. E. SCANGARELLA-OMAN[1], P. Dixon[2], L. M. Koeth[3], J. DiFranco-Fisher[3], L. A. Miller[1]; [1]GSK, COLLEGEVILLE, PA, [2]UAB, Birmingham, AL, [3]LSI Inc., Westlake, OH

Abstract Body:

Background: Gepotidacin (GEP), a novel triazaacenaphthylene antibiotic which inhibits bacterial DNA replication, has *in vitro* activity against susceptible and drug-resistant pathogens associated with a range of conventional and biothreat infections, including *Neisseria gonorrhoeae* (GC).**Methods**: 145 GC isolates selected from the University of Alabama at Birmingham's isolate collection were tested by agar dilution according to Gonococcal Isolate Surveillance Program and CLSI methodology. The effect of Mueller-Hinton agar manufacturer, temperature, incubation time, atmospheric conditions, inoculum concentration and pH on the *in vitro* activity of GEP were also studied.**Results**: The MIC_{50} and MIC_{90} for GEP against the 145 GC isolates tested were 0.25 and 0.5 µg/mL, respectively (highest GEP MIC was 1 µg/mL). Against 108 ciprofloxacin-susceptible (CIP-S) and 37 non-susceptible (CIP-NS) isolates, GEP MIC_{90}s were 0.25 and 1 µg/mL, respectively. A 2-dilution higher shift in GEP MICs was noted for the CIP-NS subset when compared with the CIP-S isolates. Variables that affected GEP MICs were media, low inoculum concentrations, pH levels and atmospheric conditions, Media had the most effect, but the effect was not specific to GEP. Remel GC agar supplemented with GCHI enrichment did not support the growth of any study isolate. Lower MIC results and poor/no growth were observed with all agents tested with Oxoid GC agar supplemented with GCHI enrichment. Inoculum concentration also affected and caused lower GEP MICs. Use of an organism suspension equivalent to a 0.5 McFarland (10^5 CFU/spot) was necessary to obtain sufficient growth of all study strains and acceptable quality control results. GEP MICs were affected by pH and by 10% CO_2 (29/30 were within +/-2 dilutions and 25/30 were lower than the reference method MIC).**Conclusions**: GEP was active *in vitro* with MICs 1 µg/mL against the 145 strains of GC tested. Further evaluation is recommended to understand the mechanism causing the 2-dilution higher GEP MICs against CIP-NS GC isolates. When performing MIC testing with GEP, it is important to control media manufacturer, inoculum, CO_2 and pH. These *in vitro* data indicate that further study of GEP is warranted for potential use in treating infections caused by GC.

***In Vitro* Biology and Pharmacokinetics of Novel Bacterial Topoisomerase Inhibitors**

Author Block:

C. Charrier, A-M. Salisbury, V. Savage, E. Moyo, N. Ooi, N. Chaffer-Malam, H. Forward, J. Cheung, R. Metzger, M. Pichowicz, R. Sigerson, I. Cooper, P. Vince, I. Morrison, H. Butler, S. Best, A. Ratcliffe, N. Stokes; Redx Pharma Plc, Alderley Edge, United Kingdom

Abstract Body:

Background: The bacterial type II topoisomerases, DNA gyrase and topoisomerase IV (topo IV), are validated antibiotic targets. Owing to the emergence of quinolone resistance, structurally-novel inhibitors of these targets are sought. The objective of this study was to profile a new series of Novel Bacterial Topoisomerase Inhibitor (NBTI) type compounds.**Methods:** MICs and MBCs were determined according to CLSI guidelines M07-A10, M11-A8 and M26-A. Inhibition of purified DNA gyrase, topo IV and human topoisomerase II was evaluated using supercoiling, decatenation or DNA cleavage complex formation assays. Frequency of resistance was determined with *Escherichia coli* ATCC 25922. Serial passage experiments were carried out at 0.25 × MIC. Mutants were characterised by whole genome sequencing. Cytotoxicity was evaluated using the HepG2 cell line. hERG inhibition was determined using IonWorks patch clamp electrophysiology. Pharmacokinetics (PK) were measured in male CD-1 mice following intravenous dosing at 2 and 20 mg/kg.**Results:** Representative compounds REDX06213, REDX06276 and REDX07623, showed broad-spectrum activity with MICs from 0.12 to 8 µg/mL against the ESKAPE pathogens. These compounds demonstrated MIC_{90} values of 4-8 µg/mL against *Acinetobacter baumannii* and *E. coli* compared to 16 µg/mL for levofloxacin. REDX06213 had IC_{50} values of 1.66 and 0.17 µM against *E. coli* and 0.14 and 0.37 µM against *S. aureus* DNA gyrase and topo IV, respectively and an IC_{50} of ~100 µM against human topoisomerase II. REDX06213 did not stabilise double-strand DNA cleaved complexes. The mutation rate of *E. coli* against this series was $<4.2 \times 10^{-9}$ at 4 × MIC. Unique mutations were identified in the mutants. HepG2 IC_{50} values were typically 32 - >128 µg/mL and hERG inhibition IC_{50} values >33 µM. PK profiling showed good tolerability and exposure for REDX06213.**Conclusions:** Compounds of this NBTI series demonstrated broad-spectrum potency against clinically-important pathogens, a low potential for resistance development and a mechanism-of-action distinct from the quinolones. The biological properties of these novel dual-targeting NBTIs merit further exploration of their potential as new antibacterial agents.

Novel and Potent Dual Bacterial Dna Topoisomerase Inhibitors Active Against Gram-positive and Gram-negative Bacteria: from Target to Lead

Author Block:

R. Ombrato, C. Apicella, A. Capezzone De Joannon, G. Corso, N. D'Atanasio, G. Furlotti, B. Garofalo, G. Mangano, G. Magarò, C. Milanese, S. Tongiani; Angelini Res. Ctr., S Palomba-Pomezia Rome, Italy

Abstract Body:

DNA gyrase and topoisomerase IV (topo IV) are clinically validated bacterial targets. Our team is involved in the discovery and development of Novel Bacterial Topoisomerase Inhibitors (NBTIs) acting concurrently on both DNA gyrase and topo IV. This program started with the identification of a series of hit compounds following a structure-based screening campaign. The X-ray structure of *S. aureus* DNA gyrase with the DNA and co-crystallized with one of our hits was used to further optimize the new NBTIs as more potent dual enzyme inhibitors. The *in vitro* results together with the knowledge of the 3D-structure supported an extensive hit to lead program around the hit core scaffolds generating a patentable series. Our NBTIs were assessed for antibacterial activity against key Gram-positive, Gram-negative strains and clinical isolates and found to possess broad-spectrum activity, especially against antibiotic-resistant strains, with MIC ranges of 0.016-4 mg/l. The bactericidal activities against *S. aureus* ATCC 29213 and *S. aureus* BAA1720 was recorded by time-kill experiments at concentrations equal to 4× MIC. Presently, the identified compounds show an exquisite antibacterial profile with a selective DNA Synthesis inhibition while having a low to moderate *in vitro* frequency resistance. To our knowledge, in comparison with NBTI currently in development, Angelini's proprietary compounds showed an improved antibacterial profile against selected panels of both Gram-positive and -negative bacteria. The ADME *in vitro* profile was investigated and the most promising compounds show low *in vivo* clearance, slow elimination rate, rapid absorption and a high distribution volume which make them potentially suitable for oral administration. So, these compounds are going to be evaluated for *in vivo* efficacy in the murine sepsis model to assess their efficacy in comparison with quinolone treatment. Ongoing, *in vivo* PK/PD studies in mice are planned to support *in vitro* results. Angelini's new proprietary bacterial topoisomerase inhibitors show very promising properties to be transformed into clinically useful antibacterial agents.

Drug Candidate Discovery: Targeting Bacterial Topoisomerase I Enzymes for Novel Antibiotic Leads

Author Block:

S. Sandhaus; Florida Intl. Univ., Miami, FL

Abstract Body:

Introduction: The global community is facing a crisis—antibiotics are often ineffective due to the emergence of multi-drug resistant bacterial pathogens. The need for new antibiotics acting against novel bacterial cell targets is dire. Bacterial topoisomerase I (TopoI) is an attractive target for new antibiotics, since it should be vulnerable to bactericidal topoisomerase poison inhibitors in every bacterium, and its function is known to be required for the survival of certain bacterial pathogens including *Mycobacterium tuberculosis*. Selective and potent inhibitors of bacterial TopoI can be useful as new antibiotic leads. Bacterial TopoI relaxes supercoiled DNA by using its active-site tyrosine residue to attack the phosphodiester backbone of the DNA, forming a covalent intermediate and cleaving one strand of the DNA. It then passes the other strand through the break and rejoins the DNA to increase the DNA linking number by one. Catalytic inhibitors of topoisomerase I may prevent the enzyme from binding or cleaving the DNA, while poison inhibitors can stabilize the DNA-enzyme covalent intermediate, thus causing the accumulation of DNA breaks, leading to bacterial cell death. This project seeks novel inhibitors of bacterial topoisomerase I in various bacterial strains such as *E. coli*, *M. tuberculosis*, and *Y. pestis*. **Methods:** Two main assays are used to find antibacterial compounds that target TopoI—an enzyme inhibition assay (a gel-based assay that monitors the formation of relaxed DNA in the presence of inhibiting compounds), and a growth inhibition assay (an assay that monitors the growth of bacteria in the presence of topoisomerase inhibitors). **Results:** Several promising compounds have been found from various screens—an *in silico* study has uncovered several small molecule inhibitors, and a mixture-based compound screen has revealed several polyamine inhibitors—that inhibit bacterial TopoI well, and are able to prevent bacterial cell growth as well. Specifically, many of the discovered compounds are effective against *M. tuberculosis* topoisomerase I, and can prevent the growth of *M. smegmatis*, a non-pathogenic homolog of *M. tuberculosis*. **Conclusions:** The use of diverse approaches such as *in silico* docking studies and mixture-based compound screening is effective at finding novel inhibitors of bacterial topoisomerase I, and may bring us one step closer to new and effective antibiotics.

Targeting Bacterial Topoisomerase I for Selective Anti-streptococcal Drug Design

Author Block:

J. A. Jones, E. Price, K. E. Hevener; Idaho State Univ., Meridian, ID

Abstract Body:

Background: Viridans Group Streptococci (VGS) are increasingly implicated in a variety of diseases such as endocarditis, pneumonia and bacteremia. Furthermore, VGS predominates the oropharynx and a primary representative of the group, *Streptococcus mutans*, is the principal cause of costly dental cariogenesis. With drug-resistant VGS infections on the rise and the dangers associated with the collateral eradication of beneficial bacteria within the oropharynx and gastrointestinal tract via the use of wide-spectrum antibacterials, the need for novel and selective VGS-directed antibacterial targets has become more apparent. Bacterial topoisomerase I may constitute such a potential target as studies have arisen showcasing the essentiality of topoisomerase I in bacterial species lacking the only other type IA topoisomerase, topoisomerase III. Accordingly, the goals of these studies were to develop a simplified purification protocol for topoisomerase I from *S. mutans* that would result in a significant increase in pure protein suitable for crystallography and assay development; and to develop and optimize a high-throughput assay suitable for screening and identification of selective anti-streptococcal agents. **Methods and Results:** Via the systematic analysis of different target protein affinity and fusion tag constructs utilizing immobilized metal affinity chromatography (IMAC) and gel filtration techniques, as well as auto-induction, we successfully developed a simplified, rapid expression and two-step purification protocol resulting in >20 mg/L of high-purity *S. mutans* topoisomerase I—a significantly higher yield than previously reported bacterial topoisomerase I purifications. Furthermore, we have also developed and optimized a microplate-based, fluorescence intensity assay for use in high-throughput compound screening against bacterial topoisomerase I. **Conclusion:** With the ease and speed afforded by the protocol, a considerable amount of bacterial topoisomerase I can be obtained without difficulty. As successful drug discovery efforts require substantial amounts of target protein for use in reliable high-throughput assays and structural studies, these results are anticipated to aid in the discovery and development of novel inhibitors of bacterial topoisomerase I, a potentially promising selective antibacterial drug target.

Phase I Study to Determine the Safety and Pharmacokinetics (Pk) of Single and Multiple Oral Doses of Lascufloxacin (Am-1977) in Healthy Subjects

Author Block:

K. Totsuka[1], M. Odajima[2], M. Nakauchi[2], S. Sesoko[3], M. Nakashima[3]; [1]Tokyo Women's Med. Univ., Tokyo, Japan, [2]Kyorin Pharmaceutical. Co. Ltd., Tokyo, Japan, [3]Maruyama Hosp., Shizuoka, Japan

Abstract Body:

Background: Lascufloxacin is a new generation fluoroquinolone with superior activity against respiratory tract pathogens, especially Gram-positives and anaerobes. A combined Phase I study protocol was designed to evaluate the safety and PK of single and multiple ascending oral doses of lascufloxacin in healthy adult subjects.**Methods:** In the single-dose study, 46 Japanese healthy adult males were included, 6 of which received single oral dose of 20 or 50 mg lascufloxacin under open-label design, 40 of which received single oral doses of 100-800 mg lascufloxacin/placebo under single-blind design. After safety was confirmed in the single-dose study, single-blind, placebo-controlled, multiple-dose study was performed. 16 subjects (in groups of 6 active and 2 placebo) received daily oral doses of 200 or 400 mg lascufloxacin for 7 consecutive days.**Results:** Lascufloxacin rapidly appeared in plasma with mean Tmax values ranged from 1.50 to 2.58 hours, and was slowly eliminated with mean t1/2 values ranged from 15.6 to 18.2 hours at 100-800 mg single doses. Mean Cmax and AUClast for lascufloxacin increased linear and approximately dose-proportional manner (0.732-6.00 μg/mL and 12.1-135 μg*h/mL respectively). %UR and CLr values were ranged from 11.7 to 15.0%, and 0.899 to 0.987 L/h, respectively. In the multiple dose study, mean Tmax value was 2.50 hours, and mean t1/2 values ranged from 22.8 to 24.2 hours on Day 7. Day 7 mean Cmax and AUCt for lascufloxacin 200 and 400 mg administration reached 2.61-6.55 μg/mL and 46.3-113 μg*h/mL respectively. Lascufloxacin was well tolerated at all doses. No serious adverse events (AEs) were observed, all AEs were mild to moderate in severity and disappeared without treatment.**Conclusions:** Overall safety and tolerability of lascufloxacin were excellent up to a single dose of 800mg and a repeated dose of 400mg. Lascufloxacin is expected to be clinically useful due to its favorable pharmacokinetics.

Pharmacodynamics of a Novel Fluoroquinolone, Lascufloxacin (Am-1977) in Polymicrobial Murine Pneumonia Model Caused By *Streptococcus pneumoniae* and *Prevotella intermedia*

Author Block:

M. Hagihara, H. Kato, N. Nishiyama, Y. Koizumi, D. Sakanashi, H. Suematsu, Y. Yamagishi, H. Mikamo; Aichi Med. Univ., Nagakute, Aichi, Japan

Abstract Body:

Background: Lascufloxacin (AM-1977) is a novel fluoroquinolone antimicrobial agent which has antimicrobial activity against aerobes and anaerobes, and could be administered orally or intravenously. *Streptococcus pneumoniae* (*Sp*) and *Prevotella intermedia* (*Pi*) are major aerobic and anaerobic pathogens of RTI, respectively. The purpose of this study is to compare the antimicrobial activities of lascufloxacin and levofloxacin (LVX) for the treatment of polymicrobial pneumonia caused by *Sp* and *Pi* in the neutropenic mice model.**Methods:** We used clinical isolates of *Pi* (MICs of lascufloxacin and LVX were 0.5 and 4 mg/L, respectively) and *Sp* (MICs of lascufloxacin and LVX were 0.06 and 1 mg/L, respectively) in neutropenic pneumonia polymicrobial infection model. Lascufloxacin and LVX were administered at the single doses of 25 or 50 mg/kg 1h after inoculation. 50 mg/kg was determined according to the AUC in mouse, which was nearly equivalent to the AUC of the clinical dose of lascufloxacin in human (i.e. 75mg q.d.). Efficacy was evaluated after 24h of therapy for the change of bacterial quantity in treated animals as compared with the 24h control animals.**Results:** At the start of the antimicrobial treatments (0h), bacterial quantities of *Sp* and *Pi* were 7.7 and 7.8 $\log_{10}$CFU, respectively. After 24h incubation, bacterial densities of *Sp* and *Pi* were 8.5 and 6.4 $\log_{10}$CFU, respectively. Lascufloxacin showed good *in vivo* activity against *Sp* (-1.7~-4.2 $\Delta\log_{10}$CFU) and *Pi* (-6.0~-6.5 $\Delta\log_{10}$CFU). On the other hand, the treatment with LVX resulted in lower activity against *Sp* isolates tested, while *in vivo* activity of lascufloxacin against *Sp* showed dose dependency. When comparing the antimicrobial activity of LVX at 50mg/kg, lascufloxacin revealed significantly higher bacterial density reduction against *Sp* (-4.2±0.3 vs. 0.7±0.1 $\Delta\log_{10}$CFU, $p<0.001$) and *Pi* (-6.9±0.7 vs. -4.7±0.8 $\Delta\log_{10}$CFU, $p=0.002$).**Conclusions:** Lascufloxacin showed greater *in vivo* activity not only for *Sp*, but also *Pi* in mouse mixed-infection model. Therefore, our results suggested that lascufloxacin would be potent candidate for the therapy of polymicrobial pneumonia caused by aerobes and anaerobes.

Intrapulmonary Pharmacokinetics of Lascufloxacin (Am-1977), a New Generation Fluoroquinolone, in Healthy Japanese Subjects

Author Block:

H. Furuie[1], H. Yoshida[2], K. Kume[2], Y. Owada[1], M. Yagi[1], H. Mikami[1], M. Nishimura[3]; [1]Osaka Pharmacology Clinical Res. Hosp., Osaka, Japan, [2]Kyorin Pharmaceutical Co., Ltd., Tokyo, Japan, [3]Hokkaido Univ. Sch. of Med., Sapporo, Japan

Abstract Body:

Background: Lascufloxacin (AM-1977) is a new generation fluoroquinolone with superior activity against respiratory tract pathogens, especially Gram-positives and anaerobes which causes a variety of infections including bacterial pneumonia in the elderly. This study was to evaluate the drug concentration in epithelial lining fluid (ELF) and alveolar macrophages (AMs) adding to plasma as a surrogate marker for lung penetration in order to assess the bronchopulmonary drug disposition of orally administered lascufloxacin 75 mg in healthy volunteers.**Methods:** Thirty never-smoked healthy Japanese male subjects were randomly allocated to 5 groups of 6 subjects each according to the time of bronchoalveolar lavage (BAL) at 1, 2, 4, 6, and 24 hours after dose. Blood samples were also taken at the corresponding time. Lascufloxacin was measured in plasma, ELF and AMs, and the pharmacokinetics analysis was performed.**Results:** Lascufloxacin was rapidly distributed to plasma and ELF while it slowly distributed to AMs. Tmax of ELF and plasma were 1 hour, and Tmax of AMs was 6 hour. Cmax of plasma, ELF and AMs were 0.576 μg/mL, 12.3 μg/mL and 21.8 μg/mL, respectively. The mean drug concentrations in ELF and AMs were much higher than those in plasma at all sampling points. The average drug concentration ratios of ELF/plasma and AMs/plasma were in the range of 15.0-22.4 and 18.5-56.4, respectively. And AUC of plasma, ELF and AMs were 7.67 μg*h/mL, 123 μg*h/mL, and 325 μg*h/mL, respectively.**Conclusions:** These excellent penetrations of lascufloxacin into the lung together with the activity against respiratory tract pathogens suggest that lascufloxacin is a promising new agent for treatment of respiratory tract infections.

Abstract Body:

Background: Lascufloxacin is a new generation fluoroquinolone with superior activity against respiratory tract pathogens, especially Gram-positives and anaerobes. The primary objective of this study was to evaluate the safety and PK of IV doses of lascufloxacin in healthy adult subjects.**Methods:** This presentation includes 2 studies. (1) Single-does study: 43 Japanese healthy adult males were received single IV doses of 50-800mg lascufloxacin. In the open-label arm, 3 subjects received 50mg lascufloxacin. In the single-blind arm, each cohort of 8 subjects (6 active and 2 placebo) received 100, 200, 400, 600, 800 mg lascufloxacin. (2) Multiple-dose study: single-blind, multiple-dose study was performed in each cohort of 8 subjects (6 active and 2 placebo) received daily 200, 400 and 400 mg loading doses (400 mg LD; 400 mg BID on Day1, 400 mg QD on Day 2-7) of lascufloxacin for 7 consecutive days.**Results:** In a single IV infusion over 1 hour of 100, 200, and 400 mg lascufloxacin, mean Cmax (1.09, 2.91, and 3.45 μg/mL) and AUClast values (12.7, 39.8, and 68.8 μg*h/mL) were dose proportional. In a repeated dose of 200 or 400mg infusion for 7 days, Accumulation ratio (Racc) values of Cmax and AUCt on Day7/Day1 were 1.32 -1.84 and 1.91-2.22, respectively. In the 400 mg LD arm, Racc values of Cmax and AUCt on Day7/Day1 were 1.13 and 1.34, respectively. Lascufloxacin was well tolerated at all doses. No serious adverse events (AEs) were observed, all AEs were mild to moderate in severity and disappeared without treatment.**Conclusions:** Overall safety and tolerability of intravenous lascufloxacin were excellent up to a single dose of 800mg, a repeated dose of 400mg and 400 mg LD. Plasma concentration with LD regimen was reached on steady level from the first day. The LD regimen is expected clinically useful.

In Vivo* Bactericidal Activity of Lascufloxacin (Am-1977), a Newly Developed Fluoroquinolone, Against Mouse Pulmonary Infection Model Caused by *Streptococcus pneumoniae

Author Block:

R. Kishii, N. Yamamuro, Y. Yamaguchi, H. Abukawa, M. Takei; Kyorin Pharmaceutical Co., Ltd., Tochigi, Japan

Abstract Body:

Background: Quinolones are known to possess the bactericidal property, therefore, they are expected to eradicate pathogenic bacteria quickly from the patients. Lascufloxacin (AM-1977) is a novel fluoroquinolone in clinical phase with potent antibacterial activity especially against respiratory tract pathogens. In this study, *in vitro* and *in vivo* bactericidal activity of lascufloxacin was evaluated.**Methods:** *In vivo* bactericidal activity was evaluated against mouse model of pulmonary infection caused by *Streptococcus pneumoniae*. The dose of each drug for *in vivo* model was determined according to the AUC in mouse, which was equivalent to the AUC of the clinical dose in human (i.e. lascufloxacin, 75 mg q.d.; levofloxacin, 500 mg q.d.).**Results:** *In vitro* time-kill study showed that lascufloxacin had rapid bactericidal activity with dose dependent manner. The *in vitro* activity of lascufloxacin was similar to that of other quinolones tested, however, lascufloxacin had more potent activity against *S. pneumoniae* pulmonary infection model in mouse than levofloxacin. 24 h after drug administration, 2.0 log cfu/lung of bacterial reduction from first inoculums were observed in the mouse treated with levofloxacin, whereas bacteria was decreased close to the assay limit (4.2 log cfu/lung reduction) in the mouse treated with lascufloxacin. Lung-to-plasma concentration ratio of lascufloxacin was 3.7 in rodent and it was higher than that of levofloxacin (0.9, reported data).**Conclusions:** Lascufloxacin showed potent bactericidal activity both *in vitro* and *in vivo*. In particular, lascufloxacin showed significant bacterial killing in mouse when the AUC in the model was same as that in the clinical dose, although the estimated clinical dose of lascufloxacin is the lowest level in the marketed quinolones. Good distribution of lascufloxacin in lung is likely to contribute to the potent efficacy *in vivo*. Clinical pharmacological study revealed that lascufloxacin showed excellent tissue distribution to lung. The results in this study suggest that lascufloxacin possesses rapid bactericidal activity and highlight the potential of lascufloxacin as a potent bactericidal agent for the treatment of respiratory tract infections.

Bactericidal Activity of Delafloxacin Against Recent Isolates of *Staphylococcus aureus*

Author Block:

J. Remy, A. Marra, E. Duffy; Melinta Therapeutics, New Haven, CT

Abstract Body:

Background: Delafloxacin, an anionic fluoroquinolone antimicrobial agent, demonstrates excellent *in vitro* activity against Gram-positive and Gram-negative pathogens and is currently undergoing evaluation as a potential treatment for acute bacterial skin and skin structure infections. Despite increased infection control efforts in the clinic, MRSA remains an important pathogen in skin infections. MRSA isolates from a recently completed delafloxacin Phase 3 clinical trial for the treatment of skin infections were selected for experiments to determine the bactericidal activity of delafloxacin by time-kill methodology. **Methods:** Delafloxacin, levofloxacin, vancomycin, daptomycin, and linezolid MICs were determined by the broth microdilution method against MRSA isolates that were identified as harboring zero (MRSA 110), three (MRSA 124), or four (MRSA 165) mutations in the QRDR. MBCs were determined after sampling from sub-MIC and subsequent concentrations. Time-kill experiments were performed at MIC multiples for each antibiotic to include human free C_{max} concentrations, with an inoculum of ~$5x10^5$ CFU/mL of each organism. At 0, 1, 2, 4, 6, 8, and 24 hours, a sample was removed from each flask, centrifuged, washed and diluted in PBS, and plated to determine the number of viable cells. Plates were incubated overnight at 35°C in ambient air. Colonies were counted and kill-curves were plotted using GraphPad Prism. Bactericidal activity was interpreted as a 3-$\log_{10}$ or greater decrease in CFU/mL. **Results:** At 16X MIC, delafloxacin killed MRSA 124 more rapidly than the same concentration of levofloxacin, and was bactericidal at 16X and 32X MIC against MRSA 165 at 24 hours. Against all three strains, daptomycin at 8X MIC and above demonstrated the most rapid killing of all agents tested. Vancomycin was bactericidal at 24 hours against these 3 isolates at concentrations above 8X MIC. Linezolid was bactericidal against MRSA 165 at 24 hours but was bacteriostatic against MRSA 110 and 124 at all concentrations tested. Bactericidal activity was observed for delafloxacin and levofloxacin against MRSA 110 at six hours for most concentrations. **Conclusions:** Delafloxacin, with MICs and MBCs more potent than those of levofloxacin, demonstrates excellent cidal activity in vitro against MRSA, including those isolates that are levofloxacin-resistant.

***In Vivo* Pk/Pd of a Delafloxacin Against *Staphylococcus aureus* (Sa), *Streptococcus pneumoniae* (Spn), and *Klebsiella pneumoniae* (Kpn) in the Murine Lung Infection Model**

Author Block:

A. Lepak, **D. R. Andes**; Wisconsin Univ., Madison, WI

Abstract Body:

Background: Delafloxacin is a broad-spectrum anionic fluoroquinolone under development for the treatment of pneumonia. The goal of the study was to determine the PK/PD targets in the murine lung infection model for SA, SPN, and KPN. **Methods:** 4 isolates of each species were utilized for in vivo studies: SA (1 MSSA, 3 MRSA), SPN (2 PCN-S, 2 PCN-R), KPN (3 ESBL, 1 WT). MICs were determined using CLSI methods. A neutropenic murine lung infection model was utilized for all studies. Single dose plasma PK was determined in the mouse model after SC administration of 2.5, 10, 40 and 160 mg/kg. For in vivo studies, four fold increasing doses of delafloxacin (range 0.03 to 160 mg/kg) were administered q6h. Outcome was measured by determining organism burden in the lung (CFU) at 24 h. The Emax Hill equation was used to model the dose-response data. The magnitude of the PK/PD index AUC/MIC associated with net stasis and 1-log kill were determined in the lung model for all isolates. **Results:** MICs ranged from 0.06-1 mg/L. Single dose PK parameter ranges include: Cmax 2-70.7 mg/L, $AUC_{0-\infty}$ 2.8-152 mg*h/L, $T_{1/2}$ 0.7-1 h. At the start of therapy mice had 6.3 ± 0.09 $\log_{10}$ CFU/lung. In control mice the burden increased 2.1 ± 0.44 $\log_{10}$ CFU/lung over the study period. There was a relatively steep dose-response relationship observed with escalating doses of delafloxacin. Maximal organism reductions ranged from 2- to more >4-$\log_{10}$. The median AUC/MIC magnitude associated with each endpoint for each species group is shown in the table.

Organism	Stasis	1-log kill				
Dose (mg/kg/24h)	24h AUC/MIC	24h free drug AUC/MIC	Dose (mg/kg/24h)	24h AUC/MIC	24h free drug AUC/MIC	
SA Median	0.73	1.64	0.04	1.74	3.90	0.09
SPN Median	1.36	16.7	0.40	4.97	89.2	2.14
KPN Median	106	403	9.68	217	752	18.1

Conclusion: Delafloxacin demonstrated in vivo potency against a diverse group of pathogens including those with phenotypic drug-resistance to other classes. Median free drug AUC/MIC targets associated with net stasis were very low for all pathogen groups: SA 0.04, SPN 0.4, and KPN 9.68. 1-log kill targets were 2- to 5-fold higher. These results have potential relevance for

clinical dose selection and evaluation of susceptibility breakpoints for delafloxacin for the treatment of lower respiratory tract infections involving these pathogens

Wck 4873 (Nafithromycin): Preclinical Cardiovascular Safety Assessment of a Novel Lactone-Ketolide Antibiotic

Author Block:

A. M. Patel, R. P. Chavan, A. D. Patil, V. S. Zope, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 4873 is a novel lactone-ketolide antibiotic currently under development and has completed Phase 1 - single, multiple ascending dose and intra-pulmonary pharmacokinetic (PK) studies, following oral administration in US and Europe. QT prolongation risk has been associated with certain macrolide and ketolide antibiotics. Therefore, we tested the preclinical cardiovascular safety of WCK 4873 by both *in vitro* and *in vivo* methods.**Methods:***In vitro* inhibition of potassium selective IKr current by WCK 4873 was investigated using Chinese Hamster Ovary (CHO) cells stably transfected with hERG, using whole cell patch-clamp technique. *In vivo*, cardiovascular safety and PK profile of WCK 4873 (single intravenous dose of 7.5, 15 and 25 mg/kg) were assessed in six conscious telemetered Beagle dogs employing a cross-over study design. Haemodynamic parameters including heart rate, arterial blood pressure, body temperature and electrocardiogram were recorded before and after treatment up to a period of 24h. Serum WCK 4873 levels were analysed using LC-MS/MS and the PK parameters were calculated by non-compartmental analysis (WinNonlin).**Results:**WCK 4873 showed 50% inhibition of hERG current at a concentration of 36.39 µM (31.26 µg/mL). This concentration was 78 times higher than the intended therapeutic *free* plasma C_{max} (0.4 µg/mL). In dog telemetry study, up to maximum dose of 25 mg/kg, no changes were observed in haemodynamic and electrocardiographic parameters including PR and PQ interval duration, QRS complex duration, QT interval duration and QT interval corrected for heart rate using Bazette's formula, in comparison to vehicle group. The *free* serum C_{max} at 25 mg/kg (No observed effect level) dose in dog was 11 times higher than the intended free therapeutic C_{max} (0.4 µg/mL), suggesting a good cardiac safety margin.**Conclusion:**WCK 4873 (Nafithromycin) showed favourable cardiac safety as evident by both *in vitro* and *in vivo* studies undertaken at significantly supra-therapeutic concentrations, and therefore is potentially unlikely to cause prolongation of QT interval.

In Vitro* Activity of a Novel Lactone Ketolide WCK 4873 against Resistant *Streptococcus pneumoniae* and *Haemophilus influenzae

Author Block:

J. Dubois, M. Dubois, J-F. Martel; M360, Sherbrooke, QC, Canada

Abstract Body:

Background: WCK 4873 is a lactone ketolide antimicrobial agent possessing potent activity against macrolide and ketolide resistant strains of *S. pneumoniae* due to its dual mechanism of action targeting both Domain V and Domain II of 23S rRNA. To determine if this compound could be used as monotherapy for the treatment of LRTI pathogens, *in vitro* activity against a variety of resistant *S. pneumoniae* and *H.* was investigated.**Methods:** The *in vitro* activity of **WCK 4873** was compared with that of telithromycin (TEL), azithromycin (AZ), erythromycin (ER) and levofloxacin (LE) against a total of 199 resistant *S. pneumoniae* and 190 *H. influenzae* by standard broth microdilution MIC determination. The tested strains included macrolide or ketolide-resistant (*erm* B (109) and *mef*E (52)) and ciprofloxacin (CIP)-resistant (gyrA and *par*C (38) *S. pneumoniae* and macrolide (*erm* A, B, C (137)) and CIP-resistant (gyrA and *par*C (53) *H. influenzae*.**Results:** Against ER-resistant *S. pneumoniae* strains (*ermB* genotype), the MIC of **WCK 4873** ranged from equal or less than 0.004 to 0.25 mg/L and the activity of **WCK 4873** (MIC_{90} 0.25mg/L) was superior to LE (MIC_{90} 1mg/L), TEL (MIC_{90} 2mg/L), AZ (MIC_{90} 128 mg/L or ER (MIC_{90} 128 mg/L). Against the 45 ER-resistant (*mef*E genotype*)*, strains of *S. pneumoniae*, **WCK 4873** (MIC_{90} 0.12 mg/L) was the most active agent followed by TEL (MIC_{90} 1 mg/L), LE (MIC_{90} 2mg/L), AZ (MIC_{90} 8 mg/L) and ER (MIC_{90} 32 mg/L). Against the CIP-resistant (gyrA & *par*C genotype) 38 strains of *S. pneumoniae*, **WCK 4873** (MIC_{90} 0.016 mg/L) was the most active among tested agents, followed by TEL (MIC_{90} 1 mg/L), LE (MIC_{90} 2mg/L), AZ (MIC_{90} 128 mg/L) and ER (MIC_{90} 128 mg/L). Against the ER-resistant (*erm* A, B, C genotype) 137 strains of *H. influenzae* the MIC of **WCK 4873** ranged from equal to or less than 0.25 to 16 mg/L and the activity of **WCK 4873** (MIC_{90} 2mg/L) was significantly superior to ketolide (TEL: MIC_{90} 16mg/L) or macrolides tested (AZ: MIC_{90} 16 mg/L, ER: MIC_{90} 32 mg/L). Against the 53 tested strains of CIP-resistant *H. influenzae* (gyrA & *par*C genotype), the MIC_{50} and MIC_{90} of **WCK 4873**, LE and TEL were comparable, whereas AZ and ER MIC50/90 were 1 fold lower: 2 and 4 mg/L, 2 and 4 mg/L, 2 and 4 mg/L, 1 and 2 mg/L and 1 and 2 mg/L respectively.**Conclusions:** This data confirms the interesting *in vitro* activity of this new lactone ketolide, **WCK 4873** against macrolide and ciprofloxacin resistant *S. pneumoniae* and *H. influenzae*.

***In Vitro* Activity of Lactone Ketolide WCK 4873 When Tested against Contemporary Community-Acquired Bacterial Pneumonia Pathogens from a Global Surveillance Program**

Author Block:

D. J. Farrell, H. S. Sader, P. R. Rhomberg, R. K. Flamm, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: WCK 4873 is a novel antimicrobial agent of the lactone ketolide class currently in clinical development for the treatment of community acquired bacterial pneumonia (CABP). It has completed SAD and MAD Phase 1 studies in Europe and intra-pulmonary pharmacokinetic study in US. WCK 4873 was awarded QIDP status in 2015. In this study, WCK 4873 was tested against contemporary CABP clinical isolates collected in medical centers worldwide as part of the 2014 SENTRY Antimicrobial Surveillance Program.**Methods**: A total of 1,512 contemporary (2014) CABP clinical isolates from the United States, 1,505 from Europe, 558 from Asia-Pacific, and 558 from Latin America, as part of the SENTRY Program, were susceptibility (S) tested against WCK 4873 and multiple comparator agents by reference broth microdilution methods and interpretive criteria.**Results**: WCK 4873 was very active ($MIC_{50/90}$, 0.015/0.06 µg/mL) against 1,911 *Streptococcus pneumoniae* (SPN) and inhibited all strains at MIC values ≤0.25 µg/mL. Telithromycin (TEL) S (CLSI) was 99.9% against SPN, and WCK4873 was up to eight-fold more potent than TEL ($MIC_{50/90}$, 0.015/0.5 µg/mL). Overall, 37.9% of SPN were resistant (R) to erythromycin (ERY) and 19.7% were R to clindamycin (CLI). WCK 4873 retained good activity against ERY-R/CLI-S strains ($MIC_{50/90}$, 0.03/0.06 µg/mL) and ERY-R/CLI-R strains ($MIC_{50/90}$, 0.03/0.12 µg/mL). Against 716 *Staphylococcus aureus* (SA), 88.5% of isolates were inhibited by WCK 4873 at the CLSI TEL S breakpoint of ≤1 µg/mL ($MIC_{50/90}$, 0.06/>2 µg/mL). MIC_{90} values for WCK 4873 were elevated for methicillin-resistant (MR) compared to methicillin-susceptible (MS) SA (MRSA, $MIC_{50/90}$, 0.06/>2 µg/mL; MSSA, $MIC_{50/90}$, 0.06/0.06 µg/mL). WCK 4873 ($MIC_{50/90}$, 4/4 µg/mL) demonstrated similar activity to TEL ($MIC_{50/90}$, 2/4 µg/mL; 97.9% S, CLSI) against 1,002 *Haemophilus influenzae* (HI) isolates. WCK 4873 ($MIC_{50/90}$, 0.12/0.25 µg/mL) exhibited similar activity to TEL ($MIC_{50/90}$, 0.12/0.12 µg/mL; 99.6% S, EUCAST) against 504 *M. catarrhalis* (MC) isolates.**Conclusions**: WCK 4873 showed a broad range of potent *in vitro* activity against contemporary (2014) global CABP pathogens (SPN, SA, HI and MC). These results support the continued clinical development of WCK 4873 for CAPB.

In Vitro* Activity of a Novel Lactone Ketolide WCK 4873 against *Legionella pneumophila

Author Block:

J. Dubois, M. Dubois, J-F. Martel; M360, Sherbrooke, QC, Canada

Abstract Body:

Background: WCK 4873 is a lactone ketolide antimicrobial agent possessing potent activity against macrolide and ketolide resistant strains of *S. pneumoniae*, *S. pyogenes* and other *Streptococci* due to its dual mechanism of action targeting both Domain V and Domain II of 23S rRNA in these organisms. **WCK 4873** also demonstrates potent activity against penicillin, macrolide and quinolone resistant strains of *S. pneumoniae*, *S. pyogenes* and other *Streptococci*. To determine if this compound could be used as monotherapy for the treatment of community-acquired bacterial pneumonia involving typical and atypical RTI pathogens, *in vitro* activity against a variety of *L. pneumophila* was investigated.**Methods:** The *in vitro* activity of **WCK 4873** was compared with that of telithromycin, azithromycin, erythromycin and levofloxacin against a total of 150 *L. pneumophila* isolates (serogroup 1 (n=125), 2 (n=5), 3 (n=5), 4 (n=5), 5 (n=5) and 6 (n=5)) by a standard microdilution procedure using buffered yeast extract broth containing *Legionella* growth supplement (BYE). A pre-test to determine if antibiotic activity was impacted artificially by BYE supplement or iron was done by testing three ATCC quality control isolates on BYE, BYE without iron and cation-adjusted Mueller-Hinton Broth.**Results:** Only BYE supported *L. pneumophila* growth. Pilot tests indicated that BYE broth do not affect the MIC result of **WCK 4873** against *L. pneumophila* even if *L. pneumophila* strains are incubated during 48 hours.Regardless, the $MIC_{50/90}$ values of **WCK 4873**, levofloxacin, telithromycin, azithromycin and erythromycin against all *L. pneumophila* strains were 0.008/0.03, 0.016/0.016, 0.03/0.06, 0.06/0.5 and 0.25/1 mg/L respectively.Against *L. pneumophila* serogroup 1, usually the most frequently recovered serogroup, the $MIC_{50/90}$ of **WCK 4873**, levofloxacin, telithromycin, azithromycin and erythromycin was 0.008/0.03, 0.016/0.016, 0.03/0.06, 0.12/0.5 and 0.25/1 mg/L.**Conclusions:** This data confirms the interesting *in vitro* activity of this new lactone ketolide, **WCK 4873** against *Legionella pneumophila*.

Determination of Disk Mass and Correlations Between Disk Diffusion Zones and Broth Microdilution MIC's for Lactone Ketolide Nafithromycin (WCK 4873)

Author Block:

M. Hackel[1], S. Bhagwat[2], M. Patel[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: Nafithromycin **(**WCK 4873) is a new lactone ketolide discovered at Wockhardt with potent activity against macrolide / ketolide resistant *S. pneumoniae*. WCK 4873 has completed Phase 1 studies in US and Europe. As part of this drug's development it is important to determine the optimal disk mass (content) for WCK 4873 necessary to achieve high correlation with broth microdilution MICs. This study determined the optimal disk mass and the relative correlation between disk inhibitory zone diameters and broth dilution MICs for WCK 4873.**Methods:** To determine optimal disk mass, three concentrations of disk mass (10 µg, 15 µg, and 20 µg) were tested in triplicate against three ATCC quality control (QC) strains (*Streptococcus pneumoniae* ATCC 49619, *Haemophilus influenzae* ATCC 49247, and *Staphylococcus aureus* ATCC 25923). To determine correlation between disk zone and MIC, a common inoculum was used to concurrently test 511 clinical isolates selected to represent the key target pathogens against WCK 4873 by disk diffusion (10 µg, 15 µg, and 20 µg disks) and broth microdilution according to CLSI guidelines. Correlation coefficients (R^2 values) were determined using the 15 µg disk. Telithromycin was included as a control for all testing.**Results:** All WCK 4873 disk masses showed an increase in zones of inhibition in a concentration dependent manner. WCK 4873 exhibited a high correlation between zone size and MIC for *S. aureus* with an R^2 value of 0.93. WCK 4873 exhibited potent *in vitro* activity against *S. pneumoniae*, *S. pyogenes*, *H. influenzae* and *Moraxella catarrhalis* resulting in lower R^2 values as no isolates with high MICs were found (R^2 values 0.37, 0.67, 0.49, 0.0, respectively).**Conclusions:**All WCK 4873 disk masses showed an increase in zones of inhibition in a concentration dependent manner. The 15 µg disk was chosen as the optimal disk mass. The high R^2 value for *S. aureus* indicates that a disk test for the determination of susceptibility is quite feasible for this organism group. The high potency of WCK 4873 against *S. pneumoniae*, *S. pyogenes*, *H. influenzae* and *M. catarrhalis* precludes a final status of its use for disk testing against these organisms.

In Vitro* Intracellular Activity of Novel Lactone Ketolide WCK 4873 against *Legionella pneumophila

Author Block:

J. Dubois, M. Dubois, J-F. Martel; M360, Sherbrooke, QC, Canada

Abstract Body:

Background: WCK 4873 is a lactone ketolide antimicrobial agent possessing potent activity against macrolide and ketolide resistant strains of *S. pneumoniae*, *S. pyogenes* and other *Streptococci* due to its dual mechanism of action targeting both Domain V and Domain II of 23S rRNA. **WCK 4873** also demonstrates potent activity against penicillin, macrolide and quinolone resistant strains of *S. pneumoniae*, *S. pyogenes* and other *Streptococci*. *In vitro* intracellular activities using human monocytes against a variety of *L. pneumophila* were investigated.**Methods:** The intracellular activity of **WCK 4873** was compared with that of telithromycin (TE), azithromycin (AZ), erythromycin (ER) and levofloxacin (LE) against a total of 3 erythromycin-resistant strains of *L. pneumophila* serogroup 1. The intracellular activity was determined by exposing human monocytes, U937 cell line, infected with intracellular *Legionella* at the 1 or 2XMIC of antibiotic for each strain during 6 days exposure. After 2 days of antibiotic exposure, the infected cell line was split into two groups; one group was kept drug-free and the other group was treated with the same antibiotic as before till 7 days. Viable bacterial cells (CFU/mL) were enumerated for all groups at time zero, after 24h before and after washing, at 48h, then at 72h before and after washing, and every day till next 4 days, by plating on the Buffer Charcoal Yeast Extract agar in duplicate.**Results:** A significant reduction of >3 $\log_{10}$ CFU/mL or >99.9% of ER-resistant *L. pneumophila* grown in monocytes was observed after 3 days of antibiotic exposure until day 7 by **WCK 4873** (1 or 2XMIC) and TE. A regrowth of *L. pneumophila* in monocytes was observed after 1 day of ER exposure, after 3 days of AZ exposure and after 4 days of LE exposure, however such regrowth was not observed with **WCK 4873** and TE. After drug wash-out at day 3, rapid regrowth of *L. pneumophila* was observed in ER in contrast to substantially delayed regrowth observed with **WCK 4873** and that too at just 1XMIC. However **WCK 4873** concentration at 2XMIC completely prevented regrowth. Significant decrease of *L. pneumophila* count (reduction of >4 $\log_{10}$ CFU/ml or >99.99%) in human monocytes was observed with WCK 4873 until day 7 at 2XMIC.**Conclusions: WCK 4873** shows good human monocytes penetration features and demonstrates potent bactericidal effect for intracellular ER-resistant *L. pneumophila* serogroup 1.

***In Vitro* Activities of Investigational Ketolide Wck 4873 (Nafithromycin) and Other Antimicrobial Agents Against Human Mycoplasmas and Ureaplasmas**

Author Block:

K. B. Waites, D. M. Crabb, L. B. Duffy; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract Body:

WCK 4873 (INN: Nafithromycin, Phase 1 completed, Wockhardt)) is a lactone ketolide being developed for treatment of community-acquired bacterial pneumonia. We determined MICs for WCK 4873 (WCK) in comparison to azithromycin (AZI), clarithromycin (CLA), telithromycin (TEL), clindamycin (CLI), levofloxacin (LEV), and tetracycline (TET) by broth microdilution for reference strains and clinical isolates of *Mycoplasma pneumoniae* (n = 20), *Mycoplasma hominis* (n = 21), *Mycoplasma genitalium* (8), and *Ureaplasma* species (n = 23). Isolates tested included organisms known to be resistant to tetracyclines, macrolides, and/or fluoroquinolones. Results are shown in the table below.

	AZI	CLA	TEL	WCK	LEV	TET	CLI
M. genitalium (n = 8)							
Range (µg/ml)	≤0.000125-0.005	≤0.000125-0.002	≤0.000125-0.005	≤0.000125	0.25-1	0.125-4	--
M. hominis (n = 21)							
Range (µg/ml)	1-8	8-32	0.25-8	0.002-.25	0.125-1	0.063->32	0.032-0.5
MIC50	4	16	1	0.032	0.25	0.5	0.063
MIC90	8	32	8	0.125	0.5	>32	0.125
M. pneumoniae (n = 20)							
Range (µg/ml)	≤0.000125-16	0.005->32	0.00025-16	≤0.000125-16	0.5-1	0.25-1	--
MIC50	≤0.000125	0.001	0.0005	≤0.000125	1	0.5	--
MIC90	0.001	0.004	0.001	≤0.000125	1	1	--

Ureaplasma sp. *(n = 23)*							
Range (µg/ml)	0.25->256	0.008->256	0.016->256	0.001-256	0.25->32	0.125-128	--
MIC50	1	0.032	0.063	0.008	1	1	--
MIC90	2	0.125	0.25	0.032	4	128	--

WCK 4873 was uniformly active against all 8 *M. genitalium* isolates with MICs comparable to AZI, CLA, and TEL. WCK 4873 demonstrated good activity against *M. hominis,* with all MICs $\leq$ 0.25 µg/ml, including 2 strains with elevated TEL MICs ($\geq$4 µg/ml). WCK 4873 and CLI had the lowest MIC_{90} (0.125 µg/ml) for this species. WCK 4873 was active against 18 macrolide-susceptible *M. pneumoniae* with all MICs $\leq$.000125 µg/ml. However, WCK 4873 MICs for 2 strains known to be macrolide-resistant were also elevated (16µg/ml). WCK 4873 was very active against *Ureaplasma* species and had the lowest MIC_{90} (0.032 µg/ml) of all drugs tested. However, its MICs were 256 µg/ml for 2 strains that were known to have high level macrolide resistance. Tetracycline and levofloxacin resistance had no effect on WCK 4873 MICs for *M. hominis* and *Ureaplasma* spp. These data suggest that ACK 4873 may be useful to treat infections due to mycoplasmas and ureaplasmas, unless there is macrolide-resistance, thus meriting further clinical development..

Comparative *In Vitro* Activities of Ketolides Wck4873, Wck4897 and Wck4918 Against Macrolide Resistant *Streptococcus pneumoniae*

Author Block:

M. R. Jacobs[1], S. Bajaksouzian[1], S. Bhagwat[2], M. Patel[2]; [1]Case Western Reserve Univ., Cleveland, OH, [2]Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: Ketolides have been developed to overcome macrolide resistance in pneumococci, with telithromycin in clinical use and others in clinical study. Three new ketolides, WCK4873, WCK4897 and WCK4918, have been produced and are being evaluated for clinical development. **Methods:** In vitro susceptibilities of WCK4873, WCK4897 and WCK4918, Wockhardt Research Center, Aurangabad, India) and comparator agents azithromycin and telithromycin were determined by CLSI broth microdilution. Isolates tested included 63 macrolide resistant (33 clindamycin susceptible and 30 clindamycin resistant) and 27 macrolide susceptible strains.**Results:** MIC ranges and $MIC_{50/90}$ values for the 90 isolates tested are shown in the table. MIC distributions of the four ketolides were similar against macrolide susceptible and resistant strains. WCK4897 was the most potent of the agents tested (MIC_{90} 0.12 mg/L), followed by WCK4873 and 4918 (MIC_{90}s 0.25 mg/L) and telithromycin (MIC_{90} 0.5 mg/L). Azithromycin was active against macrolide susceptible (MIC_{90} 0.12 mg/L) but nor resistant isolates (MIC_{90} >2 mg/L).**Conclusion:** Among the three new ketolides evaluated, all were active against macrolide resistant pneumococci, with activity similar to that against macrolide susceptible strains. WCK4897 was the most potent of the new ketolides as well as more potent than telithromycin.

	MIC values (mg/L)		
Agent	Range	MIC50 values	MIC90 values
WCK4873	≤0.008-0.25	0.06	0.25
WCK4897	≤0.004-0.25	0.06	0.12
WCK4918	≤0.008-0.5	0.12	0.25
Telithromycin	≤0.004-2	0.25	0.5
Azithromycin (macrolide susceptible strains)	0.03-0.25	0.12	0.12

Azithromycin (macrolide resistant strains)	1->2	>2	>2

Solithromycin, a Novel Fluoroketolide, *In Vitro* Antibacterial Activity against Anaerobes Isolated in Japan

Author Block:

Y. Yamagishi, Y. Matsukawa, H. Suematsu, H. Mikamo; Aichi Med. Univ., Aichi, Japan

Abstract Body:

Background: Anaerobes invade the tissue due to a failure of defense mechanisms or through infection from the environment and can causes various infectious diseases. Solithromycin (SOL) is a novel fluoroketolide with reported high potency against diverse groups of Gram-positive and Gram-negative bacteria, including mycoplasma and ureaplasma. In this study, we evaluated the antibacterial activities of solithromycin against clinical isolates of anaerobic pathogens recently collected in Japan. **Methods:** MICs of SOL and comparator agents, including erythromycin (EM), clarithromycin (CAM), azithromycin (AZM), levofloxacin (LVFX), moxifloxacin (MFLX), sitafloxacin (STFX) and meropenem (MEPM), against clinical isolates (20 *S. anginosus*, 20 *S. constellatus*, 20 *S. intermedius*, 23 *F. magna*, 19 *P. asaccharolyticus*, 23 *P. micra*, 50 *B. fragilis*, 40 *B. thetaiotaomicron*, 16 *F. nucleatum*, 5 *F. necrophorum*, 47 *P. bivia*, 20 *P. melaninogenica*, 38 *P. intermedia*, 20 *Veillonella* species and 48 *C. difficile*), were determined by the CLSI broth dilution method.**Results:** SOL showed broad and potent anti-anaerobic activity. MIC_{90}s of SOL against Gram-positive and Gram-negative anaerobic species were <0.015-32 µg/mL and 0.06->32 µg/mL, respectively.**Conclusions:** SOL demonstrated the most potent Gram-positive anti-anaerobic activity compared to the other macrolides and quinolones tested. These results suggest SOL has a potency that is promising for the alternative treatment of anaerobic infections caused by Gram-positive bacteria.

Comparative Evaluation of Oritavancin, Dalbavancin, and Tedizolid *In Vitro* Antimicrobial Activity Against Clinical Isolates of *Enterococcus*

Author Block:

F. Foolad, C. Young, D. Newton, A. Smith, T. S. Patel; Univ. of Michigan Hlth.System, Ann Arbor, MI

Abstract Body:

Background: New antimicrobial agents with activity against *Enterococcus*, including some with activity against vancomycin-resistant and daptomycin non-susceptible isolates, have been introduced. However, there are minimal data comparing the in vitro activities of oritavancin, dalbavancin, tedizolid, vancomycin, and daptomycin for clinical isolates using a custom TREK Sensititre panel.**Methods:** All cultures from patient infections with isolated *Enterococcus* from February 2015 to November 2015 were included. Organisms were identified by MALDI-TOF mass spectrometry (Bruker Daltonik, Bremen, Germany). Minimum inhibitory concentrations (MICs) for all antimicrobials were determined using broth microdilution methods (TREK Diagnostic Systems, Cleveland, Ohio). The percentage of isolates within the susceptible range was determined using Clinical and Laboratory Standards Institute (CLSI) and US Food and Drug Administration (FDA) breakpoint criteria.**Results**: A total of 1,186 *Enterococcus* isolates from clinical specimens were included. Higher MIC_{50} and MIC_{90} were determined for *E. faecium* than *E. faecalis* (table). Using published interpretive criteria, 97.6%, 80.6%, and 99% of all *Enterococcus* isolates were considered susceptible to oritavancin, dalbavancin, and tedizolid, respectively as compared to 79.9% and 98.1% susceptible to vancomycin and daptomycin. Susceptibility to oritavancin, dalbavancin, and tedizolid was lower among vancomycin-resistant isolates (n=236; 88.6%, 3.4%, and 98.3%) and daptomycin non-susceptible isolates (n=22; 86.4%, 40.9%, and 90.9%).**Conclusions**: Oritavancin, dalbavancin, and tedizolid demonstrated good in vitro activity against *Enterococcus* isolated from a variety of clinical infections with comparatively lower activity in *E. faecium* than *E. faecalis* and even lower activity in multi-drug resistant strains. Oritavancin and tedizolid may be useful for vancomycin-resistant and daptomycin non-susceptible *Enterococcus* infections.

Wck 4873 (Nafithromycin): *In Vivo* lung Infection Studies against Macrolide-Resistant (Mr) and Telithromycin-Non-Susceptible (Tel-Ns) Pneumococci

Author Block:

S. S. Bhagwat, S. S. Takalkar, J. S. Satav, A. M. Kulkarni , A. P. Udaykar, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 4873 is a lactone-ketolide (Phase 1 studies completed in Europe) with a broad-spectrum activity against respiratory tract pathogens. WCK 4873 is characterized by potent *S. pneumonia*e (SPN) activity (global SPN n=1911, MIC_{90}: 0.06 µg/mL) including MR (SPN n=394, MIC_{90}: 0.12 µg/mL) and TEL-NS SPN (n=204, MIC_{90}: 0.12 µg/mL) possibly due to its high affinity binding to domain II and V of 23S rRNA. Herein, we describe *in vivo* efficacy of WCK 4873 against MR and TEL-NS SPN pathogens.**Method:**Neutropenic (intraperitonial cyclophosphamide on day -4 and -1) murine lung infection studies were performed employing four strains of SPN [Two MR: SPN 6683 (L4/L22 mutations) and SPN 1179 (*mef* + *ermB*); two TEL-NS: SPN 5032 and SPN 3773 (both expressing high-level *ermB*)]. MIC was determined by agar dilution method (MHA +5% sheep blood). Oral treatment was initiated 2h post-infection (initial inoculum: 6.5-7.2 $\log_{10}$ CFU/mL in lungs) administered BID/TID (3h apart) for 3 days. Bacterial enumeration in lungs was undertaken 18–20h post last dose.**Results:**MICs of WCK 4873 and TEL for SPN 6683, 1179, 5032 and 3773 were 0.06, 0.12, 0.25, 0.5 and 0.12, 1.0, 2.0, 4.0 µg/mL, respectively. Sustained progression of infection was noted with bacterial load at the start of treatment being 6.5–7.0 $\log_{10}$ CFU/lung increasing up to 8.0–9.0 $\log_{10}$ CFU/lung by the end of 3 days, resulting in mortality among untreated animals. In strains SPN 6683 and SPN 1179, WCK 4873 caused $\geq$2 $\log_{10}$ kill in lung at 6.25 and 25 mg/kg dose, respectively. While, TEL at the doses of 6.25 and 50 mg/kg doses provided mere bacteriostatic effect in the two strains, respectively. In TEL-NS SPN 5032 and SPN 3773 strains, WCK 4873 doses of 12.5 mg/kg BID and 12.5 mg/kg TID resulted in 2.87 $\log_{10}$ and 1.8 $\log_{10}$ kill in lung, respectively. Organisms recovered post 2–3 days therapy did not show any shift in WCK 4873 MICs.**Conclusion**: WCK 4873 (Nafithromycin) provided unique coverage of MR and TEL-NS pneumococci which is not evident with any other ketolides to date.

Publishing Title:

Improved Antimicrobial Activity of Fully Synthetic Macrolides Against Macrolide Resistant Gram-positive Isolates

Author Block:

S. D. Lahiri, R. A. Alm; Macrolide Pharmaceuticals, Watertown, MA

Abstract Body:

Background: Rapid emergence of resistance by multiple drug resistant (MDR) pathogens has intensified the search for new antimicrobial agents that are safe and efficacious. Methicillin-resistant *Staphylococcus aureus* (MRSA) and MDR *Streptococcus pneumoniae* remain a clinical concern for a variety of community-associated and hospital-acquired infections. Macrolides are a class of known antibiotics that are safe and effective. However, the macrolide class has limited activity against Gram-negative pathogens, as well as against Gram-positive isolates carrying macrolide resistance determinants. In particular, the utility of macrolides against MDR gram-positive pathogens, including MRSA, has been hampered primarily by various changes to the binding pocket, including the methylation of the macrolide binding nucleotide by erm methylases.**Methods:** Novel macrolides were synthesized via a fully synthetic, chemistry platform. These compounds were tested against characterized clinical isolates following CLSI methods.**Results:** These new compounds demonstrated improved activity against strains resistant to older generations of macrolides. They do not induce the *ermA* methylase gene in *S. aureus* or the *ermB* methylase gene in *S. pneumoniae*. They were also tested against MRSA strains that contained a variety of alterations in the leader peptide, resulting in constitutive expression of the *ermA* gene. The novel macrolides described here showed a >16-fold improvement in MIC compared to in-class comparators which had MIC values of >256 μg/mL. Further, these compounds were not affected by efflux-based resistance mechanisms, such as Mef(A) or Msr(A), found in *S. pneumoniae* and *S. aureus*, with MIC values of ≤ 1 μg/mL against these isolates. Lastly, *S. pneumoniae* isolates carrying 23S rRNA and ribosomal protein mutations that result in reduced susceptibility to macrolides remain susceptible to these novel compounds.**Conclusions:** These data demonstrate that leveraging the flexibility of the synthetic chemistry platform should identify promising candidate molecules that circumvent the common pre-existing resistance mechanisms.

***in Vitro* Activity Of Lefamulin Against Macrolide-Susceptible (Msmp) And Macrolide-Resistant *mycoplasma Pneumoniae* (Mrmp) From The United States, Europe, And China**

Author Block:

K. Waites[1], D. M. Crabb[1], L. B. Duffy[1], Y. Liu[2], S. Paukner[3]; [1]Univ. of Alabama at Birmingham, Birmingham, AL, [2]Fudan Univ., Shanghai, China, [3]Nabriva Therapeutics AG, Vienna, Austria

Abstract Body:

Background: Pleuromutilin (PM) antibiotics bind to the peptidyl transferase center of the 50S ribosomal subunit, blocking protein synthesis. Lefamulin (LMU, Nabriva Therapeutics) is a novel semi-synthetic PM for systemic human use with potent activity against a variety of gram-positive and gram-negative bacteria, including multi-drug resistant strains, in Phase 3 trials for the treatment of community-acquired bacterial pneumonia. In previous *in vitro* surveillance studies cross-resistance between LMU and commonly used respiratory antibiotics was not observed. Macrolide-resistance in *Mycoplasma pneumoniae* (MPN) has become increasingly prevalent globally. We performed an *in vitro* evaluation of respiratory isolates of macrolide-susceptible (MSMP) and macrolide-resistant MRMP *M. pneumoniae* from the US, Europe, and China. **Methods:** The broth microdilution MIC assay per CLSI guidelines (2011) was used to test strains against LMU and 4 comparators (see Table).**Results:** LMU was highly active against all strains, with MICs $\leq$ 0.004 µg/ml. The LMU MIC_{90} for MRMP (0.002 µg/ml) was the lowest among all 5 drugs tested. Additionally, for LMU, minimum bactericidal concentrations (MBCs) were determined for 2 macrolide-susceptible and 6 macrolide-resistant isolates and all MBCs were 2 to 4 times the MIC values, indicating a bactericidal effect.**Conclusions:** LMU has potent in vitro activity against MPN, including macrolide resistant strains. LMU may be a promising therapeutic option for infections due to MPN.

Publishing Title:

Activity of Cadazolid against Recent Clinical Isolates of *Staphylococcus aureus* and *Enterococcus* spp.

Author Block:

I. Morrissey[1], S. Hawser[1], E. Genet[1], P. Jeandey[1], T. W. Morris[2], H. H. Locher[2]; [1]IHMA Sàrl, Epalinges, Switzerland, [2]Actelion Pharmaceuticals Ltd, Allschwil, Switzerland

Abstract Body:

Objectives: Cadazolid (CDZ) is a novel quinolonyl-oxazolidinone antibacterial currently in phase III clinical trials for the treatment of *C. difficile*-associated diarrhoea. This study was undertaken to determine CDZ activity against recent clinical isolates of *S. aureus* and *Enterococcus* spp and evaluate varying test parameters.**Methods:** The minimum inhibitory concentration (MIC) for CDZ and comparators was determined by CLSI aerobic broth microdilution methodology [CLSI M07-A10]. Test isolates included *S. aureus* from 2014 and enterococci mainly from between 2012 and 2014. Varying testing parameters against CLSI quality control strains were: anaerobic conditions; addition of Ca^{2+} (50 or 100 µg/ml), Mg^{2+} (25µg/ml), human serum (25 or 50%), human plasma (50%), bovine serum albumin (0.001 - 0.1%) or tween 80 (0.002%); pH 5.8, 6.5 & 8.5 and inocula of 10^4 - 10^7 cfu/ml.**Results**: CDZ MICs were 0.12 - 0.5 µg/ml against *S. aureus* and ≤0.03 - 1 µg/ml against *Enterococcus* spp. Linezolid-resistant (LZD-R) enterococci were at the higher end of the CDZ MIC range but vancomycin-resistance (VAN-R) did not affect activity. Methicillin-resistant *S. aureus* (MRSA) and susceptible strains (MSSA) were equally inhibited by CDZ (See Table). Based on MIC_{50} or MIC_{90}, CDZ was more active than LZD, VAN or fidaxomicin (FDX). This included Van-R, LZD-R and MRSA strains. Anaerobic conditions and low pH lead to lower MICs (2-4-fold) whereas varying the other parameters had no effect.

	CDZ		**LZD**		**VAN**		**FDX**	
Organism	**MIC_{50}**	**MIC_{90}**	**MIC_{50}**	**MIC_{90}**	**MIC_{50}**	**MIC_{90}**	**MIC_{50}**	**MIC_{90}**
E. faecalis (n=108)	0.25	0.5	2	2	1	>32	4	8
E. faecialis VAN-R (n=43)	0.25	0.25	1	1	>32	>32	4	4
E. faecium (n=114)	0.5	0.5	2	2	1	>32	4	8
E. faecium VAN-R (n=42)	0.5	0.5	1	1	>32	>32	4	8
Enterococci LZD-R (n=8, range)	0.5-1		16-32		0.5->32		4-8	
S. aureus (n=106)	0.25	0.25	2	2	1	1	8	8

MSSA (n=55)	0.25	0.25	2	2	1	1	8	8
MRSA (n=51)	0.25	0.25	2	2	1	1	8	8

Conclusions: CDZ shows potent *in vitro* activity against *S. aureus* and enterococci, including resistant strains. This activity is retained or even increased under anaerobic conditions and at low pH. CDZ was more active against *S. aureus* and enterococci than current agents used to treat *C. difficile* infections, such as VAN or FDX.

Pharmacokinetics of Linezolid in Critically Ill Patients

Author Block:

S. Corcione, L. Baietto, A. d'Avolio, V. Fanelli, M. V. Ranieri, G. di Perri, F. de Rosa; Univ. of Turin, Turin, Italy

Abstract Body:

Background: Therapeutic drug monitoring (TDM) of linezolid (LZD) could be helpful in severe ill patients. The higher success occur at AUC_{0-24}/MIC values of 80-12, Cmin ≥2 mg/L or AUC_{24} > 160-200 mg h/L. Aim of this study was to evaluated the pharmacokinetic of LZD in patients admitted to Intensive care Unit (ICU).**Methods:** All patients treated with intravenous LZD (600mg twice daily), admitted to ICU at City of Science and Health, Molinette Hospital, Turin (Italy), were enrolled between 2011-2012. Plasma LZD concentrations were determined at the steady-state by 1 h-infusion. AUC_{0-24} of LNZ was calculated with blood samples collected before (time 0) and after 2.5, 4 and 8hs intravenous drug administration. Drug concentrations were determined using an ultra performance liquid chromatography (UPLC-PDA). Pharmacokinetic data were studied using Kinetica software. Simulated data for LNZ pharmacokinetic parameters were calculated with *S. aureus* MICs corresponding to 0.5, 1, 2 and 4 mg/L.**Results:** 16 patients were enrolled in the study. The mean days of ICU stay at time of diagnosis were 21.6 (SD ±14.6), mean days duration of treatment 11 (SD ± 3.9). Two patients were on ECMO and 5 on CVVH while they were treated. 21 day-mortality was 19% (3).In Table 1, the main LNZ pharmacokinetic parameters are reported. 62.5% (10) patients achieved C_{min} >2 mg/L and 31.6% (5) had AUC_{0-24} > 160-200.At univariate analysis, mortality was associated with high APACHE score (p=0.012) but PK parameters were not associated with mortality. Simulated data calculated showed that Pk parameters are satisfactory when the MIC is 0.5 mg/L.**Conclusion:**The peculiar pathophysiological conditions of these patients, might have a considerable impact on the therapeutic effect of LNZ, even when PK/PD parameters fall in the favourable range.

Patients in the Intensive Care Unit Exhibit a Higher Target Attainment for β-Lactam Antibiotics When Actual Compared to Estimated Minimum Inhibitory Concentrations Are Applied

Author Block:

H. Woksepp[1], A. Hällgren[2], S. Borgström[1], F. Kullberg[3], A. Wimmerstedt[3], A. Oscarsson[2], P. Nordlund[4], M-L. Lindholm[1], J. Bonnedahl[1], B. Carlsson[5], T. Schön[1]; [1]County Hosp., Kalmar, Sweden, [2]Linköping Univ., Linköping, Sweden, [3]Central Hosp., Växjö, Sweden, [4]Ryhov Hosp., Jönköping, Sweden, [5]County Council of Östergötland, Linköping, Sweden

Abstract Body:

ICU patients are at risk for low antibiotic levels which may lead to poor treatment efficacy. Our aim was to investigate if empirical treatment with β-lactams in ICU patients results in sufficient serum drug levels during the first three days of treatment to cover 100% time over the minimum inhibitory concentration (MIC) (100 % *f*T>MIC), both in relation to the estimated and actual MIC. In a prospective, multicenter study, 111 consecutive ICU patients, treated with piperacillin-tazobactam (PIP n=49), meropenem (MER n=24) or cefotaxime (CTX n=38) were included. Clinical and laboratory data including MIC testing by E-test for relevant bacteria (MIC_a) were recorded. The MIC_a was compared to the highest estimated MIC (MIC_e) for susceptible pathogens commonly used for defining targets in clinical studies. Blood samples were collected as through levels three consecutive days and analyzed by LC-MS. Based on the MIC_e 54% (60/111) of patients reached the target. A higher rate 78% (31/40) reached 100% *f*T>MIC_a compared to 50 % for the same patients using MIC_e. Drug levels were stable over time within patients but varied extensively between patients (Figure 1). The actual MIC, when available, results in higher target attainment for broad spectrum β-lactams in ICU patients. Considering the variability in the serum drug levels between ICU patients, the dosage should be individualized based on the actual MIC and antibiotic concentrations to maximize clinical efficacy.

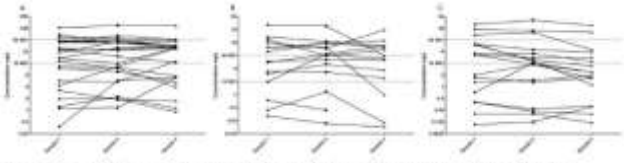

Figure 1. Plot over individual concentrations from three consecutive samples (day 1-3) of PIP (A), MER (B) and CTX (C). Mean concentrations day 1-3 were 10.1, 10.5 and 11.8 mg/L for PIP, 9.93, 9.34 and 8.44 mg/L for MER and 6.38, 6.66 and 5.02 mg/L for CTX. Dotted lines indicate 1x MIC equal to 100% T>MIC, (16, 2 and 4 mg/L for PIP, MER and CTX respectively) and 4x MIC, (64, 8 and 16 mg/mL).

Improving the Bayesian Prediction of Vancomycin Exposure in Obese Adults with Trough Only Measurements

Author Block:

L. C. Krop[1], J. Hong[1], M. P. Pai[2]; [1]Morton Plant Hosp.; BayCare Hlth.System, Clearwater, FL, [2]Albany Coll. of Pharmacy and Hlth.Sci., Albany, NY

Abstract Body:

Background: Bayesian modeling can predict vancomycin area under the concentration-time curve over 24 hours (AUC_{24}) using trough only measurements and a reliable population pharmacokinetic model. The standard model estimates central compartment volume of distribution (V) with total body weight (TBW) and clearance (CL) with estimated creatinine clearance (CLcr) that may be biased in obese patients.**Objective:** To compare the precision and bias of vancomycin AUC_{24} estimates using a TBW independent model (Model-1) to the standard TBW dependent model (Model-2) in obese patients. **Methods:** Vancomycin plasma concentration-time data from 75 obese adults (BMI≥30 kg/m^2) with peak and trough measurements were best modeled by a 1-compartment system (PMID 26011138), that served as the Bayesian prior for Model-1. The Bayesian prior for Model-2 was 0.7 L/kg for V, (0.79 x CLcr + 15.7) x 0.06 for CL (L/h) (PMID 3415206), and a covariance matrix based on a 50% coefficient of variation (CV) for both system parameters. Reference AUC_{24} values were computed for each model based on 2-4 plasma samples per patient by individual model-based integration (ADAPT 5, BMSR, Los Angeles, CA). The analyses were repeated for each model after inclusion of trough only data (peak data removed). External validation was performed in a similar manner using data from an additional 31 obese patients not included in the original model. Bias (percent difference) and precision (R^2) were determined for models with trough only data compared to their respective base models (peak and trough data).**Results:** The mean (CV) age, TBW, and CLcr for the base data set was 57.9 (26.1%) years, 112 (22.4%) kg, and 101 (42.3%) mL/min/1.73m^2. The mean (CV) for V and CL was 71.9 (24.4%) L and 5.18 (40.4%) L/h, respectively. The precision of AUC_{24} estimation with trough only data was higher with Model-1 (R^2= 0.820) compared to Model-2 (R^2 = 0.537). The mean [95% CI] %bias of AUC_{24} estimation was lower with Model-1 (2.79 [0.452, 5.12]) compared to Model-2 (12.5 [8.01, 17.0]). The external validation data set had similar demographics and revealed higher precision and lower %bias with Model-1 compared to Model-2 with use of trough only data.**Conclusions:** Use of a TBW independent model improves estimation of AUC_{24} with trough only data in obese patients compared to the standard model.

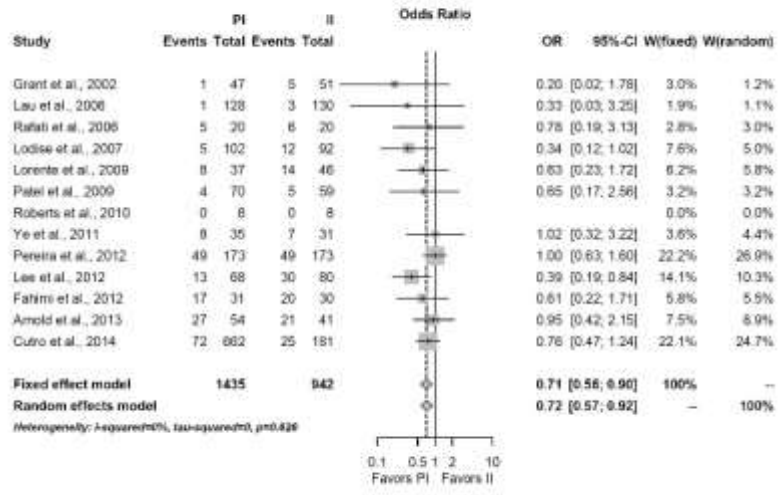
Impact of Piperacillin-Tazobactam Prolonged Infusion Schemes on Clinical Outcomes: A Meta-Analysis and Meta-Regression

Author Block:

N. J. Rhodes[1], J. Liu[1], B. Nadler[2], J. O'Donnell[1]; [1]Midwestern Univ., Downers Grove, IL, [2]Midwestern Univ., Glendale, AZ

Abstract Body:

Background: While prolonged-infusion (PI) dosing of piperacillin-tazobactam (TZP) has been found beneficial compared to intermittent infusion (II), few studies have examined the impact of covariates on observed mortality. **Methods:** MEDLINE (Pubmed) was searched for studies of TZP or piperacillin alone PI v. II. The following terms were searched: "piperacillin AND (infusion OR infusions OR infusion*) AND (outcome OR outcomes OR outcom* OR mortality)". Studies were screened by title and abstract to determine if inclusion criteria were met. Severity of illness scores (e.g., APACHE II, SAPS II) were converted to % predicted mortality using published regression equations. Other covariates were directly extracted. Fixed and random-effects meta-analysis of included studies were conducted using the *meta* package for R (v.4.3-0). Meta-regressions of the log-odds ratio (PI v. II) were carried out for covariates if ≥10 studies reported both the outcome and the covariate value and the covariate had a plausible biologic relationship to the outcome. **Results:** The search identified 31 studies, of which 13 were included. Sample sizes ranged from n=8 per group (PI v. II) to greater than 150 patients in each group. The results of the meta-analysis are shown in Figure 1. Both the fixed (P=0.005) and random-effects (P=0.008) models found a protective effect of PI v. II TZP against the study-defined mortality outcome. Severity of illness scores, transformed to % predicted mortality, had a borderline significant (P=0.07) impact on the log-odds ratio.



Conclusions: PI was significantly protective against mortality in published studies. The impact of patient covariates on this benefit warrants additional study.

Antibioperf: A Nationwide Survey on Beta-Lactams Administration and Therapeutic Drug Monitoring Practices in Critically Ill Patients in France

Author Block:

A. Charmillon[1], E. Novy[1], N. Agrinier[2], M. Leone[3], A. Kimmoun[1], B. Levy[1], B. Demoré[1], J. Dellamonica[4], **C. Pulcini**[1]; [1]CHU de Nancy, Vandœuvre-lès-Nancy, France, [2]Université de Lorraine, Vandœuvre-lès-Nancy, France, [3]CHU de Marseille, Marseille, France, [4]CHU de Nice, Nice, France

Abstract Body:

Background: Recent studies have suggested that continuous or extended infusions with beta-lactams may be associated with improved clinical outcomes, especially in critically ill patients. However, not much is known on how these studies translate into practice. Our objective was to assess current practices concerning the administration (intermittent, extended or continuous infusions) and therapeutic drug monitoring (TDM) of beta-lactam antibiotics and vancomycin in France. **Methods:** We conducted a nationwide cross-sectional survey between May and August 2015, using an online questionnaire, sent by e-mail to infectious diseases specialists (IDS) and intensivists through national mailing lists. We used clinical vignettes of critically ill patients to assess physicians' practices regarding administration and TDM practices for amoxicillin, cloxacillin, piperacillin/tazobactam, cefotaxime, ceftazidime, cefepime, meropenem and vancomycin. **Results:** Five-hundred and seven physicians participated (response rate 42%), 71% intensivists and 20% IDS. TDM of beta-lactams was rarely available (ranging from 16.5% for cloxacillin to 30% for ceftazidime), whereas vancomycin TDM was available in 97% of the cases. In the clinical vignettes, ceftazidime and piperacillin/tazobactam were the beta-lactams the most frequently administered using extended or continuous infusions respectively in 76% and 57% of cases. Gaps in knowledge regarding the duration of stability of intravenous beta-lactams were common (correct answers ranging from 8% for cloxacillin to 33% for ceftazidime). The majority of physicians (76%) were convinced of the interest of extended or continuous infusions for beta-lactams in critically ill patients, but 45% declared that having no easy access to practical guidelines was a barrier. **Conclusions:** Our survey found that most IDS and intensivists are favourable to optimised administration of beta-lactams in critically ill patients. But the lack of guidelines and limited TDM availability of beta-lactams in hospitals are potential barriers to its implementation.

Pharmacokinetic/Pharmacodynamic (PK/PD) Determinants of Vancomycin Efficacy in Enterococcal Bacteremia

Author Block:

M. Bin Jumah[1], S. Vasoo[2], S. R. Menon[1], P. P. De[1], **C. B. Teng**[3]; [1]Tan Tock Seng Hosp., Singapore, Singapore, [2]Inst. of Infectious Diseases and Epidemiology, Tan Tock Seng Hosp., Singapore, Singapore, [3]Natl. Univ. of Singapore, Singapore, Singapore

Abstract Body:

Background: PK/PD determinants of vancomycin efficacy are unclear for enterococcal infections. We studied vancomycin PK/PD and clinical outcomes in a cohort of patients with *Enterococcus* bacteremia.**Methods:** Laboratory and clinical records from 1st January 2009 to 31st May 2015 were reviewed for blood cultures positive for *Enterococcus* sp. Subjects were excluded if they received < 72 hours of I.V. vancomycin, had polymicrobial bacteremia, had vancomycin-resistant *Enterococcus* (VRE), or if vancomycin concentrations were not performed. The average vancomycin $AUC_{0\text{-}24hrs}$ was computed using a Bayesian approach based on patient-specific creatinine clearance, vancomycin dosing and concentrations available in the first 72 hours of therapy. MIC was determined by E-test (bioMerieux) and the average $AUC_{0\text{-}24hrs}$/MIC over the 72 hours was calculated. Primary outcomes examined were: 30-day all-cause mortality and treatment failure (defined as 30-day mortality, persistent bacteremia $\geq$ 5 days or relapse at $\leq$ 90 days).**Results:** There were 417 index cases of *Enterococcus sp*. bacteremia; 174 with polymicrobial bacteremia, 145 with $\leq$ 3 days of vancomycin therapy, 23 VRE, 7 without vancomycin concentrations, and 5 with isolates unavailable for MIC testing were excluded. Thus, 63 cases (34 *E. faecium*, 25 *E. faecalis*, 4 other *Enteroccocus* sp.) were included in the analysis. Median vancomycin MIC was 0.75 mcg/ml (range 0.38-3 mcg/ml). Univariate analysis revealed that the median $AUC_{0\text{-}24hrs}$/MIC was significantly associated with treatment failure [failure, 479 (IQR 324-714) vs success, 723 (IQR 484-873); P = 0.03] and mortality, [death, 449 (IQR 296-714) vs survival, 662 (IQR 465-873); P = 0.04]. In the multivariate analysis with a model that also included APACHE II scores, and creatinine clearance, the association of $AUC_{0\text{-}24hrs}$/MIC with mortality approached but did not achieve statistical significance (P = 0.06).**Conclusions:** Lower vancomycin $AUC_{0\text{-}24hrs}$/MIC may be associated with increased mortality and treatment failure in enterococcal bacteremia. Further studies are needed to define the breakpoints that will optimize patient outcomes.

Population Pharmacokinetic of Fosfomycin in Non-Critically Ill Patients with Bacteremic Urinary Infection Caused by Multidrug-Resistant *Escherichia coli*

Author Block:

V. Merino-Bohórquez[1], F. Docobo-Pérez[2], M. Cameán[1], J. Sojo-Dorado[1], P. Retamar[1], L. López-Cortés[1], I. Morales[1], I. López-Hernández[1], A. Pascual[2], J. Rodríguez-Baño[1]; [1]Hosp. Univ.rio Virgen Macarena, Sevilla, Spain, [2]Univ. de Sevilla, Sevilla, Spain

Abstract Body:

Background: Fosfomycin (FOS) is a potential treatment of invasive infections caused by MDR Enterobacteriaceae. Scarce data are available on the PK/PD parameters of I.V. FOS in non-critically ill patients. PD target is not clear, due to the appearance of resistant bacteria. The aim is to develop a population PK model to describe the FOS concentrations variability in bacteremic patients with UTI by MDR *E. coli* and exploring its efficacy using *in vitro* PD targets. **Methods:** 10 patients with bacteremic UTI due to MDR *E. coli* (FOS MIC=0.5-8 mg/L) were included. 8 received FOS 4g/6h, and 2 with renal impairment (CrCl <40 mL/min) 4g/12h. Serum samples obtained from 4 time-points within the interval dose were analyzed by LC-MS/MS. A population PK model was built (Pmetrics). *f*T>MIC was used as PD efficacy target predictor and $fAUC_{48\text{-}72h}$/MIC for resistance suppression. The probability to reach $fAUC_{48\text{-}72h}$/MIC=1000 or 5000 and *f*T>MIC of 50% or 100% were explored by Monte Carlo simulations. **Results:** 7 patients were men. Median (IQR) age was 66 years (61-72.8), weight 74 kg (65.8-76.3), BMI 26 kg/m^2 (23.8-31.4), and CrCl 76 mL/min (54.3-107.8). A two-compartment model with CrCl as covariate (R^2=0.977) was used. The probabilities for target attainments are in the Figure. All the patients were cured. **Conclusion:** With a dosage of FOS 4g/6h, efficacy would be achieved for *E. coli* strains with MIC of 32-256 mg/L. However, resistance suppression prevention would be reached for low FOS MICs (0.5-2 mg/L). Higher doses should be explored to increase the therapeutic range of FOS.

Publishing Title:

Maximizing Efficiency Of Vancomycin Dosing And Monitoring

Author Block:

K. R. Beaulac, F. Massaro, T. Chang, S. Doron; Tufts Med. Ctr., Boston, MA

Abstract Body:

Background: Pharmacists often manage dosing and monitoring of vancomycin (VAN), due to their expertise in attaining target levels and limiting nephrotoxicity. At our institution, the VAN per pharmacy (VPP) program was successful, but labor intensive requiring 1.2 pharmacist full-time equivalents (FTE). Upon discontinuation of VPP, the Infectious Diseases Pharmacist (ID Pharm) provided didactic training to house officers and performed targeted surveillance and intervention for high-risk patients on VAN.**Methods:** A quasi-experimental study was performed to assess the rate of nephrotoxicity (NT) for 4 months periods during VPP (pre), immediately after VPP (post), and eight months after VPP (late post). NT was defined as serum creatinine (SCr) increase 0.5 mg/dL or 50% from baseline. Additionally, NT recovery (SCr 10% from baseline) and VAN troughs (tr) were assessed. Patients were excluded if they had kidney disease (eGFR<30 mL/min), were on a pediatric unit, or had no SCr measured. In patients with NT, concomitant nephrotoxins (CNs) were documented. Student t-test and χ^2 test were used compare the post and late post to the pre cohort.**Results:** There were 640, 648, and 767 patients (pts) included in the pre, post, and late post cohorts respectively. NT occurred in 48 patients (7.5%) in the pre phase, with 35% recovering and 40 (83%) pts receiving CNs. In the post phase, NT increased to 10.5% (72 patients) (p=0.05), with recovery in 39 (54%) and all 72 receiving CNs. After months of didactic training of housestaff and targeted interventions, the NT incidence returned 7.6% (61 patients) (p>0.05), with 57% recovering and 90% receiving CNs. Pts with a VAN tr >20 mg/dL were more likely to develop NT than pts with a tr ≤20, 29% vs. 15% (p=0.001). The frequency of VAN tr >20 and tr 10-20 were not different in the 3 phases (p>0.05), although trs were obtained in 37%, 22% and 40% during the 3 phases respectively. During the late post phase, 0.125 ID Pharm FTE was required to maintain the surveillance and interventions.**Conclusions:** Though pharmacist-guided dosing and monitoring of VAN can optimize target attainment and lower rates of NT, this goal can be efficiently attained with targeted surveillance and intervention by an ID Pharm.

Publishing Title:

Validation Of A Bayesian Approach To Estimate Vancomycin Exposure In Obese Patients With Limited Pk Sampling

Author Block:

J. J. Carreno[1], B. Lomaestro[2], J. Tietjan[2], T. Lodise[1]; [1]Albany Coll. of Pharmacy and Hlth.Sci., Albany, NY, [2]Albany Med. Ctr. Hosp., Albany, NY

Abstract Body:

Background: Vancomycin (VAN) area under the curve (AUC) can be accurately estimated using a Bayesian approach with limited PK sampling. However, the validity of this approach in obese subjects is not well described. This study evaluates the validity of a Bayesian approach for AUC estimation in obese subjects. **Methods:** This was an IRB-approved prospective PK study. Inclusion criteria: inpatients age ≥ 18 y, IV VAN for treatment and weight ≥ 110 kg. Exclusion criteria: ANC < 1000/mm^3, pregnancy, SCr ≥ 2.0 mg/dL and CrCL <50 mL/min. Five serum VAN levels were obtained from each subject. VAN 24-hour AUC (AUC_{24}) was estimated using the MAP procedure within ADAPT 5 using two vancomycin PK models as priors: (1) Rodvold population PK model (non-obese PK mode) and (2) population PK model derived from this dataset (obese PK model). AUC_{24} estimates from data depleted subsets (trough only: AUC_T; peak and trough: AUC_{PT}; midpoint and trough: AUC_{MT}) were compared to AUC estimates from full data (AUC_{FULL}). **Results:** 12 patients were enrolled. Median (IQR) age, CrCL, and BMI were 61 y (39 - 71), 86 mL/min (75 - 120), and 45 kg/m^2 (40 - 52) respectively; 7 (58%) were male. The obese PK model derived from this dataset had a mean (SD) V_D, K_{12}, K_{21}, CL_{INT} and CL_{SLOPE} of 25.76 L (11.68), 2.29 h^{-1} (2.42), 1.44 h^{-1} (1.73), 3.054 L/h (0.71) and 0.036 (0.02) respectively. AUC estimates and comparisons are shown in Table 1. For both priors, the AUC with trough only data (AUC_T) tended to overestimate AUC_{FULL}. Use of 2 levels to estimate the AUC_{FULL} was associated with greater precision and less bias relative to trough only data. **Conclusions:** The data from this study suggests that obtaining multiple levels improves the ability to accurately dose vancomycin in obese patients.

Table 1. Comparison of AUC estimates using two Bayesian priors and data subsets

	Median (range) AUC (mg-h/L)	Computed AUC to AUC_{FULL} Ratio (95% CI)	R^2
Non-Obese Prior			
Full Data Set (AUC_{FULL})	493 (280 - 756)	1.00 (N/A)	N/A
Trough Only (AUC_T)	687 (399 - 1046)	1.43 (1.33 - 1.53)	0.986
Peak and Trough (AUC_{PT})	463 (243 - 702)	0.93 (0.90 - 0.96)	0.998

Midpoint and Trough (AUC_{MT})	584 (359 - 850)	1.21 (1.14 - 1.27)	0.995
Obese Prior			
Full Data Set (AUC_{FULL})	483 (257 - 767)	1.00 (N/A)	N/A
Trough Only (AUC_{T})	549 (174 - 1121)	1.12 (0.81 - 1.44)	0.851
Peak and Trough (AUC_{PT})	441 (241 - 698)	0.93 (0.84 - 1.01)	0.981
Midpoint and Trough (AUC_{MT})	478 (217 - 653)	1.01 (0.91 - 1.10)	0.983

Adequacy of Recommended Cefazolin (Cfz) Prophylaxis in Cardiac Surgery: A Prospective Pharmacokinetic (Pk) Study

Author Block:

D. Calic, R. E. Ariano, R. C. Arora, H. P. Grocott, T. M. Lakowski, R. G. Lillico, S. A. Zelenitsky; Univ. of Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: Although practice guidelines recommend the standard CFZ dosing for antimicrobial prophylaxis (AP) in cardiac surgery (1), there is limited study as to whether adequate concentrations (concs) are achieved in this population. The purpose of this PK study of CFZ AP in patients undergoing cardiac surgery was to determine the incidence of sub-therapeutic intra-op concs and to identify risk factors for failure to maintain target concs.**Methods:** The study was conducted with consent in adults undergoing cardiac surgery with cardiopulmonary bypass and receiving CFZ AP as per institutional protocol (1 or 2 g IV pre-op based on body weight, repeated every 4 h during surgery). Blood samples were collected 30 min after the pre-op dose, prior to intra-op doses and within 15 min of wound closure. A quantitative liquid chromatography-tandem mass spectrometry assay was developed to measure total CFZ concs. Based on pharmacodynamic (PD) principles for AP (1), the therapeutic target was defined as maintaining total CFZ concs ≥ 40 mg/L during surgery (≥ 8 mg/L free concs, assuming 80% protein binding).**Results:** Fifty-five subjects (69% male) with a mean age of 65 ± 10 yrs, weight of 90 ± 17 kg and Clcr of 80 ± 19 mL/min/72 kg completed the study. Twelve (22%) subjects received 1 g CFZ doses and 43 (78%) were given 2 g doses. Total CFZ concs at closure ($C_{closure}$) were < 40 mg/L in 5 (9.6%) of the 52 evaluable cases, whereas levels below the target were observed at some point during surgery in 30.9% (17/55). A sub-therapeutic $C_{closure}$ was more frequently observed with 1 g doses for CFZ (P = 0.009), most often used in females (P=0.001) and those with increased age (P=0.037) and lower body weight (P < 0.001). Further analysis identified a critical dose threshold of > 24 mg/kg for maintaining target CFZ conc during surgery (P=0.035).**Conclusion:** Under current dosing guidelines sub-therapeutic CFZ concs occur frequently during cardiac surgery. As antimicrobial concs at wound closure are a risk factor for surgical site infections (2), current dosing guidelines may not be adequate. In addition, we demonstrate how PK-PD directed targets might be used to optimize AP and thus potentially reduce post-op infections.

Publishing Title:

Development of a Population Pharmacokinetic Model of Cefepime

Author Block:

A. Muller[1], S. Bhagwat[2], M. Patel[2], J. W. Mouton[3]; [1]Med. Ctr. Haaglanden, The Hague, Netherlands, [2]Wockhardt Res. Ctr., Aurangabad, India, [3]ErasmusMC, Rotterdam, Netherlands

Abstract Body:

Background: Cefepime is a cephalosporin with broad spectrum activity including Amp-C producing Gram-negatives. Cefepime is being developed as a high -proportion combination with tazobactam as an extended infusion (WCK 4282), to extend its coverage against ESBL, Class C β-lactamases, and KPC producing micro-organisms. Given the relatively poor availability of pharmacokinetic data and population models to perform Monte Carlo simulations and determine target attainment for various potential dosing schedules, pharmacokinetic studies were performed over one week of exposure.**Methods:** 44 healthy volunteers received dosing regimens of cefepime (in combination with tazobactam) of 1 gr or 2 gr given either bid or tid with infusion times of 0.5-1.5 hour for 6 days. Creatinine clearance ranged from 85-181.4 ml/min and weight 53-91 kg respectively. Blood samples were collected just before administration and after infusion at 0.08, 0.5, 1, 1,5, 2, 4, 6.5 or 7 h, and trough during the whole first day and whole 6^{th} day; peak and trough concentrations were determined on day 1-5. 2155 concentrations were analyzed with nonlinear mixed effect modeling (NONMEM, version 7.2) and the ADVAN5 subroutine. Different one- two-and three compartment disposition models were evaluated and the impact of covariates were determined. Model selection criteria were decrease in objective function, diagnostic plots and visual predictive checks.**Results:** The data were best described by a two-compartment model. In the analysis of covariates, it appeared that there was a slight, but significant difference in V1 and V2 between groups receiving different dosing schedules. However, the variability was similar for these schedules for V1 and V2, respectively. The final estimates were 5.86 L/h for clearance, 9.67-11.6 L for V1, 3.97 -5.69 L for V2 and 4.38 L/h for Q. Creatinine clearance and body weight were significant covariates for Cl and V1 respectively with estimates of 0.00384 and 0.011.**Conclusions:** Cefepime pharmacokinetics was well described by a two-compartment population model. The model allows Monte Carlo simulations to be performed and determine target attainments, including longer infusion duration.

Publishing Title:

Comparison and Evaluation of Vancomycin Trough Levels in Critically Ill Obese Pediatric Patients

Author Block:

D. Boeck[1], B. Duhon[2], K. Reveles[3], E. Hand[1]; [1]Univ. Hlth.System, San Antonio, TX, [2]Univ. of Texas Coll. of Pharmacy, Austin, TX, [3]Univ. of Texas Hlth.Sci. Ctr. at San Antonio, San Antonio, TX

Abstract Body:

Background: Vancomycin is the drug of choice for invasive methicillin-resistant *Staphylococcus aureus* infections in pediatric patients. Although data pertaining to dosing in adults is well-documented, appropriate weigh-based pediatric dosing recommendations, specifically in critically ill overweight and obese children, is lacking. The purpose of this study is to compare vancomycin serum concentrations in critically ill pediatric patients of varying body mass index percentiles (BMI%).**Methods:** This was a single-center, retrospective chart review of pediatric patients in the pediatric intensive care unit receiving scheduled vancomycin between July 1, 2009 and August 31, 2015. Patients were differentiated based upon BMI%. **Results:** A total of 130 patients met inclusion criteria, 76 with normal body weight (NBW), 21 considered overweight (85^{th}-94^{th} percentile), and 33 deemed obese ($\geq 95^{th}$ percentile). Median vancomycin doses were 50 mg/kg/day for NBW patients and 45 mg/kg/day for overweight and obese patients. There was a trend toward higher initial trough levels in overweight (10.2 mg/L,) and obese children (9.3 mg/L) when compared the NBW cohort (7.7 mg/L)($p = 0.18$ and $p = 0.08$, respectively). Significantly more overweight patients (52.4%) achieved initial troughs within the therapeutic range (10 - 20 mcg/mL) when compared to those with NBW (23.7%) ($p = 0.01$). More NBW patients obtained subtherapeutic troughs than overweight patients ($p = 0.03$). Supratherapeutic concentrations were more common in obese (18.2%) compared to NBW (7.9%) children, although not statistically significant ($p = 0.11$). **Conclusions:** Critically ill overweight and obese pediatric patients may obtain higher initial vancomycin concentrations compared with NBW patients. However, these patients may also be more likely to achieve supratherapeutic vancomycin concentrations with more aggressive dosing, increasing the risk for nephrotoxicity. Further investigation into the optimal dosing strategy for this patient population should be undertaken.

Development of a Population Pharmacokinetic Model of Tazobactam Including High Doses

Author Block:

A. E. Muller[1], S. Bhagwat[2], M. Patel[2], J. W. Mouton[3]; [1]Med. Ctr. Haaglanden, The Hague, Netherlands, [2]Wockhardt Res. Ctr., Aurangabad, India, [3]ErasmusMC, Rotterdam, Netherlands

Abstract Body:

Background: Tazobactam is a β-lactamase inhibitor that is used in combination with several β-lactams to extend coverage against ESBL producing micro-organisms. It is being developed in combination with cefepime with larger doses, up to 2 gr of tazobactam (WCK 4282) to include coverage of KPC producing bacteria. Given the relatively poor availability of pharmacokinetic data and population models, as well as the unavailability of data at high dosages of tazobactam, pharmacokinetic studies were performed over one week of exposure.**Methods:** 44 healthy volunteers received dosing regimens of tazobactam of 1 gr or 2 gr given either bid or tid with infusion times of 0.5-1.5 hour for 6 days. Creatinine clearance ranged from 85-181.4 ml/min and weight 53-91 kg respectively. Blood samples were collected just before administration and after infusion at 0.08, 0.5, 1, 1,5, 2, 4, 6.5 or 7 h, and trough during the whole first day and whole 6th day; peak and trough concentrations were determined on day 1-5. 1615 concentrations were analyzed with nonlinear mixed effect modeling (NONMEM, version 7.2) and the ADVAN5 subroutine. Different one- two-and three compartment disposition models were evaluated and the impact of covariates were determined. Model selection criteria were decrease in objective function, diagnostic plots and visual predictive checks.**Results:** The data were best described by a three-compartment model. In the analysis of covariates, there were some interoccasion effects but not significantly for the full sampling days 1 and 6. The final estimates were 19.8 L/h for clearance, 5.45 L for V1, 7.44 L for V2, 3.92 L for V3, 33.4 L/h for Q and 1.89 L/H for Q1. Creatinine clearance and bodyweight were significant covariates for Cl and V2 respectively with estimates of 0.00617 and 0.051.**Conclusions:** Tazobactam pharmacokinetics was well described by a three-compartment population model. The model allows Monte Carlo simulations to be performed and determine target attainments, including longer infusion duration and doses up to 2 gr.

Association between Initial Vancomycin (Van) Exposure Profile and Nephrotoxicity (Nt) among Hospitalized Patients with Bacteremia

Author Block:

E. J. Zasowski[1], K. P. Murray[2], T. D. Trinh[1], N. A. Finch[2], R. P. Mynatt[2], M. J. Rybak[1]; [1]Wayne State Univ., Detroit, MI, [2]Detroit Med. Ctr., Detroit, MI

Abstract Body:

Data indicate VAN area under the curve (AUC) predicts efficacy while troughs do not. AUC monitoring may maintain efficacy while reducing the # of patients requiring troughs associated with NT (>15 mg/L), yet data for AUC ranges associated with NT in adults are limited. This study examines the association between initial VAN exposure profiles & NT.Single center retrospective cohort, 6/2014 - 5/2015. Inclusion: age ≥ 18 y; ≥ 72 h VAN for bacteremia; ≥ 1 serum concentration during 1st 96 h. Exclusion: baseline serum creatinine (SCr) ≥ 2 mg/L; renal replacement therapy during 1st 96 h; cystic fibrosis; concomitant TZP. NT defined as > of SCr increase of 0.5 mg/L or 50% measured consecutively from initiation to 72 h after VAN. Bayesian estimated AUCs & troughs on days 1 & 2. Thresholds of VAN exposure variables strongly associated with NT were identified via classification & regression tree analysis. Exposure thresholds & characteristics were compared between NT & non-NT groups. Poisson regression was used to adjust for confounders & quantify association between VAN exposure thresholds & NT.74 patients included: mean (SD) age 62.7 (17.2) y; 54.1% male; median (IQR) wt & APACHE II score 80 (65, 108) kg & 14.5 (10, 20) respectively. NT occurred in 10.8%, median (IQR) time to NT 83 (759, 200) h. 67.6% received ≥ 1 nephrotoxin (24.3% intravenous contrast, 39.2% furosemide, 18.9% lisinopril (LIS), 4.1% aminoglycoside). Median (IQR) VAN duration, $AUC_{0\text{-}24}$, $AUC_{24\text{-}48}$, Cmin D1 & Cmin D2 were 6 (4, 8.25) days, 564 (383, 746) mg*h/L, 578 (441, 831) mg*h/L, 12.1 (8, 15.4) mg/L & 14.8 (9.7, 20) mg/L respectively. Following table shows results of the final Poisson regression models. There was no significant threshold in Cmin D2.

Variable	Non-NT (N=66) n (%)	NT (N=8) n (%)	RR (95%CI)	aRR (95% CI)
$AUC_{0\text{-}24} \geq 857$ mg*h/L	11 (16.7)	4 (50)	3.93 (1.11, 13.93)	3.90[a] (1.06, 16.06)
$AUC_{24\text{-}48} \geq 730$ mg*h/L	20 (30.3)	6 (75)	5.54 (1.20, 25.51)	6.33[b] (1.28, 31.40)

Cmin D1 ≥ 15.9 mg/L	11 (16.7)	5 (62.5)	6.04 (1.61, 22.62)	4.48[c] (1.06, 21.30)

[a] Liver disease & concomitant LIS retained[b] APACHE II score retained[b] Liver disease, concomitant LIS & APACHE II score retainedPreliminarily, daily VAN AUCs > 730 – 857 mg*h/L in 1st 48 h were associated with increased NT. Further analyses are needed to define therapeutic VAN AUC range.

Genetic Polymorphism Relating to the Concentration and Adverse Drug Reactions of Sulfamethoxazole- Trimethoprim and Metabolite

Author Block:

T-L. Chien[1], C-Y. Wang[1], C-C. Hung[2], S-Y. Chang[1], J-H. Yang[1], C-H. Kuo[1], Y-T. Lin[1], W-C. Liu[2], **S-W. Lin**[1]; [1]Natl. Taiwan Univ., Taipei, Taiwan, [2]Natl. Taiwan Univ. Hosp., Taipei, Taiwan

Abstract Body:

Background: Combination of sulfamethoxazole-trimethoprim (SMX-TMP) is the drug of choice in the treatment of *Pneumocystis jirovecii* pneumonia (PJP). Limited studies suggested peak plasma levels of SMX and TMP should target 100-200 and 3-10 μg/mL, respectively. SMX is mainly metabolized to N-acetyl SMX via N-acetyltranferase (NAT). The other pathway is CYP2C9-mediated bioactivation to a reactive, toxic metabolite. In Asian population, 20~30% are slow acetylators (SA) who may be more vulnerable to adverse drug reactions (ADRs). This study aimed to investigate single nucleotide polymorphism (SNP) of NAT and its correlation with levels of SMX-TMP and N-acetyl SMX, and ADRs.**Methods:** Adult inpatients receiving SMX-TMP ≥ 5 mg/kg/day (TMP) were enrolled in this prospective study. Blood samples of peak levels were drawn 3 hrs after oral dose or 1 hr after intravenous infusion at steady state. Trough levels were collected just before the next dose. The plasma levels of SMX-TMP and N4-acetyl SMX were assayed using a validated HPLC-UV method. SNP were determined by PCR amplification and restriction fragment-length polymorphism method. Chi-square test and Mann-Whitney U test were used to compare the differences between two groups. A p-value of <0.05 was considered statistically significant.**Results:** A total of 82 inpatients with a median age of 45 years (range, 23-87) were enrolled between January 2014 and December 2015. Thirty-six patients (43.9%) had HIV infection and 53 (64.6%) had cancers. Fifty-two patients (70.2%) had confirmed or presumed PJP. Approximately 70% of the patients achieved peak levels within therapeutic range for treating PJP. We found 14 patients (22.2%) were SAs in NAT1 and 22 (32.4%) were SAs in NAT2. Despite no significant differences between the ratio of N4-acetyl SMX/SMX (N/S) and NAT SNPs, lower ratios were observed in SAs. Of the 50 ADRs such as hepatotoxicity, nausea and vomiting, thrombocytopenia, skin rash, and psychosis, patients with definite or probable ADRs had lower ratio of N/S (p<0.05), suggesting the metabolism of SMX prone to CYP2C9 toxic pathway.**Conclusions:** A correlation between ratio of N/S and SMX-associated ADR indicated the critical role of NAT enzymes. More studies are needed to confirm this finding.

The Combination of Polymyxin B, Ampicillin/Sulbactam, and Meropenem Combats Polymyxin-Resistant *Acinetobacter baumannii* Over 14 Days

Author Block:

J. R. Lenhard[1], N. M. Smith[1], Z. P. Bulman[1], J. B. Bulitta[2], C. B. Landersdorfer[3], V. Thamlikitkul[4], P. N. Holden[1], R. L. Nation[5], J. Li[5], B. T. Tsuji[1]; [1]SUNY, Buffalo, NY, [2]Florida Univ., Orlando, FL, [3]Monash Univ., Melboure, Australia, [4]Mahidol Univ., Bangkok, Thailand, [5]Monash Univ., Melbourne, Australia

Abstract Body:

Background: The emergence of polymyxin-resistant *A. baumannii* (PRAB) has forced clinicians to use empiric, non-optimized triple antibiotic combinations; however, combinatorial pharmacodynamics (PD) of such regimens are poorly defined. Our objective was to characterize the PD of single, double, and triple combinations of polymyxin B (PB), ampicillin/sulbactam (A/S), and meropenem (MERO) against PRAB in a hollow fiber infection model (HFIM).**Methods:** Two extensively-resistant *A. baumannii* isolates resistant to PB (MIC 32 mg/L for 03-149-2, MIC 64 mg/L for N5406), A/S (MIC both strains 32/16 mg/L), and MERO (MIC both strains 64 mg/L) were investigated in a HFIM over 14 days at a 10^8 CFU/mL inoculum. PB (3.33 mg/kg x 1 dose, then 1.43 mg/kg q12h [fAUC$_{0\text{-}24h}$ 48.2 mg*h/L, fAUC$_{ss}$ 35.9 mg*h/L], $t_{1/2}$ 8h), A/S (8/4g q8h, $t_{1/2}$ 1.5h), and MERO (2g q8h, $t_{1/2}$ 1.5h, 3h prolonged infusion) were all administered alone and in double/triple combinations. Viable counts and PB population analysis profiles were conducted.**Results:** Against strain 03-149-2, single agents and double combinations were unable to achieve sustained killing. PB + MERO was the only double combination that resulted in early bactericidal activity, with a maximal reduction of 4.2 $\log_{10}$CFU/mL at 6h; however, drastic regrowth occurred by 72h and the percentage of the population capable of growing on 10 mg/L of PB was amplified 55,932 times higher compared to 0h. The triple combination also achieved a 4.2 log reduction at 6h, followed by eradication at 96h. Against strain N5406, PB or MERO alone and the combination of both agents achieved maximal reductions of 0, 0.6, and 1.9 logs, respectively, followed by regrowth. In contrast, A/S alone and in combination eradicated N5406. The triple combination displayed the most rapid killing with a 3.2 log reduction at 6h, while A/S alone, A/S + PB, and A/S + Mero resulted in 0.1, 0.6, and 1.9 log reductions at 6h, respectively, followed by sustained killing.**Conclusions:** The triple combination was the most active regimen against both *A. baumannii* strains and may offer a promising countermeasure for combating PRAB.

Optimization of Synergistic Combinations Against Carbapenem- and Aminoglycoside (Ags)-Resistant Clinical Isolates of *Pseudomonas* a*eruginosa* (Pa) *via* Mechanism-based Modeling

Author Block:

R. Yadav[1], J. Bulitta[2], R. L. Nation[1], C. B. Landersdorfer[1]; [1]Monash Univ, Melbourne, Australia, [2]Univ of Florida, Orlando, FL

Abstract Body:

Background: Carbapenem-resistant Pa are highly challenging clinically and effective early therapy is likely critical for treatment success. We aimed to systematically evaluate synergistic killing and prevention of resistance of Pa by carbapenem + AGS combinations and to rationally optimize combination dosage regimens *via* MBM.**Methods:** We studied imipenem (IPM) in monotherapy & combination with tobramycin (TOB) or amikacin (AMK) *vs.* 3 carbapenem- & AGS-resistant clinical Pa isolates. Serial viable counts of total & resistant populations (at 3×MIC) were determined in 48-h static concentration time-kill studies (inoculum $10^{7.5}$ CFU/mL). MBM characterized the time-course of bacterial killing & resistance. Optimized clinically relevant combination dosage regimens *vs.* a Pa isolate representing the 98th percentile of the EUCAST MIC distributions for IPM (MIC 16 mg/L) & TOB (MIC 32 mg/L) were proposed *via* Monte Carlo simulations.**Results:** Monotherapies provided little bacterial killing, except for < 2 $\log_{10}$ killing at 1-3h by high (24 & 36 mg/L) IPM concentrations followed by extensive regrowth with resistance. Clinically relevant IPM + AGS concentrations achieved synergistic killing (>2 $\log_{10}$ *vs.* the most active monotherapy at 24 h and 48h) and suppression of resistance for all isolates (MIC: IPM 16 to 32 mg/L & AGS 4 to 32 mg/L). MBM revealed an up to 3-fold decrease in the IPM conc. required for half-maximal bacterial killing with increasing AGS conc. Synergy was likely caused by the AGS enhancing target site penetration of IPM. Lower TOB (1/32th of MIC) than AMK (1/4th of MIC) conc. were sufficient for synergy with IPM, possibly due to the higher outer membrane affinity of TOB *vs.* AMK. An optimized combination regimen (IPM continuous infusion at 16.7 [9.63 - 29.1] mg/L (median [5th - 95th percentile]) + TOB 7 mg/kg body weight q24h) was predicted to achieve >2 $\log_{10}$ killing & prevent regrowth over 48 h in 90.3% of simulated critically-ill patients *vs.* the double-resistant isolate.**Conclusion:** The optimized IPM + TOB regimen is highly promising against Pa strains resistant to both carbapenems and AGS. Future evaluation in dynamic infection models will provide guidance on effective early therapy *vs.* infections by these extremely difficult-to-treat Pa.

Pharmacological Basis of Cd101 Efficacy: Exposure Shape Matters

Author Block:

E. A. Lakota[1], C. M. Rubino[1], V. Ong[2], K. Bartizal[2], L. Miesel[3], S. M. Bhavnani[1], P. G. Ambrose[1]; [1]ICPD, Latham, NY, [2]Cidara Therapeutics, San Diego, CA, [3]Europhins Panlabs, Ltd., St. Charles, MO

Abstract Body:

Introduction: All commercially available echinocandin antifungal agents are administered once daily, with efficacy driven by AUC. CD101 is a novel echinocandin with a concentration-dependent pattern of fungicidal activity *in vitro* and a long half-life (up to 150 h in humans, approximately 70-80 h in mice). Given these distinct characteristics, it is likely that the shape of the CD101 AUC greatly influences efficacy. **Methods:** To test this hypothesis, we administered the same total AUC to groups (n=5) of neutropenic ICR mice infected with *Candida albicans* using 3 different schedules. A total CD101 dose of 2 mg/kg was administered as a single IV dose or in equal divided doses of either 1 mg/kg twice weekly or 0.29 mg/kg/d over 7 days. The studies included a no-treatment control group. Animals were rendered neutropenic by 2 IP cyclophosphamide doses (150 mg/kg and 100 mg/kg, administered at -4 and -1 days) and inoculated with *C. albicans* R303 (1×10^3 CFU/mouse) 24 h prior to treatment. Animals were euthanized at 192 h post-inoculation. Paired kidneys were harvested, homogenized, serially diluted and plated for CFU determination. **Results:** As shown in the figure, fungi grew well in the no-treatment control group with variable activity in treatment groups. When the CD101 $AUC_{0\text{-}168h}$ was administered as a single dose, there was a >2 $\log_{10}$ CFU reduction from baseline at 192 h. When that same AUC was administered in 7 equal divided daily doses, there was an increase by >1 log10 CFU from baseline at 192 h. **Conclusions:** These data support the hypothesis that the shape of the CD101 AUC greatly influences efficacy. CD101 was significantly more effective when given once per week compared to the same dose divided into twice weekly or daily regimens.

Determination of the Tazobactam (Taz) Exposure Required for Piperacillin (Pip) Efficacy Using a One-compartment *In Vitro* Infection Model (Ivim)

Author Block:

B. D. VanScoy, C. M. Rubino, J. McCauley, J. Adams, C. Jones, S. M. Bhavnani, P. G. Ambrose; ICPD, Latham, NY

Abstract Body:

The PK-PD index describing TAZ efficacy in combination with PIP was recently determined to be % time > a TAZ threshold concentration when examined against a panel of isogenic laboratory-derived isolates. In the studies described herein, we identified a translational relationship for TAZ threshold concentrations which describes PIP/TAZ efficacy for a panel of Enterobacteriaceae (ENT) clinical isolates. A series of 24 h dose range studies were completed using a one compartment IVIM and 3 clinical ENT isolates known to produce extended spectrum beta-lactamase enzymes. Challenge inoculums of 10^6 were exposed to PIP and TAZ concentrations using a $t_{1/2}$ = 1h for both compounds. A 4 g PIP regimen was administered in combination with a range of TAZ doses every 6 h, using a 30 min infusion. The data from the dose range studies were pooled and an evaluation of %T>TAZ threshold values equivalent to 0.5, 1, 2, and 4 times the PIP/TAZ potentiated MIC (with TAZ at a fixed concentration of 4 mg/L) were completed. Discrimination of potential translational relationships for TAZ threshold concentrations were evaluated by dispersion of data across the X-axis and optimization of r^2 values. As evidenced by r^2=0.887, the relationship between change in $\log_{10}$ CFU from baseline at 24 h and %T>TAZ threshold concentration, the translational relationship best describing the efficacy of TAZ in combination with PIP was the %T>PIP/TAZ MIC (figure). The %T>PIP/TAZ MIC required for net bacterial stasis as well as a 1- and 2-$\log_{10}$ CFU reduction from baseline was determined to be 63.9, 77.4, and 100, respectively. The identified translational relationship allows for the evaluation and of PIP/TAZ regimens currently utilized in the clinic to treat ESBL-producing ENT.

Anti-staphylococcal Activity Resulting from Achievable Epithelial Lining Fluid (Elf) Concentrations of Amikacin Inhalation Administered via the Pulmonary Drug Delivery System

Author Block:

I. M. Ghazi, M. Grupper, D. P. Nicolau; Hartford Hosp., Hartford, CT

Abstract Body:

Background: Amikacin Inhale (BAY41-6551), a unique drug-device combination of a specially formulated drug solution and a Pulmonary Drug Delivery System device (AMK-I) is currently under phase III study as an adjunctive therapy to IV antibiotics for the treatment of Gram-negative pneumonia in mechanically ventilated patients. While the epidemiology of nosocomial pneumonia is predominated by Gram-negative pathogens such as *P. aeruginosa* and the Enterobacteriaceae, *Staphylococcus aureus* is increasingly recognized as a pathogen of concern for these pulmonary based infections. Since the aminoglycosides are historically quite active against *S. aureus* the use of adjunctive AMK-I may enhance bacterial eradication. Herein, we aimed to characterize the *in vitro* pharmacodynamic (PD) profile of human-simulated ELF exposures of AMK-I against both methicillin-sensitive (MSSA) and -resistant (MRSA) *S. aureus*.**Methods:** An *in vitro* model was used to simulate the resultant ELF pharmacokinetic profile of amikacin after the administration of AMK-I 400mg q12h. The antibacterial activity of this regimen was tested against 7 *S. aureus* isolates that display MIC profiles encountered clinically (4 MRSA; MIC range 4-64, 3 MSSA; MIC range 8-16 mg/L). Experiments were conducted over 24 h and samples were taken throughout this period to assess the bacterial density in both control and treatments.**Results:** The mean ± SD inoculum 0h bacterial density was 6.4 ± 0.09 which increased to 8.6 ± 0.19 $\log_{10}$ CFU/mL in the control models by the end of 24 h experiments. Simulated ELF concentrations of AMK-I resulted in a rapid, 5 $\log_{10}$ declined in CFU over the initial 12 h for all MRSA and MSSA isolates. After 12 h, all bacterial counts remained below the limit of detection (LOD, 1.7 $\log_{10}$ CFU/mL) and no regrowth was evident at the end of the study.**Conclusions:** AMK-I produced an ELF exposure profile that was rapidly bactericidal against *S. aureus* displaying typical MICs to amikacin irrespective of their phenotypic profile to methicillin. While the Gram-negative organisms are the target pathogens for AMK-I in the ongoing clinical trials, these data suggest that this adjunctive regimen may also have the potential to eradicate both MSSA and MRSA from lower airway which needs to be further evaluated in randomized-controlled clinical trials.

Hollow Fiber *In Vitro* infection Model (Hfim) Simulating Pharmacokinetics (Pk) in Critically Ill (Icu) Patients: Substantial Impacts on Anti-Bacterial Effects of Meropenem

Author Block:

P. J. Bergen[1], J. B. Bulitta[2], C. M. J. Kirkpatrick[1], M. McGregor[1], K. Rogers[1], S. C. Wallis[3], D. L. Paterson[3], J. Lipman[3], J. A. Roberts[3], **C. B. Landersdorfer**[1]; [1]Monash Univ., Melbourne, Australia, [2]Univ. of Florida, Orlando, FL, [3]The Univ. of Queensland, Brisbane, Australia

Abstract Body:

Background: ICU patients can have severely altered PK leading to widely varying antibiotic exposures. This study aimed to characterize the impact of altered plasma PK on bacterial killing and resistance for meropenem in the dynamic hollow fiber infection model (HFIM).**Methods:** A clinical *Pseudomonas aeruginosa* isolate (MIC 0.25 mg/L) was studied in the HFIM (inoculum $10^{7.5}$ cfu/mL). PK profiles of 3 meropenem dosing regimens (0.5g, 1g and 2g q8h, administered as 30 min intravenous infusions) as observed in ICU patients with augmented renal clearance (ARC), normal or impaired renal function (creatinine clearances 250, 120 or 30 mL/min) were simulated in the HFIM over 10 days. The time-courses of viable counts for the total bacterial population and less-susceptible populations (at 5× and 10×MIC) were determined.**Results:** For all regimens with ARC, initial bacterial killing of 2.5 $\log_{10}$ cfu/mL at 7 h was followed by regrowth to 10^9-10^{10} cfu/mL at 72 h; less susceptible bacteria (on 10xMIC plates) amplified by 5 $\log_{10}$ compared to controls. The 0.5g q8h regimen at normal renal function provided 3.4 $\log_{10}$ killing at 24 h followed by regrowth to 10^9 cfu/mL at 72 h; less susceptible bacteria (10x MIC) almost completely replaced the susceptible population (7 $\log_{10}$ increase *vs.* control). The 2g q8h regimen at normal renal function and the 1g q8h and 2g q8h regimens at impaired renal function, *i.e.* regimens that provided 100% $fT_{>MIC}$, suppressed regrowth over 10 days.**Conclusions:** Standard meropenem dosing regimens led to extensive emergence of resistance in the hollow fiber system when simulating patients with ARC. High meropenem concentrations were required to prevent regrowth of *P. aeruginosa*. Individualized dosing regimens that account for altered plasma PK in ICU patients and aim for higher than standard antibiotic exposures were necessary to maximize bacterial killing and suppress emergence of resistance.

Abstract Body:

Background: The management of serious MRSA infections presents therapeutic challenges to clinicians and is compounded by the emergence of DAP-nonsusceptible (DNS) MRSA strains during therapy. Recent studies demonstrate that DAP+nafcillin or ceftaroline is effective in the treatment of prolonged bacteremia and infections caused by DNS MRSA. There are limited data on alternative combination therapy using DAP + BL/BLI. **Methods:** Eight clinical strains of MRSA were used, 4 of which were DNS. ß-lactamase production was tested using nitrocefin disks. Minimum inhibitory concentrations (MICs) to DAP, ampicillin (AMP), piperacillin (PIP), AMP+sulbactam (SUL), and PIP+tazobactam (TAZ) were obtained by broth microdilution using standard techniques. MICs to DAP in the presence of BL and BL/BLI were also obtained. Time kill experiments (TKEs) were used to evaluate synergy between DAP+BL and DAP+BL/BLI using DAP and BL concentrations at 0.5xMIC; BLIs were given at free peak concentrations. Samples were obtained at 0, 4, 8, and 24 h of incubation. Synergy was defined using standard definitions. The ΔT24 log CFU/mL was obtained as the difference between the log CFU/mL of DAP and DAP+BL or DAP+BL/BLI at 24 h. **Results:** The DAP MICs ranged from 0.125 to 4 µg/mL. DAP MICs decreased further in the presence of BL and BL/BLI in all 8 isolates. All strains produced ß-lactamase. Synergy between DAP and BL/BLIs was demonstrated in 7 out of 8 strains. In 5 out of 8 strains, synergy was demonstrated only in the presence of the BLI. Doubling the BLI concentration had little effect on bacterial killing in 3 of 3 isolates tested.

Isolate	**675**	**R8845**	**494**	**67**	**684**	**R8846**	**R6253**	**R9024**
DAP MIC (µg/mL)	0.25	0.125	0.25	0.25	2	4	2	2
ΔT24 log CFU/mL$_{DAP+PIP}$	-0.93	-0.65	-0.19	+0.12	-6.94	-4.64	-1.64	+0.04
ΔT24 log CFU/mL$_{DAP+PIP+TAZ}$	-6.31	-5.72	-2.37	-1.53	-6.66	-4.63	-7.42	-2.88
ΔT24 log CFU/mL$_{DAP+AMP}$	-0.86	-0.35	-0.14	-0.04	-1.94	-4.55	+0.48	-0.03
ΔT24 log CFU/mL$_{DAP+AMP+SUL}$	-6.95	-6.53	-4.7	-1.53	-7.22	-4.67	-8.31	-3.04

Conclusions: This preliminary *in vitro* study demonstrated the synergy between DAP and BL/BLI. In the majority of the isolates tested, the BLI demonstrated a significant effect in enhancing bacterial killing. Further *in vitro* modeling and clinical trials are needed to evaluate these combinations.

The Antibacterial Effects of Two Dosing Regimens of Ceftolozane (TOZ) in Combination with Tazobactam (TAZ) in Comparison to Meropenem (MER) against *Pseudomonas aeruginosa* (PA)

Author Block:

K. E. Bowker, A. R. Noel, S. Tomaselli, M. Attwood, A. P. MacGowan; BCARE, North Bristol NHS Trust, Bristol, United Kingdom

Abstract Body:

Background: TOL/TAZ is an anti-pseudomonal cephalosporin (TOL) combined with a B.lactamase inhibitor (TAZ). TOL has marked in vitro potency against PA being active against many multi-drug resistant and extensively drug resistant strains. With anti-pseudomonal antibiotics, emergence of resistance (EoR) is a significant issue, hence it is important to optimise dosing regimens to limit this risk. We used an in vitro pharmacokinetic model (IVPKM) to simulate two human dose regimens of TOL/TAZ and measured their effect on 3 strains of PA and potential EOR over 7 day exposure.**Methods:** A one compartment IVPKM was used to simulate free drug serum concentrations associated with 1G TOL/0.5TAZ (Cmax 46/16mg/L) and 2G TOL/IG TAZ (Cmax 112/32); TOL t½ 2.5h, TAZ t½ 1h. Dosing was q8hly for 7d (168h). MER 1G (Cmax 80mg/L); t½ 1h was also simulated against one strain. 3 strains of PA were used, one wild type strain, one with AmpC hyper-expression and the other with a meropenem MIC 6mg/L: TOL/TAZ MICs were 0.5, 1 and 2mg/L. The inoculum was 10^6 CFU/ml and simulations were performed in triplicate. ABE was measured by log change in viable count and area-under-the-bacterial-kill-curve (AUBKC) over 168h. EOR was assessed by growth on nutrient agar plates containing x2, x4 MIC of the test antibiotic 24hly over 7 days..**Results:** Both TOL/TAZ regimens produced a >4 log reduction in viable count (below the limit of detection) by 12h for all three PA strains. Some regrowth occurred with all three strains after 24h with the TOL/TAZ 1G/0.5G regimen resulting in a log drop of 0-1 log at 168h. Regrowth also occurred with all three strains with the 2G/1G regimen after 48h with a 1-2 log drop at 168h. The 1G/0.5G was less effective at producing pathogen clearance than the 2G/1G regimen against all strains (AUBKC 168h 1G/0.5G 320±90; 2G/1G 172±117 log CFU/mL.h $p<0.01$). Against a single strain MER 1g q8h (MER MIC 1mg/L) was less effective than either TOL/TAZ regimen (ANOVA $p<0.01$). EOR on MICx2 plates was present with TOL/TAZ from 144h, and meropenem at 96h.**Conclusions:** TOL/TAZ was effective at reducing PA bacterial load. The 2G/1G regimen was more effective than the 1G/0.5G and EOR delayed until 144h. TOL/TAZ appeared more effective than MER in reducing bacterial load and preventing EOR.

Aminoglycoside Resistance Prevention by Short-Term, High Concentration Exposure in *Pseudomonas aeruginosa* Assessed *via* Novel Mechanism-Based Modeling (MBM)

Author Block:

V. E. Rees[1], J. B. Bulitta[2], B. T. Tsuji[3], A. Oliver[4], R. L. Nation[1], C. B. Landersdorfer[1]; [1]Monash Univ., Melbourne, Australia, [2]Univ. of Florida, Orlando, FL, [3]Univ. of Buffalo, Buffalo, NY, [4]Hosp. Son Espases, Palma, Spain

Abstract Body:

Background: Hypermutable *Pseudomonas aeruginosa* (Pa) are highly problematic. For aminoglycosides (AGS) the area under the free concentration-time curve divided by the MIC (*f*AUC/MIC) is used to predict bacterial killing and clinical success. We hypothesized that delivering the same *f*AUC over short *vs.* long durations of exposure would provide better killing and minimize AGS resistance in both hypermutable and non-hypermutable Pa. **Methods:** *P. aeruginosa* PAO1 and PAOΔ*mutS* (hypermutable) were studied in 24 h *in vitro* static time-kills with tobramycin (TOB; MIC=0.5 mg/L for both). This was carried out at *f*AUC/MIC of 36, 72 and 168 with initial inocula (CFU_o) of $\log_{10}$ 4 and 6, in duplicate. Antibiotic concentrations were calculated by the exposure durations and targeted *f*AUC/MIC. Tobramycin was added at 0 h and removed at 1, 4, 10 or 24 h *via* multiple centrifugation and re-suspension of bacteria in antibiotic-free broth. Viable counts of the total and resistant populations (mutation frequencies, MF) were determined and then characterized by novel MBM. MIC were assessed at 0 & 24 h.**Results:** For both strains at the same *f*AUC/MIC more rapid and extensive killing was observed with high concentrations over 1 and 4 h exposures (4 to 6 $\log_{10}$) compared to 10 and 24 h exposures (<4 $\log_{10}$). Regrowth by 24 h was extensive after 1 and 4h exposures, but the regrowing bacteria had unchanged MICs and MF compared to 0 h. While regrowth was less pronounced for 24 and 10 h exposure, susceptible bacteria had been completely replaced by AGS-resistant bacteria at CFU_o 6 and MICs increased up to 8-fold. The hypermutable PAOΔ*mutS* revealed higher MF at 0 and 24 h. Viable counts were well described by MBM (r=0.97).**Conclusions:** The AGS concentration profile shape was vital for resistance prevention. Short durations of exposure yielded extensive killing without resistance, whereas resistance was substantial for 24 and 10 h durations of exposure. High dose, short durations of exposure of AGS antibiotics are promising for innovative combination regimens to combat the susceptible regrowth.

Pharmacodynamics of Combination Therapy with Colistin and Meropenem Against Carbapenemase Producing *Klebsiella pneumoniae* Isolates in an *In Vitro* Pk-Pd Model

Author Block:

M. Tsala[1], S. Vourli[1], V. Miriagou[2], L. Tzouvelekis[1], L. Zerva[1], G. Daikos[1], J. Mouton[3], **J. Meletiadis**[3]; [1]Univ. Athens, Athens, Greece, [2]Hellenic Pasteur Inst., Athens, Greece, [3]Erasmus MC, Rotterdam, Netherlands

Abstract Body:

Background: As the last resort, colistin is often used for the management of carbapenamase producing *Klebsiella pneumoniae (CP-Kp)* infections. Since meropenem possesses some activity against these isolates, combination therapy may enhance efficacy of monotherapy regimens. We therefore assessed the combination of standard dosing regimens of colistin and meropenem against CP-Kp in an *in vitro* PK-PD model. **Methods:** Three clinical isolates with colistin and meropenem CLSI MIC's 0.5, 0.25, 0.5 mg/l and 0.06, 16 (CP-Kp1), 256 (CP-Kp2) mg/L, respectively were used at 10^7CFU/ml in an in vitro PK-PD model. The human plasma concentration-time profiles of 4.5MU q12 colistin and 1g q8 of meropenem was simulated for 48h targeting colistin and meropenem free serum maximum concentrations of 1.6 and 60 mg/L with half-lives 12h and <2h, respectively. Drug levels were determined with microbiological assays and bacterial growth by quantitative cultures estimating the CFU/ml at regular time points. **Results:** The pharmacokinetics of both drugs were well simulated in the model and within the target concentrations of mean±SD colistin and meropenem fC_{max} 1.86±0.27 mg/l and 47.82±11.56 mg/l and $t_{1/2}$ of 8-12h and 2-3h, respectively. Drug concentrations remained above the MIC for all three isolates for colistin and for 100%, 38% and 0% of the dosing interval for isolates with MICs 0.06, 16, 256 mg/L, respectively for meropenem. Colistin monotherapy exhibited rapid killing (>5$\log_{10}$CFU/ml reduction) within 2h exposure against all three isolates followed by regrowth after 12h reaching 9$\log_{10}$CFU/ml at 48h. Meropenem monotherapy exhibited rapid killing (4-5$\log_{10}$CFU/ml reduction) within 2h followed by regrowth within 24h only for the isolates with MIC 16 and 256 mg/l reaching 9$\log_{10}$CFU/ml at 48h. The combination regimen resulted in complete killing of the isolates with meropenem MICs 0.06 and 16 mg/l and 1.3$\log_{10}$CFU/ml reduction of the isolate with meropenem MIC 256 mg/l at 48h. **Conclusions:** Combination therapy with standard dosing regimens of colistin and meropenem enhanced efficacy of monotherapy regimens against CP-Kp but did not prevent regrowth of the highly meropenem resistant isolate.

***In Vitro* Evaluation of Resistance Selection in *Shigella flexneri* by Azithromycin, Ceftriaxone, Ciprofloxacin, Levofloxacin, and Moxifloxacin**

Author Block:

G. P. Allen, K. Harris; Univ. of New England Coll. of Pharmacy, Portland, ME

Abstract Body:

Background: *Shigella flexneri* has developed resistance to many antimicrobials. Alternate agents with superior pharmacodynamics are thus needed. The mutant prevention concentration (MPC) is a susceptibility parameter that measures the selection of mutant bacterial subpopulations. The MPC is the MIC of the most resistant mutant in a heterogeneous inoculum. Resistance is promoted when antimicrobial concentrations fall in the mutant selection window (MSW), the concentration range between the MIC and MPC. We used MSW testing and time-kill assays to compare the activity of azithromycin (AZM), ceftriaxone (CRO), ciprofloxacin (CIP), levofloxacin (LVX), and moxifloxacin (MXF) against *S. flexneri*.**Methods:** We studied ATTC 12022 and an isogenic *gyrA* mutant (m-12022). MPCs were determined by culturing 10^{10} CFU of *S. flexneri* on agar with increasing supra-MIC concentrations of each antimicrobial. Pharmacokinetic parameters attained by therapeutic doses of AZM (500 mg PO q24h; *f*C_{max} 0.28 mg/L, $T_{1/2}$ 68 h), CRO (250 mg x1 IM; *f*C_{max} 0.95 mg/L, $T_{1/2}$ 8 h), CIP (500 mg PO q12h; *f*C_{max} 2.08 mg/L, $T_{1/2}$ 4 h), LVX (500 mg PO q24h; *f*C_{max} 3.93 mg/L, $T_{1/2}$ 7 h), and MXF (400 mg PO q24h; *f*C_{max} 2.7 mg/L, $T_{1/2}$ 12 h) were used to assess the relationship between antimicrobial concentrations and the MSW. A time-kill assay was used to evaluate bacterial killing over 24 h.**Results:** For ATCC 12022, MIC/MPC (mg/L) were: AZM 4/>64, CRO 0.0625/0.5, CIP 0.03125/0.25, LVX 0.0625/0.5, and MXF 0.0625/0.5. For m-12022, MIC/MPC (mg/L) were: AZM 8/>64, CRO 0.125/2, CIP 0.25/2, LVX 0.25/2, and MXF 0.5/2. Concentrations of CRO, CIP, LVX, and MXF exceed the MPC for ATCC 12022, although concentrations of CRO and LVX fall in the MSW for 69.1% and 13.2% of the dosage interval, respectively. For m-12022, concentrations of CRO, CIP, LVX, and MXF fall in the MSW for 97.5%, 98.1%, 71.6%, and 78.3% of the dosage interval, respectively. Concentrations of AZM fall below the MIC, MPC, and MSW for both strains. In time-kill assays, CRO, CIP, LXV, and MXF were bactericidal (> 3 $\log_{10}$ CFU/mL kill) against both strains, while AZM was bacteriostatic.**Conclusion:** As *S. flexneri* resistance continues to emerge, new antimicrobial therapies are needed. The tested agents pose a variable risk of resistance selection, particularly in a *gyrA* mutant. The development of novel antimicrobials for shigellosis is needed.

Exploring the Activity of Tedizolid in Combination with Other Orally Bioavailable Antimicrobials Against *Staphylococcus aureus* and *Staphylococcus epidermidis*

Author Block:

B. J. Werth; Univ. of Washington Sch. of Pharmacy, Seattle, WA

Abstract Body:

Background: Tedizolid (TDZ) is an oxazolidinone, with high oral bioavailability, once-daily dosing, and broad-spectrum activity against gram-positives. Unlike linezolid, TDZ carries a reduced risk of hematologic toxicities with prolonged use and may fill a therapeutic gap where long-term, oral therapy against MDR gram-positives is desirable. Combination therapy is commonly indicated to improve efficacy against difficult to treat pathogens and biofilms. *S. aureus* and *S. epidermidis* are among the most commonly identified pathogens in orthopedic infections requiring prolonged therapy. To date there are no studies describing the pharmacodynamic interactions between TDZ and other orally bioavailable antimicrobials.**Methods:** MICs of TDZ, rifampin (RIF), trimethoprim/sulfamethoxazole (TMP/SMX), doxycycline (DOX), and moxifloxacin (MOX), were determined by broth microdilution against a convenience sample of 45 staphylococcal isolates. 7 MRSA isolates including 2 hVISA, 1 VISA and 4 VSSA, and 3 *S. epidermidis* were evaluated by time-kill using concentrations equal to 0.5 x the MIC. These strains had variable susceptibility to study antimicrobials. Synergy was defined as a $\geq$2 $\log_{10}$CFU/mL reduction of the combination over the most active single agent, antagonism was defined as $\geq$1 $\log_{10}$CFU/mL growth compared to the most active single agent, and other interactions were indifferent.**Results:**

Susceptibilities n=45 strains				
TDZ (MIC50)	**DOX (MIC50)**	**TMP/SMX (MIC50)**	**MOX (MIC50)**	**RIF (MIC50)**
0.25mg/L	0.25mg/L	0.125/2.38mg/L	2mg/L	0.02mg/L
TDZ (MIC90)	**DOX (MIC90)**	**TMP/SMX (MIC90)**	**MOX (MIC90)**	**RIF (MIC90)**
0.5mg/L	8mg/L	≥4/76mg/L	16mg/L	4mg/L
Time kills: interactions with tedizolid n=10 strains				
	Synergy	**Synergy**	**Synergy**	**Synergy**
	2/10	0/10	0/10	2/10
	Antagonism	**Antagonism**	**Antagonism**	**Antagonism**
	0/10	0/10	3/10	0/10

Conclusions: Pharmacodynamic interactions between TDZ and other agents were largely indifferent. Antagonism with MOX has been seen with linezolid, which may be evident with TDZ. MOX antagonism was observed in MOX susceptible and resistant strains. TDZ plus DOX or RIF had the most favorable activity but further research is warranted to assess the therapeutic potential of these combinations.

Publishing Title:

The Affect of Timing of Synergistic Antimicrobials on Bacterial Killing Against Methicillin Resistant *Staphylococcus aureus*

Author Block:

S. N. Leonard[1], T. A. Arriola[2]; [1]Ohio Northern Univ., Ada, OH, [2]Northeastern Univ., Boston, MA

Abstract Body:

Background: When considering combination antimicrobials for synergy it is thought that those drugs should and will be administered at the same time. However, in reality many issues complicate this notion. There may be more drugs than IV lines available for administration, there may be incompatibilities, the nursing staff may not know to administer them at the same time, and more. The goal of this project was to evaluate the effect of different administration times of two synergistic drugs on bacterial killing against methicillin resistant *Staphylococcus aureus* (MRSA) using an in vitro PK/PD model with simulated human pharmacokinetics. **Methods:** 2 isolates of MRSA were evaluated using a PK/PD model with simulated doses of vancomycin (VAN) q12h with a trough of 15 mg/L combined with gentamicin (GEN) 5 mg/kg daily, nafcillin (NAF) 2 g q4h, or cefazolin (CFZ) 1 g q8h with a starting inoculum of ~10^7 CFU/mL over 24 h in duplicate. VAN was always administered at T = 0 h while GEN, NAF, and CFZ were started at T=0, 1, 2, 3, 4, 5, or 6 h so that the effect of different start times could be evaluated. Total reduction in $\log_{10}$ CFU/mL over 24 h was determined by plotting time kill curves. Time to bactericidal activity was defined as 99.9% kill from initial inoculum ($T_{99.9}$) and determined by linear regression. Differences in CFU/mL at 24 h as well as $T_{99.9}$ were evaluated by using ANOVA with Tukey's post-hoc test. $P \leq 0.05$ was considered significant.**Results:** For both isolates there was no difference in the amount of kill at 24 h between the different administration times of each respective synergistic agent ($P \geq 0.24$). For CFZ and NAF combinations there were no differences in $T_{99.9}$ between administration times. For GEN combinations there was a difference in $T_{99.9}$ with later administration time having a longer $T_{99.9}$ (1.75-6.4 h, $P \leq 0.01$).**Conclusions:** Altering the administration time of GEN can increase the time to bactericidal activity when given in combination with VAN against MRSA. This effect was not observed with beta lactams (NAF or CFZ). There were no differences in magnitude of kill at 24 hours for any combination based on administration time of each respective synergistic agent.

Synergy Between Beta-Lactams (Bls) and Daptomycin (Dap) Against Vancomycin-resistant *Enterococci* (Vre) in an *In Vitro* Pharmacokinetic/Pharmacodynamic (Pk/Pd) Biofilm Model: Does This Apply to All Vre?

Author Block:

J. Yim[1], J. R. Smith[1], J. A. Hallesy[1], N. Singh[1], C. A. Arias[2], M. J. Rybak[1]; [1]Wayne State Univ., Detroit, MI, [2]Univ. of Texas Med. Sch. at Houston, Houston, TX 77030, TX

Abstract Body:

Background: *Enterococcus faecium (Efm)* may cause biofilm-associated infections. *Efm* strains are often resistant to vancomycin and BLs, posing important clinical challenges. We previously reported data supporting a potential role for the DAP+ ampicillin (AMP) and DAP+ ertapenem (ERT) combinations against *Efm* in an *in vitro* PK/PD biofilm model. Here, we further investigate the ability of AMP, ERT and ceftaroline (CPT) to enhance DAP activity against *Efm*. **Methods:** Treatment of *Efm* S447 was evaluated in a PK/PD biofilm models over 7 days, simulating human PK of DAP 14 mg/kg/day, DAP 12, DAP 12 + AMP 2g q6h, DAP 12 + CPT 600 mg q8h, DAP 12 + ERT 1g q24h and drug-free control. *Efm* biofilm was developed on titanium coupons using the CDC biofilm reactor. Synergy of these combinations in the absence of biofilm was further evaluated in a 1-compartment PK/PD model for 96 h and by time-kill analysis (TKA) methods over 48h.**Results:** DAP, AMP, CPT and ERT MICs for *Efm* S447 were 2 µg/mL, 32 µg/mL, > 16 µg/mL and > 64 µg/ml, respectively. DAP 14 mg/kg/day achieved bactericidal activity at 168h in S447 biofilm (-Δ3.5 $\log_{10}$CFU/cm^2 from 0h). Addition of ERT enhanced DAP activity, allowing DAP 12+ERT to produce bactericidal activity at 168h (-Δ3.87 $\log_{10}$ CFU/cm^2). DAP 12+AMP and DAP 12+CPT failed to demonstrate synergy in comparison to DAP 12 alone (DAP 12, -Δ2.4 $\log_{10}$CFU/cm^2; DAP 12+AMP, -Δ0.47 $\log_{10}$CFU/cm^2; DAP12+CPT, +Δ0.13 $\log_{10}$CFU/cm^2). While both DAP+AMP and DAP+CPT were synergistic at 48h in TKA at an initial inoculum of ~6.5 $\log_{10}$CFU/mL, no synergy was found at an initial inoculum of ~8 $\log_{10}$CFU/mL. In a 1-compartment PK/PD model at ~10^7 CFU/ml, both combinations were synergistic at 96h compared to DAP 12 alone (DAP 12, -Δ 0.08 CFU/mL; DAP12+AMP, -Δ 5.02 CFU/mL; DAP12+CPT, -Δ 4.8 CFU/mL).**Conclusions:** Our data provide further support for the potential use of DAP+ERT against biofilm-associated infections by *Efm*. Enhanced DAP activity by AMP or CPT against *Efm* may be both organism and inoculum dependent, and potentially affected by biofilm presence. Further research is warranted to examine the impact of these conditions on DAP + BL combinations against *Efm*.

Publishing Title:

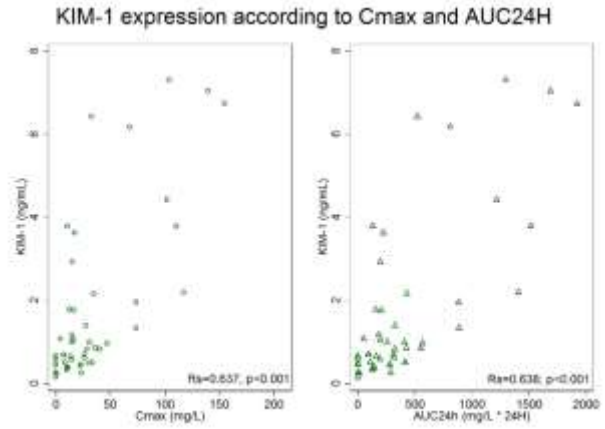
24-Hour Pharmacokinetic Relationships for Vancomycin (Van) and Novel Urinary Biomarkers of Acute Kidney Injury (Aki)

Author Block:

J. O'Donnell[1], N. J. Rhodes[1], T. Lodise[2], W. Prozialeck[1], C. M. Miglis[1], V. Natarajan[3], M. Joshi[1], G. Pais[1], P. Lamar[1], C. Cluff[1], A. Gulati[1], M. H. Scheetz[1]; [1]Midwestern Univ., Downers Grove, IL, [2]Albany Coll. of Pharmacy, Albany, NY, [3]TesoRx Pharma LLC, Pomona, CA

Abstract Body:

Background: VAN has been associated with AKI in both laboratory and clinical settings, however the precise pharmacokinetic (PK) exposures associated with the toxicodynamics (TD) have not been defined. We sought to determine exposures associated with the development of AKI using highly sensitive novel biomarkers. **Methods:** Male Sprague-Dawley rats received clinical grade VAN or normal saline as an intraperitoneal injection for 24 hours. Total daily doses ranging from 0 to 400 mg/kg/day were administered either as single or 2 divided doses. At least 5 rats were utilized for each dosing protocol. A max of 7 plasma samples per rat were obtained. 24-hour urine was collected and KIM-1, clusterin and osteopontin were determined using MILLIPLEX MAP Rat Kidney Panels. VAN plasma concentrations were determined via HPLC. PK analyses were conducted using Pmetrics for R and a 3-compartment model. Bayesian maximal a posteriori concentrations were fit to calculate 24-hour AUC, Cmax, and Cmin. PK/TD relationships were determined with non-parametric Spearman's rho (rs).**Results:** 47 rats contributed PK/TD data. Observed vs. predicted plots demonstrated a R2 of 0.833 for VAN model fit. VAN Cmax and AUC were most predictive, demonstrating Rs values of 0.637, 0.414, and 0.579, and 0.638, 0.418, and 0.567 for KIM-1, clusterin, and osteopontin respectively. All P-values for these relationships were </= 0.01. Cmin was less predictive with Rs values of 0.308, 0.040, 0.361 respectively.



Conclusions: Novel urinary biomarkers demonstrate that kidney injury occurs early with VAN and as a function of AUC or Cmax.

Probability of Target Attainment for Meropenem (Mero) and Polymyxin B (Pb) Combinations Against Carbapenem-Resistant *Acinetobacter baumanii* (Crab)

Author Block:

N. M. Smith[1], J. R. Lenhard[1], M. Trang[2], Z. Bulman[1], J. Bulitta[3], C. Landersdorfer[4], R. L. Nation[5], J. Li[4], A. Forrest[6], B. T. Tsuji[1]; [1]SUNY Buffalo, Buffalo, NY, [2]ICPD, Latham, NY, [3]Univ. of Florida, Orlando, FL, [4]Monash Univ., Parkville, Australia, [5]Monash Univ., Parkville, Austria, [6]UNC, Chapel Hill, NC

Abstract Body:

Background: Although the PK/PD targets for MERO and PB are well defined individually, there is a paucity of data on targets for combination, especially against carbapenem-resistant strains. Our objectives were to determine the likelihood of attaining desired bacterial reduction targets for MERO in combination with PB . **Methods:** AB strain N16870 (PB MIC 0.5 mg/L, MERO MIC 16 mg/L) was previously studied over 14 days in a hollow fiber infection model (HFIM) at a starting inoculum of 10^8 CFU/mL (Lenhard et. al., ICAAC 2015 A-938). The HFIM regimens included a growth control, a PB loading-dose (LD) monotherapy (2.22 mg/kg x1, then 1.43 mg/kg q12h [$fAUC_{0\text{-}24}$ 35.9 mg*h/L]), and PB LD plus dose escalated MERO (2, 4, 6, 8 g doses 3h prolonged infusion (PI) q8h [$fAUC_{24}$ 337, 673, 1010, 1347 mg*h/L, respectively]). Monte Carlo simulations (MCS) for 1000 patients was used to determine MERO concentrations, along with resulting reductions in area under the bacterial CFU/mL vs. time curve (AUCFU). The resulting patients were divided into groups by MERO AUC_{24} of <632, 687, 758, 824, and >824 mg*h/L, which were associated with <0.5, 1, 2, 3, >3 log decreases in AUCFU, respectively.**Results:** In the HFIM, PB monotherapy produced modest changes in AUCFU, whereas the PB-MERO combo showed maximal reductions in AUCFU (4.85 CFU*hr/mL). The AUCFU vs. MERO-fAUC24 relationship was described by a Hill-function with (E_{max}: 4.87 CFU*hr/mL, E0: 0 [fixed], EC50: 786 mg*hr/L, and Hill: 10). In presence of PB. The MCS predicted that, for a 2g regimen, 0% of patients would achieve >0.5 log decrease in AUCFU. The 4g regimen displayed a distribution of target attainment with 0.70%, 11.8%, 53.8%, 27.8%, and 5.9% of the patients seeing decreases in bacterial AUCFU of <0.5, 1, 2, 3, and >3 log reductions, respectively. Both the 6g and 8g regimens showed that all patients would respond with >3 log decreases in AUCFU.**Conclusion:** In the face of carbapenem resistance, escalation of meropenem ≥ 4g PI q8h in the presence of PB was necessary to achieve adequate target attainment in patients, which may provide insights to the benefits-risks of increasing MERO dose.

Combination of Daptomycin (Dap) and Ceftaroline (Cpt) or Gentamicin (Gen) Against *Streptococcus mitis* in an *In Vitro* Model of Simulated Endocardial Vegetations (Sevs)

Author Block:

J. Yim[1], J. R. Smith[1], N. Singh[1], J. A. Hallesy[1], C. Garcia de la Mària[2], A. S. Bayer[3], N. N. Mishra[4], J. M. Miro[5], C. A. Arias[6], T. T. Truc[6], P. Sullam[7], M. R. Rybak[1]; [1]Wayne State Univ., Detroit, MI, [2]Hosp. Clinic-IDIBAPS, Univ. Barcelona, Barcelona, Spain, [3]David Geffen Sch. of Med. at UCLA, Los Angeles, CA, [4]LA BioMed. Res. Inst., Torrance, CA, [5]Hosp. Clinic-IDIBAPS, Univ. Barcelona, Spain, Spain, [6]Univ. of Texas Med. Sch. at Houston, Houston, TX, [7]UCSF and VA Med. Ctr, San Francisco, CA

Abstract Body:

Background:S. mitis is a frequent cause of streptococcal endocarditis. Management of S. mitis infective endocarditis (IE) poses a clinical challenge, as strains are frequently resistant to β-lactams. Our study objective was to evaluate the efficacy of DAP alone and in combination with CPT or GEN against S. mitis in an in vitro SEV model.**Methods:**DAP, CPT, and GEN MICs were determined for S. mitis 351 and SF 100 by broth microdilution. DAP MICs were re-measured in presence of 0.5 x MIC of CPT or GEN to determine the DAP 'MIC lowering effect' of each agent. Both isolates were evaluated in a 96 h SEV model, mimicking human pharmacokinetics of DAP 6 mg/kg q24h, CPT 600 mg q8h, and GEN 3 mg/kg q24h alone and in combination. Emergence of resistance to DAP (DAP-R) was evaluated at 96 h.**Results:**CPT reduced the DAP MIC against S. mitis 351 and SF100 by more than 8-fold, whereas GEN decreased the DAP MIC only against *S. mitis* 351 and by 2-fold. In SEVs infected with either isolate, DAP alone was not bactericidal at 96h (351, $+\Delta 0.17$ $\log_{10}$ CFU/ml from 0h; SF100, $-\Delta 0.07$ $\log_{10}$ CFU/ml), and DAP-R was detected at 96h. GEN alone demonstrated little activity against these strains at 96h. CPT alone was bactericidal as soon as 24h and 8h for the two strains, and maintained its efficacy at 96h (351, $-\Delta 5.18$ $\log_{10}$ CFU/ml; SF 100, $-\Delta 6.57$ $\log_{10}$ CFU/ml). Addition of GEN to DAP was not synergistic in either strain at 96h. (351, $-\Delta 0.77$ $\log_{10}$ CFU/ml; SF100, $-\Delta 0.42$ $\log_{10}$ CFU/ml), and not prevent DAP-R. DAP+CPT was synergistic and rapidly bactericidal at 8h and 4h, and showed sustained efficacy at 96h. (351, $-\Delta 8.17$ $\log_{10}$ CFU/ml; SF100, $-\Delta 6.57$ $\log_{10}$ CFU/ml). DAP + CPT prevented emergence of DAP-R in both strains.**Conclusions:**DAP+CPT is a promising therapeutic option for treatment of S. mitis IE both in terms of efficacy and prevention of DAP-R. DAP + GEN appears to possess limited synergistic activity in this regard. Further investigation in animal IE models is warranted.

Histamine-Induced Toxicity in Rats with Antibiotic Compounds

Author Block:

S. S. Ubhayakar[1], X. Liang[2], Y. Chen[1]; [1]Genentech, Inc, South San Francisco, CA, [2]Genentech, Inc., South San Francisco, CA

Abstract Body:

During drug discovery rat PK/TK studies with antibiotic compounds, it was observed that certain compounds would cause some rats to experience adverse effects often resulting in death. It was thought that perhaps the release of histamine could be attributed to these effects. Histamine has a large part in the inflammatory process and is released by mast cells in response to foreign pathogens.To correlate the release of histamine with the compound concentration, a LC/MS/MS quantitative method was developed to monitor histamine.A Histamine working standard of 0.01 mg/ml was prepared in which serially diluted calibration curve spiking solutions were generated. Because histamine is endogenous, calibration curves were prepared in water. 5 µL of standard working solutions were spiked into 25 µL of water to generate a calibration curve ranging from 0.1 ng/ml to 2000 ng/ml. 25 µL of histamine-d4 solution (500 ng/ml) were added to all samples, including calibration curves. 50 µL of ammonium hydroxide (5%) was added to all samples. The samples were vortexed, transferred to an Isolute SLE+ plate, and extracted with 900 µL of ethyl acetate using positive pressure. PK plasma extracts were then analyzed using a Shimadzu Nexera system coupled to a Sciex 5500 Qtrap mass spectrometer. A Waters BEH Amide (50x2 mm, 1.7 µm) column with a generic HILIC gradient was used. Mobile phase A consisted of 25mM ammonium formate in 95:5 ACN:water with 0.1% formic acid and mobile phase B was 25 mM ammonium formate in 50:50 ACN:water.For all rat PK/TK studies, histamine concentrations were measured along with quantitation of the test article. Of the over 100 compounds dosed, at least 50% of the compounds showed histamine-induced effects. The baseline levels for histamine in rats ranged between 5-10 ng/ml. However, when particular compounds were dosed, as the drug concentrations increased, histamine concentrations also increased, sometimes to even tenfold of the baseline concentrations. This result proved that there was a positive correlation between increasing drug concentration in plasma and histamine release.Our findings indicated that these antibiotic compounds often triggered histamine release in rats. Compound optimization mitigating these histamine-induced toxicological effects is imperative to producing a safe, efficacious and reliable antibacterial drug.

High Rate of Carbapenemase-Producing Enterobacteriaceae in a Hospital in Angola; The Oxa-181 Threat

Author Block:

L. Poirel[1], N. Kieffer[1], M. Aires de Sousa[2], P. Nordmann[1]; [1]Univ. of Fribourg, Fribourg, Switzerland, [2]Univ. of Fribourg, Lisbon, Portugal

Abstract Body:

Background: The class B carbapenemase NDM-1 and the class D carbapenemase OXA-48 are increasingly identified worldwide, being mostly found in Enterobacteriaceae. No epidemiological data are available regarding the occurrence of carbapanemases in Angola. We conducted a prospective study in order to evaluate the rate of colonization of patients by carbapenemase producers at a Pediatric hospital in Luanda. **Methods**: Rectal swabs were collected from children being either inpatients or outpatients during a one-week screening period, May 2015. After a pre-enrichement in broth supplemented with ertapenem 0.25 µg/ml, samples were screened for the occurrence of carbapenem-resistant enterobacterial isolates using Chrom ID Carba SMART agar plates (bioMérieux). Colonies were tested with the Rapidec Carba NP test (bioMérieux) for detection of carbapenemase production. PCR experiments were further performed using primers specific for all carbapenemase genes (KPC, NDM and OXA-48-like). Conjugation experiments were realized by broth mating method in order to detect the possible transfer of the carbapenemase genes. Genotyping was performed by PFGE analysis and MLST. **Results:** A total of 157 samples were collected from children being 3 months to 13 years-old. A total of 90 carbapenem-resistant Gram negative isolates were recovered, the majority being *K. pneumoniae* (n=34) and *E. coli* (n=37) isolates. A total of 74 carbapenemase producers were identified, including 34 *K. pneumoniae*, 33 *E. coli*, and 4 *A. baumannii*. The most common carbapenemase identified was OXA-181 (a derivative of OXA-48) found in 32 *K. pneumoniae*, 29 *E. coli*, and a single *E. cloacae*. Nine NDM-1-producing isolates were identified, being 4 *E. coli*, 2 *K. pneumoniae*, a single *P. stuartii*, a single *P. retgeri*, and a single *A. baumannii*. PFGE analysis indicated that eleven different clones were identified among the 32 *K. pneumoniae* isolates. Seventeen different clones were identified among the 31 *E. coli* isolates. MLST indicated that Among the *E. coli* isolates, the most frequent Sequence Type was ST5692.**Conclusion:** This study identified for the first time carbapenemase producers in Angola. Noteworthy, those isolates were recovered from children. There was a significant number of NDM-1 producers, there was a large majority of OXA-181-producing isolates.

Characterization of Three *Escherichia coli* Clinical Isolates Carrying Plasmid-Mediated *oqxab* Genes

Author Block:

G. Rincon, M. Papalia, M. Rolan, **G. Gutkind**, M. Radice, J. Di Conza; UBA, BA, Argentina

Abstract Body:

Background: *oqxAB* genes encoding a multidrug efflux pump that commonly confer low resistance to quinolones and other antibiotics, but its presence may contribute to the selection of quinolone resistant mutants. *oqxAB* was initially detected in *E. coli* isolated from swine manure. However, it is infrequently reported in clinical isolates. The aim of this study was to characterize three clinical isolates of *oqxAB*-harboring *E. coli*, evaluate the inhibitory effect of phenylalanylarginine-β-naphthylamide (PAβN) and reserpine, and describe the genetic environment of this resistance marker. **Methods:** *E. coli* isolates (ER2, ER3 and DAC3) were collected in the metropolitan area in Lima, Peru. They were categorized as quinolone resistant and CTX-M-65 producers. Antimicrobial susceptibility and inhibitory effects of PAβN (50 mg/L) and reserpine (20 mg/L) were evaluated by agar dilution method according to CLSI. PMQR genes and QRDR mutations were determined by PCR and sequencing. *XbaI*-PFGE and MLST were used to characterize the isolates. *oqxAB*-containing plasmids were transferred to *E. coli* DH5α by electroporation. The genetic context of *oqxAB* was determined by PCR mapping and sequencing. **Results:** Isolates were resistant to nalidixic acid (NAL ≥1024 μg/ml), ciprofloxacin (32 μg/ml), levofloxacin (LVX 32 μg/ml), gatifloxacin (≥ 32 μg/ml), norfloxacin (≥128 μg/ml) and also trimethoprim- sulfamethoxazole (TMS ≥ 32/608 μg/ml) and chloramphenicol (CHL ≥128 μg/ml). In addition of *oqxAB*, ER3 also harbored *aac(6')-Ib-cr.* All of them carried two mutations in GyrA (S83L, D87N) and one in ParC (S80I). ER2 and ER3 strains were clonally related and were typified as ST602. DAC3 displayed a different banding pattern and was identified as ST448. The transfer of plasmids carrying *oqxAB* from ER2 and ER3 displayed an increase in TMS and CHL MICs (≥ 4 fold dilutions), however, quinolone MICs increased slightly. NAL, LVX and CHL MICs were reduced only in the presence of PAβN. The *oqxA1* and *oqxB3* alleles were identified in these isolates and they were always flanked downstream by IS*26* and upstream by a *tnpA* which displayed 99% identity with IS*15DI*. **Conclusions:** *E. coli* harboring *oqxAB* displayed the same allelic variants which were surrounded by insertion sequences belonging to IS*26* family. This operon has lightly modified the MICs of quinolones when it was transferred

***klebsiella Pneumoniae* Viability And Antibiotic Resistance Reduced By Peptide Phosphorodiamidate Morpholino Oligomers (Ppmos)**

Author Block:

E. Sully[1], L. Li[1], S. Bailey[2], M. Wong[2], D. E. Greenberg[3], **B. L. Geller**[1]; [1]Oregon State Univ., Corvallis, OR, [2]Sarepta Therapeutics, Cambridge, MA, [3]Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract Body:

Peptide phosphorodiamidate morpholino oligomers (PPMOs) are antisense nucleic acid analogs designed silence expression of specific genes through sequence specific binding to the coded mRNA resulting in translation inhibition. PPMOs targeted to essential genes inhibit growth of many Gram-negative bacteria, including *Escherichia coli* and *Acinetobacter*. It is now shown for the first time that PPMOs targeted to essential genes of *Klebsiella pneumoniae* inhibited growth and were bactericidal. In another strategy, PPMOs were targeted to the bla_{KPC} carbapenemase, and were found to restore susceptibility to meropenem. PPMOs were designed to complement the regions around the AUG start codons of the mRNA of essential or KPC genes, conjugated to a cell penetrating peptide, and evaluated *in vitro* by measuring the minimal inhibitory concentration (MIC) and the reduction of viability. Twelve PPMOs that target essential genes such as *acpP* (acyl carrier protein), *rpmB* (ribosomal protein), and *ftsZ* (cell division ring) were analyzed for potency in a panel of 40 strains, including multidrug-resistant and KPC-expressing strains. The most potent PPMO targeted *acpP* and had an IC_{90} of 1 μM. This AcpP PPMO (at 2 x MIC) reduced viability of selected strains by > 10^3 cfu/ml within 8 h. Two PPMOs were designed to inhibit expression of bla_{KPC} carbapenemase. Using 2 μM (12 μg/ml) of either KPC PPMO in combination with meropenem reduced the MIC of meropenem from 32 μg/ml to 4 μg/ml. These data show that a PPMO targeted to a highly conserved, essential gene (*acpP*) has broad bactericidal efficacy across multiple *K. pneumoniae* strains. In addition, the data show that PPMOs can be used in a strategically different way, as an adjunct therapeutic acting as a highly specific beta-lactamase inhibitor, that restores susceptibility to approved antibiotics.

Carbapenem-inactivating Effects of L-Cysteine Derived from A549 Cells

Author Block:

H. Takemura, S. Terakubo, N. Okamura, J. Shimada, H. Nakashima; St. Marianna Univ., Kawasaki, Japan

Abstract Body:

Background: At the 52nd ICAAC in San Francisco, CA, in 2012, we reported that antimicrobial activities of several carbapenems (Cps) decreased in the supernatants of the human alveolar epithelial cell line A549. In the subsequent experiments metabolomics analysis of the culture supernatants revealed that they contained L-cysteine (L-cys), which was not among the original contents of the medium, RPMI1640 (RPMI). RPMI contains L-cystine (LC), one of the L-cys oxide, but does not L-cys. L-cys has been reported to hydrolyse imipenem (IPM) concentration dependently. In this study, we investigated how L-cys production by A549 cells causes Cp inactivation.**Methods:** Cells were incubated in RPMI, RPMI supplemented with 10% FCS (F-RPMI), Earle's balanced salt solution (EBSS), and EBSS supplemented with amino acids for 1, 3, 6, 8, and 12 hours at 37 °C in an atmosphere with 5% CO_2. L-cys in the collected culture supernatants were measured by a colorimetric assay using Ellman's reagent. For the assay for Cp inactivation, diluted supernatants were incubated with IPM for 3 hours, and the activities of IPM were detected by an agar diffusion microbiological bioassay with *Micrococcus luteus*. To reveal the contribution of LC in the medium, similar experiments were performed in RPMI without LC.**Results:** L-cys in the A549 RPMI culture supernatants increased time-dependently from 57.1±19.0 μM (n=3) at 1h to 280.0±23.7 μM (n=3) at 8 h. L-cys in the F-RPMI supernatants was about half of that in RPMI. The supernatants exhibited IPM-inactivating effects according to their L-cys contents. The supernatants cultured with EBSS and RPMI without LC did not contain detectable L-cys and did not inactivate IPM while those cultured with the medium containing LC inactivated IPM. The concentration adjusted L-cys control solutions exhibited Cp-inactivating effects consistent with the results.**Conclusions:** The A549 culture supernatants exhibited strong IPM-inactivating effects according to their L-cys contents. As LC in the medium were necessary for the effects, it is speculated that L-cys, the reductive products of LC with the A549, was a major potent contributor to the effects.

Clinical Characteristics & Risk Factors for Acquisition of Less Commonly Isolated (Lci) Carbapenem-Resistant Enterobacteriaceae (Cre): A Case-Case-Control Study

Author Block:

Y. Cai, S-R. Chandra, C. Seah, J. Teo, T-P. Lim, W. Lee, T-H. Koh, T-T. Tan, A-L. Kwa; Singapore Gen. Hosp., SG, Singapore

Abstract Body:

Background: CRE infections are a major healthcare problem. While focus has been on common CRE [*K. pneumoniae* (KP), *E. coli* (EC) & *Enterobacter spp.* (ENT)], infections caused by LCI CRE (e.g. *Citrobacter spp., Serratia spp.*) are increasingly seen. It is unknown if unique risk factors are associated with LCI CRE acquisition. Our study aimed to elucidate factors associated with LCI CRE acquisition & describe outcomes of patients with LCI CRE. **Methods:** A matched case-case-control study was conducted at a tertiary Singapore hospital. Patients admitted from 2013 - 14 with positive LCI (defined as non-KP, EC or ENT) CRE cultures & those with LCI carbapenem-susceptible Enterobacteriaceae (CSE) were compared with a common control group with no Gram negative infections. Case & controls were matched for time at risk & location. Variables analyzed include demographics; comorbidities; healthcare exposure & antibiotic use. Two parallel multivariable logistic regression models were used to identify unique risk factors for LCI CRE. Outcomes of patients with clinically significant LCI CRE & LCI CSE infections were compared. **Results:** 42 patients with LCI CRE [31 (74%) surveillance; 11 (26%) clinical isolates], 42 patients with LCI CSE & 126 controls were included. *Citrobacter spp.* (95%) was the most common LCI CRE. Of the 11 clinical LCI CRE, the most common isolation site was urine (55%) & wound (27%). Half (52%) of LCI CRE patients had previous hospitalization. In the univariate analysis, old age, high SOFA score, previous hospitalization or instrumentation, & exposure to $3^{rd}/4^{th}$ generation cephalosporins & carbapenems were associated with LC CRE acquisition. In multivariable analysis, old age (OR: 1.06, 95% CI: 1.01-1.11) & high SOFA score (OR: 1.21, 95% CI: 1.00-1.46) independently predicted LCI-CRE acquisition. Patients with LCI CRE infe**c**tions had longer post-infection stay (median: 27 days vs. 13 days) & higher in-hospital mortality (18% vs. 7%) when compared to LCI CSE infections, but the differences were not statistically significant. **Conclusion:** Infections caused by LCI CRE are emerging, & may be associated with poorer outcomes. As age & SOFA score predicts LCI CRE acquisition, risk-based screening (i.e. in elderly or critically-ill) may be valuable to limit LCI CRE spread.

OXA-48 and OXA-370 Detection Directly from Spiked Blood Culture Vials and Fecal Swabs

Author Block:

C. S. Nodari[1], A. C. Gales[2], A. L. Barth[1], C. M. Magagnin[1], A. P. Zavascki[1], C. G. Carvalhaes[2]; [1]Hosp. de Clínicas de Porto Alegre, Porto Alegre, Brazil, [2]Univ.e Federal de São Paulo, São Paulo, Brazil

Abstract Body:

Oxacillinases are carbapenemases with low hydrolytic activity against carbapenems. Although many variants have been described worldwide, OXA-48 group is the most relevant among *Enterobacteriaceae.* To date, only OXA-370-producing isolates were reported in Brazil. Recently, an immunochromatographic assay has become commercially available for the detection of OXA-48 and its variants. The aim of this study was to evaluate the performance of OXA-48 K-SeT® (CORIS BioConcept) assay for the detection of OXA-48- and OXA-370-producing isolates directly from spiked blood cultures and stool swabs. A serial ten-fold dilutions obtained from a 0.5 McFarland inoculum of two *K. pneumoniae* strains (one OXA-48 producer and one OXA-370 producer) was obtained from overnight cultured colonies. Each dilution was plated for counting of viable colonies. One mililiter of each dilution was inoculated in sterile blood culture vials (VersaTREK® system), as well as 1 mL of donated human blood. When blood culture vials signalled positive, bacterial pellet was obtained by centrifugation. One mililiter of each bacterial suspension was also inoculated into E-Swab® vials (Copan) containing AMIES media, TSB, and donated stool, and incubated for two hours. The bacterial pellet was obtained by centrifugation. A 10 µL loop of the bacterial pellet was added to 10 drops of LY-LA buffer (TRIS, NaN_3, detergent; pH 7.5). Then, 3 drops of the resulting suspension were placed on the designated spot of the OXA-48 K-SeT cassette and interpreted as recommended by the manufacturer. The inoculum obtained ranged from 10 to 10^5 UFC/mL for both, blood culture vials and E-swabs. We were able to detect OXA-48 and OXA-370 directly from blood culture vials, regardless of the starting inoculum but the differences remained in the time of positivity (from 5 to 10 hours). We were also able to detect the carbapenemases from swabs inoculated with stool, with a sensitivity of 10^4 UFC/mL for both OXA-48 and OXA-370. In summary, the OXA-48 K-SeT assay is a rapid and reliable test for detecting OXA-48 and OXA-370 directly from clinical specimens.

Rapid Detection of Polymyxin Resistance in Enterobacteriaceae; The Missing Tool

Author Block:

L. Poirel, A. Jayol, P. Nordmann; Univ. of Fribourg, Fribourg, Switzerland

Abstract Body:

Background. Enterobacterial strains resistant to polymyxins are increasingly reported worldwide. Currently available polymyxins susceptibility methods are fastidious, time-consuming (24 h) and some methods are not reliable. They are poorly adapted to the clinical need and to the prevention of the dissemination of those multidrug resistant isolates. Therefore, we have developed the Rapid Polymyxin NP test that is rapid, reliable and cost-effective detect polymyxin resistant *Enterobacteriaceae.* **Materials/methods.** The Rapid Polymyxin NP test is based on the detection of bacterial growth in presence of a defined concentration of colistin (or polymyxin B) meaning colistin resistance in a well-defined medium. Growth is evidenced by acid formation related to glucose metabolism (aerobic and anaerobic) observed through a color change (orange to yellow) of a pH indicator (red phenol). A total of 196 enterobacterial strains from varied species were used to evaluate the performance of the Rapid Polymyxin NP test. Five strains were intrinsically resistant to colistin, 152 strains had an acquired mechanism of resistance to colistin, and 39 strains were susceptible to colistin. For 93 *Klebsiella* spp. isolates, resistance to colistin was associated to chromosomic alterations in genes modifying the LPS. For 10 *E. coli* isolates, resistance to colistin was mediated by the plasmid-borne *mcr-1* gene. The mechanism of colistin resistance was unknown for the remaining enterobacterial isolates. MICs of polymyxins were determined using the reference broth microdilution technique according to the CLSI guidelines and results were interpreted according to the breakpoints of the EUCAST.**Results.** The sensitivity and the specificity of the Polymyxin NP test were excellent, being 99.3 and 92.3 %, respectively, as compared to the broth microdilution taken as the gold standard. It was rapid (less than 2h) and reproducible.**Conclusion.** The Rapid Polymyxin NP test combines multiple advantages. It is easy to perform, rapid, reliable, cost-effective, sensitive, specific and implementable worldwide. It detects polymyxin-resistant enterobacterial strains from any species regardless the molecular mechanism of resistance to polymyxins (intrinsic, chromosomic and/or plasmid-mediated).

Modifying the Structure of a Membrane-targeting Small Molecule Antibiotic Alters Its Mechanism of Action

Author Block:

K. Hurley, V. Heinrich, T. Santos, D. Weibel; Univ. of Wisconsin, Madison, Madison, WI

Abstract Body:

The bacterial membrane is a clinically validated antibacterial target, however FDA-approved antibiotics that target the membrane are largely ineffective against gram-negative organisms. Developing chemotherapeutic agents that target the cellular membrane of both gram-positive and gram-negative bacteria can expand the clinical significance of this target. 2-((3-(3,6-dichloro-9*H*-carbazol-9-yl)-2-hydroxypropyl)amino)-2-(hydroxymethyl)propane-1,3-diol (DCAP) and its hydrophobic analog isopentyl-DCAP (i-DCAP) are broad-spectrum, membrane-targeting small molecules that increase the permeability of the membrane. Analogous to some membrane-active antimicrobial peptides, the antibacterial activity of DCAP and i-DCAP is antagonized by divalent cations (e.g., Mg^{2+} and Ca^{2+}). Using epifluorescence microscopy, we observed the temporal and local characteristics of membrane permeability after treatment of *E. coli* MG1655 cells with DCAP and i-DCAP. We discovered that cell lysis occurred after treatment with DCAP, however this phenotype was not observed after treatment with i-DCAP. Cells that became permeable after treatment with DCAP were predominantly dividing and contained a septum. After treatment with i-DCAP, cells from all phases of growth and division became permeable. Liposomal calcein release assays with liposomes constructed of various phospholipid compositions established that DCAP and i-DCAP disrupt artificial lipid bilayers of all bacterial phospholipids. We are currently investigating the effect of DCAP and i-DCAP on the membrane fluidity of the phospholipid bilayer in vivo using FRAP (fluorescence recovery after photobleaching). We are also pursuing computational modeling studies with stimulated phospholipid bilayers to determine the depth of insertion of DCAP and i-DCAP into the membrane. The DCAP-family of antibiotics may be an effective scaffold for developing chemotherapeutic agents that target the cellular membrane of both gram-negative and gram-positive bacteria.

Class A and D Carbapenemases Can be Differentiated by Indirect Tris/Edta (Te) Disk Testing with Boronic Acid

Author Block:

K. S. Thomson, J. W. Snyder, G. K. Thomson; Univ. of Louisville, Louisville, KY

Abstract Body:

Background: Convenient tests are needed to detect isolates producing OXA-48 and other class D carbapenemases. The lack of OXA-48-producing isolates available to US labs makes it difficult to evaluate OXA-48 detection tests, but a small 2015 US study showed that indirect tests with TE disks (BD Diagnostics) detected OXA-48 carbapenemases but did not differentiate them from class A carbapenemases (1). BA inhibits AmpCs and class A but not OXA (class D) carbapenemases. Therefore a study was designed to investigate whether the Indirect TE disk test could be modified by incorporating an additional TE disk containing BA (TEBA) to differentiate between AmpCs and class A vs class D carbapenemases.**Methods:** The isolates were 10 *K. pneumoniae* isolates producing OXA-48-like carbapenemases, 5 OXA-23-producing *A. baumannii*, 26 *Enterobacteriaceae* (EBE) producing the class A carbapenemases KPC-2, -3, -4, KPC-like, NMC-A, or SME-like, 8 EBE and 1 *P. aeruginosa* producing high level AmpC, 4 EBE and 1 *A. baumannii* MBL producers, and 2 EBE producers of a class A and B carbapenemase. The Indirect TE test was performed on a Mueller-Hinton agar plate inoculated with a lawn of *E. coli* ATCC 25922. A TE and a TEBA disk (containing 200 μg BA) were inoculated heavily with the test organism and positioned with the inoculated side in contact with the agar 1 mm to either side of an imipenem disk. After overnight incubation at 35^{o}C, an indentation of the inhibition zone near an inoculated TE disk indicated a positive test. No indentation indicated a negative test.**Results:** All 15 OXA carbapenemase producers were positive with both TE and TEBA disks. All 26 class A carbapenemase-producing EBE were positive with TE disks but negative with TEBA disks. One AmpC producer was positive in TE disk tests but all 9 AmpC producers were negative with TEBA disks. As expected, MBL producers yielded mixed results with one isolate positive with both disks and 4 isolates negative with both disks.**Conclusions:** Indirect TE tests differentiated between producers of class D carbapenemases vs AmpCs and Class A carbapenemases. Variable results with MBL producers indicated that this test is unsuitable for MBL-positive isolates. A limitation of the study was the small number of class D carbapenemase producers but the promising results suggested that further testing of a larger number of OXA carbapenemase producers is warranted.

Salicylate Induced Antibiotic Resistance Through the *Marrab*-Independent Pathway

Author Block:

T. Wang, I. El Meouche, M. J. Dunlop; The Univ. of Vermont, Burlington, VT

Abstract Body:

It has long been known that salicylate can induce antibiotic resistance by inhibiting MarR binding with the *marRAB* promoter and further activating MarA and its downstream genes related to resistance. Salicylate imposes a significant cost, slowing cell growth. This cost is traditionally attributed to expression of MarA-activated downstream resistance genes. Here, we show that salicylate can also induce equal levels of antibiotic resistance in *E.coli* through a *marRAB*-independent and *marRAB*/*rob*/*soxRS*-independent pathway. Unlike the findings from previous studies with salicylate, we find MarA activation to be a low-cost process. In order to study the cost of antibiotic resistance we established a genomic model which has MarR binding site mutations in *marRAB* promoter. We find that, unlike data obtained with salicylate treated cells, the genomic MarR binding inhibition model has a significantly higher minimum inhibitory concentration (MIC) for carbenicillin without a detectable cost of resistance. Our research indicates that the *marRAB*-independent pathway plays an important role in salicylate induced resistance. Furthermore, we demonstrate that the *marRAB* system is highly efficient, induce high levels of antibiotic resistance without detectable cost.

Mechanism Of Resistance In Carbapenem-Resistant Enterobacteriaceae Isolates At A Single Center In Northern California

Author Block:

C. Truong[1], N. Watz[2], I. Tickler[3], I. Budvytiene[2], N. Amiali[1], F. Tenover[3], N. Banaei[1]; [1]Stanford Univ. Sch. of Med., Stanford, CA, [2]Stanford Hlth.Care, Stanford, CA, [3]Cepheid, Sunnyvale, CA

Abstract Body:

The mechanism of carbapenem-Resistant Enterobacteriaceae (CRE) resistance is commonly due to carbapenemases and/or high-level of expression of ampC and ESBL coupled with altered outer membrane porins (omp). The underlying mechanism of resistance may have therapeutic implications for the newer β-lactam combination drugs. The aim of this study was to characterize the underlying mechanism of resistance in CRE isolates at our institution.From 2013-2015, all CRE isolates at Stanford Health Care meeting the pre-2015 CDC definition were included in this study. MICs for imipenem, meropenem, and ertapenem were established using MicroScan and confirmed by Etest. Real-time PCR and CheckPoint assay were used to detect carbapenemase (KPC, VIM, IMP, NDM-1, OXA-48 like) and cephalosporinase (ESBL and ampC) genes, respectively. Reverse transcriptase real-time PCR was used to quantify expression of *ompC* and *ompF* and their analogs. In total, 45 CRE infections were detected (11 in 2013, 14 in 2014, 20 in 2015). Carbapenemase genes could be detected in 38% (17/45) and included 4 KPC, 5 NDM, 1VIM, 2 IMP, and 5 OXA-48 like. In CREs characterized thus far, 69% (9/13) and 15% (2/13) of carbapenemase-positive isolates and 33% (9/27) and 15% (4/27) of carbapenemase-negative isolates were positive for ESBL and ampC, respectively. *ompC* and *ompF* expression were down regulated at least 2-fold in 0% (0/14) and 50% (7/14) of isolates with carbapenemase genes compared with 56% (10/18) and 56% (10/18) of isolates without a carbapenemase gene (78% [14/18] showed down regulation of either *ompC* or *ompF*), respectively.In summary**,** majority of CRE isolates at our institution do not encode a carbapenemase gene. Downregulation of omp is consistent with a porin loss in majority of carbapenemase-negative isolates.

Avibactam (AVI) Inactivation of PER-2 β-Lactamase: Exploring the Landscape of Diazabicyclooctane (DBO) Inhibition

Author Block:

M. Ruggiero[1], K. M. Papp-Wallace[2], G. Gutkind[1], R. A. Bonomo[2], **P. Power**[1]; [1]U. Buenos Aires, Buenos Aires, Argentina, [2]Cleveland VAMC, CWRU, Cleveland, OH

Abstract Body:

Background: PER β-lactamases are prevalent in South America and the Middle East and readily hydrolyze oxyimino-cephalosporins. This enhanced hydrolytic activity may result from the presence of a unique fold in the Ω loop and in the β3 strand. These structural differences enlarge the active site entrance by 2-fold compared to other class A β-lactamases. PER-2 possesses higher catalytic efficiency towards ceftazidime (CAZ) compared to PER-1 (~22-fold higher). Examination of the apo-structure reveals that the H-bonding (HB) network between S70-Q69-HOH-T237-R220 may also play a role in their different catalytic profiles. AVI is a reversible DBO β-lactamase inhibitor (BLI) that inactivates Ambler class A and C β-lactamases. Our goal was to assess the ability of AVI to inhibit PER-2, restore susceptibility to clinical strains when combined with CAZ, ceftaroline (TAR), and aztreonam (ATM) and to probe the mechanism of inhibition. **Methods:** MIC testing was conducted using clinical isolates of *Enterobacteriaceae* (Ent) possessing PER-2 using ampicillin (AMP), AMP-AVI, CAZ, CAZ-AVI, TAR, TAR-AVI, ATM, and/or ATM-AVI. AVI inhibition constants (k_2/K) were determined using nitrocefin as a reporter substrate. Modeling of PER-2 with AVI was conducted with Autodock Vina and Yasara.**Results:** Ent possessing PER-2 demonstrated high MICs to CAZ (≥ 512 μg/ml), TAR (16-512 μg/ml), and ATM (≥ 128 μg/ml). When CAZ, TAR, and ATM were combined with AVI, only the TAR-AVI combination restored susceptibility (MICs ≤1 μg/ml) for all isolates. The k_2/K value for AVI was 2,000 $M^{-1}s^{-1}$, similar to AmpC inactivation constants (10^3 $M^{-1}s^{-1}$ range), but 100-fold less than that for other class A β-lactamases (e.g., TEM-1 and CTX-M-15), and 10-fold less than KPC-2. As observed in other class A β-lactamases, HB interactions between AVI and S130, E166, T235, and T237 are postulated. The Q69, H170, N132 and T104 residues are predicted to form hydrophobic interactions with AVI.**Conclusions:** Compared to CAZ and ATM, AVI combined with TAR effectively lowers MICs vs. Ent. The unique structural features of the PER active site and new interactions formed impact AVI inhibition of PER-2 and likely effect the deacylation of the AVI-PER-2 complex.

Potentiating Fluoroquinolone Bactericidal Activity by Increasing Reactive Oxygen Species Production in Quinolone-Resistant *Escherichia coli*

Author Block:

J. Machuca[1], E. Recacha[1], P. Diaz de Alba[1], M. Ramos-Guelfo[1], Á. Pascual[1], J. Rodríguez-Martínez[2]; [1]Univ. Hosp. Virgen Macarena, Seville, Spain, [2]Univ. of Seville, Seville, Spain

Abstract Body:

Background: Bactericidal antibiotics, including fluoroquinolones (FQ), share a common mechanism of action involving the Reactive Oxygen Species (ROS) as part of its bactericidal power. The aim of this study was to evaluate the contribution of ROS overproduction in the bactericidal activity of microorganisms with acquired FQ resistance mechanisms.**Methods:** *E. coli* ATCC 25922 and three isogenic mutants harbouring chromosomal- and/or plasmid-mediated quinolone resistance mechanisms were used as background strains [EC04: S83L (*gyrA*) + S80R (*parC*); EC09: S83L-D87N (*gyrA*) + S80R (*parC*) + Δ*marR*; EC59: S83L-D87N (*gyrA*) + S80R (*parC*) + Δ*marR* + *qnrS1*]. Derived strains containing deletion in *sdhC* (Succinate dehydrogenase complex subunit C) or *cyoA* (Cytochrome oxidase subunit II) genes that increase ROS were obtained by chromosomal inactivation. MICs of FQs [ciprofloxacin (CIP), levofloxacin, moxifloxacin, norfloxacin, ofloxacin (OFX)] and nalidixic acid were determined by microdilution. Frequency of mutants was calculated at 4xMIC of CIP and OFX, 1 mg/L of CIP and 2 mg/L of OFX for selected strains. Time-kill curves were determined in Mueller-Hinton broth at CIP and OFX concentration of 2xMIC values. Growth curves of each strain in LB and M9 were drawn (with and without FQs).**Results:** Deletion in sdhC and cyoA genes did not affect the MICs of FQ in any E. coli genotype. No significant increase in the rate of mutation was observed in tested strains (ATCC 25922, EC04 and derived strains with deletion in sdhC or cyoA genes). For both quinolones evaluated, killing-curves assays showed a significant increased killing for strains with deletion in sdhC gene (sdhC inactivation reduced the survival in 1 - 2 log10 at 4 hour). cyoA inactivation effect on bacterial survival was lower than that of sdhC inactivation (0.3 - 1 log10 at 4 hour). The growth curve of strains with sdhC inactivation in M9 medium without antimicrobial showed a shorter lag phase compared to wild-type strains. This effect was not observed in LB medium.**Conclusions:** Inactivation of *sdhC* gene potentiates the killing of *E. coli* with acquired quinolone resistance mechanisms by FQ. Potentiation of ROS production might be used as adjuvant therapy of FQ use.

Characterisation Of A Tigecycline Specific Abc Transporter Isolated From A Human Saliva Metagenomic Library

Author Block:

L. J. Reynolds[1], M. F. Anjum[2], A. P. Roberts[1]; [1]UCL Eastman Dental Inst., London, United Kingdom, [2]Animal and Plant Hlth.Agency, London, United Kingdom

Abstract Body:

Background: Tigecycline is a novel glycylcycline that has been developed for the treatment of infections caused by antibiotic resistant pathogens including MRSA and *Acinetobacter baumannii*. Although the antibiotic is able to overcome most tetracycline resistance mechanisms, resistance to this antibiotic has been described.**Methods:** A human saliva metagenomic library was created in *E. coli* EPI300 using pCC1BAC. The library was screened for the presence of tetracycline resistant clones by growing them on 5 µg/ml tetracycline. Plasmid inserts from clones of interest were sequenced to determine any open reading frames (ORFs) were present. To determine the genes responsible for observed resistance phenotypes subcloning and site directed mutagenesis was employed.**Results:** 28,000 clones from the human saliva metagenomic library were screened to identify any tetracycline resistant members. A tetracycline resistant clone that also had reduced susceptibility to tigecycline was isolated. The plasmid isolated from the clone contained a 7,766 base pair insert with five ORFs, two of which encoded putative ABC transporters. These two genes were shown to confer resistance to tetracycline and tigecycline indicating their products created a heterodimeric ABC transporter. Mutants with deleted Walker A motifs were unable to confer resistance to these antibiotics.**Conclusions:** Screening of the metagenomic library revealed a clone exhibiting high levels of tetracycline and tigecycline resistance. Two genes encoding a putative heterodimeric ABC transporter were shown to be solely responsible for this phenotype. Walker A motifs are required for ABC transporter functionality and deletion of these regions resulted in a loss of resistance indicating that an ABC transporter is responsible for the observed phenotype.

Elucidating the Mechanisms of *Staphylococcus aureus* Pathogenesis During Urinary Tract Infections

Author Block:

J. Walker, A. Flores-Mireles, C Pinkner, HL. Schreiber, MG Caparon, and SJ Hultgren; Washington Univ. Sch. of Med., St. Louis, MO

Abstract Body:

Background: *Staphylococcus aureus* is a cause of urinary tract infections (UTI) in high-risk patient populations, with catheterized patients particularly susceptible. Importantly, methicillin-resistant *S. aureus* (MRSA) bacteriuria in high-risk populations has a high rate of dissemination to bacteremia and is a significant cause of shock following bacteremic UTI. *S. aureus* invasive infections, such as bacteremia, are associated with significant morbidity and mortality. Although invasive infections have been under intense research, few studies assess how MRSA enters the bloodstream to cause severe disease.**Results:** To address important gaps in understanding the mechanisms of MRSA dissemination, we adapted a mouse model of catheter-associated UTI (CAUTI). It is well established that catheterization leads to bladder tissue damage in patients and recent studies of mouse models of CAUTI indicate damage induced by the catheter triggers the release of fibrinogen (Fg) in the bladder. Further, we conducted a small clinical study assessing catheters from 50 patients undergoing catheterization as part of a standard of care and confirmed Fg was deposited on catheters, replicating what we see in the mouse model. Importantly, in our adapted MRSA CAUTI model **i)** MRSA required a catheter to establish persistent UTI; **ii)** Fg accumulated in the bladder and subsequently coated the catheter; **iii)** MRSA co-localized with Fg deposited on catheters; and **iv)** MRSA rapidly disseminated to bacteremia and subsequently colonized the spleen and heart. Further, *in vitro* data shows MRSA grown in human urine supplemented with Fg produces a thick, extracellular-like matrix via MRSA-Fg interactions, potentially capable of providing protection from the host immune system and antibiotics during CAUTI. Importantly, two patients enrolled in our clinical study had positive *S. aureus* urine cultures prior to their procedures. Surprisingly, even after appropriate antibiotic treatment, *S. aureus* was detected on these patient's catheters and the pathogen co-localized with Fg.**Conclusions:** These studies indicate the catheterized bladder is an ideal environment for MRSA infection and will provide a better understanding of MRSA dissemination in order to develop more effective treatment options to prevent progression of CAUTI to invasive disease.

Acute Injury to Internal Organs During Staphylococcal Infective Endocarditis

Author Block:

K. Kulhankova, J. M. King, K. Gibson-Corley, C. Stach, B. Vu, W. Salgado-Pabon; Univ. of Iowa, Iowa City, IA

Abstract Body:

Staphylococcal infective endocarditis (SIE) is a serious complication of hospital- and community-acquired staphylococcal infections. Clinical course of SIE is accompanied by acute damage to deep tissues and organ systems that manifests in about 40-70% of cases. These systemic complications are a primary cause of death in SIE patients. In humans, pathogens as *Staphylococcus aureus*, viridans streptococci, and enterococci induce different types of complications during IE. However, whether different *S. aureus* strains with varying repertoire of virulence factors differentially induce systemic complications is not known. Utilizing a rabbit model of IE and the four clinical *S. aureus* isolates with different superantigen (SAg) and hemolysin profiles, we investigated the gross pathology and histological characteristics of various organs during course of the disease. IA116 (α-toxin^{HI}) and IA209 (β-toxin^{HI}) are two current USA100 isolates that produce SAgs at low level. IA1471 (staphylococcal enterotoxin C, SEC^{HI}) and IA1871 (SEC negative) are two current USA600 isolates with low-level of hemolysins. Diffuse liver damage was significantly greater in rabbits infected with IA116 and IA209 compared to IA1471, consistent with their significantly greater production of hemolysins. On the other hand, IA1471, which expresses SEC, but low levels of hemolysins, resulted in a significantly greater acute lung damage and greater lethality. Acute kidney injury tended to be more severe in rabbits infected with IA116 - a high α-toxin and PSMs producer, compared to IA209. Altogether, these data provide evidence for the differential role of SEC and hemolysins in acute multi-organ injury during SIE. Elucidating the role of *S. aureus* genotypic and phenotypic characteristics in pathogenesis of clinical IE complications will further our understanding of the role of virulence factors in organ-tropism during complicated SIE.

Overexpression of Heat Shock Protein 70 Reduces *Chlamydia* Induced Pathology in Mice in a Tissue-Specific Fashion

Author Block:

W. Li, K. Vlcek, J. Do, A. Seetharaman, M. Ciancio, K. Ramsey, A. K. Murthy; Midwestern Univ., Downers Grove, IL

Abstract Body:

Chlamydia trachomatis genital infection leads to severe pathological consequences including hydrosalpinx (fluid-filled oviduct dilatation), pelvic inflammatory disease and infertility in a subset of untreated women. In the mouse model, a variety of host immunological mediators have been implicated in pathogenesis. Therefore, we hypothesized that over-expression of heat shock protein 70 (Hsp70), an evolutionarily conserved stress-induced protein with significant cytoprotective and immunoregulatory activities, would protect against *Chlamydia*-induced oviduct pathology in mice. C57BL/6 mice with Hsp70 transgene under the control of villin promoter were generated. The villin promoter is active only in the ciliated columnar epithelium of the mouse oviduct but not in other parts of the female mouse genital tract. HSP70 levels in transgenic (Tg) mice oviduct tissue were higher than that in non-transgenic mice. Six- to ten-week old female Hsp70 Tg and non-transgenic (NTG) littermates (n=12) were infected intravaginally with $5x10^4$ IFU of *C. muridarum*. Vaginal chlamydial shedding and chlamydial burden in the upper genital tract, and serum antibody levels were comparable between Hsp70 Tg and NTG mice. However, *Chlamydia*-specific cytokine production (IFN-γ, TNF-α, and IL-17) from medial iliac lymph nodes were significantly reduced in Hsp70 Tg mice. Hsp70 Tg mice displayed significant reduction in incidence and severity of oviduct dilation, not uterine horn pathology, at 80 days after bacterial inoculation when compared to NTG mice. In summary, these results suggest that Hsp70 over-expression in the oviduct epithelium leads to reduced antigen-specific cytokine production and to reduced oviduct pathology following chlamydial infection. These results support further evaluation of Hsp70 as a target to reduce clinically relevant *Chlamydia*-induced pathology.

Impact of Trauma on *Streptococcus pyogenes* Dissemination

Author Block:

L. Lamb[1], C. Scudamore[2], N. N. Lynskey[1], L. Tan[1], C. E. Turner[1], S. Sriskandan[1]; [1]Imperial Coll., London, United Kingdom, [2]MRC, Oxford, United Kingdom

Abstract Body:

Background: Historically, invasive infections caused by *S.pyogenes* or group A streptococcus (iGAS) were associated with penetrating trauma during combat until the introduction of penicillin. More recently, cases of severe iGAS and toxic shock have been reported in healthy individuals subjected to blunt trauma. We aimed to determine if contusion injury enhances the development or dissemination of iGAS systemically. **Methods:** A murine model of mild blunt contusion was developed and characterized. The effects of soft tissue contusion were assessed on a model of bacteremia and soft tissue infection with *S.pyogenes*. Bacterial phenotypic changes observed after contusion were investigated by sequencing. **Results:** Application of a 15.7mJ force resulted in histological changes in muscle consistent with mild contusion with no bony injury and minimal cytokine response. In a mouse model of bacteremia, blunt contusion did not lead to specific seeding of contused tissue and had no effect on bacterial burden or cytokine response. In a mouse model of soft tissue infection, blunt contusion was associated with increased dissemination of *S.pyogenes* to ipsilateral draining lymph node, and linked to an increase in a stable mucoid phenotype in both lymph node and spleen. Hyaluronan production wasenhanced in these colonies. Whole genome sequencing of mucoid colonies from spleen demonstrated a mutation in the global regulator covRS, and from lymph node an unexpected deletion in the promoter region of the *hasABC* capsule operon. *HasABC* promoter GAS mutants demonstrated a clearly enhanced ability to disseminate to local lymph node, consistent with a recently described interaction between hylauronan and the lymphatic endothelial receptor (LYVE-1). **Conclusions:** Contusion enhanced lymphatic dissemination of *S.pyogenes* to local lymph nodes. Potentially contusion leads to damaged lymphatic endothelium and enhanced exposure of GAS to LYVE-1. Whether lymphatic transit or local inflammation select for hyperencapsulated GAS mutants is uncertain. Although the findings do not rule out the possibility of seeding following more severe blunt trauma, mild contusion appears likely to impact on lymphatic spread. The study highlights a possible mechanism for interaction between contusion and *S. pyogenes* virulence.

Bacterial Presence and Histopathology in an Experimental Animal Model of Chronic *Propionibacterium acnes* Foreign Body Infectionhistopathology in a Prolonged Infection Model

Author Block:

H. Tyner[1], K. Greenwood Quaintance[2], R. Patel[2]; [1]Mayo Clinic Sch. of Graduate Med. Ed., Rochester, MN, [2]Mayo Clinic, Rochester, MN

Abstract Body:

Background: *Propionibacterium acnes* is a common contaminant in surgical specimens, but can also cause foreign body (especially shoulder arthroplasty) infection. *P. acnes* prosthetic joint infection is often not associated with elevated inflammatory markers or other classic features of infection.**Methods**: We developed a new rat model of chronic *P. acnes* foreign body infection wherein threaded stainless steel Kirschner wires were infected with *P. acnes* by allowing a *P. acnes* biofilm to form on the wires prior to surgical implantation into the tibia of rats. At 3 and 6 week time points, 9 rats were sacrificed, 2 uninfected rats and 7 infected rats per time point. After the surgically manipulated tibias were removed, bone within 5 mm of the implanted wire (one uninfected and 5 infected) was weighed, crushed, and quantitatively cultured. The remaining bones (one uninfected and 2 infected for each time point) were sent for histopathology to evaluate for evidence of inflammation and to undergo Brown and Brenn Gram staining.**Results**: At week 3, *P. acnes* was recovered from 5 of 5 infected bones (mean, range: 4.80, 1.64-6.15 $\log_{10}$cfu/g bone), and at week 6, *P. acnes* was recovered from 4 of 5 infected bones (mean, range: 2.81, 0-5.08 $\log_{10}$cfu/g bone). Histopathologically, infected 3 week bones showed no evidence of inflammation and bacterial stains were negative. One infected six week bone stained positive for many Gram-positive rods and the other showed no organisms; however, neither showed evidence of inflammation.**Conclusion**: In an experimental animal model of chronic foreign body infection, *P. acnes* can persist over time. A lack of inflammation was observed on histopathological examination.

Abnormal Intestinal Function in Kittens Experimentally Infected with Enteropathogenic *E. coli*

Author Block:

V. E. Watson, M. Jacob, J. Bruno-Barcena, J. L. Gookin; North Carolina State Univ., Raleigh, NC

Abstract Body:

Infectious diarrhea is a leading cause of death in children and kittens. In children, enteropathogenic *E.coli* (EPEC) is a common cause of diarrhea and is associated with an increased risk of mortality. We demonstrated that sick kittens dying in animal shelters have colonization of the intestinal epithelium by EPEC and PCR amplification of the intimin gene (*eae*) from fecal DNA is significantly associated with diarrhea. We hypothesize that EPEC is an important cause of intestinal dysfunction and diarrhea in kittens.Sixteen purpose-bred kittens were randomized to receive antibiotic-induced dysbiosis or no antibiotics prior to infection with 3 different serotypes of atypical EPEC (10^8 CFU each) obtained from kittens with diarrhea. To establish an infectious dose, the EPEC burden of naturally infected kittens with diarrhea was estimated by establishing a qPCR assay relating amplification of *eae* from fecal DNA to CFU of EPEC. Survival of EPEC following gavage was estimated by quantitative culture of each isolate in a simulated gastric environment. Following experimental infection, feces were cultured and isolated *E. coli* confirmed as EPEC by *eae* amplification. The effect of EPEC infection on intestinal absorption of D-xylose and permeability to iohexol were quantified and diarrhea established on the basis of fecal frequency, consistency score, and wet weight.Efficiency of *eae* qPCR for estimating fecal CFU of EPEC was 110 ± 4.7%. *Eae* qPCR of fecal DNA from 34 shelter kittens with diarrhea estimated carriage of 4×10^8 ($\pm 1.6 \times 10^8$) CFU of EPEC per 100 g of feces. No loss of EPEC was observed upon culture in a simulated gastric environment. After experimental infection, EPEC was cultured from feces of all kittens. EPEC infection led to significant malabsorption of D-xylose and a significant decrease in intestinal permeability to iohexol. In kittens with antibiotic induced dysbiosis prior to infection, EPEC significantly increased fecal wet weight at 3 days post infection ($p<0.01$;t-test).This study is the first to demonstrate that EPEC infection is sufficient to cause a significant decrease in intestinal absorption in kittens. Dysbiosis prior to infection increases the impact of EPEC on fecal water content. These results suggest a significant effect of EPEC on intestinal function in kittens and a role for intestinal bacterial dysbiosis in susceptibility to diarrhea.

Investigating the Relationships between Virulent *Dichelobacter nodoosus*, Interleuken-1-Beta (IL1β) and Histopathology Lesions in Footrot

Author Block:

M. Agbaje, G. Maboni, M. Bexon, C. S. Rutland, M. A. Jones, S. Tötemeyer; Univ. of Nottingham, Loughborough, United Kingdom

Abstract Body:

Background: Footrot is the major cause of lameness and a predominant welfare and economic concern for sheep farmers worldwide. Footrot is characterized by the separation of the hoof from the skin and this morphologic pathology has been attributed to the host immune response rather than the bacterial aetiology. In a study, IL1β (pro-inflammatory cytokine) was reported to have an increased expression in footrot ovine feet in comparison with healthy feet. However, the role of the innate immune system in footrot remains unclear. Virulent *Dichelobacter nodosus* is the causative agent of underrunning footrot. The aim of this study was to investigate the relationships between virulent *D. nodosus*, expression of the pro-inflammatory cytokine IL1β and histopathological lesions in footrot. **Methods:** From 55 healthy and 30 footrot ovine feet, two sets of parallel biopsies (one fixed for histology, one stored in RNA later for total DNA and RNA extraction) were collected post-slaughtered from an abattoir. H&E stained sections were analysed for histological lesions, virulent *D. nodosus* load quantified by qPCR and IL1β mRNA expression was determined by RT-qPCR. **Results:** We observed that significantly higher levels of IL1β corresponded with increased inflammatory cell infiltration score in footrot ($p<0.05$) but not in healthy biopsies. However, virulent *D. nodosus* load as well as histological lesions including cell ballooning, parakeratosis, epidermal micro-abscesses and inflammatory cell infiltration were similar in healthy and footrot conditions. **Conclusions:** This suggests, while virulent *D. nodosus* is the primary aetiology of footrot, other factors contribute to the exacerbation of the host immune response leading to footrot lesions. Also, the presence of virulent *D. nodosus* as well as histological lesions observed in the healthy ovine feet with no clinical symptoms of footrot may indicate on-going subclinical infections or early stages of infection.

Development of an *In Vitro* Wound Model of Infection to Evaluate the Effect of Topical Application of Antimicrobials

Author Block:

B. L. Price, C. B. Dobson; Univ. of Manchester, Manchester, United Kingdom

Abstract Body:

Background: A relevant and reliable model for infected wounds colonised with biofilm has not yet been established. We have previously developed a collagen gel *in vitro* model for a chronic diabetic foot ulcer contaminated with a *P. aeruginosa* or *S. aureus* biofilm. In the present study we have further refined the model by introducing mammalian cells into the matrix, enabling release of cytokines and other inflammatory markers to be measured in response to microbial colonisation. **Methods:** Collagen gel matrices seeded with human neonatal foreskin fibroblasts were prepared containing central 'voids' bathed in media. Cells were incubated for five days, before models were inoculated with *Pseudomonas aeruginosa* PA01 and incubated for one day. The model was then incubated with calcium sulfate beads containing gentamicin for one day. Following incubation bacteria from the model were counted. We confirmed characteristics indicative of biofilm formation and the growth of mammalian cells was confirmed using fluorescent microscopy. Mammalian cell biochemical responses were investigated using Luminex targeting specific cytokines.**Results:** Histology confirmed the production of bacterial polysaccharide matrix while the presence of microcolonies within the matrix indicated growth of a biofilm. The biofilm was visualised within the collagen matrix by SEM. The biofilm showed decreased susceptibility to antimicrobials. Fluorescent microscopy identified fibroblasts growing within the collagen matrix and Luminex confirmed the presence of pro-inflammatory cytokines in the culture medium in response to infection. After one day of incubation with gentamicin loaded calcium sulfate beads, no bacterial colonies were recovered from the wound model.**Conclusions:** We have successfully developed an *in vitro* collagen wound model combined with fibroblasts, to assess biofilm colonisation of wounds confirmed using a range of techniques. We have demonstrated with this model that both biofilm colonisation of a wound and the resulting early inflammatory events can be modelled using this system. Addition of calcium sulfate beads combined with antibiotics directly to a novel biofilm wound model clears an established biofilm. This approach may offer an alternative clinical strategy for patients who are not responding to oral antibiotics.

Characterization of Pathogenesis Observed in BALB/c Mice Exposed to Aerosolized *Burkholderia pseudomallei* HBPUB10134a

Author Block:

K. A. Fritts, M. Hunter, C. P. Klimko, J. A. Bozue, R. G. Toothman, J. J. Bearss, J. L. Dankmeyer, P. L. Worsham, K. Amemiya, S. L. Welkos, C. K. Cote; USAMRIID, Frederick, MD

Abstract Body:

Burkholderia pseudomallei, the etiologic agent of melioidosis, is a gram negative bacterium designated a category B threat agent by the CDC. This bacterium is endemic in Southeast Asia and northern Australia and can infect humans and animals by several routes of infection. It has also been estimated to present a considerable risk as a potential biothreat agent. There are currently no effective vaccines for B. pseudomallei and antibiotic treatment can be hampered by nonspecific symptomology and also the high rate of naturally occurring antibiotic resistant strains. .Our goal is to develop well-characterized animal models to facilitate research on disease pathogenesis and evaluation of novel medical countermeasures. Female BALB/c were infected with a low dose of aerosolized B. pseudomallei HBPUB10134a (approximately 6 CFUs). Mice were euthanized on days 1, 2, 3, 4, 7, 10, and 14 post-infection. Some of these mice were used for pathological analyses and others were used to determine the bacterial burden on selected tissues (blood, lungs, and spleens). Additionally, spleen homogenate, lung homogenate, and sera samples were analyzed to better characterize the resulting host immune response after exposure to aerosolized bacteria. This work represents the next step in our efforts to developing standardized animal models for melioidosis. The data when compared to those collected using differentially virulent strains of B. pseudomallei (i.e. 1106a) demonstrate differences in pathogenesis amongst strains of bacteria in the mouse model and adds to the growing body of data concerning appropriate animals models for B. pseudomallei infections.

Serratia marcescens*: Blowing Corneal Epithelial Cell Bubbles with *gumB

Author Block:

R. M. Q. Shanks, K. M. Brothers, N. A. Stella; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: *Serratia marcescens* causes bacterial keratitis and contact lens associated complications. Previous studies have shown that another bacteria, *Pseudomonas aeruginosa*, induces blebs in corneal cells using a type III secretion system. We observed that *S. marcescens* induced epithelial bleb formation in human corneal limbal epithelial cells (HCLE) and human keratinocytes in vitro, yet *S. marcescens* lacks a type III secretion system. The purpose of this study was to identify the novel mechanism by which *S. marcescens* causes epithelial cell bleb formation.**Methods:** A mariner transposon library of corneal keratitis isolate K904 was screened for mutations that inactivated the bacterial bleb induction in HCLE cells.**Results:** ~7,000 mutants were used to challenge HCLE layers and the challenged epithelial cells were examined microscopically. Of the tested mutants, 5 were defective in inducing bleb formation. Two of the bleb-induction deficient isolates had transposons that map to different loci in an uncharacterized gene in *S. marcescens* named *gumB*. A deletion mutation of the *gumB* gene was generated and the resulting mutant was defective in bleb formation. Complementation of the *gumB* open reading frame mutant confirmed the role of this gene in bleb induction. Other bleb-inducing defective bacteria had mutations in a type V secretion system. Expression of the type V system in *Escherichia coli* conferred the ability to induce blebs.**Conclusions:** This analysis identified a novel mechanism for inducing necrotic blebs in corneal cells. Future studies to inhibit this mechanism may help reduce contact lens associated complications and keratitis associated vision loss.

In Susceptible Mice Infected with *M. pulmonis*, Host Lung Damage Is Associated with Recruitment of Il-17a$^+$ Lymphocytes and Neutrophils into the Lung

Author Block:

M. Mize, J. Simecka; Univ. of North Texas Hlth.Sci. Ctr., Fort Worth, TX

Abstract Body:

Background: Possessing the smallest genomes, *mycoplasma* induce pneumonia in humans and animals resulting in chronic airway inflammation. Exacerbating other respiratory conditions (i.e. asthma), *mycoplasma* have evolved to resist modern antibiotics and vaccines induce the same damage seen during actual infection[1]. A cytokine contributing to chronic pathology and neutrophil-mediated host protection, IL-17A is secreted during infection with *mycoplasma*. Here, we investigate whether IL-17A can promote damage characteristic of *mycoplasma* disease. Our results will help development of vaccines that confer protection and lack side-effects. **Methods:** Murine pneumonia, induced by *M. pulmonis*, resembles the pulmonary pathogenesis seen in human *mycoplasma* diseases. Furthermore, BALB/c models have been well established for studying chronic *mycoplasma* infection[2]. Briefly, *M. pulmonis* was administered intra-nasally. At select time points post-infection, mice were sacrificed and aspects of pathogenesis analyzed. **Results:** Injecting neutralizing antibodies against IL-17A into BALB/c mice reduced inflammation during infection without altering bacterial burden. Attenuating the effects of IL-17A reduced both airway cell numbers and total lung IL-17A$^+$ lymphocytes by Day (14). The increase in IL-17A$^+$ cells was associated with increased airway neutrophils, appearing as early as Day (1) post-infection. The early presence of neutrophils appears alongside CD4$^+$, CD8$^+$, and γδ T-cells that secrete IL-17A. By Day (9) post-infection, the described T-cell populations are replaced by CD4$^+$, SCA-1$^+$, and NK cells that contribute to IL-17A levels. While IL-17A$^+$CD4$^+$ T-cells reach their maximum response at Day (1) post-infection, this was the only T-cell population that persisted in their production of IL-17A by Day (14). The generation of IL-17A$^+$ lymphocytes, and subsequent recruitment of neutrophils was associated with disease pathogenesis. **Conclusions:** During infection with *M. pulmonis*, neutrophil recruitment into the lungs is associated with the presence of IL-17A$^+$ lymphocytes. Neutrophils and IL-17A$^+$ cells drive host damage; neutralizing IL-17A reduces airway neutrophils, total IL-17A$^+$ lung cells and host damage. Blocking IL-17A lowers lung lesion development, thus IL-17A and neutrophils promote respiratory damage.

Atypical Enteropathogenic *E. coli* Is Associated with Diarrhea and Diarrheal Death in Kittens

Author Block:

V. E. Watson[1], M. Jacob[1], J. Elfenbein[1], C. DebRoy[2], J. L. Gookin[1]; [1]North Carolina State Univ., Raleigh, NC, [2]Pennsylvania State Univ., University Park, PA

Abstract Body:

Infectious diarrhea is a leading cause of death in children and kittens. In children, enteropathogenic *E.coli* (EPEC) is a common cause of diarrhea and is associated with increased risk of mortality. We demonstrated that sick kittens dying in animal shelters have colonization of the intestinal epithelium by EPEC. We hypothesized that EPEC is significantly associated with diarrhea in kittens and that phenotypic or genotypic characteristics could be used to distinguish pathogenic from non-pathogenic EPEC in kittens.A prospective, case-controlled study of EPEC infection in shelter kittens with and without diarrhea was performed. DNA was extracted from feces for conventional and qPCR amplification of intimin (*eae*). Feces were cultured and isolated *E. coli* identified as EPEC by PCR (*eae+*, *stx1/2-*). EPEC were genotypically characterized using PFGE, serotyping, and PCR detection of *bfp* (atypical -vs- typical EPEC) and virulence genes on the Locus of Enterocyte Effacement (*EspA*, *EscN*, *Ler*). Phenotypic characteristics of EPEC were determined by quantifying motility on semi-solid media and adherence to HEp-2 cells examined using FITC-phalloidin.Conventional PCR detected *eae* in fecal DNA from 50% (31/62) of kittens with and 23% (12/53) of kittens without diarrhea (OR=3.4; 95% CI=1.5 to 7.7; $p<0.01$). Quantitative PCR demonstrated a greater copy number of *eae* in feces from kittens with diarrhea ($p<0.01$;t-test). Culture of live EPEC was achieved in 21% (6/29) of kittens with diarrhea-associated death and 16% (3/19) of control kittens. All culture isolates of EPEC were identified as atypical (*eae+*, *bfp-*). Methods to identify genotypic or phenotypic differences were not able to distinguish pathogenic from non-pathogenic EPEC.This study demonstrated that *eae* can be commonly amplified from the feces of kittens and is significantly associated with diarrhea and diarrheal death. Isolates of EPEC from kittens are phenotypically and genotypically diverse. Naturally occurring EPEC infection in kittens may represent a novel animal model for study of EPEC infection in children.

Role of *msaabcr* Operon in the Staphylococcal Chronic Osteomyelitis Pathogenesis

Author Block:

G. S. Sahukhal[1], M. A. Tucci[2], G. A. Wilson[2], H. A. Benghuzzi[2], M. O. Elasri[1]; [1]The Univ. of Southern Mississippi, Hattiesburg, MS, [2]Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract Body:

Background: *Staphylococcus aureus* is a major cause of both health care associated and community-associated infections. *S. aureus* is a primary agent of chronic bone infection also known as osteomyelitis. Treatment of osteomyelitis is very complicated and may require surgical debridement followed by prolonged antibiotic courses. Osteomyelitis patients often experience serious life threatening complications like septicemia, thrombosis and pathological fractures thus leading to high mortality and morbidity. In this study, we have investigated the role of the operon, *msaABCR* in pathogensis of osteomyelitis caused by *S. aureus*.**Methods:** In this study, we used the modified chronic osteomyelitis infection model using SD rats. Medical implants (K-wire pin) were coated with *S. aureus* biofilm (wild type, *msaABCR* deletion mutant and the *msaABCR* complement), and surgically transplanted transcortically through the metaphysis in the tibia. The infected tibias were harvested after 4, 8 and 15 days and were used for microbiological, X-ray and Microcomputed tomography (MicroCT) analysis.**Results:** X-ray and MicroCT images revealed that the wild type *S. aureus* strain colonized bone tissue and triggered significant bone damage of the infected tibia, whereas the *msaABCR* deletion mutant of *S. aureus* was attenuated and unable to cause chronic osteomyelitis. Bacterial count from infected tibias, blood and various organs (Liver, kidney, heart, spleen, testes) showed a significant difference between animals infected with the *msaABCR* mutant versus the wild type.**Conclusions:** This study shows that the *msaABCR* operon plays a role in the pathogenesis osteomyelitis cause by *S. aureus*. In particular, this model shows the importance of the operon in implant-associated infections which cause significant morbidity.

Trx1 Is Required For Candida Albicans Biofilm Formation

Author Block:

A. T. Fishburn, C. J. Nobile, M. Gulati; Univ. of California, Merced, Merced, CA

Abstract Body:

Background: *Candida albicans* is the predominant pathogenic fungus in humans, causing mucosal and life-threatening bloodstream infections. A major virulence factor of *C. albicans* is its ability to form biofilms, particularly on medical devices (e.g. catheters and heart valves). Biofilms are communities of adhered cells encased in a protective extracellular matrix. We previously discovered the entire transcriptional network controlling biofilm formation in *C. albicans*, which consists of six "master" transcriptional regulators (Bcr1, Tec1, Efg1, Ndt80, Rob1, and Brg1), and over 1000 downstream target genes. Here we report on the analysis of nine selected target genes of the biofilm network that are highly downregulated upon deletion of *NDT80*. **Methods:** We constructed deletion mutants for each of the nine target genes, and assessed biofilm formation using the following standard in vitro C. albicans biofilm assays: dry weight, optical density, and quantitative biofilm dispersion. In addition to these traditional biofilm assays, we also developed a new in vitro assay for biofilm formation using a customizable BioFlux microfluidic flow device. This device allows biofilm formation to be monitored over time by live microscopy under shear flow conditions, thereby allowing us to mimic physiological biofilm conditions found in catheters and blood vessels.**Results:** Our results indicate that deletion of TRX1 leads to defects in biofilm formation. Biofilms formed by the trx1Δ/Δ strain are thin and fragile, and show an optical density reduction of 68.5% relative to wild-type (p=0.0032). Real-time BioFlux videos of biofilm development over time revealed alterations in cell morphologies and overall biofilm architectures in the trx1Δ/Δ strain. The majority of cells in the trx1Δ/Δ strain biofilm are predominantly pseudohyphal, compared with the round yeast and true hyphal cells observed in the wild-type biofilm. Our results also indicate that the trx1Δ/Δ strain is defective in biofilm dispersion in a 24, 48, and 60 hour biofilm, the largest deficiency observed at the 60 hour time point (reduced six-fold relative to wild-type; p=5.1E-11).**Conclusions:** In summary, Trx1 plays a role in cell morphology and is required for normal biofilm development. Trx1 is particularly important for biofilm dispersion, which is the least understood stage of the biofilm life cycle, where cells leave the biofilm to seed new sites of infection.

A Single Amino Acid Change in *Burkholderia dolosa* FixI Alters Biofilm Formation and Pathogenicity

Author Block:

M. M. Schaefers, T. L. Liao, G. P. Priebe; Boston Children's Hosp., Boston, MA

Abstract Body:

Background: While investigating the genomic diversity of 112 isolates of the *Burkholderia cepacia* complex member *B. dolosa* collected from an outbreak in chronically infected cystic fibrosis patients over 16 years, we identified *fixL* (BDAG_01161) as a gene under strong positive selective pressure. This gene has homology to *fixL* of the rhizobial FixL/FixJ two-component system. FixL is a sensory histidine kinase that detects oxygen tension and phosphorylates the transcription factor FixJ under low oxygen conditions, leading to activation of the *fixK* gene. Our previous work identified that the *fixLJ* system is involved in biofilm formation, motility, and persistence in a murine model. Interestingly the reference strain, *B. dolosa* AU0158, which was isolated from the index patient after several years of colonization, contains a mutation in the *fixL* gene compared to the ancestral isolate. In this study we sought to understand the implications of this mutation in *fix*-mediated phenotypes. **Methods:** A *fixLJ* deletion mutant was constructed in *B. dolosa* strain AU0158 using allelic replacement. We constructed isogenic strains by complementing the deletion mutant with either S439 *fixL* (reference sequence) or W439 *fixL* (ancestral sequence) and *fixJ*. We measured swimming motility as well as the ability of these constructs to form biofilm on PVC plates. In a murine model of pneumonia after intranasal inoculation, we assessed the ability of *B. dolosa* to persist in the lung and disseminate to the spleen.**Results:** *B. dolosa* carrying the ancestral FixL sequence (W439) produced significantly (*p* value <0.001) more biofilm than isogenic bacteria carrying the reference *fixL* sequence (S439). Interestingly, *B. dolosa* carrying the ancestral *fixL* were non-motile while *B. dolosa* carrying the reference sequence were motile. In the murine pneumonia model, *B. dolosa* carrying the ancestral FixL (W439) was cleared faster in the lungs and spleen than *B. dolosa* carrying the reference FixL (S439) at 7 days post infection (*p* value <0.05).**Conclusion:** *B. dolosa* carrying a FixL sequence variant arising later during human infection is less able to form biofilms, more motile, and better able to persist in vivo in the murine lung and spleen compared to *B. dolosa* carrying the ancestral genotype.

Implications of an *Frha* snp Affording Enhanced Attachment on Increased Virulence Capabilities of *Vibrio cholerae* Clinical Isolates

Author Block:

K. D. Brumfield, B. M. Carignan, M. S. Son; Plymouth State Univ., Plymouth, NH

Abstract Body:

Background: Cholera is a severe diarrheal disease caused by the consumption of food or water contaminated with the aquatic Gram-negative bacterium *Vibrio cholerae*. Infected hosts will experience vomiting and severe watery diarrhea, and if not treated properly, will ultimately succumb to death by dehydration. Recently, *V. cholerae* clinical isolates have demonstrated increase virulence, with patients experiencing more severe symptoms and the disease progressing at a faster rate than previously observed. In the environment, *V. cholerae* is commonly found attached to the chitinous exoskeleton of planktonic crustacean copepods, allowing for increased survivability of the bacteria. The *f*lagellar *r*egulated *h*emagglutinin A, coded by *frhA*, is known to mediate chitin attachment by *V. cholerae*. Through deep sequencing data analysis, a single nucleotide polymorphism (SNP) in *frhA*, as well as four regulatory genes (*hns*, *hapR*, *luxO*, and *vieA*), has been identified in clinical isolates of *V. cholerae* (compared to the wild-type (WT) El Tor N16961). The purpose of this study is to assess the effects of the *frhA* SNP in concert with the other regulatory SNPs while developing a *V. cholerae* attachment model. We hypothesize strains containing the *frhA* SNP will have increased attachment capabilities and promotes increased virulence capabilities of *V. cholerae*. **Methods:** The *frhA* SNP was introduced into the WT N16961 using allelic exchange, and enhanced attachment determined using a newly developed copepod model. Briefly, *V. cholerae* cultures were incubated with planktonic marine copepods for 18 to 24 hours, and attachment levels determined by PCR. **Results:** The clinical isolate harboring the *frhA* SNP demonstrated earlier attachment to the copepod compared to the WT N16961. In addition, a working model using marine copepods has been developed allowing qualitative measurement of attachment by *V. cholerae*. **Conclusion:** The clinically relevant *frhA* SNP demonstrated enhanced attachment compared to the WT N16961 strain, and the copepod model demonstrated proof-of-principle. Understanding the role of this *frhA* SNP alone and in conjunction with the other identified SNPs, and its effects on attachment will provide insight into regulatory mechanisms linking attachment and virulence gene expression during *V. cholerae* pathogenesis.

Esta Controls Virulence Gene Expression in *Enterohemorrhagic e. coli* O157:H7

Author Block:

E. S. McKenney, M. M. Kendall; Univ. of Virginia, Charlottesville, VA

Abstract Body:

Enterohemorrhagic *Escherichia coli* O157:H7 (EHEC) is a foodborne, intestinal pathogen that causes hemorrhagic colitis and hemolytic uremic syndrome. Each year, more than 70,000 people in the United States become ill due to EHEC infections, resulting in approximately 50 deaths and an estimated $1 billion per year in economic costs. EHEC establishes infection in the human colon by intimately attaching to epithelial cells through the formation of attaching and effacing (AE) lesions. Additionally, EHEC produces Shiga toxin, which causes hemolytic uremic syndrome and the mortality associated with EHEC infections. In order to establish infection, EHEC must sense molecules within the host to control the expression of genes that encode for AE lesion formation and Shiga toxin production. For example, the metabolite ethanolamine is abundant in the intestinal tract and is an important signaling molecule for EHEC.Ethanolamine controls the expression of several EHEC virulence factors through the transcription factor EutR. However, ethanolamine induces the expression of some virulence factors independent of EutR, suggesting a second ethanolamine-signaling pathway. We identified an ethanolamine responsive gene that influences the expression of virulence factors in a Δ*eutR* background, and we renamed this gene ethanolamine signal transduction gene A, or *estA*. To determine a global role for EstA, we generated an *estA* deletion strain and performed microarray analysis, which demonstrated that EstA influences the expression of genes with diverse functions in EHEC, including virulence genes. These data suggest that EstA is involved in a complex regulatory network. For example, genes encoding Shiga toxin are upregulated at both the transcript (measured by qRT-PCR) and protein level (measured by western blot) in Δ*estA*, indicating that EstA negatively regulates Shiga toxin expression. Additionally, EstA positively influences the formation of AE lesions, as Δ*estA* was deficient in forming AE lesions on HeLa cells in a fluorescein actin staining assay. Elucidating how EstA influences gene expression is ongoing, and will contribute to the understanding of a novel ethanolamine-dependent signaling pathway that modulates virulence in EHEC.

A. C. Jacobs, S. D. Tyner, **D. V. Zurawski**; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

Acinetobacter baumannii is a Gram-negative bacterial species that in the last several decades has emerged as an important nosocomial, opportunistic pathogen. In the last 10 years this pathogen has gained more attention as Wounded Warriors returning to the U.S. from Iraq and Afghanistan have been infected. While *A. baumannii* infections were reduced with the end of these conflicts, XDR and pandrug resistant strains are still being isolated from Wounded Warriors and civilians, and still represent a significant percentage of all bacterial wound infections at Walter Reed National Military Medical Center. While a handful of virulence factors have been described for *A. baumannii*, none of these elements provide a comprehensive understanding of pathogenesis. One way to address this issue is to study global gene regulators in order to gain insight into the signaling networks required for survival in environments such as the host. With this idea in mind, our laboratory began studying LysR-Type Transcriptional Regulators (LTTR), a helix-turn-helix superfamily of DNA binding proteins that regulate a diverse set of genes, including genes related to biofilm and virulence. In *P. aeruginosa* the LTTR MvfR was found to regulate quorum-sensing, was required for virulence, and interruption of MvfR activity with novel compounds remediated *P. aeruginosa* infection in mouse models. Based on these data, our laboratory hypothesized that LTTRs may also play an important role in *A. baumannii* pathogenesis. As part of our preliminary work, 25 Tn*5*-insertion mutants with LTTR homology were assessed in various assays. First, biofilm formation was assessed using a standard crystal violet method. Ratios of biofilm formation to culture growth were determined and compared to wild type. Five mutants were found to have aberrant biofilm formation, and one of these interrupted genes had homology to the *P. aeruginosa* MvfR. When compared in the wax worm model of *A. baumannii* infection, this homologue also had reduced fitness compared to wild type. Taken together, these data demonstrate that some LTTRs in *A. baumannii* play a role in biofilm formation, and suggest at least one regulator is required for virulence. Further characterizing these genes will provide a better understanding of *A. baumannii* pathogenesis and possible novel targets for therapeutic intervention.

Elucidating the Function of *Enterococcus faecalis* Eep Protease in Virulence-related Peptide Signaling and Biofilm Formation

Author Block:

K. L. Frank[1], A. M. T. Barnes[2], G. M. Dunny[2]; [1]Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, [2]Univ. of Minnesota, Minneapolis, MN

Abstract Body:

The *E. faecalis* Eep site 2 membrane metalloprotease contributes to the spread of antibiotic resistance by processing signal peptides of certain lipoproteins into peptide pheromones that induce conjugative transfer of certain plasmids (e.g., pCF10). Eep also plays a role in *E. faecalis* evasion of the innate immune response by conferring resistance to lysozyme. We previously established that a Δ*eep* mutant has an aberrant cell and matrix distribution phenotype in biofilms and is attenuated in animal models of biofilm-associated infection involving both a foreign body (catheter-associated urinary tract infection) and a host surface (infective endocarditis). In wild-type cells with pCF10, endocarditis virulence is primarily mediated by pheromone-induced expression of aggregation substance (PrgB), which mediates cell clumping. One mechanism preventing autocrine induction of conjugation machinery by endogenous pheromone involves a plasmid-encoded inhibitory pheromone (e.g., iCF10) that is also processed by Eep. The tight ratio between inducer and inhibitor peptides that usually prevents autocrine activation is perturbed *in vivo*, allowing self-induction that leads to enhanced expression of PrgB. Our previous data revealed that the Δ*eep* endocarditis attenuation phenotype is rescued by pCF10 in a PrgB-independent manner. In contrast, our recent data show that exogenous induction of pCF10 does not restore lysozyme resistance in Δ*eep* cells, suggesting that Eep contributes to multiple steps in *E. faecalis* endocarditis pathogenesis. Our data show that Δ*eep*(pCF10) cells clump in response to a lower concentration of exogenous activator peptide compared to the wild-type strain. This is correlated with a 5-fold increase in the transfer frequency of pCF10 in Δ*eep* relative to wild-type cells in solid-surface conjugation assays. This effect is a result of Eep proteolytic activity, as evidenced by the fact that a strain with a point mutation in the catalytic site phenocopies the Δ*eep* strain in conjugation assays. Exogenous induction of pCF10 during biofilm formation also results in differences between wild-type and Δ*eep* biofilm biomass accumulation and biofilm architecture. Our data suggest that Eep has a fundamental role in virulence related peptide signaling and biofilm formation.

Role of Acetyltransferase *pg1842* in Activation and Maturation of Gingipains in *Porphyromonas gingivalis*

Author Block:

A. Mishra, F. Roy, Y. Dou, H. M. Fletcher; Loma Linda Univ., Loma Linda, CA

Abstract Body:

Porphyromonas gingivalis, the major etiologic agent in adult periodontitis, produces large amounts of proteases that are important for its survival and pathogenesis. Activation/maturation of gingipains, a major protease, in *P. gingivalis* involves complex networks of processes which are not fully understood. VimA, a putative acetyltransferase, is a virulence modulating multifunctional protein in *P. gingivalis* that is known to be involved in gingipains biogenesis. Deletion of the *vimA* gene resulted in an isogenic mutant (Δ*vimA*) that showed late onset gingipain activity at stationary phase indicating that there could be a functional VimA homolog that is most likely upregulated in stationary phase to overcome the *vimA* mutation. The aim of this study is to identify any functional homolog which may play a role in activating the gingipains in absence of VimA at stationary phase. Bioinformatics analysis showed five putative acetyltransferase genes in *P. gingivalis* genome structurally similar to *vimA*. Allelic exchange mutagenesis was used to make deletion mutants of all five acetyltransferases in *P. gingivalis* Δ*vimA* background. One of the mutants, Δ*PG1842*, did not show any late onset of gingipain activity at stationary phase as compared to parent strain Δ*vimA*. Comparison of western blot analysis of stationary phase extracellular fractions from the Δ*vimA* and Δ*PG1842* isogenic mutants showed the active catalytic domain band in Δ*vimA*, whereas only inactive proenzyme species were seen in Δ*PG1842*. This suggested that in absence of *PG1842*, the inactive proenzyme in Δ*vimA* was not processed into active catalytic form. Real time PCR showed similar expression level of *PG1842* during both exponential and stationary phase in Δ*vimA*. Collectively, these findings indicate that *PG1842* may play a significant role in activation/maturation of gingipains in *P. gingivalis*.

Characterizing the Mechanism of Bile Resistance and Related Biofilm Formation in S*higella flexneri*

Author Block:

K. P. Nickerson[1], R. B. Chanin[1], J. R. Sistrunk[2], P. Fink[1], D. K. V. Kumar[1], D. A. Rasko[2], **C. S. Faherty**[1]; [1]Massachusetts Gen. Hosp., Charlestown, MA, [2]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Shigella flexneri is a Gram-negative, facultative intracellular pathogen that causes millions of cases of diarrhea each year, predominantly in children in developing countries. While many aspects of colonic cell invasion are known, a crucial gap in knowledge remains regarding how the bacteria survive, transit, and regulate virulence gene expression prior to infection. *S. flexneri* is exposed to bile, a bactericidal host factor essential for digestion, as it enters the small intestine. Previous research has demonstrated that bile salts induce both *S. flexneri* adherence to and invasion of epithelial cells. In this study, we further characterized the effects of bile salts exposure on *S. flexneri* 2a strain 2457T. Growth curve analysis in the presence of bile salts revealed that 2457T grew normally within the physiological range of 0.2% to 2% w/v, but growth was slowed or inhibited at 5% and 10% w/v. Using RNA-sequencing as a comprehensive analysis of gene expression, we identified 172 genes induced in 0.4% w/v bile salts that are involved with central metabolism, gene expression, membrane structure, drug resistance, and virulence. Interestingly, to mimic small intestine transit, extended periods of bile salts exposure led to biofilm formation, which was confirmed by crystal violet staining, analysis of exopolysaccharide matrix production, and electron microscopy. Analysis of additional *Shigella*, *Salmonella*, and *Escherichia coli* strains demonstrated a common theme of bile salt-induced biofilm formation among enteric pathogens. Finally, analysis of a transposon mutant library has identified several 2457T mutants unable to survive bile salts exposure or form a biofilm. Our data demonstrate that *S. flexneri* has several mechanisms to survive bile exposure, and we hypothesize that biofilm formation is crucial in that process. Moreover, bile serves as an *in vivo* signal to activate *S. flexneri* virulence prior to entry in the colon. This work has led to a greater understanding of how *Shigella* transits the host to establish infection in the colon.

Non-pathogenic *Escherichia coli* Enhance Stx2a Production of *E. coli* O157:H7 by Multiple Mechanisms

Author Block:

L. Xiaoli, K. Goswami, E. Dudley; Penn State Univ., University Park, PA

Abstract Body:

Inestinal colonization by the foodborne pathogen *E. coli* O157:H7 causes serious disease symptoms, including bloody diarrhea and severe abdominal cramps. The disease can further develop into hemolytic uremic syndrome (HUS) and hemorrhagic colitis (HC). Synthesis of one or more Shiga toxins (Stx) is essential for HUS and HC development. The genes encoding Stx, including Stx2a, are encoded by a lambdoid prophage integrated into the *E. coli* O157:H7 chromosome. Enhanced Stx2a expression was reported when specific non-pathogenic *E. coli* strains were co-cultured with O157:H7, and it was hypothesized that this phenotype required the former to be sensitive to infection by the Shiga toxin-converting phage. We tested this hypothesis by using a previously published method to replace *bam*A (an essential gene and phage receptor) in non-pathogenic *E. coli* strains with the ortholog from *Salmonella enterica*. Such heterologous gene replacement abolished the ability of *E. coli* strain C600 to enhance toxin production when co-cultured with *E. coli* O157:H7 strain PA2, which belongs to the hypervirulent clade 8 cluster. Two extracellular loops of BamA (loops 4 and 10) were further shown to be important for infection by Stx2a-converting phage. However, gene replacement in other non-pathogenic *E. coli* strains revealed a *bamA*-independent mechanism for toxin amplification. Collectively, these data suggest that multiple mechanisms exist for commensal *E. coli* to increase Stx production when they co-exist with *E. coli* O157:H7.

The Role of H. *Pylori baba* Gene in Persistent Infection and Chronic Inflammation

Author Block:

S. A. Ansari[1], S. U. Kazmi[2]; [1]Dow Univ. of Hlth.Sci., Karachi, Pakistan, [2]Immunology and Infectious Disease Res. Lab. - Dadabhoy Inst. of Higher Ed. - Karachi - Pakistan, Karachi, Pakistan

Abstract Body:

Pathogenesis of Helicobacter pylori in severe gastric disorders is multifactorial and it involves intricate microbial communications with gastric mucosa. Several adhesion proteins *of H.pylori* which also have tendency to bind with Lewis a-1, 3/4 difucosylated blood group antigens found on gastric mucosa play an important role in the establishment of persistent infection and chronic inflammation whereas fucosylated host secretions inhibit adherence of *H. pylori* and other pathogens to the mucosal cell surfaces. The histo-blood group antigen binding adhesin (BabA) is one of the best-characterized *H. pylori* adhesins which binds in the gastric mucosa specially to the Lewis b antigen (Leb). We investigated the binding properties of *H.pylori* to gastric epithelium in humans, mediated by blood group antigens in control and test group to establish a correlation of *H. pylori* infection with gastritis and (BabA) adhesin. Gastric biopsies , saliva and blood samples of 574 patients who underwent gastro duodenal endoscopy during 2011 to 2014 were subjected to Helicourease (IIDRL- Rapid Urease) test, culture, histological examination and PCR for the detection of *H. pylori* and *babA* gene. . *H. pylori* infection was detected in biopsies of 138(24%) patients by rapid urease 263 (55.4%) by culture . Histologic observation confirmed infection in biopsy specimens (154) from patients who had inflamed and ulcerated gastric mucosa were positive for *H. pylori* by histology , PCR, cultures and rapid urease. Patients who had intact mucosa were excluded. A total of 343 (60%) biopsy samples we were positive for *H. pylori by PCR* using *16SrRNA (*HP1 andHP2) whereas 250 (43.55 when we used second *16SrRNA* (JW22, JW23). Among PCR positive *H. pylori* subjects 91(36%) had BabA gene . We observed a high frequency of *babA* gene in patients with gastritis , highly inflamed and ulcerated mucosa , which is strongly associated with colonization of *H. pylori* that contributes to virulence and development of *H. pylori* infection. Our study supports a strong association between gastritis, (BabA) adhesin and *H. pylori* infection.

Mechanics of Gram-Positive Bacterial Adhesion: Covalent Attachment and Energy Dissipation

Author Block:

D. J. Echelman[1], J. Alegre-Cebollada[2], J. M. Fernandez[1]; [1]Columbia Univ., New York, NY, [2]Natl. Inst. of Cardiovascular Res. (CNIC), Madrid, Spain

Abstract Body:

Background: The challenges of microbial adhesion are as ancient as life. Bacteria, whether sticking to rocky surfaces, congregating in biofilms, or colonizing hosts, must withstand forces that are sufficient to cleave covalent bonds. Extracellular protein appendages, including bacterial pili, are necessary for adherence under mechanical stress. In Gram-positive bacteria, these extracellular structures harbor an abundance of unique *intra*molecular isopeptide and thioester bonds. However, it remains unknown how these structures function under force and manage adherence in such mechanically chaotic environs.**Methods:** Using AFM-based single molecule force spectroscopy, we measured the mechanical behavior of purified pili and of engineered polyproteins of pilus shaft and adhesin subunits.**Results:** We find that the pilus shaft subunits SpaA from *Corynebacterium diphtheriae*, and FimA from *Actinomyces oris*, exhibit partial unfolding under force that is delimited by internal isopeptide bonds. The forces of unfolding are unprecedented in strength, 525 ± 65 pN for SpaA (n = 25) and 690 ± 70 pN for FimA (n = 96), and weaken with loss of the isopeptide bond. Moreover, refolding after mechanical extension occurs rapidly at rates of 14 s^{-1} or greater. Meanwhile, the pilus adhesin Spy0125 from *Streptococcus pyogenes* exhibits partial unfolding under force that is delimited by an internal thioester bond. This thioester bond has previously been reported to mediate covalent attachment to host (1). Uniquely, we find that the thioester-containing domain is buried within the fold of a more mechanically stable domain that serves to protect the bond from mechanical exposure. Finally, we integrate our mechanical measurements to estimate the energy dissipation from pilus extension, which is many-fold greater than rigid “rod-like” or yielding “helix-like” models of pilus mechanics.**Conclusions:** We propose that Gram-positive pili are optimized to sustain the covalent attachment to host through mechanical protection of the thioester bond and mechanical energy dissipation.

Increased Expression of Fibrinogen-Binding Protein (*sdrg*) By Late Phase *Staphylococcus epidermidis* May Contribute to Increased Stiffness of Infected Fibrin Clots

Author Block:

R. A. Sturtevant, T. Ma, M. J. Solomon, J. VanEpps; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Biofilm colonization of medical devices is known to be facilitated by a number of host factors, including the presence of a fibrin clot. We previously demonstrated that the mechanical properties of an infected fibrin clot depend on the growth phase of *Staphylococcus epidermidis*. That is, clots infected with late growth phase cells are stiffer than those infected with early growth phase cells. We hypothesize that these differences may be due to differential expression of adhesion-related proteins affecting cellular binding to the fibrin. Here we examine the expression of *sdrG*, a cell-surface receptor protein with a high affinity for fibrinogen binding, and *icaA*, which is involved in the synthesis of a key biofilm exopolymer, polysaccharide intercellular adhesion (PIA), as a function of growth phase.**Methods:** RNA was isolated from both early (mid-log) and late (stationary) phase planktonic cultures of *S. epidermidis*. One-step Taqman® RT-PCR was performed using primers and dual-labeled probes against *sdrG* and *icaA*. 16S rRNA was used as the endogenous control, and early phase as the reference sample. A fold-change in gene expression relative to the reference was expressed as $2^{-\Delta\Delta CT}$.**Results:** Compared to early phase, late phase cells exhibited a 45% increase in *sdrG* expression. On the other hand, *icaA* expression decreased by 93% in late vs early phase.**Conclusions:** An increase in *sdrG* expression supports our hypothesis that cellular adhesion proteins may play a role in the enhanced mechanical properties of clots infected with late phase *S. epidermidis.* Our future work will further investigate how these changes in *sdrG* expression specifically affect fibrinogen binding and will also examine the role of other adhesion related proteins, including accumulation associated protein (*Aap*) and a major autolysin (*atlE*).

Unveiling the Soil Metazoan Microbiome and Its Contribution to Nutrient Cycling

Author Block:

J. A. Ceja-Navarro, A. Arellano, M. Kvietok, E. L. Brodie; Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

Arthropods represent more than 60% of all living species on Earth, with an estimated global mass of 1 to 14 billion tons[1]. During their evolution, arthropods incorporated microbes and their genes into their living machinery where commensal microbes cooperate by conveying processes such as N fixation, transformation of complex plant polymers and the degradation of toxic compounds.In this study we have characterized the prokaryotic microbial communities associated with soil arthropods and tested their potential for nitrogen fixation and plant polymer transformation. Soil arthropods were separated from soil samples using Berlese funnels. Each individual was surface sterilized prior to DNA extraction. The DNA was then used for the amplification and high throughput sequencing of 16S and 18S rRNA markers. Most abundant arthropod populations were separated in groups and used for the isolation of nitrogen fixing bacteria, and cellulose and lignin degrading microorganisms. Selected arthropod groups were incubated under an atmosphere of 98% $^{15}N_2$ and 2% Oxygen while feeding on ^{13}C-labelled cellulose. Carbon and Nitrogen enrichment was measured with Gas Chromatography Isotope Ratio Mass Spectrometry (GC-IRMS) and Nanoscale Secondary Ion Mass Spectrometry (nanoSIMS).One hundred arthropods were extracted from soil samples and categorized based on morphology and 18S rRNA sequencing/phylogenetics. In broad terms the isolated arthropods were identified as collembolans, mites, pseudoscorpions, beetles, millipedes, and centipedes. The analysis of the 16S rRNA sequences confirmed that each group contains a distinct makeup of microbial communities that are possibly related to their feeding habits/position in the food web. Nine different bacterial species among fifty microbial isolates were obtained from selected groups of arthropods using N deficient media and media containing cellulose or lignin as a sole source of C. Our incubation experiments and analysis of enrichment are still ongoing.The study of soil arthropods and other members of the soil fauna as vessels of biological transformation will allow us to improve the current models for the study of soil nutrient cycling and may help to improve soil management practices while also extending the frontiers for bioprospecting.

Endophyte Populations And Induced Disease Resistance Following Treatment Of Plants With A Mixture Of Branched-Chain Alkanes

Author Block:

P. Goodwin, W. Gao; Univ. of Guelph, Guelph, ON, Canada

Abstract Body:

Eight bacterial endophyte types matching six species of *Bacillus* and two species of *Pseudomonas* were cultured from roots, stem+petioles and/or leaves of *Nicotiana benthamaiana* growing in an organic soil. Treatment of the soil with a branched-chain alkane mixture resulted in both induced resistance against foliar infection by *Colletotrichum orbiculare* and changes in the populations of several of the endophytes. Increased populations compared to the controls were observed for the *Pseudomonas* sp. LW3, *Bacillus simplex* LW4 and *Bacillus pumilis* LW5 colony types in roots and the *B. simplex* strain LW4 colony type in stem+petioles. The LW3 and LW4 colony types also had higher populations in pure cultures grown in minimal media containing the branched-chain alkane mixture compared to controls. All eight colony types were able to induce resistance against *C. orbiculare* when inoculated into roots, but differed in their effectiveness. All the endophyte colony types, except *B. simplex* LW4 and *B. marisflavi* LY1, could inhibit *C. orbiculare* growth *in vitro*, but the level of inhibition was not correlated with the level of induced resistance *in planta*. It appears that branched-chain alkanes can result in selective endophyte growth promotion *in planta*, affecting populations of endophytes that can possibly both catabolise alkanes and induce systemic resistance in plants.

Endophytic Microbiome Of Jatropha Curcas

Author Block:

K. Mighell[1], S. Van Bael, 70118[1], K. Saltonstall[2]; [1]Tulane Univ., New Orleans, LA, [2]Smithsonian Tropical Res. Inst., Panama City, Panama

Abstract Body:

Background: The soil is the principle source of bacterial symbionts of plants. Select bacteria colonize the rhizosphere and endophytic bacteria colonize root tissue and shoot tissue through the vascular system. Soil chemistry, edaphic factors, biogeography, and host biology all influence the rhizosphere and endophytic community of bacteria. *Jatropha curcas* (Euphorbiaceae) is a drought-tolerant biodiesel crop plant native to Central America. How do soil edaphic factors and biogeography affect the recruited endophytic and rhizosphere community?**Methods:** We transplanted sterile jatropha seedlings into three sites along a 125km transect in Panama. Each site had different soil chemical properties, experienced a range of precipitation levels, and had different use histories. Leaves, roots and rhizosphere samples were collected from the seedlings after growing in the soil at each site for ten weeks. We extracted the DNA for all samples. For a selection of roots and rhizosphere, we also extracted RNA and created cDNA libraries of the 16S gene. We sequenced the 16S community on a MiSeq and analyzed the results using Qiime.**Results:** Bacterial communities were all distinct by organ. Leaf and root communities were dominated by Proteobacteria, with leaves containing mostly Alphaproteobacteria and roots containing even mixtures of Alphaproteobacteria and Betaproteobacteria. The rhizosphere was dominated by Proteobacteria and Acidobacteria. The cDNA library showed that many different groups, principally Acidobacteria, were present in lower abundances in the cDNA library as compared to the DNA library. Ordination revealed that site was a significant factor driving community clustering, with sites experiencing similar rainfall being more similar, despite edaphic differences.**Conclusions:** We conclude that climatic factors have an effect on the symbiotic community of *J. curcas*. Bacterial 16S presence and activity differed, demonstrating that the select groups are more metabolically important than previously thought. Plant associated communities can strongly affect plant performance. As *J. curcas* is a drought tolerant plant, the symbiotic community may play a profound role in mitigating its stress tolerance. By comparing this work to plant performance data and bacterial community function, we can predict how different bacterial communities may act within the host.

Analysis of Volatile Organic Compounds Emitted by Biological Control Trichoderma and Volatile-Mediated Plant Growth

Author Block:

S. Lee, J. W. Bennett; Rutgers, The State Univ. of New Jersey, New Brunswick, NJ

Abstract Body:

Volatile organic compounds (VOCs) are a small portion of the total metabolites produced by organisms; however, their unique properties enable them to mediate important biological functions, especially in aerial and terrestrial environments. In agriculture, the potential uses of VOCs include volatile-mediated inhibition of pathogen growth and increased plant systemic resistance. Filamentous fungi in the genus *Trichoderma* are robust biological control agents as they utilize several modes of action including resistance, antibiosis, competition and myco-parasitism. Earlier work by our laboratory demonstrated the ability of *Trichoderma*-derived VOCs to stimulate *Arabidopsis* growth. In this study, *Trichoderma* emission profiles, concentrations, quantities, and VOC-mediated effects on plants were measured in order to develop a mechanistic understanding of the volatile-mediated *Trichoderma*-to-plant interactions. We identified several volatile-mediated plant growth promoting *Trichoderma* isolates. Volatile-mediated plant growth promotion was dependent on the age of the fungal culture, developmental stage of the plant, duration of the exposure, and was isolate-specific. GC-MS analysis of VOCs from *Trichoderma* isolates led to identification of more than hundred unique compounds and several unknown sesquiterpenes, diterpenes, and tetraterpenes. A large number of compounds were selected and tested individually on *Arabidopsis* in order to determine if individual compounds could mimic the effects of *Trichoderma* volatile mixtures on plant growth. Exposing plants to single compounds yielded significant increases in seed germination, plant fresh shoot weight, and chlorophyll. RNA sequencing analysis of *Arabidopsis* shoots treated with VOC for 72 hours identified differentially expressed genes involved in volatile response. Up-regulated genes were related to growth, responses to hormone and cell wall modifications inducible by auxin. We provide a list of candidate genes to screen in future research on the biological activities of fungal VOCs.

Flavonoids and Auxin are Part of the Chemical Talk Between Plant and Cyanobacteria in the Rhizosphere

Author Block:

A. Hussain; Absul Wali Khan Univ., Mardan, Pakistan

Abstract Body:

Rhizospheric region of the roots is richly supplied with the secondary metabolites that orchestrate all sorts of rhizospheric interactions and hence communicate plant roots with their belowground competitors. A chemical dialogue is established between the microbe and plant roots, creating an atmosphere of complex and dynamic interactions flourishing either symbiosis or pathogenicity. A wide range of secondary metabolites are found there in rhizospheric region but particularly flavonoids and auxins are documented to be the most important signalling elements in plant-microbe interactions. Role of synthetic flavonoids and auxins as signalling compounds have largely documented in case of legume-rhizobia symbiosis but the field is lacking regarding the symbiosis of cyanobacteria with higher plants. Focusing on the establishment of artificial symbiosis between rice plant and the cyanobacteria, in the present study 21 different strains were isolated from the rice roots, rhizospheric region and the surface soil in rice fields of different areas of District Mardan. Under hydroponic condition, the strains were able to colonize on rice roots thereby enhancing seedling growth significantly. Root exudates showed increased flavonoid and auxin content in case of all the tested strains. Application of exogenous flavonoids and auxins increase the growth of the seedlings while the flavonoid and auxin content was significantly reduced in the root exudates. While opposite trend was observed in case of axenic strains where the both metabolites were significantly increased as compared to non-treated strains. Regarding co-culturing treatments exogenous flavonoids and auxins also show positive differences with the fact that the flavonoids and auxins in combination improved the colonization of roots by cyanosymbiont as well as the exogenous flavonoid and auxin content. Also, IAA and flavonoids producing strains of cyanobacteria efficiently colonized on rice root and enhanced growth of the seedlings.

Metagenomic Analysis of the Root Nodule Endophyte Community of the Actinorhizal Plant Casuarina Glauca

Author Block:

T. S. D'Angelo[1], F. Ghodhbane-Gtari[2], A. Ktari[2], K. Hezbri[2], A. Gueddou[2], M. Gtari[2], L. S. Tisa[1]; [1]Univ. of New Hampshire, Durham, NH, [2]Univ. of Tunis El Manar, Tunis, Tunisia

Abstract Body:

Background: Actinorhizal plants host mutualistic symbionts of the nitrogen-fixing actinobacterial genus *Frankia* within nodule structures formed on their roots. Several plant-growth-promoting bacteria have also been isolated from actinorhizal root nodules, but little is known about them. We were interested investigating the *in planta* microbial community composition of actinorhizal root nodules using culture-independent techniques. To addresses this knowledge gap, 16s rRNA amplicon and shotgun metagenomic sequencing was performed on DNA from the nodules of the *Casuarina glauca.* **Methods:** DNA was extracted from *C. glauca* nodules collected in three different sampling sites in Tunisia, along a gradient of aridity ranging from humid to arid. Sequencing libraries were prepared using Illumina Nextera technology and 150 BP paired-end reads were sequenced using the Illumina HiSeq 2500 platform. After quality filtering, the three data sets, totaling 83 million reads, were combined *in silico* and assembled using the SPAdes assembler. Reads from each sampling location were aligned to the assembly using the Bowtie2 alignment tool. Unique coverage values, tetranucleotide frequency and GC content was used to cluster contigs into genome bins using the mmgenome R package. Genome bins extracted from the metagenome were taxonomically and functionally profiled. Community structure based off of preliminary 16s rRNA amplicon data was analyzed via the QIIME pipeline.**Results:** Reconstructed genomes were comprised of members of *Frankia*, *Micromonosopora*, *Bacillus*, *Paenibacillus*, *Phyllobacterium* and *Afipia*. *Frankia* dominated the nodule community at the humid sampling site, while the absolute and relative prevalence of *Frankia* decreased at the semi-arid and arid sampling locations. The genera of non-*Frankia* members in this community have been isolated from legumes and other plants.**Conclusions:** Actinorhizal plants harbor similar non-*Frankia* plant-growth-promoting-bacteria as legumes and other plants. The data suggests that the prevalence of *Frankia* in the nodule community is influenced by environmental factors, with *Frankia* being less abundant under more arid environments.

Phyllosphere Microbial Ecology of Succulent Plants in a Greenhouse Environment

Author Block:

J. E. Einson, X. You, C. Randell, A. Rodriguez, M. Bartlett, D. Sela; Univ. of Massachusetts, Amherst, MA

Abstract Body:

It is established that the plant phyllosphere is a readily habitable environment for a wide range of microorganisms. The phyllosphere microbiome varies profoundly between plant species, suggesting that specific host traits may enhance or restrict cognate microbial populations. Here we have characterized the microbial communities associated with several succulent plants that are co-housed in the same environment. Succulents have experienced convergent evolution over the past 250 million years, where plant lineages have converged on similar phenotypes to thrive in arid environments. Although succulents exhibit physical similarities, their associated microbial communities may vary to reflect the underlying biology of plant-microbial interactions. Using culture-independent techniques, microbial community structure is characterized with much higher resolution, and in the absence of selective bias of culturing. Thus we tested the hypothesis that there is no significant difference in phylogenetic diversity between phyllospheres of succulent plants that are located in the same greenhouse. We collected samples (n≈30) from members of *Liliaceae, Cactaceae, Aizoaceae,* and *Crassulaceae* by swabbing various surfaces of these plants. Extracted community DNA was subjected to PCR amplification of the 16S rRNA phylogenetic marker gene using broad-range primers. Libraries were constructed and sequenced to characterize phylogenetic diversity. Various non-parametric statistical methods were employed to verify non-random diversity measurements. This study builds on our knowledge of how the eukaryotic world interacts with the bacterial world. If bacterial communities remain constant regardless of succulent host, the greenhouse environment would likely contribute the largest role in microbiome composition. However, if each plant fosters a distinct microbial community, this will require further investigation to determine the factors underlying these host-microbial relationships. One possibility is that the phyllosphere composition of succulent plants helped conserve water in their relatively harsh environment.

Formate, a Driver of Anaerobic Processes in the Rhizosphere of a Methane-Emitting Fen

Author Block:

H. L. Drake, S. Hunger, O. Schmidt, A. S. Goessner; Univ. Bayreuth, Bayreuth, Germany

Abstract Body:

Wetlands are important sources of globally-emitted methane. Plants mediate much of that emission by releasing root-derived organic carbon, including the root leakage of direct precursors of methane such as formate. Thus, the objective of this study was to identify potential formate-driven anaerobic processes linked to methanogenesis in the root-zone of fen-derived plants. Although formate was anticipated to trigger methanogenesis, the rapid anaerobic consumption of formate by *Carex* roots unexpectedly yielded H_2 and CO_2, an activity indicative of formate-H_2-lyase (FHL). Formate-derived H_2 augmented methanogenesis and acetogenesis, and molecular and cultivation approaches identified hydrogenotrophic methanogenic (*Methanoregula*, *Methanobacterium*, *Methanocella*) and acetogenic (*Acetonema*, *Clostridum*, *Sporomusa*) genera. Fifty-seven hydrogenase-containing family-level phylotypes were detected, and *Proteobacteria* appeared to contribute to the production of H_2. Root-derived FHL-containing fermentative *Citrobacter* and *Hafnia* isolates produced H_2 in response to formate, and co-substrate utilization of formate enhanced the utilization of glucose by the *Citrobacter*-affiliated species, an activity indicative of 'priming' observed at the system-level. The findings (a) indicate that root-associated FHL-containing fermenters produce formate-derived H_2 that can subsequently drive secondary anaerobic processes proximal to fen roots, (b) provides novel insights on remarkably diverse hydrogenase-containing taxa potentially linked to this trophic interaction, and (c) raise questions regarding the fate of formate-derived H_2 when it diffuses out of the root-zone.

Influence of Seed Microbiome on Fitness of *Epichloë* Infected Tall Fescue Seedlings

Author Block:

E. Roberts, **B. Mormile**; Southern Connecticut State Univ., New Haven, CT

Abstract Body:

Increased fitness in tall fescue (*Schedonorus arundinaceaus)* is attributed to infection by *Epichloë coenophiala*. However, the mechanisms of some host benefits associated with *Epichloë* infection are poorly understood. Similarly, plant-growth promoting (PGP) bacteria increase fitness of many types of plants, and PGP bacteria have been shown to dominate the rhizosphere microbiome of *E. coenophiala* infected (E+) tall fescue. While it is likely that some PGP bacteria are recruited from the soil, we hypothesized that such bacteria are dominant members of tall fescue seed microbiomes. Furthermore, we expect that PGP seed colonizers influence the fitness of developing tall fescue seedlings.Genetically identical clone pairs of endophyte-infected (E+) and endophyte-free (E-) tall fescue seeds were surface sterilized to remove epiphytic bacterial colonizers. Twenty surface sterilized and 20 control plants of each type were grown for six weeks prior to dry weight measurements of the above ground tissues. Forty individuals from certified E- (K32) and certified E+ (K31) tall fescue varieties were treated as mentioned above. Additionally, total 16S amplified DNA washed from the surfaces of each seed type was analyzed with Illumina sequencing to assess the microbial communities.Control E+ plants averaged 35% higher biomass than surface sterilized E+ plants. Conversely, biomass comparisons between the surface sterilized and non-sterilized E- varieties showed no statistical difference. E+ plant seeds are also dominated by plant-growth promoting bacteria (41% of the total community) *Rhizobium* sp., *Pedobacter* sp., *P. agglomerans, Agrobacterium* sp., and *Enterobacter cowaanii* which are either absent or in very minor quantities (6% of the total community) on E- fescue varieties. Our findings indicate that *Epichloë* infection influences the bacterial community composition of tall fescue seed surfaces, and that those bacteria play an important role in fitness of host seedlings.

Microscale Imaging of Microbial Communities on *Arabidopsis thaliana* L. Leaf Surfaces Using Confocal Laser Scanning Microscopy and Fluorescence *In Situ* Hybridization

Author Block:

E. L. Peredo, S. L. Simmons; Marine Biological Lab., Woods Hole, MA

Abstract Body:

The plant phyllosphere, formed by leaves and other aerial organs, harbors diverse microbial communities composed of yeast, fungi, archaea, bacteria and viruses. The leaf habitat is characterized by extreme environmental conditions with high UV and low water and nutrient availability. Leaf-associated taxa often display specialized adaptive traits such as aggregation, chemotaxis, and production of phytohormones, antibiotics or pigments. Microbes can also overcome harsh conditions in the phyllosphere by preferentially colonizing specific leaf microhabitats such as cuticle cracks, stomata, hydathodes, veins, trichomes, and glands. Variables at the microscale, not detectable by bulk methods, can play a key role on the assembly of microbial communities and affect the establishment of human pathogens on leaves, an important issue for food safety.We developed a microbial visualization protocol adapted to leaf surfaces, with specific fixation steps to minimize autofluorescence. We used CLSM (Zeiss LSM 780, lambda mode) to generate crosstalk-free multi-fluorescence images by parallel or sequential acquisition of images with spectral information of each pixel, followed by linear unmixing processing. Autofluorescence, greatly reduced after tissue pretreatments, was incorporated in the images as another spectral character.We demonstrate that our method is suitable for visualization of occurring bacteria on leaves of *in vitro* or glasshouse-grown *Arabidopsis*. Using CLASI-FISH (Valm *et al*., 2012) approaches we report simultaneous detection of at the genus level of three phylogenetically diverse microbes *in situ*. Finally, we demonstrate the difficulty of predicting bacterial distributions in the phyllosphere based solely on phylogenetic and physiological information. We investigated the spatial distributions of a reference and a newly isolated strain of the common pink-pigmented phyllosphere genus *Methylobacterium.* We initially hypothesized similar distributions on leaves due to their shared metabolic niche (facultative methylotrophy) and ability to produce active phytohormones. Our results demonstrate, however, that even closely-related bacterial species sharing common physiological traits can consistently occupy extremely different leaf microniches.

***Bacillus* sp. Inhibits Fungi and Enhances Resistance of Cotton Seedlings against Damping-off Disease Caused by *Fusarium* sp.**

Author Block:

I. Irizarry, Q. Chen, M. Bergen, J. White; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Wild relatives of crops are sources of beneficial microbes that can improve health and promote growth of economically important crops. *Bacillus* sp. was isolated from the tropical coastal tree *Thespesia populnea* (Malvaceae), evaluated for its antifungal properties, and its ability to promote growth of cotton seedlings (*Gossypium hirsutum*; Malvaceae). *Bacillus* sp. was co-cultured with various seed-transmitted fungi on potato dextrose agar to observe its effects on fungal growth. The colony diameters and growth rates of fungal cultures were measured along with the width of 20 hyphal cells. Genes for lipopeptide synthesis in *Bacillus* sp. were amplified by PCR. Lipopeptides produced by *Bacillus* sp. in 1L of potato dextrose broth were extracted, identified by MALDI-TOF molecular weight estimation analysis, and tested for antifungal activity by disk diffusion assays. *Bacillus* sp. was also tested for its ability to enhance cotton seedling resistance against *Fusarium* sp. damping-off disease. Cotton seedlings were grown for 21 days on inoculated soil inside magenta vessels. The average total dry weight and the root/shoot ratio of four 21 day old cotton seedlings were calculated. T-tests were used to show significant difference between means. *Bacillus* sp. significantly reduced the colony diameter, growth rates, and hyphal width of *L. theobromae, Phomopsis* sp., *B. ochroleuca, Rhizopus* sp., *Curvularia lunata,* and *Fusarium* sp. ($p=<0.01$). The genes for surfactin and iturin synthesis, *srfC* and *ituD,* were amplified and a mixture of lipopeptides was detected in the extract including fengycin, iturin A, surfactin, and kannurin. The extract inhibited growth and induced chlamydospore production in *L. theobromae, B. ochroleuca, Phomopsis* sp., *C. lunata, Fusarium* sp., *Cladosporium cladosporioides, Neofusicoccum australe, Fusarium brachygibbosum,* and *Setosphaeria rostrata* ($p=<0.01$). Cotton seedlings inoculated with *Bacillus* sp. along with *Fusarium* sp. had increased biomass, root to shoot development, and enhanced resistance to *Fusarium* sp. damping-off disease ($p=<0.01$) after 21 days of growth. Our findings show that bioprospecting for beneficial bacteria in wild relatives of crops is a useful strategy. Bacteria like *Bacillus* sp. could be commercialized as biofertilizers to protect vulnerable cotton seedlings against fungal pathogens.

Estimation of Generation Times in Planta for the Non-cultivable Citrus Pathogen '*Candidatus* Liberibacter Asiaticus'

Author Block:

M. E. Hilf; USDA-ARS, Fort Pierce, FL

Abstract Body:

'*Candidatus* Liberibacter asiaticus' is an insect-transmitted bacterial pathogen of citrus. Infection of citrus trees by '*Ca.* Liberibacter asiaticus' results in a chronic, degenerative decline disease called huanglongbing or citrus greening. Its presence in the US was confirmed in Florida in August 2005. The bacterium can infect a range of economically important citrus varieties and since 2005 crop losses in Florida have approached 50% from tree and fruit loss due to infection. In citrus '*Ca.* Liberibacter asiaticus' colonizes phloem sieve cells, which are specialized vascular cells which transport carbohydrates synthesized in leaves to local and distal portions of the tree. A sustained laboratory culture of '*Ca.* Liberibacter asiaticus' has not been established, so population growth characteristics from *in vitro* culture are unknown. To characterize the growth of bacterial populations in planta trees with established infections were pruned to force the growth of new branches which would be of equivalent physiological and temporal age and which would have an equivalent susceptibility to colonization. Real time PCR assays were performed on nucleic acid extracts from leaves collected from the new growth at 30, 60 and 90 days post-pruning. Assuming binary fission as the primary mode of cell division, bacterial populations calculated from mean cell numbers indicated that population doubling times between 30 and 60 days post-pruning were 10.2, 5.3 and 7.2 days for the citrus varieties 'Carrizo' citrange, sour orange and *Citrus macrophylla* respectively. The calculated mean cell numbers suggested that populations were in an exponential phase of growth between 30 and 60 days, but by 90 days populations had transitioned to a slower-growing, possible stationary phase. For the 60 to 90 day period, the calculated doubling time for '*Ca.* Liberibacter asiaticus' in sour orange was 17.1 days, which was more than triple the calculated doubling time for the 30-60 day period. Data from this study indicates that forcing new growth on infected trees can help synchronize colonization of tissues by '*Ca.* Liberibacter asiaticus' and that populations of bacteria display host-dependent growth characteristics which may influence disease development in infected trees.

The Genome and Genetics of a High Oxidative Stress Tolerant *Serratia* sp. LCN16 Isolated from the Plant Parasitic Nematode *Bursaphelenchus xylophilus*

Author Block:

C. Vicente[1], F. Nascimento[2], Y. Ikuyo[1], M. Mota[3], K. Hasegawa[1]; [1]Chubu Univ., Kasugai, Japan, [2]Univ.e Federal de Santa Catarina, Florianópolis, Brazil, [3]Univ.e de Évora, Évora, Portugal

Abstract Body:

Pine wilt disease (PWD) is an important disease of pine forests in East Asia and Europa forests and is caused by the pine wood nematode (PWN) *Bursaphelenchus xylophilus*. Bacteria are known to be associated with PWN in the host tree and may have an importante role in PWD. *Serratia* sp. LCN16 is an PWN associated bacterium that is highly resistant to oxidative stress *in vitro*, and which beneficially contributes to the PWN survival under these conditions. Oxidative stress is generated as a part of the basal defense mechanism used by plants to combat pathogenic invasion. Here, we investigated the interaction of the *Serratia* sp. LCN16 and PWN interaction in the disease development by exploring the LCN16 genome and functionally characterized some of the genes behind its impressive oxidative stress resistance. *Serratia* sp. LCN16 is phylogenetically most closely related to the phytosphere group of *Serratia*, which includes *S. proteamaculans*, *S. grimessi* and *S. liquefaciens*, and which have the ability to survive and colonize a plant-environment. Under conditions of oxidative stress (with H_2O_2, as the main stressor), LCN16 expresses *katG* (hydroperoxide I, HPI) under the positive regulation of OxyR. LCN16 *kat* (HPII) is OxyR-independent. LCN16 Δ*oxyR* was more sensitive to H_2O_2 than LCN16 Δ*kat*, and both deletion mutants failed protect the PWN from H_2O_2-stress exposure. *In planta*, co-inoculation of LCN16 Δ*oxyR* with PWN resulted in a slower development of disease symptoms. In contrast, the co-inoculation of wild-type LCN16 and PWN led to a faster PWD development than only PWN inoculation. This study provides new insights into the bacteria-nematode interaction in the natural host of PWD and provides further evidence of the potential role of bacteria in the first stages of PWN infection.

Study of Bacterial Diversity in Rhizosphere Soil of Two Caesalpinioideae (*Piliostigma reticulatum* and *Erythrophleum guineense*) Associated with Dry Cereal Crops in West Africa

Author Block:

N. NIANG[1], S. DEMANECHE[2], K. ASSIGBETSE[3], M. GUEYE[3], I. NDOYE[1], P. SIMONET[2], I. NAVARRO[2], **S. FALL**[4]; [1]Université Cheikh Anta DIOP (UCAD), LCM,LMI LAPSE, Dakar, Senegal, [2]Équipe "Génomique Microbienne Environnementale" (Environmental Microbial Genomics Group), UMR CNRS 5005, Ecully, France, [3]Inst. de Recherche pour le Développement (IRD), Dakar, Senegal, [4]Inst. Sénégalais de Recherches Agricoles, LNRPV, LCM, LAPSE, Dakar, Senegal

Abstract Body:

In Africa, 65% of agricultural lands are severely or moderately degraded. The association of cereal-legume crops is proposed as an alternative to improve both their organic status and productivity. In woodlands in Senegal, shrub and tree belonging to subfamily Caesalpinoideae (*Piliostigma reticulatum* and *Erythrophleum guineense*) are deliberately left in the fields by farmers for their roles in the water supply in the intercropping system and traditional medicines. However, their involvement in the soil nutrient cycles including nitrogen nutrition are very few documented. Therefore, the high-throughput sequencing technique (HTS) using Illumina Miseq platform combined with a profiling method (RISA) were used to assess the structural differences of bacterial communities, taxonomic groups and alpha and beta diversity between treatments (rhizosphere versus bulk soils). RISA analyses have shown a slight heterogeneity of bacterial community structure between the different treatments while HTS analysis showed high heterogeneity of bacterial community structures of soil rhizosphere associated with great diversity. Significant variations in relative abundances of dominant taxonomic groups were observed between the two types of soil, with the rhizosphere soils being dominated by *Proteobacteria* (35.8%) while *Actinobacteria* (26%) were dominant in the bulk soils. Bacterial communities associated with the rhizosphere of *P. reticulatum* were different from those of *E. guineense* and were dominated respectively by *Acidobacteria* (24.6%) and *Verrucomicrobia* (8.4%).Briefly, the high-throughput sequencing methods had increased our knowledge of the bacterial communities diversity in the rhizosphere of P. reticulatum and E. guineense associated with cereal crops in the savanna area.

Relation Between Pathogen Resistance and Rhizosphere Microbiome in Common Bean

Author Block:

L. W. Mendes[1], R. Mendes[2], M. de Hollander[1], J. M. Raaijmakers[1], S. M. Tsai[3]; [1]Netherlands Inst. of Ecology, Wageningen, Netherlands, [2]Embrapa Environment, Jaguariuna, Brazil, [3]Ctr. for Nuclear Energy in Agriculture, Piracicaba, Brazil

Abstract Body:

The microbial community in the rhizosphere plays a key role in the functioning of the host plant, influencing its physiology, growth & development. It has been postulated that plants modulate the microbiome composition to fend off pathogens. In this context, we investigated the rhizosphere microbiome of common bean cultivars that differ in resistance to the soil-borne pathogen *Fusarium oxysporum* (Fox). Using 16S rRNA sequencing and metagenomics we assessed the taxonomic composition and functional potential of the rhizosphere microbiome of common bean. The results show that bacterial abundance increased with an increase in resistance to Fox. The Fox-resistant bean cultivar presents a higher abundance Pseudomonadaceae, Bacillaceae, Solibacteraceae and Cytophagaceae as compared to the Fox-susceptible cultivar. At a finer taxonomic level, *Bacillus* and *Pseudomonas* were highly abundant in the rhizosphere of the Fox-resistant cultivar. The network analysis, with taxonomic, functional and environmental parameters, presented 3-4 fold more complexity in the Fox-resistant cultivar and showed a non-modular topology, indicating a more complex and highly connected community. Although the Fox-resistance of the common bean is cultivar linked to plant genetic traits our findings suggest that Fox-resistance also impacts the microbiome selected in the rhizosphere. Whether these changes in the rhizosphere microbiome contribute to the Fox-resistance phenotype, by means of specific microbial groups, functional traits, diversity and abundance, and network structure, is subject of ongoing experiments.

Variation in the Microbiome of Wine Grapes from the Willamette Valley, Oregon

Author Block:

M. VandenBerg, D. Grenier, J. Weisz, A. Kruchten; Linfield Coll., McMinnville, OR

Abstract Body:

Numerous abiotic environmental factors influence the maturation of grapes and subsequently the wine made from them. It has recently by hypothesized that, in addition to these factors, the microbiome of the wine grapes may also have a significant effect on the maturation of grapes and contributions to wine that are not fully understood. To determine if small-scale environmental differences influence the composition of the microbiome, samples were taken across several blocks in a single vineyard in Amity, Oregon. Full clusters of grapes were sampled from the vineyard using sterile technique and DNA was extracted from four grapes of each cluster. DNA was sequenced via high throughput sequencing with a primer set for the 16S gene. Results show significant differences in microbiome composition between grapes of different varieties in neighboring blocks. Further, microbiomes also varied within a grape variety in blocks across the vineyard. Within the same vineyard, where macroenvironmental conditions are largely uniform, it is significant that the microbiome is highly variable. These data suggest that "microbial terroir" may be influenced by a variety of factors, including the nature of the grapes and microenvironmental variables.

Genomic Evidence Of A Recent Host Restriction In An Emerging Plant Pathogen

Author Block:

L. R. Shapiro[1], O. Zhaxybayeva[2], J. Paulson[3], E. Scully[4], N. Pierce, 02138[1], G. Beattie[5], M. Gleason[5], R. Kolter[3]; [1]Harvard Univ., Cambridge, MA, [2]Dartmouth Univ., Hanover, NH, [3]Harvard Univ., Boston, MA, [4]USDA, Manhattan, KS, [5]Iowa State, Ames, IA

Abstract Body:

Background: Extensive landscape modification has accompanied human transition from nomadic to agricultural societies. This has resulted in the conversion of intact ecological habitats to simplified agro-ecosystems, containing large and genetically homogeneous populations of domesticated plants and animals with reduced genetic diversity. Some novel microbial variants are able to emerge into these populations and cause diseases that threaten agricultural production. Here, we present evidence that *Erwinia tracheiphila* (Smith) is one such recently emerged pathogen. *E. tracheiphila* infects two genera of wild and cultivated cucurbits, native *Cucurbita* spp. (squashes, pumpkins, and gourds), and introduced *Cucumis* spp. (cucumbers and melons). Despite the worldwide distribution of susceptible host plants, *E. tracheiphila* epidemics are geographically restricted to the Eastern United States and Southern Canada. **Results**: To investigate the evolutionary history of *E. tracheiphila*, we used long read PacBio sequencing to generate a reference sequence of an isolate from a *Cucurbita* plant and an isolate from a *Cucumis* plant, and then sequenced a 100 strain collection of isolates from across the geographic range where *E. tracheiphila* occurs. We find that the *E. tracheiphila* genome shows signs of recent, rapid change, including active phage infection, dramatic invasion and proliferation of transposable elements, horizontal acquisition of genes putatively important for host interactions, and extensive pseudogenization. Despite evidence of rapid change, sequences from the strain collection display negligible SNP diversity, and coalescent estimates suggest a recent emergence into its current niche. Further, *E. tracheiphila* appears to be undergoing an incipient lineage split associated with host adaptation to the two plant genera (*Cucumis* spp. and *Cucurbita* spp) it infects. This system provides a model to better understand the genetic and ecological factors affecting the evolution and rapid emergence of novel pathogens.

Cellulose-targeting Sus-like Systems within the Gut Metagenomes of Herbivores

Author Block:

C. M. Bahr[1], P. B. Pope[2], A. E. Naas[2], N. M. Koropatkin[1]; [1]Univ. of Michigan Med. Sch., Ann Arbor, MI, [2]Norwegian Univ. of the Life Sci., Aas, Norway

Abstract Body:

Human gut Bacteriodetes target dietary glycans via the expression of several outer membrane complexes termed starch utilization (Sus)-like systems. Each Sus-like system targets a distinct carbohydrate and is comprised of proteins that sequentially bind, degrade and import carbohydrates. The proteins within individual Sus-like systems are functionally conserved, although they target different glycans, and it is the specificity of these proteins that dictate which glycans the cell can utilize. The focus of my research is to understand the molecular basis of how glycans are recognized by different Sus-like systems. Because Sus-like systems for nearly every plant cell wall fiber except cellulose have been identified in human gut isolates, it was thought that cellulose degradation in all mammalian guts, including herbivores, was likely regulated by Gram positive bacteria. Here we have characterized the extracellular glycan binding lipoproteins of a predicted Sus-like system within an uncultured Bacteroidales, found in the cow rumen metagenome, that is likely to target cellulose. Using non-denaturing affinity electrophoresis and isothermal titration calorimetry we demonstrate that these proteins target longer cello-oligosaccharides, comprised of five or more glucose residues, with high affinity. Interestingly, these Sus-like protiens from the cow rumen Bacteroidales systems can target a wide variety of β-glucan structures, in contrast to many human gut Sus-like systems that are highly specific for a discrete carbohydrate structure. We determined the crystal structure of the SusD-like protein in this system, and by comparison to other SusD-like protein structures we predicted and confirmed, via site directed mutagenesis, the cellulose-binding residues of the protein. The glycan-binding residues within the structure are arranged as a planar platform of tryptophans, giving it the ability to recognize the linear structure of cellulose, which reveals how and why specific Sus-like proteins can target one or more plant cell wall glycan. This important structural information may facilitate the development of novel probiotic strains that can target cellulose in the human diet.

Influence of Dietary and Ontogenetic Factors on the Microbiome of Blacklegged Ticks (*Ixodes scapularis*)

Author Block:

C. P. Zolnik[1], R. C. Falco[2], T. J. Daniels[1], S. O. Kolokotronis[1]; [1]Fordham Univ., Bronx, NY, [2]New York State Dept. of Hlth., Armonk, NY

Abstract Body:

Blacklegged ticks (*Ixodes scapularis*) are important disease vectors in the United States, capable of maintaining and transmitting a number of human pathogens. Although over 98% of their life is spent off-host in forested settings, they require three bloodmeals throughout the course of their life cycle. Blood feeding usually lasts for several days and involves the transfer of host blood to the tick. This close interaction between host and tick likely influences the overall bacterial community within the tick. The purpose of this study was to explore the influence of host bloodmeal, engorgement, digestion, and sex on the *I. scapularis* microbiome over the nymph-to-adult transition period. Nymphal blacklegged ticks were collected in June 2014 from a field site in southern NY, an area with high tick populations and associated tick-borne pathogen prevalence. Ticks were fed on white-footed mice (*Peromyscus leucopus*) and were sacrificed at intervals (immediately post-feeding, two weeks post feeding, immediately post-molt). Additionally, host-seeking nymphs (before feeding) were also used to provide a baseline. DNA was extracted from each tick and 16S rRNA gene amplicon sequencing was carried out on the MiSeq (300bp PE) Illumina platform. OTUs were clustered *de novo* using a 97% identity threshold and identified with the Greengenes database. Our results demonstrate bacterial community structuring between host bloodmeal sources and engorged ticks. Although 82 taxa were shared between blood and tick samples, an additional 90 were found exclusively in ticks. A decrease in bacterial diversity was noted from field-collected nymphs through the various levels of digestion and after molting into adults, suggesting that bacterial OTUs are lost after feeding and throughout digestion. These results are in contrast to our previous study where bacterial diversity across all developmental stages was highest in field-collected adult males. It is likely that ticks lose bacterial OTUs after feeding but continual exposure to the bacteria from the field environment counters this loss in field-collected ticks. Maintaining the ticks from engorgement, through digestion and molting in sterilized vials and incubators allowed us to observe the decrease in bacterial diversity.

Cockroach Gut Microbiome Considering the Presence of a Gut Parasitic Nematode

Author Block:

C. Vicente, S. Ozawa, K. Hasegawa; Chubu Univ., Kasugai, Japan

Abstract Body:

Since the ancestor of the Blattodea spread from Mantodea in about 200 million years ago, cockroaches have evolved to cope with harsh climate changes and survival competition during long evolutional history and now being considered as one of the most successful insect groups on earth. From the fact that thelastomatid parasitic nematodes have been reported from many Blattodea species (Ozawa et al., 2014), it is very interesting to examine the evolutionary history of the cockroach and gut parasitic nematodes. In addition, cockroach microbiome, specifically, gut microbiota is extremely specified and adapted to the gut environment, their mutualistic balance might be highly sophisticated and indispensable for the host high environmental adaptability. The present study aims to understand the effect of the parasitic nematode *Leidynema appendiculatum* on the microbiome of the Smokybrown cockroach *Periplaneta fuliginosa* using a metagenomic approach. A total of 18 lab-reared cockroach individuals (9 nematode-infected and 9 nematode-free), fed with the same diet, were dissected, the gut extracted and divided into foregut, midgut and hindgut. Six independent libraries of the V3-V4 region of the 16S rRNA gene were prepared and sequenced using Illumina MiSeq System. Intraspecific variation between individuals is not considered in our analysis. Our results contribute to shed light into the ecological role of the universal symbiotic relationship between host animals, parasitic nematodes and microbiome.

Restriction of Dietary Zinc and Its Impact on the Structure and Function of the Gut Microbiome of Adult Zebrafish

Author Block:

C. A. Gaulke, L. M. Beaver, C. L. Barton, R. L. Tanguay, E. Ho, T. J. Sharpton; Oregon State Univ., Corvallis, OR

Abstract Body:

Growing evidence suggests that the microbiome plays an important role in establishing and maintaining gastrointestinal homeostasis. Changes in diet are known to have rapid and profound impacts on microbiome structure. However, less is known about how micronutrients contribute to the structure and function of the gut microbiome and how this in turn can influence host health. Zinc is an essential micronutrient that plays a vital role in normal growth and development, protein synthesis and immune function. Zinc is also essential for the growth of most microorganisms and the host microbiota competes for zinc in the gastrointestinal tract. We examined the effects of limiting dietary zinc concentrations on the host microbiome structure and function using whole-genome shotgun and 16S amplicon sequencing for adult zebrafish fed a zinc deficient defined diet (n=15), zinc adequate defined diet (n =15), and a zinc adequate commercially available zebrafish chow (n=15). While the animals receiving the zinc adequate diets harbored microbiomes similar in taxonomic composition and abundance, significant differences in taxonomic abundance and composition were observed between the microbiome of fish receiving the zinc adequate and zinc deficient diets. The abundance of the phyla Fusobacteria and Tenericutes were significantly increased and Proteobacteria decreased in the animals receiving the zinc deficient diet when compared to those receiving zinc adequate diets ($p < 0.05$). Similar observations were made at lower taxonomic and OTU level analysis. The functional capacity of the gut microbiomes of fish receiving zinc deficient and zinc adequate diets was then quantified using shotgun metagenomics. Comparisons of functional differences between fish receiving zinc deficient and zinc adequate diets were correlated to host transcriptional profiles to examine potential relationships between altered microbiome function and host physiology. These experiments provide novel insights into the effects of nutrient limitation on gut microbiome structure and function and expand our understanding of how these shifts may be involved in altered host physiology.

Evaluation of 16s Rrna Amplicon Sequencing Using Two Next-Generation Sequencing Technologies for Phylogenetic Analysis of the Rumen Bacterial Community in Steers

Author Block:

P. R. Myer[1], M. Kim[2], H. C. Freetly[2], T. P. L. Smith[2]; [1]Univ. of Tennessee, Univ. of Tennessee Inst. of Agriculture, Knoxville, TN, [2]USDA-ARS, U.S. Meat Animal Res. Ctr., Clay Center, NE

Abstract Body:

Next generation sequencing technologies have vastly changed the approach of sequencing of the 16S rRNA gene for studies in microbial ecology. Three distinct technologies are available for large-scale 16S sequencing. All three are subject to biases introduced by sequencing error rates, amplification primer selection, and read length, which can affect the apparent microbial community. The objective of this study was to compare and analyze short read 16S rRNA variable regions, V1-V3, with that of near-full length 16S regions,V1-V8, using highly diverse microbial communities from the rumen contents of steers (n=32), in order to examine the impact of technology selection on phyogenetic profiles. Short paired end reads from the Illumina MiSeq platform were used to generate V1-V3 sequence, while long "circular consensus" reads from the Pacific Biosciences RSII instrument were used to generate V1-V8 data. The two platforms predicted similar microbial operational taxonomic units (OTUs) as well as species richness, Good's coverage, and Shannon diversity. However, the V1-V8 amplified ruminal community resulted in significant increases in several orders of taxa, such as phyla Proteobacteria and Verrucomicrobia ($P < 0.05$). Taxonomic classification accuracy was also greater for the near full-length read ($P < 0.05$). UniFrac distance matrices using jackknifed UPGMA clustering also noted differences between the communities. These data support the general consensus that longer reads result in a finer phylogenetic resolution that may not be achieved by shorter 16S rRNA gene fragments. Our work on the cattle rumen bacterial community demonstrates that utilizing near full-length 16S reads may be useful in conducting a more thorough study, or for developing a niche-specific database to use in analyzing data from shorter read technologies when budgetary constraints preclude use of near-full length 16S sequencing.

In-Depth Analysis Of Broiler Chicken Gut Microbiome Responses Over Time Fed A Commercial Yeast-Based Prebiotic

Author Block:

S. Park, S. Lee, S. C. Ricke; Univ. of Arkansas, Fayetteville, AR

Abstract Body:

Prebiotics are considered fermentable food additive that selectively utilized by beneficial bacteria in lower gastrointestinal tracts of host. Several prebiotics based on yeast cell walls have been developed and evaluated for the effects on host for pathogenic bacteria reduction since usage of antibiotics in poultry industry has been identified with the rise of multidrug resistant pathogens. The aims of this study were to assess commercial broiler cecal microbiome response over time when supplemented by an antibiotic (BMD50) or a commercial yeast-based prebiotic (Biolex® MB40) into feeds. For microbiome analysis, DNA from individual birds was extracted to construct libraries and sequenced using an Illumina MiSeq platform. Acquired sequencing data sets were applied to QIIME pipeline to generate operational taxonomic units (OTUs) tables and identify relative abundance of microorganisms from phyla to genus levels. Although there were no significant increases or reductions of microorganisms in relative abundance among groups, the maturity of birds exhibited specific microbial population shifts in the prebiotic supplemented group. By considering and comparing cecal microbiomes of birds that are supplemented with feed additives, a better understanding of the relationship between specific microbial abundance and bird growth performance as well as health status can be achieved for developing a rationale on prebiotic selection strategies.

Effect of Diet on Enterobacterial Community Composition of the Wood-eating Catfish *Panaque nigrolineatus*

Author Block:

R. C. McDonald[1], J. E. M. Watts[2], H. J. Schreier[1]; [1]Univ. of Maryland Baltimore County, Baltimore, MD, [2]Univ. of Portsmouth, Portsmouth, United Kingdom

Abstract Body:

The Amazonian catfish *Panaque nigrolineatus* consumes large quantities of wood as part of its diet and may rely heavily on the metabolic activities of its enteric microbial community for nutrient acquisition. However, unlike exclusively wood-feeding organisms, *P. nigrolineatus* is capable of transitioning between wood-only and mixed wood/detritus diets depending on environment. This strategy provides a unique opportunity to examine the impact of a changing diet in a wood-feeding organism and enables the description of the core microbiome composition essential for fish nutrition. In the present study, the MiSeq platform was used to compare 16S rRNA gene sequences of the enteric microbial communities from fish fed either a wood/algae (mixed) diet or wood alone. A shift in microbiome composition and structure was observed across feeding regimens and within different GI tract regions. The wood-fed fish microbiome included predominantly Alphaproteobacteria, Sphingobacteriia, Gammaproteobacteria, Verrucomicrobiae and Bacilli, while mixed diet comprised predominantly Alphaproteobacteria, Gammaproteobacteria, Clostridium, Bacteroidetes, and Flavobacteria. Unlike mixed diet-fed fish, the microbial communities of wood-fed fish were remarkably consistent across tissue regions, suggesting wood consumption selects for a specific community across the entire GI tract length. This contrasts with the highly compartmentalized microbial communities observed in other wood-feeding organisms. Phylogenetic analysis identified two predominant OTUs with high sequence similarity to *Candidatus* Amoebophilus asiaticus (7-10%) and *Candidatus* Cardinium hertigii (5-8%) found exclusively in wood-fed fish. Both organisms are obligate intracellular symbionts of eukaryotes, but their role in fish nutrition is unclear. In addition to the symbionts, several phylotypes with high sequence similarity to nitrogen-fixing Alphaproteobacteria were identified in both diets in agreement with our previous findings. This study demonstrates that diet has a major impact on the microbiome of *P. nigrolineatus;* the ability to shift microbiomes may provide a selective advantage allowing the fish to assimilate less refractory substrates when available and has implications for microbial recruitment.

Bat Microbiota as Biocontrols for White-Nose Syndrome

Author Block:

D. E. Northup[1], A. S. Kooser[1], N. A. Caimi[1], P. S. Hamm[2], A. Porras-Alfaro[2], J. C. Kimble[1], J. M. Young[1], D. C. Buecher[3]; [1]Univ. of New Mexico, Albuquerque, NM, [2]Western Illinois Univ., Macomb, IL, [3]Buecher Biological Consulting, Tucson, AZ

Abstract Body:

Background: Recent studies have shown that mammals, such as humans, have a natural external microbiota that acts as a filter against pathogens. We know little about this potential defense in bats and its effectiveness against *Pseudogymnoascus destructans*, the causative agent of white-nose syndrome (WNS). **Methods:** One hundred-eighty-six bats from 14 species from pre-WNS New Mexico (NM) and Arizona (AZ) were swabbed and sequenced using 454 next gen sequencing.**Results:** Our Qiime and R Studio analysis of bat bacterial microbiota revealed that microbiota present on bats caught in caves are substantially different from those netted on the surface. Our results also reveal that the ecoregion from which the bat was caught, helps to differentiate different sampled microbiota. One major group present is the microbiota is the Actinobacteria, which are one of the most prolific producers of secondary metabolites, such as antifungals. These Actinobacteria may represent an effective biocontrol agent against *P. destructans*. To test this, we cultured external Actinobacteria from NM and AZ cave-caught and surface netted bats, subcultured 2100 isolates using media targeting Actinobacteria, and tested for the production of antifungals that are effective against *P. destructans*. Tests were conducted using a bi-layer method in the laboratory. Thirty-five isolates inhibited *P. destructans*, most of which were *Streptomyces* spp. One *Rhodococcus rhodochrous* also produced significant inhibition.**Conclusions:** Understanding the antifungal potential of the external microbiota on bats will help to identify potential WNS biocontrol agents. Also, investigations of microbiota, and Actinobacteria in particular, give us insight into what management strategies are likely to be successful.

Different Influence of *Mycobacterium tuberculosis* H37Rv and *Mycobacterium bovis* BCG Infections in the Expression of Toll-Like Receptor Signaling and Pro-Inflammatory Cytokines of A549 Alveolar Epithelial Type II Cells

Author Block:

Y. Li[1], D-x. Liu[2], L. Cheng[2], X-p. Liu[3], Q-j. Ren[2], X-m. Liu[1]; [1]Key Lab. of Ministry of Ed. for Conservation and Utilization of Special Biological Resources in the Western China, Yinchuan, Yinchuan, China, [2]Coll. of Life Sci., Ningxia Univ., Yinchuan, China, [3]The Fourth People's Hosp. of Ningxia Hui Autonomous Region, Yinchuan, China

Abstract Body:

Background: Alveolar epithelial type II cells (AEC II) are the first target cells infected by pathogens of pulmonary tuberculosis inhaled through respiratory tracts. **Methods:** The objective of present study was to explore the molecular mechanisms of immune response and persistent infection of *M.tuberculosis* (Mtb) in A549 AEC II cells by analyzing the differential expression of TLRs signaling and pro-inflammatory cytokines in A549 cells infected with H37Rv and BCG at different time points. The A549 cells were infected by H37Rv or BCG bacilli for different times (6, 12 and 24 h), and the expression of key molecules and proinflammatory cytokines in TLR signaling cascade were ascertained in terms of qRT-PCR and Western-blotting assays.**Results:** The result showed that, the expression of *TLR2, TLR4, NF-κB* and *MyD88* were up-regulated significantly in cells infected with H37Rv as compared with BCG-infected group at 6 h time after the infection. However, *TLR2/4* was also increased in both H37Rv and BCG infected groups, there was no statistically significant difference of increase between cells infected with these two strains at 24 h time point. In addition, the expression of IRAK4 and TRAF3 were significantly higher in the infected A549 cells with BCG than that of H37Rv-infected cells, in which the expression of IRAK4 in BCG-infected cells was up-regulated at the time of 6 and 12 h but was down-regulated at 24 h post-infection. Furthermore, the expression of pro-inflammatory cytokines *IL-1a, IL-6, IL-12a, IL- 8, TNF-α* and *CSF2* were significantly increased in both H37Rv- and BCG-infected A549 cells in a time-dependent manner, and the expression of *IL-1a, IL-6 IL-8, TNF-α* and *CSF2* was more pronounced in H37Rv-infected relative to the BCG infection.**Conclusions:** These results indicated that the TLRs signaling pathway was apparently suppressed in AECII cells infected with the virulent *Mycobacterium* strain H37Rv, but it induced more robust inflammation responses in A549 cells as compared with the attenuated strain BCG.

The Voltage-Dependent Anion Channels in the Membrane of *Mycobacterium avium* Phagosome is Required for the Transport of Lipids into the Macrophage Cytosol and for Pathogen Survival

Author Block:

L. Danelishvili, L. E. Bermudez; Oregon State Univ., Corvallis, OR

Abstract Body:

Background: *Mycobacterium avium* subsp. *hominissuis* is an environmental mycobacteria associated with infection of immunocompromised individuals as well as patients with chronic lung disease. *M. avium* infects macrophages and prevents the maturation of the phagosome. The bacterium also interferes with trafficking and many pathways inside of the macrophage, indicating that bacterial effector molecules perform functions in the cytoplasm, after being secreted and transported across the vacuole membrane. Since intracellular mycobacterium is found juxtaposed to the phagosome membrane, our goal of this study was to identify possible phagosomal proteins that are employed by *M. avium* to export virulence factors into the cytosol of host cells. **Methods:** To investigate whether *M. avium* structures to attach to proteins on the internal surface of the vacuole before releasing secreted molecules, intravascuolar *M. avium* and vacuole membrane proteins were purified using biotin labeling and magnetic purification technique, and interactions among both were evaluated with the yeast two-hybrid system. **Results:** The voltage dependent anion channels (VDAC) were identified as components of *M. avium* vacuoles in macrophages. *M. avium* mmpL proteins were found to bind to VDAC-1 protein. The inactivation of VDAC-1 function by pharmacological means or siRNA lead to significant decrease of intracellular *M. avium* survival. Although we could not establish a role of VDAC channel in the transport of known secreted *M. avium* proteins, our data suggests that at least in some cases, the secretion of effectors begins with the recognition of a transport system in the vacuole membrane by a *M. avium* protein. We demonstrated that the VDAC porin channels are associated with the transport of bacterial cell wall lipids outside of vacuole. **Conclusions:** We identified a transport mechanism for *M. avium* secreted lipids. Suppression of the transport of pathogeneffectors may serve as an approach for therapy of infectious diseases.

***Mycobacterium tuberculosis* Dissemination and Extrapulmonary Spread**

Author Block:

M. G. Moule, Preeti Sule, Hee-jeong Yang, Katri Anttonen, Denise K. Zinniel, Raul G. Barletta, Jeffrey D. Cirillo; Texas A&M Hlth.Sci. Ctr., Bryan, TX

Abstract Body:

Mycobacterium tuberculosis is the causative agent of tuberculosis, a disease that remains one of the leading causes of death worldwide despite major advances in diagnostics and therapeutics. An estimated one third of the global population is currently infected with *M. tuberculosis,* with 8.6 million new cases and 1.3 million deaths each year. The majority of these infections are latent, capable of reactivation at any time, and cannot be completely cleared even with antibiotic treatment. In addition, up to 20% of infections in healthy adults and over 50% of infections in children and immunocompromised patients result in extrapulmonary infections that are particularly difficult to detect and treat and have high mortality rates. While most clinical interventions against *M. tuberculosis* have focused on pulmonary infections, developing approaches that target dissemination could lead to diagnostics capable of detecting extrapulmonary infection and therapeutics that prevent the disease from progressing to a more lethal stage. In addition, *M. tuberculosis* latency is highly associated with secondary lesions in the lungs that are established following bacterial dissemination out of primary lesions, and thus targeting dissemination could also potentially address the establishment of latent infections. We have developed a genetic approach to investigate the mechanisms of *M. tuberculosis* dissemination using Tn-seq to identify genes required for *M. tuberculosis* dissemination using a library of 50,000 *M. tuberculosis* CDC1551 mutants. By combining this screen with a real-time live imaging technique known as reporter enzyme fluorescence (REF), we can characterize the role of each gene identified in our screen in the context of an infection. REF imaging will allow us to follow the progress of dissemination in individual animals over time, determining the nature and kinetics of each attenuated dissemination mutant to establish extrapulmonary infections. Our initial pilot screen has identified multiple candidate dissemination mutants, the first of which has been tested and confirmed by REF imaging, validating the effectiveness of our screening method. We believe these experiments will lead to a greater understanding of this critical disease process and open the door for the development of novel therapeutics designed to prevent bacterial dissemination.

***Mycobacterium tuberculosis* Interact with Stem Cell Self-Renewal Mechanism Through Hypoxia-Inducible Factor 1 Alpha Signaling Pathway**

Author Block:

J. Garhyan[1], S. Gayan[2], R. Bhatnagar[1], B. Das[3]; [1]Jawaharlal Nehru Univ., New Delhi, India, [2]Kavikkrisna Lab., Guwahati, India, [3]The Forsyth Inst., Cambridge, MA

Abstract Body:

Background: Adult stem cells employ self-renewal mechanisms to remain quiescent for a prolonged period of time. We speculated that Mycobacterium tuberculosis (Mtb) might interact with the self-renewal mechanisms to hide intracellular to adult stem cells in a non-replicating state for a prolonged period of time. Indeed, our work in human and mice with Mtb infection identified CD271+/CD133+ bone marrow mesenchymal stem cells (CD271+ BM-MSCs) as a candidate stem cell type, where Mtb reside intracellular for months. Importantly, Mtb infected CD271+ BM-MSCs exhibited high expression of hypoxia inducible factor-1α (HIF-1α), a transcription factor involved in the self-renewal of both hematopoietic and mesenchymal stem cells. Here we investigated the host/pathogen interaction between Mtb and HIF-1alhpa mediated metabolism in CD271+ BM-MSCs. **Method:** GFP-H37Rv infected and healthy human CD271+BM-MSCs were cultured under aerobic condition and qRT-PCR was carried out to compare the H1F1 α transcript levels. MRC-5 cell derived CD271+ cells were also used to study Mtb-H37Rv modulation of HIF-1alpha signaling. **Result:** Here we show that under aerobic condition, HIF-1α and related genes including genes involved in aerobic glycolysis and LD formation were induced in Mtb infected CD271+BM-MSCs by 3-5-fold as compared to non-infected cells. Increased LD formation were confirmed by 3-fold increase in Nile red RFU and a 2 fold increment in TG content in infected CD271+BM-MSCs compared to healthy cells. Silencing of HIF-1α with siRNA lead to differentiation of loss of Mtb viability, increased ROS production, and reversal of aerobic glycolysis, as well as LD formation. Importantly, siRNA HIF-1alpha led to loss of self-renewal capacity of CD271+ BM-MSCs. Next, in a mouse model of Mtb-m18b infection, a streptomycin dependent strain of 18b (2), we show that inhibition of HIF-1alpha by FM19G11 led to the differentiation of CD271+ BM-MSCs and the loss of Mtb viability. **Conclusion and significance:** Our findings suggest that Mtb evolved to interact with the self-renewal mechanism of stem cells.

Identification of Genes Involved with Bicarbonate Sensing and Extracellular Dna Export in Nontuberculous Mycobacterial Biofilms

Author Block:

S. J. Rose, L. E. Bermudez; Oregon State Univ., Corvallis, OR

Abstract Body:

We recently reported the initial finding and characterization of extracellular DNA (eDNA) in mycobacterial biofilms. When studied further, we have determined that bicarbonate triggers the export of eDNA in *Mycobacterium avium* and other nontuberculous mycobacteria (NTM) including *M. abscessus*. Various pathogens use elevated carbon dioxide or bicarbonate in the host to upregulate virulence gene expression, but a link to biofilms or eDNA has not been described. The current study was carried out to identify genes associated with eDNA export in NTM. An *M. avium* strain A5 bank of mutants was screened for eDNA production by co-incubating inoculums with 3µM cell-impermeable propidium iodide and fluorescently measuring undisturbed biofilms over a time course. eDNA-deficient mutants were complemented with wild-type gene and native promoter using an integrative pMV306Apr plasmid. Out of 4,048 mutant clones screened in *M. avium* for eDNA export, we identified and sequenced 145 mutants that were severely deficient. Mutants included a unique DNA transporting FtsK-like pore, a carbonic anhydrase, 8 mutants located in a novel genomic region, various transcriptional regulators, many genes encoding hypothetical proteins, and genes associated with metabolism and energy production. Interestingly, most of the eDNA deficient mutants tested were attenuated during *in vitro* macrophage infections. Additionally, we sequenced the surface proteome of the bicarbonate-exposed biofilm and found many proteins that match sequenced attenuated mutants, or are located in operons with mutants. Ten mutants of interest were complemented and upon biofilm formation exhibited restoration of eDNA to wild-type levels. To corroberate the findings in *M. avium*, 1,080 *M. abscessus* mutants were also screened for eDNA export and 69 of them were classified as eDNA deficient. Thirty of the most deficient mutants were sequenced and several of the genes inactivated are located in operons with genes identified in the *M. avium* screen. Multiple laboratories, including ours, have suggested active export of eDNA in bacterial biofilms, but the mechanisms are unknown. Our findings identify genes involved with bicarbonate sensing and eDNA export, which could be potential virulence factors for mycobacterial infection.

Nontuberculous Mycobacteria from Hawaii Demonstrate Varying Degrees of Virulence

Author Block:

J. R. Honda[1], N. A. Hasan[2], Y. Zhou[2], E. D. Chan[2]; [1]Univ. of Colorado Anschutz Med. Campus, Aurora, CO, [2]Natl. Jewish Hlth., Denver, CO

Abstract Body:

Hawai'i has the highest rate of NTM lung disease in the U.S. Our previous work indicates that *Mycobacterium chimaera* predominates in clinical samples and households in Hawai'i. It's plausible that clinical and environmental isolates vary in virulence. We previously show a unique virulence mechanism of pathogenic NTM; *i.e.*, resistance to and inactivation of cathelicidin (LL-37). Intracellular growth in macrophages and evasion to LL-37 were used to assess virulence differences between genetically similar clinical and environmental *M. chimaera* from Hawai'i. *rpoB* sequence analysis was used to speciate NTM and phylogenomic methods were used to assess genetic relatedness between identified *M. chimaera* strains. Two pairs of clinical (CL) and environmental (ENV) *M. chimaera* were shown to have a high degree of genetic similarity within each pair. Virulence differences were determined by the number of intracellular *M. chimaera* recovered from THP-1 cells and whether *M. chimaera* resist and inactivate LL-37. The antimicrobial activity of LL-37 following exposure to NTM was assessed by *Escherichia coli* viability. *M. chimaera* pairs CL10 and ENV56 and CL8 and ENV16 were shown to be genetically similar within each pair. Among the pairs, no difference in the number of *M. chimaera* were observed between the clinical and environmental isolates at any timepoint tested; but, compared to the CL10 and ENV56 pair, significantly more intracellular CL8 and ENV16 were recovered from THP-1 at the 96-hour timepoint ($p=0.03$). Incubation with 25 and 125 μg/ml of LL-37 did not affect the viability of CL8 or ENV16 and the LL-37 exposed to this pair lost its potent antimicrobial activity against *E. coli*. In contrast, CL10 and ENV56 showed susceptibility to 125 μg/ml of LL-37. Whereas CL8 and ENV16 inactivated all LL-37 concentrations tested, 125 μg/ml of LL-37 incubated with either CL10 or ENV56 retained activity. Our data indicate that virulence does not significantly differ between clinical and environmental *M. chimaera*, but genetically dissimilar *M. chimaera* do differ in virulence and evasion capacity to LL-37. The genetic differences between *M. chimaera* isolate pairs likely determine the observed variation in virulence.

Cross Talk Between T-Cells and Antigen Presenting Cells During Mice Infection with *Mycobacterium avium* subspecies

Author Block:

K. Abdissa[1], A. Nerlich[1], S. Weiss[2], R. Goethe[1]; [1]Univ. of Vet. Med. Hannover, Hannover, Germany, [2]Helmholtz Ctr. for Infection Res., Braunschweig, Germany

Abstract Body:

Background: *Mycobacterium avium* subspecies (ssp.) represent a group of genetically closely related bacteria with different, specific phenotypical and genotypical features. *M. avium* ssp. *paratuberculosis* (MAP) is the causative agent of paratuberculosis (Johne's disease), a chronic intestinal disease, in cattle and other ruminants. MAP is also suggested as the possible cause of Crohn's disease, a persistent inflammation of the bowel in humans. In contrast to its closest relatives *M. avium* ssp. *avium* (MAA) and *M. avium* ssp. *hominissuis* (MAH) MAP exhibits a strong intestinal tropism. There is strong evidence that MAP escapes local immune surveillance to establish long term infection leading to clinical disease. However, only little is known about the underlying immunological mechanism.**Objectives:** The presented study was performed to analyze the functional capacity and the phenotypes of antigen presenting cells and T-cell response after MAP infection of mice in comparison to infection with the closely related MAA. **Methods:** We established *ex vivo* and *in vivo* antigen specific T-cell proliferation assays. Female C57BL/6 mice were infected with MAP or MAA. At different time points after intraperitoneal infection, splenic dendritic cells (DCs) were sorted and co-cultured with CD4 T-cells from OT II TCR transgenic mice in the presence ovalbumin protein or peptide. T-cells proliferation was measured in terms of CFSE dilution. Similarly, antigen specific proliferation was measured *in vivo* after adoptive transfer of OT-II CD4 T-cells.**Result:** Our *ex vivo* and *in vivo* experiments showed that MAA but not MAP infection of mice affected the antigen presenting capacity of splenic DCs resulting in the inhibition of antigen specific CD4 T-cell proliferation. Antigen presenting cells co-stimulatory and co-inhibitory molecules were differently regulated. In contrast to MAP infection MAA infection affected the myeloid cell compartment by inducing B-cells and T-cells loss. TLR2 dependent interleukin 10 production was common to all subspecies *in vitro*.**Conclusion:** Overall, these data show that MAP and MAA differ in their immune escape mechanism in mice. They suggest that MAP escapes the host immune response while MAA seems to actively subvert it.

Human Endosomal Tlr Response Upon Recognition of *Mycobacterium tuberculosis* Nucleic Acids

Author Block:

J. Cervantes[1], E. Oak[2], J. Garcia[2], J. C. Salazar[3]; [1]UConn Hlth., Farmington, CT, [2]Univ. of Connecticut, Storrs, CT, [3]Connecticut Children's Med. Ctr., Hartford, CT

Abstract Body:

Mtb, the causative agent of TB, is a facultative intracellular pathogen that infects macrophages where it avoids elimination by interfering with host defense mechanisms. Toll-like receptors (TLRs) expressed on macrophages can recognize Pathogen Associated Molecular Patterns (PAMPs) on Mtb and mediate the production of immune-regulatory cytokines such as tumor necrosis factor (TNF) and type I Interferons (IFNs). The latter are produced by activation of endosomal TLRs after recognition of nucleic acids in the phagosome. TLR importance is underlined by the fact that the TLR-adaptor molecule MyD88 pathway in macrophages is important in confining Mtb within phagolysosomes, and it is required for mycobacterial clearance and an adequate innate and adaptive immune response against mycobacterial infection. We herein aimed to characterize the endosomal TLR-signaling of human macrophages, as they are appear crucial in determining the fate of the disease. To explore if variations in Type I IFN responses correlates with differences in Mtb nucleic acids derived from different Mtb genotypes, human monocytic cell line THP-1 derived macrophages, expressing two inducible reporter constructs for interferons (IFNs) and for NF-kB, were stimulated with DNA obtained from Mtb strains of different lineages. We found that DNA from different *Mtb* phylogenetic lineages elicits differential NF-kB and IRF inflammatory responses in human macrophages. We also studied the effect of Vitamin D (VD) on these responses, as it is known to activate macrophages and enhance their antimycobacterial activity. Pretreatment of cells with VD increased the response to DNA from HN878 and virulent strain H37Rv, and increased phagocytosis of live *M.smegmatis*. It also enhanced the response to RNA from *M.smegmatis* and attenuated *M.bovis* strain BCG. Although correlation between different Mtb strains and lung epithelial invasiveness and inflammatory response has been reported, none of these studies evaluated Type I or Type II IFNs. The significance of the herein reported differences between different Mtb strains is of great importance as type I IFNs have been demonstrated to strongly inhibit monocytes and macrophages responsiveness to IFN-γ, and are associated with active TB disease.

Profiling the Mouse Genome to Find Correlates of Vaccine-Induced Protection against *Mycobacterium tuberculosis*

Author Block:

S. L. KURTZ, K. L. Elkins; U.S. Food and Drug Admin., Silver Spring, MD

Abstract Body:

Despite extensive world-wide use of BCG, tuberculosis (TB) remains a serious global public health threat. New vaccines are difficult to develop due to incomplete understanding of optimal protective mechanisms of immunity against *M. tuberculosis* (*M. tb*). Using mouse models, our laboratory adapted an *in vitro* co-culture system to identify immune mediators whose relative gene expression is significantly associated with the degree of protection. In this strategy, *Mycobacteria*-infected macrophage monolayers are co-cultured with TB-immune lymphocytes to evaluate control of intramacrophage bacterial replication. Previously, we used a panel of BCG-related vaccines to establish a hierarchy of vaccine-induced protection against *M. tuberculosis* challenge. Splenocytes or peripheral blood lymphocytes (PBL) from vaccinated mice controlled intracellular *Mycobacteria* replication in patterns that represented the relative protection afforded against *in vivo* MTB challenge. We further applied this approach to study protective mechanisms. We hypothesized that genes specifically upregulated in protective versus less or non-protective vaccines represent potential immune correlates. We then screened a panel of 90 chemokine and cytokine genes, and found several molecules whose expression levels in splenocytes and PBLs corresponded with protection. Given this success, here we expanded screening to include the whole mouse genome as measured by microarray. We used RNA derived from splenocytes co-cultured with *M.tb*.-infected macrophages. In addition to mediators found in our original screen, such as IFN-gamma, Hmox, and Nos-2, we found an additional ~830 genes whose expression was at least two-fold different between the “best” vaccine and the naïve samples. Of these, the 190 strongest candidates have subsequently been validated with qRT-PCR. We are now also evaluating this subset in samples derived from PBL. To date, the strongest associations include Cxcl9, Ubd, Mgl, Lpl, and Plin2. Further, pathway analysis of the most upregulated gene targets show involvement of pathways related to cell maintenance, cell death, and cell trafficking. These findings will expand the knowledge of immune mechanisms that underlie successful vaccination, and may ultimately provide a panel of relevant correlates.

Meta-analysis of the Sputum Microbiome in Pulmonary Tuberculosis

Author Block:

A. Adami, B-Y. Hong, J. Cervantes; UConn Hlth.Ctr., Farmington, CT

Abstract Body:

Background: The lung has received less attention compared to other body sites in terms of microbiome characterization, and its study carries special technological difficulties related to obtaining reliable samples as compared to other body niches. Tuberculosis (TB) is a worldwide health problem with high morbidity and mortality. It is still unclear if changes in the lung microbiome composition are associated with pulmonary TB. Up to date, five studies reported the sputum microbiome on TB patients and controls, with somewhat contradictory results [1-5].**Methods:** A systematic NCBI PubMed searched identified 5 studies on sputum microbiome and TB through December 2015. Available sequence data from three of these studies plus a recen analysis of the lung microbiota in healthy individuals [6] were analyzed by phylotype approach using microbiome analysis platforms mothur and qiime. We compared data from lower respiratory tract samples, i.e. sputum and/or bronchoalveolar lavage (BAL), in both TB cases vs. healthy controls.**Results:** Overall, a signature of TB did not appear consistent between studies, even when the data were analyzed with consistent methods. A decreased in diversity was found in the sputum bacterial composition of TB patients compared to healthy controls. A predominance of *Prevotella* and *Streptoccocus* was observed in the composition of TB sputum at the genus level, while *Clostridia* and *Bacteroides* were the most predominant genera in healthy controls.**Conclusions:** Although our findings are narrowed by a limited number of studies, they underline the fact that the lung microbiome in TB patients differs from normal individuals. Future larger studies are needed to validate a consistent presence of a few genera across the studies analyzed. This could potentially allow for discrimination from healthy controls with significant accuracy statistically. Lung microbiome dysbiosis observed in TB patients may play a role in disease onset, progression, recurrence, and outcome after treatment. Understanding the composition of the lung microbiome in health and comparing it to that of pulmonary TB cases would elicit clues into the pathogenesis of *Mycobacterium tuberculosis* infection at the pulmonary alveolus and would help the design of promising treatment options for TB with potential direct beneficial consequences for patients and public health.

Identification of *Borrelia burgdorferi* Oxidative Stress Response Genes and Characterization of Their Role *In Vivo* Using Transposon Insertion Sequencing

Author Block:

M. E. Ramsey[1], J. A. Hyde[2], T. Lin[3], L. Gao[3], M. E. Lundt[1], S. J. Norris[3], J. T. Skare[2], L. T. Hu[1]; [1]Tufts Univ., Boston, MA, [2]Coll. of Med., Texas A&M Hlth.Sci. Ctr., Bryan, TX, [3]UTHlth.McGovern Med. Sch., Houston, TX

Abstract Body:

The Lyme disease spirochete *B. burgdorferi* lacks homologs of several canonical oxidative stress response genes, and the cellular targets of oxidative damage differ compared to model organisms such as *E. coli*. We conducted an unbiased search for genes involved in the *B. burgdorferi* oxidative stress response using transposon insertion sequencing (Tn-seq). Tn-seq relies on high-throughput sequencing to quantify the frequency of transposon (Tn) mutants in a population before and after a selective pressure. A *B. burgdorferi* Tn library was exposed to DEA/NO (a nitric oxide donor) and to two ROS reagents: hydrogen peroxide (H_2O_2) and t-butyl hydroperoxide (TBHP). Tn mutants with insertions in DNA repair genes exhibited the largest decreases in frequency following DEA/NO exposure, consistent with previous reports that DNA is a target of RNS in *B. burgdorferi*. We confirmed the NO-sensitivity of several Tn mutants, including those with insertions in genes encoding the excinuclease subunit UvrC (previously shown to be important for RNS resistance), the helicase UvrD, and the ribonuclease RnhA. In contrast, after exposure to H_2O_2 and TBHP, Tn mutants with insertions in genes encoding transmembrane proteins exhibited the largest decreases in frequency. We confirmed the ROS-sensitivity of Tn mutants with insertions in four of these genes: *bb0202*, encoding a hemolysin-like protein, *bb0017*, encoding a GlnB-like protein, *bb0164*, encoding a putative sodium/calcium exchanger, and *bb0412*, encoding a putative membrane protein. We then investigated whether the genes identified in the *in vitro* screens played a role *in vivo* by infecting C57BL/6 mice with a mini-library of 39 Tn mutants and found that all of the Tn mutants exhibited fitness defects *in vivo*. Collectively, these studies identify new gene functions involved in ROS and RNS resistance in *B. burgdorferi* and demonstrate a role for these genes *in vivo*. Ongoing studies aim to test the infectivity of the Tn mutants in mice deficient in ROS and RNS production.

Effects of *Moraxella Catarrhalis*-Derived Nitric Oxide on Different Human Cell-Lines in Co-Cultures

Author Block:

B. MOCCA, C. Johnson, W. Wang; FDA, Silver Spring, MD

Abstract Body:

Moraxella catarrhalis is an important cause of the most common childhood infectious diseases, such as acute otitis media (AOM) and OM with effusion (OME) and forms biofilms on the mucosal surface of the mid-ear of children with OME. In adults with chronic obstructive pulmonary disease (COPD), *M. catarrhalis* infection can cause exacerbations of COPD. Recent study reported that the expression of a nitrite reductase (AniA) is up-regulated in *M. catarrhalis* biofilms formed on human bronchial epithelial cells (HBEC) in co-cultures, which, in the presence of pathological levels of nitrite, produces higher levels of nitric oxide (NO) that stimulated host cell expression of proinflammatory cytokines, including IL-1α and TNF-α, and induces HBEC to undergo apoptotic death. In addition, bacteria-derived NO is toxic to biofilm-grown bacteria but not to planktonically-grown *M. catarrhalis*. These study results indicated that bacteria-derived nitric oxide might paly pathogenic roles in *M. catarrhalis*-associated otitis media. Because *M. catarrhalis* caused childhood disease is very different from *M. catarrhalis* associated exacerbation of COPD, it is important to examine the effects of *M. catarrhalis*-derived NO on different human cells. When the A549 cells (adenocarcinomic human alveolar basal epithelial cells) were used as host cells in co-cultures, preliminary data showed that bacterial cells can grow either attached or unattached to A549, and the growth of A549 was only slightly reduced by bacteria-derived NO.

Bacterial Production of Glutathione Protects Group B *Streptococcus* from Killing by Healthy and Nadph Oxidase - Deficient Murine Macrophages

Author Block:

T. Vongsurbchart, S. Rowse, B. Branneky, A. Riffle, T. Khurana, C. Kranz, K. Vyas, A. Modi, **B. E. Janowiak**; Saint Louis Univ., St. Louis, MO

Abstract Body:

Background: Group B Streptococcus (GBS) is a pathogen that can cause sepsis in immune compromised patients. Previously, we have found that GBS produces and uses large amounts of a potent antioxidant, glutathione (GSH), to protect itself against immunologically relevant reactive oxygen species (ROS). We hypothesize that a glutathione-deficient strain of GBS (in which we genetically inactivated the gene *gshAB*) would be cleared more readily by weakened macrophages than either the parental (wild type) strain or a genetically complemented strain of GBS.**Methods**: In order to test our hypothesis, we infected J774A.1 macrophage-like cells, as well as freshly isolated murine intraperitoneal macrophages from either NADPH oxidase-deficient (NADPH oxidase is the rate-limiting enzyme in the ROS cascade) or wild type mice, with GSH-deficient, GSH-complemented, or wild type GBS. We then measured how efficient the macrophages were at clearing the GBS strains, and we also measured the effect of GBS strains on the viability of the macrophages over time.**Results**: We observed significantly higher killing of GSH-deficient GBS than wild type or GSH-complemented GBS for all three infections (J774A.1 cells, healthy macrophages, and NADPH-oxidase deficient macrophages). Likewise, we observed less macrophage cytotoxicity post infection with GSH-deficient GBS than wild type or GSH-complemented GBS for all three infections. Supporting our hypothesis, we observed that GSH-deficient GBS were efficiently cleared from both healthy and NADPH-oxidase deficient macrophages.**Conclusion**: Our studies suggest that GSH plays an important role in helping GBS to survive in both healthy and immune compromised immune cells. Additionally, since GSH seems to be critical for both the survival of GBS as well as the cytotoxic activity in macrophages, GSH synthesis may be a viable drug target. Future studies will explore that possibility.

Catabolite and Oxygen Regulation of Enterohemorrhagic *Escherichia coli* Virulence

Author Block:

K. Carlson-Banning, V. Sperandio; UT Southwestern Med. Sch., Dallas, TX

Abstract Body:

Nutritional competition among human gastrointestinal (GI) bacteria drives differential gene expression, including expression of virulence factors. The host mucus layer provides sugars for GI commensal bacteria while preventing enteric pathogens from directly accessing intestinal cells. However, the enteric pathogen enterohemorrhagic *Escherichia coli* (EHEC) uses these mucus derived sugars (i.e. glucose and fucose) to regulate virulence gene expression. EHEC express the locus of enterocyte effacement (LEE) pathogenicity island, which encodes a type three secretion system, effectors, and an adhesin protein necessary to form attaching and effacing lesions on enterocytes. LEE activity is modulated by many signaling molecules. Under gluconeogenic conditions, the transcription factors, KdpE and Cra, activate expression of the LEE; however, under glycolytic conditions, expression of the LEE is decreased. In addition to glycolytic environments, high fucose concentrations also repress expression of the LEE. EHEC senses fucose through a histidine sensor kinase, FusK, which constitutes a two-component system with its cognate response regulator FusR. FusR represses expression of the LEE genes and prevents premature LEE expression before EHEC finds a target enterocyte. Once EHEC reaches the enterocyte and senses low concentrations of carbon sources, LEE expression is activated. Therefore, EHEC regulates expression of the LEE through the spatial and temporal sensing of sugars. In addition to sensing sugars, EHEC also uses oxygen to control expression of virulence factors. We have measured expression of the LEE under different oxygen concentrations under gluconeogenic conditions using qPCR and Western blots for secreted virulence proteins. These data enhance our understanding of how the host environment is sensed by EHEC to coordinate expression of virulence factors required for infection.

Identification of the Cellular Targets of Nitric Oxide in the Lyme Disease Spirochete Borrelia Burgdorferi

Author Block:

T. J. Bourret[1], F. C. Gherardini[2]; [1]Creighton Univ., Omaha, NE, [2]Rocky Mountain Lab., Hamilton, MT

Abstract Body:

Borrelia burgdorferi is the etiologic agent of Lyme disease and is transmitted to humans by ticks of the genus *Ixodes*. During its lifecycle in *Ixodes* ticks, *B. burgdorferi* encounters various environmental challenges including shifts in pH, temperature, and nutrient availability, as well as innate host defenses, including reactive oxygen species (ROS) and reactive nitrogen species (RNS). We show here that *I. scapularis* ticks produce RNS both in the salivary glands and midguts during feeding. Therefore, *B. burgdorferi* likely encounters a significant degree of nitrosative stress during its lifecycle in its arthropod host. Previously, we have shown that RNS produced *in vitro* are cytotoxic for *B. burgdorferi* due to the *S*-nitrosylation of cysteine thiols of both zinc-dependent and zinc-independent proteins. The aim of this study was to identify *B. burgdorferi* proteins that are subject to *S*-nitrosylation following the exposure of cells to sublethal concentrations of the NO donor diethylamine NONOate. In addition to our previously identified targets, the *Borrelia* oxidative stress regulator (BosR) and the neutrophil activating protein A (NapA), we have identified 29 additional proteins subject to *S*-nitrosylation at 1 or more cysteine residues using the biotin-switch technique combined with LC-MS sequencing analysis. Targets identified include enzymes involved in central metabolism, transcription/translation, DNA replication/repair, protein turnover, chaperones, transport, gene regulation, antioxidant defenses and cell division. Collectively, these data suggest that RNS may have a significant impact on the physiology, gene expression and overall virulence of *B. burgdorferi*.

Immunomoduratory Roles of Metformin in Murine *Legionella* Infection

Author Block:

C. Kajiwara, Y. Kusaka, S. Kimura, K. Tateda; Toho Univ., Tokyo, Japan

Abstract Body:

Background: *Legionella pneumophila* (*Lp*) is a facultative intracellular pathogen which replicates within macrophages and monocytes and finally causes a severe pneumonia known as Legionnaires' disease. Reactive oxygen species (ROS) production, autophagy network, shift to Th1 phenotype immune response were required for the effective control of intracellular pathogens. Metformin (MET: dimethylbiguanide) a prescribed drug for type 2 diabetes, has been reported to have anti-tuberculosis effect caused by increasing the ROS production via AMPK signaling. However, the all other pathogens were incompletely understood. Here we showed that MET inhibited the intracellular growth of *Lp*, restricted the progression of disease. **Methods:** *In vivo* studies were performed to determine the effect of MET on survival, bacterial counts, and expression of Th1 cytokines in the lungs after administration of *Lp*. A/J mice were received 5mg/ml MET or not dissolved in the drinking water 7 day before the infection, and then mice were i.t. administered with *Lp* (10^5 CFU). *In vitro* studies, bone marrow-derived macrophages (BMMs) and RAW264.7 cells treated with different doses of MET were infected with *Lp* (MOI: 0.1). ROS production was determined using a flow cytometer. Phosphorylated AMPK was detected by western blotting. **Results:** Significantly higher survival rates were observed in mice treated MET. No difference in bacterial burden was observed on day 2 and day 3 post challenge between control and MET groups, however, significantly lower bacterial number was observed in MET-treated mice on day5 (p=0.035). In MET-treated mice, sustained productions of Th1 cytokines, such as IFN-gamma and IL-12, were observed in the lungs during the first 3 days, whereas early reductions of these cytokines were noted in control mice (p=0.03 and p=0.0026, respectively). MET treatment inhibited the intracellular growth of *Lp* in a dose-dependent manner in BMMs and RAW264.7 cells. Interestingly, MET treatment reversed *Lp* -induced suppression of ROS synthesis within just 6 hours of drug exposure. **Conclusion:** The present data demonstrated that MET pretreatment significantly enhanced host defense systems against *Lp* infection, probably through Th1-directed responses and sustained ROS productions. Potential of MET as immunomodulators is warranted for future' investigation.

Effects of Neutrophil Depletion on M1/M2 Macrophage Polarization and Lethality of Mice with *Legionella pneumophila* Pneumonia

Author Block:

Y. Kusaka[1], C. kajiwara[2], K. Tateda[2]; [1]Tokyo Med. and Dental Univ., Tokyo, Japan, tokyo, Japan, [2]Toho Univ. Sch. of Med., Tokyo, Japan, tokyo, Japan

Abstract Body:

Background: *Legionella pneumophila* is an intracellular pathogen, which replicate mainly in macrophages, and cause severe pneumonia. Lately, the role of macrophage subtypes and polarization in M1/M2 are becoming a topic in host immunity. Previously, we have reported that neutrophil depletion by anti-Gr-1 antibody induced immunological shift from T1 to T2 lymphocyte subset, characterized by T1/T2 cytokine valances. In the present study, we analyzed effects of neutrophil depletion on M1/M2 macrophage polarization and lethality of mice with *L. pneumophila* pneumonia.**Methods**: We induced *L. pneumophila* pneumonia by intratracheal administration of bacteria. To deplete neutrophils, anti-Gr-1 antibody was administered intra-muscularly 1 day to 7 days before the infection. The infected lungs and blood were harvested and analyzed by FACS and real time PCR 2 and 3 days after the infection. M1 (CD86) and M2 surface marker (CD206) were used for FACS. M1 (iNOS) and M2 marker (Arg-1 or YM-1) were applied for real time PCR. The effect of neutrophil depletion on the survival of mice and bacterial number in the lungs was determined in the designated time points.**Results**: Anti-Gr1-treatment (1 day before the infection) induced the shift of macrophages subtypes from M1 to M2 in the lung and of peripheral blood, which was well associated with increase of mortality. On 3 days after the infection, CD 206 (M2) expression was 2-4 times higher, whereas CD86 (M1) expression decreased in neutrophil-depleted mice. Similarly, anti-Gr1-treatment induced an increase of Arg-1 (M2) and decrease of iNOS (M1). Interestingly, when anti-Gr1 treatment was performed 7 days before the infection, higher neutrophil number, lower bacterial burden and higher survival were observed in anti-Gr1-treated mice, which were well correlate with M1-directed immune responses in the lungs.**Conclusion**: The present data demonstrated that neutrophils accumulation and depletion affected M1/M2 macrophage polarization, which were associated with disease severity and survival of mice with *L. pneumophila* pneumonia.

Role of Airsr Two-component System in Survival of *Staphylococcus aureus* in Human Blood

Author Block:

J. Hall[1], **J. Yang**[1], H. Guo[2], Y. Ji[1]; [1]Univ. of Minnesota, St. Paul, MN, [2]Jilin Normal Univ., Siping, China

Abstract Body:

Staphylococcus aureus is a major pathogen and a common cause of hospital- and community-acquired infections. The pathogenicity of *S. aureus* partially relies on the coordinately-regulated expression of virulence factors that allow the bacterium to evade the host immune system or promote survival during infection. It has been demonstrated that AirSR(YhcSR) two-component system senses oxygen and modulates the expression of pathways responsible for dissimilatory nitrate reduction, cellular homeostasis and alternative sugar catabolism pathways. The role of AirSR in pathogenesis of *S. aureus* is still unclear. We conducted experiments to determine if AirSR contributes to the pathogenesis of *S. aureus* using an antisense RNA interference technology, an inducible overexpression system, and gene deletions. Depletion of AirSR by antisense RNA or deletion of the genes resulted in significant decrease in bacterial survival in human blood. Conversely, overexpression of AirR significantly promoted survival of *S. aureus* in blood. AirR promoted the secretion of virulence factors that inhibits opsonin-based phagocytosis. Move rover, we revealed that AirSR mediates the production of the cysteine endopeptidase and golden pigment. Our data demonstrated that the enhanced bacterial survival by AirR is attributable to the direct regulation of the biosynthesis of golden pigment, staphyloxanthin. Taken together, our data are the first to indicate that AirSR(YhcSR) is an important virulence regulator for modulating expression of antioxidants and survival within phagosomes. Our studies provide new insights into the molecular pathogenesis of *S. aureus.*

Characterization of the Putative Oxygen Sensor Dosp in *Listeria monocytogenes*

Author Block:

D. McClung[1], **S. White**[1], H. N. Jenkins[1], O. Paul[1], H. Abdelhamed[1], K. Pendarvis[2], J. R. Donaldson[1]; [1]Mississippi State Univ., Mississippi State, MS, [2]Univ. of Arizona, Tuscon, AZ

Abstract Body:

Background: The food-borne pathogen *Listeria monocytogenes* is the causative agent of the disease listeriosis and has a mortality rate of 20-30%. The ability of this pathogen to survive following exposure to stressors encountered throughout the gastrointestinal tract, such as acidic conditions, hypoxic conditions, and bile, is critical for the establishment of listeriosis. Recent work from our laboratory has indicated that certain strains of *L. monocytogenes* have an enhanced ability to resist stressors when exposure occurs under anaerobic conditions. It is hypothesized that the ability to sense oxygen availability can influence the stress response of *L. monocytogenes.* In this study, the involvement of the putative oxygen sensor DosP in intracellular replication was tested in relation to oxygen availability. **Methods:** The *dosP* gene was removed from the *L. monocytogenes* 4b strain F2365 and confirmed through gene sequencing. The impact of *dosP* on intracellular invasion was determined using human colon cell line C2BBe1, which is a clonal cell line of Caco-2. F2365 and the isogenic *dosP* mutant were cultured overnight in tryptic soy broth in either aerobic or anaerobic conditions. C2BBe1 cells were then infected with F2365 and the *dosP* mutant at a MOI of 1:100 for 1, 3, and 5 h. Cells were lysed and intracellular bacteria were plated to determine the intracellular survival. Proteome expression differences were also determined at 1 h using an LTQ mass spectrometer.**Results:** The data indicate that F2365 invaded uniformly at 0.03% between both aerobic and anaerobic conditions. However, the *dosP* mutant displayed variation between aerobic and anaerobic conditions, with an increased invasion potential of 0.1% under aerobic conditions compared to 0.03% under anaerobic conditions ($P < 0.007$). The intracellular proteomic expression of *dosP* in comparison to the wild type strain indicated that this protein is involved in regulation of various metabolic processes.**Conclusions:** These data indicate that DosP is involved in regulating intracellular invasion, but only in the presence of oxygen. Further research is needed to determine how the function of this protein in the progression of listeriosis.

***In Vivo* Fitness Adaptation of Colistin-resistant *Acinetobacter baumannii* Isolates to Oxidative Stress**

Author Block:

C. Jones[1], S. Singh[1], Y. Alamneh[1], L. Casella[2], R. Ernst[2], E. Lesho[1], P. Waterman[1], D. Zurawski[1]; [1]Walter Reed Army Inst. of Res., Silver Spring, MD, [2]Univ. of Maryland, Baltimore, MD

Abstract Body:

Acinetobacter baumannii is a Gram negative pathogen that acquires resistance to multiple antibiotics. Resistance of *A. baumannii* to colistin, an antibiotic of last resort, has been associated with decreased bacterial fitness. Considering the ubiquitous nature of *Acinetobacter*, we hypothesized that host-related stress placed selective pressure on *A. baumannii* to compensate for the fitness loss associated with acquisition of colistin resistance *in vivo*. For this study, we evaluated *A. baumannii* isolates serially obtained from the same patient. We show here that colistin-resistant (CR) isolates obtained shortly after *in vivo* exposure to colistin were outcompeted for growth in nutrient broth by the parental colistin-susceptible (CS) isolate. In contrast, CR isolates obtained during the latter stages of infection were able to compete for growth at a level similar to the CS isolate. This same trend was observed when colistin resistant isolates were competed for growth in the lungs of neutropenic mice after 48 hours. Decreased fitness was not associated with defects in membrane integrity or loss of LPS. Interestingly, these early CR strains exhibited increased susceptibility to hydrogen peroxide killing and decreased catalase production when compared to late CR and CS strains. Taken together, this data shows that early fitness loss of *A. baumannii* is associated with increased susceptibly to oxidative stress as a result of decreased catalase activity, and bacteria compensate for this loss during the course of infection by modulating catalase activity.

Pirin-like Proteins are Regulated by Oxidative Stress and Iron in *Bacteroides fragilis* and Involved in the Modulation of Central Energy Metabolism and Metronidazole Susceptibility

Author Block:

E. R. ROCHA[1], A. M. Gough[1], P. J. O'Bryan[2], T. R. Whitehead[2], C. J. Smith[1]; [1]East Carolina Univ. Brody Sch. of Med., Greenville, NC, [2]USDA Agricultural Res. Service, Peoria, IL

Abstract Body:

Bacteroides fragilis is the most frequent anaerobe isolated from human infections. Clinical isolates of *B. fragilis* are among the highest aerotolerant anaerobic bacteria. The oxidative stress response (OSR) in *B. fragilis* induces an array of genes enabling them to survive prolonged oxygen exposure in the aerobic extra-intestinal tissues until abscess formation provides a favourable anaerobic infectious environment. Among the OSR genes, two pirin-like homologues, Pirin 1 (Pir1) and Pirin 2 (Pir2) were found to be induced by oxygen exposure and iron availability determined by whole genome transcriptional analysis and real-time RT-PCR. Pirin-like proteins are iron-containing proteins of the cupin superfamily present in all kingdoms ranging from archae to humans. Real time RT-PCR also confirmed the up-regulation of the genes for *pir1* (7.2-fold) and *pir2* (9.5-fold) following exposure to oxygen compared to anaerobic culture controls. Under anaerobic low-iron conditions, *pir1* and *pir2* genes were induced approximately 7.6-fold and 9.3-fold respectively compared to the levels under iron-replete conditions in a Fur-independent manner. To investigate the role of Pir1 and Pir2 in *B. fragilis*, we have used bacterial two-hybrid system to show that Pir1 and Pir2 interacts with pyruvate:ferridoxin oxidoreductase (PFOR) and alcohol dehydrogenase (ADH). This suggests that pirin-like proteins possibly play a role in response to oxidative stress by interacting with enzymes involved in *B. fragilis* central energy metabolism. The *B. fragilis* strains constitutively expressing Pir1 and Pir2 had a strong reduction in lactate levels and increase in acetate and ethanol levels compared to parent strain under anaerobic conditions. Moreover, constitutively expressing Pir1 and Pir2 strains were more sensitive to the antibiotic metronidazole compared to parent strain possibly due to the protein-protein interactions between the PFOR and Pir-like proteins. Taken together, these findings show that there is a coordinate regulation of pirin proteins during OSR and iron limitation in *B. fragili*s that affects central energy metabolic fermentative pathways and antibiotic resistance.

A Novel Rtx Toxin Encoded on a Colv-type Plasmid Contributes to *Escherichia coli* Urinary Tract Infection

Author Block:

J. Saoud[1], S. Houle[1], A. Garénaux[1], F. J. Veyrier[1], F. Daigle[2], **C. M. Dozois**[1]; [1]INRS-Inst. Armand-Frappier, Laval, QC, Canada, [2]Université de Montréal, Montréal, QC, Canada

Abstract Body:

Extra-intestinal pathogenic *E. coli* (ExPEC) cause a variety of diseases in humans and animals. Some ExPEC strains contain large virulence plasmids such as Colicin V (ColV) or similar plasmids. The objective was to investigate ColV-type virulence plasmids for potential novel virulence factors. Plasmid extracts from ExPEC strains containing sequences associated with ColV plasmids were analyzed by pulsed field gel electrophoresis. Two strains found to contain very large plasmids were sent for whole genome sequencing. Sequencing results identified a large ColV-type plasmid (201 kb) in ExPEC strain QT598 containing a 7 kb gene cluster predicted to encode a RTX toxin distinct from previously characterized RTX toxins. Based on the plasmid origin of the system, it was named ***prtCABD*** (for **p**lasmid-encoded **R**TX **t**oxin). The ***prt*** genes were cloned in the pUCm-T vector in *E. coli* K-12 DH5-[[Unsupported Character - Symbol Font ]]. SDS-Page demonstrated a 91 kD protein corresponding to the ***prtA*** product secreted in the culture supernatant. Secretion was dependent on the ***prtCD*** genes as well as ***tolC*** which is required for secretion of other known RTX toxins. Tests were done to determine if the ***prt*** system conferred cytolytic and hemolytic activity. *E. coli* K-12 that secreted **PrtA** demonstrated cytolytic activity during interaction with human macrophage, human bladder epithelial, and chicken fibroblast cell lines. Further, colonies demonstrated hemolysis when grown on blood agar plates. However, wild-type strain QT598 did not demonstrate cytolytic or hemolytic activity in these assays. A ***prtCABD*** deletion mutation was constructed by allelic exchange in ExPEC strain QT598 and tested in a urinary tract model in CBA/J mice. In co-infection experiments, the WT strain outcompeted the mutant a mean of two-fold ($p=0.002$) in the kidneys and 1.5 times in the bladder ($p=0.008$). In single strain infections, the mutant demonstrated lower numbers in the kidneys ($p=0.04$), but there was no significant difference in colonization of the bladder. Taken together, results demonstrate that PrtCABD represents a new RTX toxin demonstrating hemolytic and cytolytic activity that may contribute to urinary tract colonization and virulence of certain ExPEC strains.

M. R. Wilson, C. A. Brotherton, L. Zha, E. P. Balskus; Harvard Univ., Cambridge, MA

Abstract Body:

Growing evidence suggests that the human gut microbiota influences the development and progression of several human cancers including colorectal cancer (CRC). One microbial metabolite strongly associated with cancer development is colibactin, a small-molecule genotoxin produced by commensal *E. coli* inhabiting the human gut. Colibactin-producing *E. coli* causes DNA double strand breaks *in vitro* and chromosomal instability *in vivo*. The increased abundance of *pks*$^+$ *E. coli* found in CRC patients and its ability to potentiate tumorigenesis in mice suggests that colibactin may promote the progression of CRC in humans. However, the mechanism by which colibactin exerts genotoxicity remains uncharacterized because it has not been isolated and its chemical structure is therefore unknown. Our previous characterization of the genotoxin's self-resistance mechanism revealed that colibactin is initially biosynthesized as a larger, inactive prodrug called precolibactin that is later cleaved by the periplasmic peptidase ClbP to release the active genotoxin, colibactin. Herein, we report the isolation and structural characterization of several candidate precolibactins from an *E. coli* mutant missing the peptidase ClbP. These isolation efforts revealed structural features likely present in colibactin such as a spirocyclopropane warhead and DNA intercalating elements, which suggests colibactin's mode of action may involve DNA alkylation.

The Carboxy Terminal Region Mediates Differential Cell Binding and Endocytosis between Variants of *Clostridium difficile* Toxin B

Author Block:

J. J. Hunt, J. L. Larabee, J. D. Ballard; Univ. of Oklahoma Hlth.Sci. Ctr., Oklahoma City, OK

Abstract Body:

The carboxy-terminal region of TcdB from ribotypes 012 and 027 share 88% amino acid identity. However, ribotype 027 exhibits comparatively enhanced toxicity and antibodies raised to the carboxy-terminal region of TcdB do not effectively cross neutralize toxin from dissimilar ribotypes. Several studies have indicated that there may be two distinct regions of TcdB which contribute to the binding and uptake of the toxin; residues 1500-1851 and 1851-2366 (CROP region), respectively. This suggested enhanced toxicity of $TcdB_{027}$ may be a result of structural changes in this carboxy-terminal region that affect binding of the toxin to its receptor. We sought to determine if the sequence differences proximal to the CROP region affect the clearance of toxin from the cell surface, or the localization of toxin to acidified endosomes. To this end, we tracked the binding, uptake and acidification of labeled toxin, or toxin fragments using flow cytometry and fluorescence microscopy. Our findings suggest the region proximal to the CROP domain, encompassed by residues 1653-1851, is responsible for the enhanced uptake of $TcdB_{027}$ and for proper localization of toxin to acidified endosomes.

A *Clostridium difficile* Tcdb-Derived Peptide That Blocks the Actions of Tcdb

Author Block:

J. L. Larabee, J. J. Hunt, J. D. Ballard; Univ. of Oklahoma Hlth.Sci. Ctr., Oklahoma city, OK

Abstract Body:

Clostridium difficile causes debilitating antibiotic associated diarrhea in hospital patients and is a pathogen in which alternatives to antibiotic therapies are necessitated. *C. difficile* infections (CDI) are dependent on the activities TcdB, which is an intracellular toxin whose sequence and toxicity varies among different strains of *C. difficile*. A therapy that targets TcdB along with variant forms of this toxin would be an ideal approach to counter CDI and could serve as an alternative to antibiotics. Here, we have discovered peptides derived from the carboxyl-terminal region of TcdB2 that inhibits the cytotoxicity of both TcdB1 (previously termed $TcdB_{012}$ and $TcdB_{Hist}$) and TcdB2 (previously termed $TcdB_{027}$ and $TcdB_{HV}$). This discovery built on our previous TcdB2 work that identified a region proximal to the carboxyl-terminal CROPS that mediates intramolecular interactions and protects neutralizing epitopes. In this region (1753-1851), specific sets of amino acids in TcdB2 (1773-1780 and 1791-1798) were identified that are necessary for supporting protein-protein interactions in TcdB. These studies also revealed that these carboxyl-terminal amino acids (1773-1780 and 1791-1798) influence the amino-terminal domains of TcdB. These data led to the prediction that this region proximal to the CROPS may be necessary for maintaining the overall tertiary structure of TcdB. To test this prediction, a series of peptides were designed spanning this region (1753-1851), and these peptides were screened to determine if any could disrupt inter-domain interactions and alter the activity of TcdB. As shown herein, four peptides with TcdB-inhibitory activity were uncovered in this screen and a detailed analysis of one peptide demonstrated a novel inhibitory mechanism. These studies demonstrate the principle of designing peptides that disrupt inter-domain interactions that are critical for the function of multidomain protein toxins such as TcdB.

TPL-2 Is a Key Regulator of Inflammation in *C. difficile* Infection

Author Block:

Y. Wang[1], S. Tzipori1[2], H. Feng[3], X. Sun[1]; [1]Morsani Sch. of Med., Univ. of South Florida, Tampa, FL, [2]Tufts Univ. Cummings Sch. of Vet. Med., North Grafton, MA, [3]Sch. of Med., Univ. of Maryland, Baltimore, Baltimore, MD

Abstract Body:

Background: Tumor progression locus 2 (TPL-2) has a critical role in the response to inflammatory signals as it functions as a serine/threonine kinase in the MAPK signal transduction cascade known to regulate both innate and adaptive immunity. The pro-inflammatory actions of TPL-2 are mediated by the activation of MAPKs, including ERK, c-Jun NH_2-termianl kinase (JNK) and p38 MAPK. Both *Clostridium difficile* TcdA and TcdB are capable of inducing pro-inflammatory cytokines including TNF-α and IL-1β, which are implicated in the development and progression of *C. difficile* infection (CDI). Previously, we showed that both TcdA and TcdB could activate p38 MAPK and ERK in both Raw264.7 macrophages and bone marrow-derived dendritic cells (BMDCs). We also found that TcdA-mediated TNF-α production in RAW264.7 cells was mediated through p38 MAP kinase and MEK/ERK signaling pathways. **Results:** In this study, we investigated whether TPL-2 has a central role in CDI severity by mediating the production of pro-inflammatory cytokines including TNF-α, IL-1β and IL-6. We report here that in BMDCs, a TPL2 specific inhibitor abolished TcdB-induced production of TNF- α, IL-1β and IL-6. We further demonstrated that TPL-2 inhibitor dramatically blocked TcdB-induced activation of ERK and p38 MAP kinase, but not of JNK in BMDCs. We confirmed these results using BMDCs extracted from TPL2-KO mice. Finally, we demonstrated TPL2-KO mice were significantly more resistant than wild-type mice to *C. difficile* infection in mice. **Conclusions:** Our data suggest TPL-2 represents a potential therapeutic target for CDI treatment.

Identification of Genetic Factors Required for *Serratia marcescens* Extracellular Phospholipase Activity

Author Block:

L. A. Bradford[1], M. T. Anderson[1], A. M. Machnacki[2], H. L. Mobley[1]; [1]Univ. of Michigan Med. Sch., Ann Arbor, MI, [2]Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Serratia marcescens, a widespread opportunistic pathogen, causes multiple types of infections, including urinary tract infections and bacteremia. *S. marcescens* infections are frequently healthcare-associated and are often difficult to treat due to a high incidence of antibiotic resistance. Although the mechanisms by which *S. marcescens* survives and replicates within the host remain poorly characterized, this organism is noted for secreting multiple candidate virulence factors. PhlA, an extracellular phospholipase A, is secreted by *S. marcescens* primarily during stationary phase and is predicted to have a role in pathogenesis. To identify *S. marcescens* factors that are involved in the production and secretion of PhlA, a genetic screen was conducted using a *mariner* transposon insertion library. Mutant isolates (>15,000) were screened for the loss of PhlA activity on agar plates containing phosphatidylcholine. In total, mutations were identified in six genes that resulted in the complete loss of extracellular phospholipase activity. Four genes (*cyaA, crp, fliJ and fliP)* encode products that are known to be involved in the transcriptional regulation and export of flagellar components, suggesting that a functional flagellar assembly apparatus is necessary for extracellular phospholipase activity. These results are consistent with previous studies demonstrating that *Serratia* PhlA is secreted through the flagellar transport apparatus when expressed exogenously in *Escherichia coli*. The two remaining genes identified in this screen, *helD and cysE,* are predicted to encode a DNA helicase and serine acetyltransferase, respectively, and have not been previously associated with phospholipase activity or flagellar assembly. The roles of the *helD* and *cysE* gene products in extracellular PhlA activity are currently under investigation. Together these results suggest a putative export pathway for the *S. marcescens* phospholipase exoenzyme and provide further insight into the genetic requirements for production and secretion of this putative virulence factor.

Serum Elicits a Massive Increase in Production, Secretion, and Release of *Bordetella* Adenylate Cyclase Toxin

Author Block:

L. Gonyar[1], M. Gray[1], C. Hoffman[1], F. Damron[2], E. Hewlett[1]; [1]Univ. of Virginia, Charlottesville, VA, [2]West Virginia Univ., Morgantown, WV

Abstract Body:

The number of cases of whooping cough, caused by *Bordetella pertussis*, is increasing in the United States and internationally despite high vaccine coverage. Adenylate cyclase toxin (ACT), a critical factor in establishing respiratory tract infection, intoxicates target cells by increasing levels of intracellular cyclic AMP, thereby inhibiting the immunologic response. ACT is almost exclusively surface-bound during *in vitro* growth. However, we have shown that newly secreted, not surface-associated, ACT is responsible for intoxication. Free ACT is present in nasal washes of infected baboons and humans, suggesting that it is secreted and released *in vivo.* Recently, we found that serum (fetal bovine or human) shifts the relative distribution of ACT to the supernate versus the bacterial cell surface and increases the amount up to 30-fold. This serum effect occurs in all nine *B. pertussis* and *B. bronchiseptica* strains tested, including a recent *B. pertussis* clinical isolate.Western blot analysis and J774A.1 cell cytotoxicity indicate that serum increases the amount of ACT protein, rather than just increasing enzyme activity; this is supported by inhibition of the serum effect by blocking protein synthesis with chloramphenicol. Transcript levels (by qRT-PCR) of genes that encode and secrete ACT as well as the BvgA/S two-component system, the master regulator of virulence in *Bordetella*, are unchanged +/- serum, suggesting regulation at the level of protein synthesis or stability. Other virulence determinants, specifically pertussis toxin and filamentous hemagglutinin, are also altered in response to serum, suggesting a global response resulting in coordinate expression of virulence factors. We are currently employing unbiased transcriptomic and proteomic methods to understand the regulatory mechanism/s of this striking serum effect and are working to identify the responsible component/s in serum. Our hypothesis is that these host-derived signaling molecules are present during establishment of infection in the respiratory tract and play a critical role in coordinating expression of essential virulence factors.

Pro-Inflammatory Peptidoglycan Fragment Release and Recycling in Pathogenic and Non-Pathogenic *Neisseria*

Author Block:

J. Chan, J. P. Dillard; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Neisseria gonorrhoeae (GC) and *Neisseria meningitidis* (MC) are human pathogens that cause gonorrhea and meningococcal meningitis respectively. Both GC and MC release a number of small peptidoglycan (PG) fragments, although GC releases higher levels of pro-inflammatory PG monomers compared to MC. Since MC colonizes the human nasopharynx as asymptomatic colonizers in 8-40% of the population, we hypothesize that MC limits the release of PG monomers to evade immune clearance in the nasopharynx. When applied to Fallopian tube (FT) explants, PG monomers induce the production of pro-inflammatory cytokines and cause the death and sloughing of ciliated FT cells. These PG fragments are generated in the periplasm during normal PG turnover to allow for cell growth and cell separation. Most of the PG fragments generated are efficiently taken back into the cytoplasm for recycling by AmpG, an inner membrane permease that specifically transports PG fragments from the periplasm to the cytoplasm. Substitutions of GC AmpG residues 273 and 385 from glycine to aspartate inactivate AmpG and result in a large increase in PG monomers released. Since MC is more efficient at recycling compared to GC, we hypothesize that more efficient recycling leads to lower levels of PG monomers released. When MC *ampG* is expressed in GC, we see a ~50% decrease in the amount of PG monomers released. Thus, we seek to determine the factors that modulate AmpG recycling efficiency. We found that AmpG residues 391, 398 and 402 modulate AmpG recycling efficiency through mechanisms we do not yet understand. Substitutions of these residues from the GC to the MC variants cause a ~50% decrease in the amount of PG monomers released. We also investigated PG fragment release and recycling in non-pathogenic *Neisseria*. *N. sicca* and *N. mucosa* are asymptomatic colonizers of the human nasopharynx that release a number of small PG fragments, although they release no PG dimers and lower amounts of PG monomers compared to GC. Both *N. sicca* and *N. mucosa* are more efficient at AmpG-mediated recycling compared to GC. However, expression of *ampG* from *N. sicca* and *N. mucosa* could not complement an *ampG* deletion in GC. We hypothesize that the AmpG sequence differences between *N. sicca*, *N. mucosa* and GC cause the non-pathogenic AmpG to be non- or less functional when expressed in GC, perhaps due to a loss of interaction with potential interaction partner(s).

Interaction between the Type III Effector VopO and GEF-H1 Activates the RhoA-ROCK Pathway

Author Block:

Hirotaka Hiyoshi, **T. Kodama**[1], S. Matsuda[2], K. Gotoh[2], Y. Akeda[2]; [1]RIMD, Osaka Univ., Suita, Osaka, Japan, [2]Osaka Univ., Suita, Osaka, Japan

Abstract Body:

Vibrio parahaemolyticus is an important pathogen that causes food-borne gastroenteritis in humans. The type III secretion system encoded on chromosome 2 (T3SS2) plays a critical role in the enterotoxic activity of *V. parahaemolyticus*. Previous studies have demonstrated that T3SS2 induces actin stress fibers in various epithelial cell lines during infection. This stress fiber formation is strongly related to pathogenicity, but the mechanisms that underlie T3SS2-dependent actin stress fiber formation and the main effector have not been elucidated. In this study, we identified VopO as a critical T3SS2 effector protein that activates the RhoA-ROCK pathway, which is essential pathway for the induction of the T3SS2-dependent stress fiber formation. We also determined that GEF-H1, a RhoA guanine nucleotide exchange factor (GEF), directly binds VopO and is necessary for T3SS2-dependent stress fiber formation. The GEF-H1-binding activity of VopO via an alpha helix region correlated well with its stress fiber-inducing capacity. Furthermore, we showed that VopO is involved in the T3SS2-dependent disruption of the epithelial barrier. Thus, VopO hijacks the RhoA-ROCK pathway in a different manner compared with previously reported bacterial toxins and effectors that modulate the Rho GTPase signaling pathway.

The *Legionella pneumophila M*ajor Metalloprotease is Translocated out of the Pathogen Vacuole in a Novel, Type II Secretion-Dependent Manner

Author Block:

H. K. Truchan, N. P. Cianciotto; Northwestern Univ., Chicago, IL

Abstract Body:

Legionella pneumophila is a Gram negative, facultative intracellular bacterium that is increasingly recognized as the cause of significant outbreaks of severe pneumonia, known as Legionnaires' disease. Reported cases of the disease have increased 279% since 2000. *L. pneumophila* is ubiquitous in the environment and exists in fresh waters primarily as a parasite of amoeboid protists. Human infection commonly occurs when aerosolized water droplets from contaminated water systems are inhaled. Within the infected mammalian host, the bacteria replicate in alveolar macrophages in a host-derived phagosome, termed the *Legionella*-containing vacuole (LCV). *L. pneumophila* protein secretion systems promote virulence and intracellular infection. Our lab has determined that the Lsp type II secretion (T2S) system secretes > 25 substrates including degradative enzymes as well as novel and eukaryotic-like proteins. The location of these T2S substrates during intracellular infection is unknown. Here, we show that the T2S substrate ProA, a major metalloprotease, is translocated outside the LCV and into the macrophage cytosol where it associates with the LCV membrane (LCVM). This translocation can be observed as early as 10 h post-infection (PI), approximately the midpoint of the intracellular life cycle. However, it can occur as early as 6 h PI if the protein is constitutively expressed from a plasmid. This indicates that translocation is dependent on the timing and level of ProA expression and that any other necessary factors for translocation are in place as early as 6 h PI. Our data also indicate that translocation and localization to the LCVM occur with different *L. pneumophila* strains and in both macrophages and amoebae. Moreover, we determined that ProA translocation is dependent on a functional T2S system and is not mediated by outer membrane vesicles. Thus, the protein is first secreted into the vacuolar lumen by the T2S system and is then subsequently trafficked into the macrophage cytosol via a novel mechanism. Taken together, these data represent the first evidence of a *L. pneumophila* T2S substrate in the infected host cell cytosol. We hypothesize that this localization allows ProA to target cytosolic host cell proteins and perform unique, unidentified functions.

***In Vitro* and *In Vivo* Characterization of *Stenotrophomonas maltophilia* Type II Secretion and Its Proteases**

Author Block:

A. L. DuMont, S. M. Karaba, M. Y. Nas, N. P. Cianciotto; Northwestern Univ., Chicago, IL

Abstract Body:

Respiratory and blood stream infections caused by the multi-drug resistant, opportunistic pathogen *Stenotrophomonas maltophilia* continue to rise in both the hospital and community setting. The mechanisms utilized by *S. maltophilia* to promote antibiotic resistance have been well characterized, but our understanding of *S. maltophilia* virulence remains limited. *S. maltophilia* pathogenicity in the murine lung is characterized by inflammation and tissue damage, but the virulence factors mediating these effects are not known. Our laboratory has attributed the Xps type II secretion (T2S) system, and primarily two Xps-secreted serine proteases, StmPr1 and StmPr2, to *S. maltophilia*-mediated rounding, detachment, and death of A549 human lung epithelial cells. StmPr1 and StmPr2 are also primarily responsible for the degradation of extracellular matrix (ECM) proteins and the pro-inflammatory cytokine interleukin 8 (IL-8). We now show that an additional secreted serine protease, StmPr3, contributes to Xps-mediated protease activities, by constructing a mutant lacking *stmPr1*, *stmPr2*, and *stmPr3* in the *S. maltophilia* strain K279a background. The triple protease mutant phenocopies an *xps* mutant in both A549 cell detachment and ECM protein degradation assays, indicating that StmPr1, StmPr2, and StmPr3 entirely account for these activities. StmPr1 contributes the most to strain K279a protease activities due to its high abundance in culture supernatant. Therefore, StmPr1 was overexpressed in the triple protease mutant and purified from culture supernatant using benzamidine sepharose. We found that purified StmPr1 was sufficient to cause rounding, detachment, and death of A549 cells. Lastly, to examine the role of Xps T2S *in vivo*, mice were infected intranasally with the *xps* mutant or the K279a wild type (WT) strain, and bacterial burden and histopathology was evaluated in the lungs at various time points. We found that mice infected with the *xps* mutant had lower bacterial burden in the lung at 8-12 hours post-infection compared to WT-infected mice, and that the *xps* mutant caused less lung tissue damage than the WT strain. Taken together, these data attribute the previously described Xps-dependent protease activities entirely to StmPr1, StmPr2, and StmPr3, and indicate that Xps T2S is important for *S. maltophilia* virulence.

***in Vitro* characterization Of The *pseudomonas Aeruginosa* cytotoxin Exou**

Author Block:

A. Zhang, J. L. Veesenmeyer, A. R. Hauser; Northwestern Univ., Chicago, IL

Abstract Body:

Background: *Pseudomonas aeruginosa* is a Gram-negative bacterium and an important cause of acute infections in immunocompromised patients. Its type III secretion system is a major virulence factor and allows effector proteins to directly translocate into targeted host cells. One such effector protein, ExoU, harbors a patatin-like phospholipase domain known to require two host cell factors for activation. Previous work from our lab and others has also shown that ExoU exhibits alpha-complementation. While certain truncation mutants of ExoU were non-cytotoxic inside mammalian cells, co-expression of these mutant proteins partially restored cell killing. However, the mechanism of this phenomenon is currently unknown. We hypothesize that oligomerization of ExoU mediates alpha-complementation and plays an important role in ExoU cytotoxicity. **Methods/Results:** Using lactate dehydrogenase release assays as a measure of cell death, we confirmed and extended previous results showing that transfection of HeLa cells with N- and C-terminal truncations of ExoU individually resulted in no cytotoxicity but that co-transfection of these variants resulted in partial cell death relative to wildtype ExoU. We also observed that differentially epitope-tagged ExoU could be co-immunoprecipiated when expressed in HeLa cells. Using size-exclusion chromatography and blue-native polyacrylamide gel electrophoresis, we showed that purified recombinant ExoU does not form oligomers. Co-incubation of ExoU with one of its host cofactors, ubiquitin, also did not result in oligomerization of ExoU. However, co-incubation with phosphatidylinositol 4,5-bisphosphate (PIP2), the lipid co-activator of ExoU, was sufficient to induce oligomerization *in vitro*. **Conclusion:** Our results suggest that ExoU oligomerizes *in vitro*. This oligomerization is mediated by one of the mammalian cofactors of ExoU required for phospholipase activation. In combination with the previous observation that regions of ExoU exhibit alpha-complementation, we believe this data indicates ExoU oligomerization may play a role in mediating cytotoxicity.

Bacterial Social Interactions and Their Impact on Virulence Evolution in *Pseudomonas aeruginosa*

Author Block:

E. T. Granato, R. Kümmerli; Univ. of Zurich, Zurich, Switzerland

Abstract Body:

Understanding the evolution of virulence in human pathogens is of great interdisciplinary interest. This is particularly true for opportunistic pathogens, such as *Pseudomonas aeruginosa*, that often cause chronic infections and undergo within-host evolution during disease progression. Here, we use experimental evolution to elucidate the interplay between virulence factor secretion, spatial structure and the evolution of virulence in the model host *Caenorhabditis elegans*. Virulence in bacterial infections is typically mediated through secreted metabolites that can be cooperatively shared across the bacterial collective within the host. Although many of these metabolites are essential to establish infections, populations of metabolite producers can potentially be invaded by "cheating" mutants, which no longer contribute but still benefit from the shareable metabolites produced by others. Consequently, conditions selecting for cheats should ultimately reduce virulence. We predict that the reduction of virulence due to cheat invasion should be particularly strong in spatially unstructured environments, where cheating mutants have been shown to enjoy highest selective advantage because secreted metabolites and cells mix readily. We tested this prediction by experimentally evolving *P. aeruginosa* in liquid (unstructured) and agar-based (structured) medium in the presence or absence of its host *C. elegans*. After the evolution, populations of bacteria that had evolved in a liquid environment displayed strongly decreased virulence towards *C. elegans*. Phenotypic screening revealed that many bacteria had lost the ability to produce pyoverdine, a secreted metabolite used to scavenge iron from the environment and the host tissue. This was exclusively observed in clones that evolved in liquid medium. Additionally, the production of pyocyanin, a secreted toxin important in killing *C. elegans*, dropped dramatically during evolution, and production levels were lowest among bacteria that evolved in liquid medium with the host. Altogether, our results support the idea that non-virulence factor producing cheats can invade populations of virulence-factor producing pathogens, thereby steering pathogen populations towards lower virulence. This opens possibilities for therapeutic interventions that aim at exploiting cooperator-cheat dynamics.

Prevalence of Exfoliative Toxin Gene Carriage in *Staphylococcus pseudintermedius* Isolates from Humans and Dogs

Author Block:

L. K. Bryan[1], M. Höök[2], C. A. Burnham[3], N. D. Cohen[1], S. D. Lawhon[1]; [1]Texas A&M Univ., College Station, TX, [2]Texas A&M Hlth.Sci. Ctr., Houston, TX, [3]Washington Univ. Sch. of Med., St. Louis, MO

Abstract Body:

Staphylococcus pseudintermedius is an emerging human pathogen and is the leading cause of canine pyoderma. Staphylococcal exfoliative exotoxins (ET) are thought to exacerbate skin infections in humans and dogs by cleaving cell-cell junction proteins in the superficial epidermis. Three ET genes have been identified in *S. pseudintermedius*: *siet*, *exi* and *expB*. An additional gene, *speta*, may encode an exotoxin. *S. pseudintermedius* isolates collected from healthy (n = 142) and diseased (n = 373) dogs and diseased humans (n = 45) were analyzed via polymerase chain reaction (PCR) to determine prevalence of ET gene carriage and to compare host factors and antimicrobial drug susceptibility in isolates with differing ET carriage profiles. Five ET genotypes occurred: only *speta; speta+siet; speta+siet+exi; speta+siet+expB;* and, *speta+siet+exi+expB*. The *exi* and *expB* genes always occurred in conjunction with *speta* and *siet*. The *speta+siet+exi+expB* and only *speta* genotypes were not observed in human-derived isolates. The majority of isolates from humans and dogs were *speta+siet* (84 and 71%, respectively), followed by *speta+siet+expB* (11 and 15%, respectively) and *speta+siet+exi* (5 and 12%, respectively). The proportions of ET genotypes were compared via Pearson's chi-squared and Fisher's exact tests. The *exi* gene was more prevalent (P = 0.0038) among canine pyoderma isolates than among dogs with other diseases. The odds of surgical site infection were also 3-fold greater (P = 0.0316) for isolates that were *speta+siet* than for other genotypes. The *speta+siet+expB* genotype had a higher probability of being methicillin-sensitive (P = 0.003) than resistant in dogs. There was no significant difference between ET gene carriage and overall health status in dogs or between ET genotype and methicillin resistance in the human-derived isolates.

Loss of the MFS Transporters *fptg* and *fptb* Delays Host Exit of *Francisella tularensis*

Author Block:

P. Balzano, E. Barry; Univ. of Maryland, Baltimore, Baltimore, MD

Abstract Body:

Background: *Francisella tularensis (Ft*) is a Gram negative facultative intracellular coccobacillus, and is the causative agent of the human disease tularemia. Due to past weaponization, a small inoculum through the aerosol route, a mortality rate approaching 50%, and no licensed vaccine, *Ft* is a major bioterror concern. After the bioterror attacks of 9/11, there are renewed vaccine development efforts for this select agent pathogen.**Methods:** The targeted deletion of selected genes in *Ft* to produce candidate live attenuated vaccine strains is a strategy we have pursued. We produced 2 vaccine candidates containing single deletions of major facilitator superfamily (MFS) transporters, *fptG,* and *fptB,* an isoleucine transporter, in the Type A strain Schu S4. Based on the attenuating capacity of these deletions in the LVS background, we hypothesized that deletion of either transporter would alter the intracellular replication rate of the virulent Type A strain. Gentamicin protection assays that eliminate or allow cell-to-cell spread in human THP-1 macrophage-like cells were utilized to identify intracellular replication patterns for both mutants.**Results:** Gentamicin protection assays that eliminate cell-to-cell spread yielded intracellular bacterial counts of up to ten times more bacteria for both mutants than wild type at 24 hours post infection. Further invasion assays allowing cell-to-cell spread indicated that SchuS4Δ*fptG* replicated at the same rate as wildtype, but appeared delayed in escaping the host cell compared to the wildtype. SchuS4Δ*fptB* similarly appeared delayed in exiting the host cell, but also exhibited a significant growth defect, doubling 1 to 1.5 fewer times in the first 24 hours. SchuS4Δ*fptG* and SchuS4Δ*fptB* are the first MFS transporter knockouts to be created in the virulent Schu S4 strain.**Conclusions:** The mutants' phenotype of delayed cellular escape is novel in *Ft* and suggests a more active role in host escape played by the bacteria beyond simply overwhelming the host with high levels of replication. These strains are valuable tools to study the intracellular lifecycle of *Ft* and may be candidates for a live attenuated vaccine.

Cold Shock Domain Family Proteins Promote Survival in Human Macrophages and Expression of Key Virulence Genes in Listeria Monocytogenes

Author Block:

Athmanya Eshwar, Roger Stephan, **T. Tasara**; Univ. of Zurich, Zurich, Switzerland

Abstract Body:

Background: The intracellular foodborne pathogen *Listeria monocytogenes* causes rare but serious disease (listeriosis) and high rates of mortality among those with diminished immunity. Cold shock domain protein family (Csps) are small global gene expression regulating proteins with diverse cellular functions that promote virulence and stress responses in bacteria. In this study the contribution of Csps to the intracellular survival and growth of *L. monocytogenes* within human macrophages and in modulating the expression of key virulence factors was investigated. **Methods:** A series of in-frame *csp* deletion mutants of *L. monocytogenes* EGDe that lack all (Δ*cspABD*) or retain one (Δ*cspBD*, Δ*cspAD* and Δ*cspAB*) of the three Csp encoding genes (*cspA*, *cspB* and *cspD*) in this bacterium and their parental wild type strain were compared. The strains were evaluated with respect to human macrophage infection and expression of genes encoding key virulence factors using qRT-PCR and WB analysis.**Results:** The capacity of *L. monocytogenes* to infect human macrophages and express key virulence genes was significantly compromised without Csp functions and in presence of individual Csp variants. A mutant incapable of producing Csps (Δ*cspABD*) was most severely impaired compared to the parental wild type EGDe strain in its ability to survive and grow in THP-1 human macrophages, as well as in the expression of genes encoding the PrfA, LLO, Mpl, ActA, PlcA and PlcB virulence factors. Analysis of mutants harboring individual Csp variants revealed that there is both functional redundancy and hierachy (CspB [Δ*cspAD*] >CspD [Δ*cspAB*] >CspA [Δ*cspBD*]) in the role of the individual Csps in promoting intramacrophage survival and growth, and modulating the expression of key virulence genes in this bacterium.**Conclusion:** These studies have shown that Csp-dependent gene expression regulation is crucial for the full expression of *L. monocytogenes* virulence in human host macrophages. Csp functional contribution to *L. monocytogenes* virulence responses is associated with their role in promoting the gene expression of key virulence factors in this bacterium.

Comparative Analysis of Genes Involved in Intracellular Survival of *Salmonella enterica* serovar Typhimurium in Murine Macrophages and *Dictyostelium discoideum*

Author Block:

A. Sabag[1], S. Riquelme[1], C. Valenzuela[1], C. Bravo[1], V. Barra[1], J. Ugalde[2], R. Canals[3], P. Desai[3], V. Martinez[1], F. Chavez[1], M. McClelland[3], S. A. Alvarez[1], C. A. Santiviago[1]; [1]Univ. de Chile, Santiago, Chile, [2]Univ. del Desarrollo, Santiago, Chile, [3]Univ. of California Irvine, Irvine, CA

Abstract Body:

Pathogenicity of *Salmonella* is associated to its ability to evade the innate immune system of the host. For instance, *S.* Typhimurium can replicate within phagocytic cells such as macrophages, neutrophils and dendritic cells of many hosts, causing illnesses ranging from gastrointestinal infections to severe systemic diseases. In the environment, *Salmonella* can interact with other types of professional phagocytic cells, such as free-living amoebae. Amoebas like *Dictyostelium discoideum* ingest bacteria as a source of nutrients and may provide a niche for bacterial replication similar to the intra-macrophage environment. Therefore, we hypothesized that *S.* Typhimurium survival in macrophages and amoebas involves a common set of genes. To identify these genes, we infected RAW264.7 murine macrophages and *D. discoideum* AX4 with a single-gene deletion mutant collection of *S.* Typhimurium 14028s (SGD-K) using a MOI of 10 and 100 bacteria/cell, respectively. After co-incubation, extracellular bacteria were killed by gentamicin treatment. Intracellular bacteria were recovered at different times of infection (0 and 6 h), grown in LB broth for 12 h, collected by centrifugation and treated for genomic DNA extraction, amplification and massive parallel sequencing. A preliminary analysis of the sequencing data allowed us to identify 591 and 963 mutants under negative selection in RAW264.7 murine macrophages and *D. discoideum*, respectively. The comparison of both datasets showed that 281 mutants undergo negative selection in both models. Most of these mutants are associated to genes involved in carbohydrate and amino acid metabolism and transport, energy production, cell motility, virulence and signal transduction. Altogether, our data indicate that *S.* Typhimurium requires a common set of genes to survive within murine macrophages and *D. discoideum.*

Phenotypic and Genomic Characterisation of Atypical *Salmonella enterica* Serovars Linked to Multistate Foodborne Outbreaks in the United States

Author Block:

D. Hurley[1], M. Hoffmann[2], M. Martins[1], E. W. Brown[2], S. Fanning[1]; [1]Univ. Coll. Dublin, Dublin, Ireland, [2]U.S. Food and Drug Admin., College Park, MD

Abstract Body:

Salmonella Typhimurium pathogenicity has traditionally been studied using *in vivo* models and murine cell lines. Few studies using human models for other non-typhoidal serovars have been described, despite their epidemiological importance in several outbreaks. In this study, 10 atypical serovars cultured from multistate U.S. outbreaks were characterised by infection biology techniques and comparative sequence analyses.**Objective:** To study the genomes and virulence of 10 foodborne outbreak isolates.Intracellular survival was assessed *ex vivo* in murine RAW 264.7 and human THP-1 macrophages. Release of 17 proinflammatory cytokine and chemokine proteins from infected macrophages was quantified. *S*. Typhimurium ST4/74 was used as a reference strain. Whole genome sequencing was performed using the Illumina MiSeq platform. Complete genome sequences for isolates of particular interest were determined on the Pacific Biosciences RS II.In THP-1 macrophages, *S*. Tennessee CFSAN001387 exhibited a 1-Log_{10} reduction between 2 and 168 hours post infection, demonstrating an increased ability to persist within these cells. Similarly, *S*. Weltevreden CFSAN001415 exhibited a >2-Log_{10} reduction, surviving for 7 days compared to the reference strain which was unrecoverable. Many isolates stimulated increased cytokine (IL1B, TNF) and chemokine (CCL2, CCL3/4) release compared to the reference strain.*S*. Anatum CFSAN003959 has an altered SPI-2 SsaB protein being associated with an attenuated infection phenotype thereby rendering the isolate unrecoverable early during infection. SptP, a T3SS effector, was altered in *S*. Heidelberg CFSAN002063 contributing to consistently higher levels of TNF production compared to other isolates. The SseBCD translocon is integral to the intracellular survival of *Salmonella* and in *S*. Tennessee CFSAN001387 this was highly altered when compared to *S*. Typhimurium ST4/74. This may explain the ability of the former isolate to survive within RAW 264.7 and THP-1 macrophages.These phenotypic and genomic analyses extend our understanding of the bacterial host-cell response and have identified virulence factors that further explain the ability of these isolates to cause outbreaks.

Characterization of a Temperature Sensitive Aminoacyl-tRNA Synthetase C*hlamydia trachomatis* Mutant

Author Block:

J. A. Brothwell[1], B. D. Stein[2], D. E. Nelson[1]; [1]Indiana Univ. Sch. of Med., Indianapolis, IN, [2]Indiana Univ., Bloomington, IN

Abstract Body:

Chlamydia spp. are obligate intracellular pathogens that are causative agents of blinding trachoma, sexually transmitted infections, and pneumonia in humans. These pathogens exhibit a characteristic biphasic developmental cycle, which is initiated by endocytosis of the infectious, non-metabolically active elementary body (EB). The EB then differentiates into a non-infectious, metabolically active reticulate body (RB) inside a parasitophorous vacuole, termed the inclusion. What signals EB to RB differentiation, and whether this program is dependent on activation of specific biosynthetic pathways, is unknown. Genes that control chlamydial differentiation would be predicted to be essential, so we screened a library of ethyl methanesulfonate (EMS)-mutagenized *C. trachomatis* isolates for temperature sensitive (TS) mutants that could survive in HeLa cells at the permissive temperature of 37°C, but which could not survive at the non-permissive temperature of 40°C. We identified a TS mutant that had a nonsense mutation in *gltX* (*gltX*^{Q487*}). GltX is required for aminoacylating both tRNA^{Glu} and tRNA^{Gln}, which suggested that protein synthesis of this mutant was impeded at 40°C. Previous studies have shown that *de novo C. trachomatis* protein synthesis initiates within 15 minutes of infection. However, *gltX*^{Q487*} growth could be rescued as late as 18 hours post infection, suggesting that this mutant might survive in a persistent state. *gltX*^{Q487*} exhibited normal growth kinetics at 37°C, but viable progeny and genome copy number of this strain were severely reduced at 40°C. Examination of inclusion ultrastructure at 40°C showed that *gltX*^{Q487*} was able to differentiate into RB and undergo at least 1 cellular division. These results contrast those from another persistence model where tryptophan is depleted via interferon-γ treatment. Our results suggests that *C. trachomatis* responds differently to the loss of aminoacylated tRNAs than it does to the absence of individual amino acids and that EB may contain a complete set of aminoacylated tRNAs that facilitate their early protein synthesis and differentiation.

Characterization of Virulence-Factor Deletion Strains of *Burkholderia mallei* That Are Attenuated in Inhalational Glanders Challenge in Mice

Author Block:

J. A. Bozue[1], **R. Toothman**[1], S. Chaudhury[2], K. Amemiya[1], J. Chua[1], C. Cote[1], J. Dankmeyer[1], C. Klimco[1], C. Wilhelmsen[1], J. Raymond[1], N. Zavaljevski[3], J. Reifman[2], A. Wallqvist[3]; [1]USAMRIID, Fort Detrick, MD, [2]BHSAI, Frederick, MD, [3]BHSAI, Fort Detrick, MD

Abstract Body:

Background: *Burkholderia mallei* is a highly infectious intracellular pathogen and the causative agent of glanders. It is a zoonotic disease primarily of horses, donkeys and mules and endemic to Africa, Asia, and Middle East. Human infection, although rare, is almost always fatal without antibiotic intervention. *B. mallei* has been observed to have a high level of antibiotic resistance, and there is currently no approved vaccine. **Methods:** Previously, we identified novel virulence factor genes *BMAA0553* (encoding a putative serine/threonine phosphatase) and *BMAA0728* (encoding for a hypothetical protein in gene cluster of components of a type 6 secretion system). In the present study, we used recombinant allelic exchange to successfully construct deletion mutants of *BMAA0553* and *BMAA0728*. **Results:** We showed that both deletions completely abrogated virulence at doses of >100 times the LD_{50} of the wild-type *B. mallei* strain. Subsequent *in vitro* work confirmed significantly decreased intracellular growth for both mutant strains and delayed multinuclear giant cell formation in macrophages. The Δ*BMAA0553* strain also demonstrated a defect in actin active-based motility during macrophage infection. In addition, we explored the use of Δ*BMAA0728* as a candidate live-attenuated vaccine. We vaccinated mice with two aerosolized immunizations of Δ*BMAA0728* and observed a 21-day survival rate of 67% after a high-dose aerosolized challenge with the wild-type ATCC 23344 strain, compared to a 0% survival rate for unvaccinated mice. However, the bacteria were still able to establish a chronic infection in the surviving mice. Measurement of antibody, cellular, and cytokine responses of vaccinated mice showed a modest IgG response and prolonged elevation of pro-inflammatory cytokines. **Conclusions:** These data do demonstrate the essential role of these proteins as virulence factors in both intracellular replication in macrophages and for aerosolized glanders of mice.

Two Stable Variants of *Burkholderia pseudomallei* Strain MSHR5848 Express Broadly Divergent *In Vitro* Phenotypes Associated with Their Virulence Differences

Author Block:

A. Shea, R. Bernhards, D. Rozak, M. Wolcott, D. Fetterer, J. Ladner, G. Palacios, J. Bozue, P. Worsham, C. Cote, **S. Welkos**; U S A M R I I D, Frederick, MD

Abstract Body:

Burkholderia pseudomallei (*Bp*) is the HHS Tier 1 cause of melioidosis, a disease with manifestations ranging from acute and rapidly fatal to protracted and chronic. *Bp* is highly infectious by aerosol, can cause disease with nonspecific symptoms, and is resistant to many antibiotics. Effective treatment is long and difficult, and no vaccine exists. The development of more effective countermeasures requires a better understanding of disease pathogenesis. Unlike many *Bp* strains which exhibit random variability in traits such as colony morphology, DOD Unified Culture Collection stock of BURK178 (derived from *Bp* strain MSHR5848) exhibited two distinct and fairly stable colony morphologies on sheep blood agar plates: a smooth pale yellow colony (type 1) and a flat dry white colony (type 2). Passage of these variant colonies under standard lab conditions produced cultures composed nearly exclusively of the single corresponding type 1 or type 2 morphotype. However both types could switch to the other one at frequencies which varied with the growth condition. The two MSHR5848 variants were extensively characterized to demonstrate the broadly divergent phenotypes associated with them, including differences in microscopic and colony morphologies, metabolic and antimicrobial sensitivities, and macrophage infectivity and mouse virulence. Here we present whole genome sequence comparisons which show that the variants are genetically relatively conserved. However, Biolog Phenotype Microarray^{TM} (PM) profiles revealed distinct differences between the variants. Type 1 was more metabolically active than type 2 and used a greater number of diverse carbon sources. Nevertheless, type 2 was more active in the presence of sulfur sources. The type 2 variant also had a higher response when the peptide nitrogen sources included aromatic amino acids. Also, type 1 grew more rapidly *in vitro* than type 2, and whereas type 1 cells stained with the fluorescent DNA-binding dye propidium iodide, type 2 failed to stain. These distinct phenotypic and *in vivo* differences shown by the BURK178 morphotypes may provide a model for identifying *in vitro* markers associated with different infection stages and help guide vaccine and therapeutic development.

Metabolic Evidence That Biotin Acts as a Nutritional Virulence Factor in the Intracellular Pathogen *Francisella novicida*

Author Block:

Y. Feng; Zhejiang Univ., Hangzhou, China

Abstract Body:

Background: Biotin (Vitamin H), the sulfur-containing enzyme cofactor, is an essential micronutrient for three domains of life. The physiological function of biotin requires biotin protein ligase activity in order to attach the coenzyme to its cognate proteins, which are enzymes involved in central metabolism. The model intracellular pathogen *Francisella novicida* is unusual in that it encodes two putative biotin protein ligases rather than the usual single enzyme. *F. novicida* BirA has a ligase domain as well as an N-terminal DNA-binding regulatory domain, similar to the prototypical BirA protein in *E. coli*. However, the second ligase, which we name BplA, lacks the N-terminal DNA binding motif. It has been unclear why a bacterium would encode these two disparate biotin protein ligases, since *F. novicida* contains only a single biotinylated protein. **Methods:** Integrative approaches were employed that included *in vivo* complementation, enzyme assays, biochemical & biophysical experiments, and cell lines/mice-based infection trials.**Results:** BirA and BplA both were found to be functional biotin protein ligases, but BplA is a much more efficient enzyme. BirA (but not BplA) regulated transcription of the biotin synthetic operon. Expression of *bplA* (but not *birA*) increased significantly during *F. novicida* infection of macrophages. BplA (but not BirA) was required for bacterial replication within macrophages as well as in mice. During infection, BplA seems primarily employed to maximizethe efficiency of biotin utilization without limiting the expression of biotin biosynthetic genes, representing a novel adaptation strategy that may also be used by other intracellular pathogens. We also determined a new gene *bioJ* (*FTN_0818*) with the involvement of biotin metabolism and required for *F. novicida* virulence. Genetic and biochemical analyses suggested that BioJ is functionally equivalent to the paradigm pimeloyl-ACP methyl ester carboxyl-esterase, BioH. Structure-guided mapping combined with site-directed mutagenesis revealed that the BioJ catalytic triad consists of Ser151, Asp248 and His278, all of which are essential for activity and virulence. **Conclusion:** To the best of our knowledge, the data above represents further evidence linking biotin synthesis to bacterial virulence in *F. novicida*.

Pyomelanin Production Contributes to Virulence in the Human Pathogen *Burkholderia cenocepacia* j2315

Author Block:

S. C. Fankhauser[1], M. L. Ivey[2], J. B. Goldberg[2]; [1]Oxford Coll. of Emory Univ., Oxford, GA, [2]Emory Univ. Sch. of Med., Atlanta, GA

Abstract Body:

Those living with chronic granulomatous disease (CGD) or cystic fibrosis (CF) are extremely susceptible to lung infections. Patients with CGD are particularly prone to repeat bacterial infections, and prophylactic antibiotic therapy is necessary to limit bacterial infection and the severity of bacterial infection. For CF patients, about 80-90% of these patients eventually succumb to respiratory failure due to chronic bacterial infection. Of the select pathogens that infect both these patient populations, *Burkholderia cenocepacia* is especially troublesome due to its inherent antibiotic resistance, capacity to survive in supposedly sterile hospital solutions, and ability to spread between patients. Effective prevention and treatment measures are critical to reducing the devastating impact that *B. cenocepacia* has on patients. Yet, developing these measures requires a clear understanding of the mechanisms that contribute to *B. cenocepacia* infection. We investigated whether the conspicuous phenotype of pigment production, which has been observed in several different *B. cenocepacia* strains, could impact virulence as it has been shown to in other bacterial pathogens. Specifically we investigated the role of the pigment pyomelanin, which is produced by the human pathogen *B. cenocepacia* J2315. Compared to a non-pyomelanin producing isogenic mutant, J2315 is significantly more virulent in an intratrachael mouse infection model. We have determined that pyomelanin produced by J2315 protects against the reactive nitrogen species nitric oxide, and that this increased protection may contribute to the increased virulence we observed in the mouse infections. Together our studies have identified and begun to characterize a novel virulence factor in *B. cenocepacia* and these findings may be applicable to other bacterial pathogens that produce pyomelanin.

***Legionella pneumophila* Philadelphia-1 p45 IntegrativeGenomic Element Plays a Role in Virulence**

Author Block:

L. M. Christensen, S. L. G. Cirillo, M. Strain, S. Parikh, J. D. Cirillo; Texas A&M Hlth.Sci. Ctr., Bryan, TX

Abstract Body:

As ubiquitous environmental organisms, *Legionella spp.* are capable of living in a vast array of environmental conditions. This adaptability is made possible, in part, due to the notorious plasticity of their genomes, composed of several mobile elements capable of horizontal transfer. One such site-specific integrative element, p45, is found more commonly in pathogenic strains of *Legionella,* which are capable of causing a potentially fatal form of pneumonia called Legionnaires' disease. In order to examine the role of the p45 element in virulence, we utilized *Legionella pneumophila* Philadelphia-1 (Phil-1), a clinical isolate containing p45. In addition to Lp01, a laboratory strain derived from Phil-1, which displays attenuated virulence-related phenotypes and is lacking p45. We complemented Lp01 with p45 using natural conjugation from Phil-1. The resulting p45-containing Lp01 strain ($Lp01^{p45}$), Phil-1, and Lp01 were compared for their ability to survive in the presence of sodium, infect macrophages, and cause disease in guinea pigs. Results from these experiments suggest that p45 plays a key role in *Legionella* virulence, as the $Lp01^{p45}$ strain phenotypes mimicked those of Phil-1 throughout the above assays. These exciting results warrant further study of the p45 element in order to identify the specific components and mechanisms involved.

Lipid Differentiation of *Burkholderia pseudomallei* Following *In Vitro* Infection

Author Block:

R. Dermody, D. Fletcher, T. Eckstein; Colorado State Univ., Fort Collins, CO

Abstract Body:

This experiment was conducted in order to assess the lipid makeup of *Burkholderia pseudomallei* following an *in vitro* infection. *B. pseudomallei* is a bacterium associated with the human disease melioidosis. It is observed to be similar to *Mycobacterium avium* subspecies *paratuberculosis* (MAP), which causes Johne's disease in ruminants. My work aims to further existing research that associates species similar to MAP with receptor-mediated lipid transformation. Such research has been limited in the past due to the highly infective quality of subject bacteria. The method I used began with the infection of live macrophages with a culture of *B. pseudomallei* ΔpurM (Bp82), an adenine and thiamine auxotrophic form of *B. pseudomallei* . After infection, the macrophages were lysed in order to expel the bacteria. Lipid was extracted from the bacteria post-infection by a process of lyophilization and Folsch washing. Bp82 from broth that did not undergo infection was submitted to the same lipid extraction protocol. The lipid produced from both samples was run through a series of thin layer chromatography systems of varying polarity and also submitted for LC/TOF-MS, using the Sartain Method in both positive and negative modes. My analysis has suggested that infection increases the abundance and intensity of lipids possessing greater polarity. These results may be used to improve knowledge of the composition of *B. pseudomallei* for use in vaccination and treatment.

***In vivo* Clearance and Tissue Distribution of Purified *Burkholderia pseudomallei* Capsular Polysaccharide in a Murine Model**

Author Block:

A. Kirosingh[1], T. Nualnoi[1], S. G. Pandit[1], P. Thorkildson[1], D. E. Reed[1], P. J. Brett[2], M. N. Burtnick[2], D. P. AuCoin[1]; [1]Univ. of Nevada Sch. of Med., Reno, NV, [2]Univ. of South Alabama, Mobile, AL

Abstract Body:

A Gram-negative bacillus, *Burkholderia pseudomallei,* is the causative agent of melioidosis. Melioidosis has been a significant source of morbidity and mortality in northern Australia and Southeast Asia. The "gold standard" for melioidosis diagnosis is bacterial isolation, which takes several days to complete. The delay in diagnosis can lead to administration of inappropriate antibiotics, which could result in death. *B. pseudomallei* produces a capsular polysaccharide (CPS), an outer membrane component important for the virulence of the bacterium, that has been identified as a biomarker during infection. Rapid lateral flow immunoassays using monoclonal antibodies specific to CPS have been developed and used in endemic areas for clinical testing. However, the tissue distribution and clearance of CPS is not well understood. In this study, mice were injected with purified CPS intravenously and concentrations of CPS found in the serum, urine, and major organs (kidneys, lungs, liver and spleen) were monitored using antigen capture ELISAs at different time intervals. The tissue distribution study indicates no accumulation of CPS in the major organs. Our results also show that CPS is predominantly eliminated in urine. Western blot analysis revealed that CPS was not degraded during excretion; how a large molecule like CPS was eliminated from the kidneys is still being investigated. Interestingly, 3D computer modeling reveals that CPS has a rod-like shape with a small diameter that could allow it to flow through the glomerulus. To calculate CPS clearance from serum, the data were fit to four different exponential decay models and corrected Akaike Information Criterion was used for the model selection. The results show that CPS was eliminated with a relatively short half-life of 3 to 4.5 hours. The rapid clearance of CPS through urine indicates that the presence of CPS in the serum and urine correlates with active melioidosis infection and provides a marker to monitor the effectiveness of treatment of melioidosis.

***ehrlichia Chaffeensis* Survival Is Linked To Trp120 Dependent Activation Of The Notch Pathway**

Author Block:

T. Lina; Univ. of Texas Med. Branch, Galveston, TX

Abstract Body:

Background: *Ehrlichia chaffeensis* is an obligately intracellular bacterium responsible for the life-threatening tick transmitted zoonosis, human monocytotropic ehrlichiosis (HME). *E. chaffeensis* exhibits tropism for mononuclear phagocytes and survives through a strategy of subverting innate immune defenses, but the mechanisms are unknown. We have shown *E. chaffeensis* type 1 secreted tandem repeat protein (TRP) effectors such as TRP120 promote intracellular survival through diverse pathogen-host protein interactions, including Notch signaling pathway components such as the metalloprotease, ADAM17. In our current study, we demonstrate *E. chaffeensis*, via the TRP120 effector, activates canonical Notch signaling pathway to promote intracellular survival. **Methods:** Human Notch PCR array, RT-PCR, western blot and immunofluorescence microscope (IFA) was used to study the expression of different Notch components and target genes during *E. chaffeensis* infection and TRP120 stimulation. Pharmacological inhibitors and siRNA transfection was used to inhibit different Notch signaling components and ehrlichial infection was determined by either Diff-Quick staining, or by determining the *dsb* copy number using qPCR.**Results:** Nuclear translocation of the transcriptionally active Notch intracellular domain (NICD) occurs in response to *E. chaffeensis*, resulting in upregulation of Notch signaling pathway components and target genes *notch1*, *adam17*, *hes* and *hey*. Significant differences in canonical Notch signaling gene expression levels (>40%) were observed during early and late phase of infection, indicating activation of the Notch pathway. We linked Notch pathway activation specifically to the TRP120 effector, which interacts with ADAM17 of the Notch receptor complex, and results in Notch signaling activation. Pharmacological inhibitors and siRNAs against γ-secretase enzyme, RBPjκ, Notch1 and ADAM17, confirmed that Notch signaling is required for ehrlichial survival.**Conclusions:** This investigation reveals a novel mechanism whereby *E. chaffeensis* exploits Notch pathway to promote intracellular survival. Detailed studies to identify the role of Notch signaling in inhibition of innate immune responses during ehrlichial infections are currently in progress.

***Salmonella enterica* Serovar Typhi Fails to Elicit Apoptosis and T_h1/M1 Polarization in Infected Human Macrophages and Humanized Mice**

Author Block:

L. A. Singletary, J. E. Karlinsey, S. J. Libby, T. A. Stepien, F. C. Fang; Univ. of Washington, Seattle, WA

Abstract Body:

The human pathogen *Salmonella enterica* serovar Typhi (*S.* Typhi) causes more than 20 million infections and 200,000 deaths each year. Typhoid fever is characterized by a prolonged incubation period, invasive disease and a high rate of asymptomatic carriage following disease resolution. Survival within macrophages is an essential feature of *Salmonella* pathogenesis. Accordingly, a T_H1 helper T cell response and M1 macrophage activation in response to T_H1 cytokines are important for host resistance to intracellular pathogens such as *Salmonella*. Individuals with congenital or acquired immunodeficiencies resulting in impaired T_H1 immunity, such as HIV/AIDS, are more susceptible to invasive nontyphoidal salmonellosis but not typhoid fever, suggesting that nontyphoidal serovars and *S.* Typhi may differ in their propensity to initiate a T_H1 immune response in infected hosts. We have found that *S.* Typhi persists within cultured human THP-1 macrophages, in contrast to nontyphoidal serovar *S.* Typhimurium, by avoiding the induction of apoptosis. *S.* Typhimurium induces apoptosis via caspase-3 cleavage, in a process dependent upon the *Salmonella* pathogenicity island 2 (SPI2) type III secretion system and the ADP-ribosylating toxin SpvB encoded on the *Salmonella* virulence plasmid pSLT. Furthermore, *S.* Typhi-infected macrophages exhibit reduced activation of the M1 transcription factor STAT1 and the T_H1 cytokine IL-12 in comparison to *S.* Typhimurium-infected macrophages. A hu-SRC-SCID humanized mouse model mirrors these results, with *S.* Typhi-infected mice displaying significantly lower levels of serum IL-12 and IFN-γ in comparison to *S.* Typhimurium-infected mice. The T_H1 polarization of human macrophages by *S.* Typhimurium is also SPI2-dependent. However, in contrast to apoptosis, T_H1 polarization is not dependent on SpvB, and the specific effector(s) required for STAT1 activation have not been identified. Collectively these observations suggest that the ability of *S.* Typhi to cause persistent infection may result from avoidance of a host T_H1/M1 response.

Stimulation of Large Vesicle Formation for Increased Secretion of *Salmonella* Typhimurium Effector Proteins by Overproduction of MdsABC Efflux Pump

Author Block:

Y-H. Kim, G. Kim; Catholic Univ. of Daegu Sch. of Med., Daegu, Korea, Republic of

Abstract Body:

Background: *Salmonella* Typhimurium is a primary pathogen which causes gastrointestinal disease worldwide in both humans and animals.**Methods:** In this study, we showed that overproduction of *Salmonella*-specific MdsABC efflux pump promoted the early secretion of some virulence factors and an inner membrane phospholipid, 1-palmitoyl-2-stearoyl-phosphatidylserine (PSPS), by a non-classical pathway.**Results:** This activity was related with reduced growth rate of the cells in exponential phase, but not in stationary phase. MdsABC overproduction stimulated formation of large vesicles containing DNA by changing the bacterial cell shape from confocal images. Exogenous overexpression of MdsABC and external addition of PSPS had a similar effect on the expression of high levels of *sipABCD* genes in intracellular bacteria. The two treatments on infection of mouse macrophage RAW 264.7 cells by *S.* Typhimurium influenced a complex regulatory network of the master transcription factors, HilACD. Transmission electron microscopy images showed some evidence of the pathological role of PSPS in infected cells with the loss of pseudopods.**Conclusions:** We suggest that an apoptotic mechanism of bacterial death induced by overexpression of MdsABC and hypersecretion of PSPS may contribute to pathogenesis of *S.* Typhimurium infection which stimulates cytoskeleton remodeling by the delivery of bacterial effector proteins into the host cell cytosol.

Characterizing Human Norovirus Binding to Bacterial Ligands

Author Block:

E. Almand, M. Moore, L-A. Jaykus; North Carolina State Univ., Raleigh, NC

Abstract Body:

Human norovirus is a leading cause of gastroenteritis. Recent studies suggest bacteria may influence infectivity, persistence and replication of this virus, yet bacteria-virus interactions are poorly understood. It is possible that gastrointestinal bacteria interact with human norovirus because they possess histo-blood group-like antigens (HBGAs; putative norovirus receptor), but these glycoproteins remain uncharacterized. This study sought to elucidate the bacterial moieties mediating norovirus binding. The binding of seven bacterial species (2 ATCC strains; 5 natural fecal isolates) to multiple norovirus strains was investigated. Isolates were grown in minimal media and lysed. Whole bacterial lysates were examined via Western blot for three characteristics (1) HBGA activity (AB, B, H, Le^a, Le^b, and Le^y); (2) lectin binding; and (3) human norovirus binding (GI.6, GII.1, GII.4, and GII. 17). Bacterial moieties were isolated and further assessed using LC-MS. Bacteria-virus binding was visualized via TEM to determine localization. Bacteria-norovirus interactions varied by bacteria type and virus strain. The TEM results showed that GII.4 norovirus bound select Gram-positive and Gram-negative bacteria on outer membrane and/or protruding pili structures. The seven bacterial species screened possessed varying HBGA residues with differences in (1) overall activity (Western blot relative density 0-0.79); (2) HBGA banding patterns (1 vs 7 reactive glycoproteins); and (3) glycoprotein size (13-140 kDa). To probe for specific sugars rather than the entire HBGA (i.e. N-acetyl-galactosamine, L-fucose), lectin-binding assays were done. This analysis yielded a relative density range of 0-10.68, 3-5 glycoproteins per lectin, and sizes from 17-140kDa. A virus overlay demonstrated that common human norovirus binding residues were located in association with glycoproteins of 140, 35, and 17 kDa size. A 35 kDa glycoprotein isolated from a fecally-derived *Bacillus* strain bound all four of the human norovirus strains tested, including GII.1, which currently lacks a known cellular receptor. This is one of the first studies investigating bacteria-norovirus interactions and delving into the bacterial residues responsible for those interactions. Future studies will focus on molecular binding mechanisms and how interactions with bacteria impact norovirus infection and/or environmental behavior.

Hepatitis B Spliced Protein (HBSP) Promotes Hepatoma Cell Migration and Invasion by Triggering Epithelial-Mesenchymal Transition (EMT) via Interaction with Transforming Growth Factor β-1-Induced Transcript 1 Protein (TGFβ1|1)

Author Block:

W. Chen, J-g. Huang, F-f. Liang, X-j. Lin, X. Lin; Fujian Med. Univ., Fuzhou, China

Abstract Body:

Background: The hepatitis B spliced protein (HBSP) encoded by a 2.2 kb singly spliced defective HBV genome (spliced between positions 2447 nt and 489 nt) was a ubiquitously detectable protein in the liver tissues and the serum from patients with hepatitis B (Günther *et al.*, 1997; Soussan *et al.*, 2000). In our previous study, the HBSP protein was shown to be an oncogenic protein enhancing the invasion and migration of hepatoma cells via interaction with a lysosomal cysteine protease Cathepsin B (CTSB) through activation of MMP9 and uPA and activation of MAPKs and Akt signaling pathway(Chen *et al.*, 2012). **Methods:** The cytoplasmic yeast two-hybrid screening was applied to identify the intracellular proteins interacting with HBSP, followed with protein interaction identification by in *vitro* GST pull-down and *in vivo* co-immunoprecipitation. TGFβ1-induced EMT and cell invasion and migration were explored by knockdown of TGFβ1I1 by siRNA in hepatoma cell lines expressing HBSP. **Results:** TGFβ1I1 was identified as an intracellular interacting partner of HBSP by the cytoplasmic yeast two-hybrid screening, and the interaction of TGFβ1I1-HBSP was further confirmed by in *vitro* GST pull-down and *in vivo* co-immunoprecipitation. The influences as well as the mechanisms of HBSP-TGFβ1I1 interaction on the TGFβ1-induced EMT and cell invasion and migration were also explored by knockdown of TGFβ1I1 by siRNA in hepatoma cell lines expressing HBSP. It was demonstrated that interaction of HBSP and TGFβ1I1 promote the EMT by activating TGFβ1/Smad signaling pathway, and ultimately resulted in the enhanced invasion and migration of hepatoma cells. **Conclusions:** Our findings highlight new molecular mechanisms for HBSP-induced HCC progression.

Identifying an Astrovirus Receptor

Author Block:

C. Johnson[1], S. Marvin[2], S. Schultz-Cherry[2]; [1]Rhodes Coll., Memphis, TN, [2]St. Jude Children's Res. Hosp., Memphis, TN

Abstract Body:

Infectious diarrhea is a leading cause of morbidity and mortality worldwide. Astroviruses (HAstV), small, non-enveloped positive RNA viruses, are a leading cause of diarrhea in children, the elderly, and the immunocompromised, making it a major public health problem. HAstV are extremely prevalent; around 90% of the population 9 years and older have antibodies against HAstV. However, little is known about HAstV pathogenesis including the cellular receptor(s) required for infections of enterocytes. For any intracellular pathogen, bacterial or viral, the first step in causing disease is to establish an infection by binding to cellular receptor(s) on the host cell. However, to date, no receptor for any astrovirus species has been identified. Our goal is to identify candidate astrovirus receptor(s). Crystal structure of the putative receptor binding domain of the HAstV capsid (outer coat) protein suggests the use of carbohydrates as receptors. Yet treatment of the human colorectal adenocarcinoma cell line (Caco-2), one of the few cells that productively support HAstV replication, with chondroitinase, heparinase, and neuraminidase does not impact viral replication or binding. We also explored the role of carbohydrate moieties through binding to an extensive panel of distinct carbohydrates in collaboration with the Carbohydrate consortium. This also failed to identify a candidate receptor. As an alternative approach, we found that baby hamster kidney (BHK), while able to produce progeny virions upon transfection of HAstV mRNA, do not support infection suggesting they lack surface molecule(s) important for HAstV binding and/or entry. This was confirmed by flow cytometry. Thus, BHK cells were transfected with a Caco-2 cDNA library and cells supporting HAstV infection are being sorted. The transfected gene will then be identified by PCR, followed by single cell suspension, which will allow us to sequence the plasmid containing the cDNA. Preliminary results suggest that the top 0.5% fluorescent cells to be sequenced must be captured and grown in bacteria three times in order to amplify the amount of potential receptor DNA. If successful, our studies will identify astrovirus receptor(s), important information for understanding viral pathogenesis and targeted drug design.

The Surface Protein (MPER) of HIV on the Q-Beta Coliphage as a Vaccine Candidate

Author Block:

T. Egbo[1], **C. Sanders**[1], B. K. Robertson[1], G. W. Nchinda[2], A. Bopda Waffo[1]; [1]Alabama State Univ., Montgomery, AL, [2]The Chantal Biya Intl. Reference Ctr. for Res. onn the Prevention and Maanagement of HIV/AIDS, Yaounde-Messa, Cameroon

Abstract Body:

Background: HIV infection has been of great concern to public health with the recent estimate of 1,201,100 infected with the virus in the United States, according to the Center for Disease Control (CDC). There is a critical need for a safe and effective vaccine to protect the uninfected. Studies have shown that the membrane proximal external region (MPER) represents one of the most neutralizing targets for HIV vaccine research. The tryptophan-rich proximal region of its external membrane mediates binding entry of the virion.**Methods:** We anticipate that the MPER, which is also a neutralizing site of the transmembrane protein, will serve as an antigen to stimulate antibodies once presented on the Q-Beta phage. The novel Q-Beta phage was preferred because it can be easily separated, purified with genotype and phenotype linkages. We designed the PCR template using oligos that represent a specific region of the 50 amino acid MPER. We performed the cloning by fusing the MPER motif in frame at the end of the A1 gene.**Results:** The recombinant plasmid was used to transform *E. coli* HB101. The binding of the phage exposing MPER motif with antibody was achieved using Western blot and ELISA, and the analysis of antibodies from HIV patients with Q-BetaMPER using ELISA.**Conclusions:** Further analysis will be done using dot blot, and EM to further reveal the fusion of the MPER-A1 on the surface of Q-Beta, and also, animal immunization with Q-BetaMPER. In all, we anticipate that the Q-BetaMPER will serve as a vaccine candidate and as a standard for vaccine efficacy.

Baculovirus Fibroblast Growth Factors are Mitogens for Both Insect and Mammalian Cells

Author Block:

C. M. Finnerty, D. R. Meier; Winona State Univ., Winona, MN

Abstract Body:

Nearly all baculoviruses encode homologues of fibroblast growth factor (FGF). Previous studies on baculovirus FGFs have demonstrated that these cytokines have chemotactic activity and may be involved in tissue remodeling during pathogenesis.The purpose of this study was to investigate baculovirus FGFs for mitogenic activity in both insect and mammalian cells. Our data demonstrate that recombinant baculovirus FGF induces cell proliferation in both the Sf9 and NIH/3T3 cell lines.The FGF genes from *Autographa californica* MNPV and *Choristoneura fumiferana* MNPV were separately cloned and expressed in *E. coli* to generate maltose-binding protein-FGF fusion proteins denoted as Ac6 and Cf6. A recombinant MBP-LacZ protein served as a negative control. All the MBP fusion proteins were purified via affinity chromatography using an amylose resin. For some experiments, an untagged recombinant FGF from *Cf*MNPV(denoted as "Cf8") was tested as well. The purified proteins were applied to monolayers of Sf9 and NIH/3T3 cells in 96-well plates. Human FGF-1 and FGF-2 served as positive controls. In addition, the effect of the FGF receptor inhibitor PD173074 in combination with these FGFs was also tested. Cell densities were measured using Dojindo CCK-8 reagent, and the absorbance was determined using a plate reader.At concentrations of 5 and 10 ng/ml, the Ac6 and Cf6 MBP-FGFs produced cell densities that were significantly elevated compared to the negative control protein in both the Sf9 and NIH/3T3 cell lines. Cf8 also showed mitogenic activity at the 10 ng/ml concentration. FGFR inhibitor had an inhibitory effect on cell proliferation, though this may have been a result of cell mortality due to high inhibitor concentrations. Representative data are shown. These data demonstrate that baculovirus FGF functions as a mitogen *in vitro*.

Ebola Virus Makona Infection Induces Early Transcriptome Changes *In Vivo* within T Cells and Monocytes

Author Block:

A. Rivera[1], K. Versteeg[2], T. Geisbert[2], I. Messaoudi[1]; [1]Univ. of California, Riverside, Riverside, CA, [2]Univ. of Texas Med. Branch, Galveston, TX

Abstract Body:

The high virulence of Ebola virus (EBOV) is largely attributed to the ability of this virus to: 1) subvert host innate immune pathways thereby preventing priming of an adaptive immune response; and 2) induce an uncontrolled inflammatory response that results in increased vascular permeability and lymphocyte death. However, mechanisms underlying filovirus-induced immune dysregulation are not well understood. Most studies investigating the interactions between filoviruses and the innate immune system have been mostly carried out in vitro. Genomic studies in nonhuman primates have provided us with insight into the global host response networks, but have not examined gene expression within specific immune cell subsets. Therefore, the impact of filovirus infection within specific immune cell subsets *in vivo* remains poorly understood. To address this knowledge gap, we used RNA-seq to uncover EBOV-induced changes in gene expression profiles of T cells and monocytes. Magnetic microbeads were used to purify CD2+ T cells and CD14+ monocytes from PBMCs isolated at 0, 1 and 2 days post infection (dpi) from 2 cynomolgus macaques infected with EBOV Makona strain. Purity was assessed by flow cytometry. RNA transcripts were mapped to both host as well as viral genome to determine viral replication and we detected differentially expressed genes (DEGs) at 2 dpi. Most DEGs were downregulated in T cells and functional enrichment of downregulated genes mapped to gene ontology processes related to transcriptional regulation and innate immune response. A larger number of DEGs was detected in monocytes at 2 dpi. Upregulated genes enriched to monocyte effector functions, notably regulation of tumor necrosis factor and nitric oxide biosynthesis and inflammatory response, suggesting that EBOV infection does stimulate inflammatory changes in monocytes in vivo. Moreover down-regulated genes within monocytes include genes associated with Type I IFN signaling, which is consistent with previous reports of EBOV-induced IFN suppression. Our data sheds light on the role of T cells and monocytes in EBOV pathogenesis.

Characterization of Ebola Virus Makona Pathogenesis in Cynomolgus Macaques

Author Block:

K. Versteeg[1], A. Rivera[2], I. Messaoudi[3], T. Geisbert[1]; [1]Univ. of Texas Med. Branch, Galveston, TX, [2]Univ. of California, Riverside, Riverside, CA, [3]Univ. of California, Riverside, Riverside, CT

Abstract Body:

Ebola virus (EBOV) continues to cause significant morbidity and mortality as highlighted by the recent outbreak in West Africa. With no FDA approved vaccines or therapeutics, understanding the mechanisms that contribute to EBOV pathogenesis and identifying therapeutic strategies are of utmost importance. However, much of what is known about the immune response to EBOV infection has been acquired through in vitro observations or studies focused on host response in the final stages of disease. To better understand the development of an immune response to EBOV, we used flow cytometry and RNA-seq to uncover infection-induced changes in phenotype and gene expression profiles of whole blood (WB) and peripheral blood mononuclear cells (PBMCs) isolated from cynomolgus macaques infected with wild type EBOV-Makona. A total of 10 macaques were inoculated with a 1000 PFU Makona. Blood was collected on days 0, 1, 2, 3, 4 and 6 post infection. Following infection, viral titers were detected 3 days post infection (dpi) and continued to increase throughout infection. Hematological analysis and serum biochemistry showed less dramatic clinical changes previously reported in macaques infected with previous strains. Flow cytometry revealed an increase of monocytes at 2-3 dpi and an increase in frequency of nonclassical monocytes at 4 and 6 dpi. RNA transcripts were mapped to both host as well as viral genome and we detected differentially expressed genes (DEGs) and viral transcripts at 3dpi, which steadily increased as infection progressed. There were distinct changes in gene expression in WB compared to PBMC, suggesting EBOV infections results in significant changes in RNA transcripts in cells present only in WB. Functional enrichment analysis showed that upregulated genes in WB and PBMC at 3-6dpi, which consisted largely of interferon stimulated genes, mapped to Defense Response and Immune System Process, suggesting that IFN response may correlate with disease progression. Downregulated genes in WB at 6 dpi enriched to Regulation of Vascular Permeability and Lymphocyte activation. Overall, our data give insight into the pathogenesis of the new EBOV strain.

Transcriptional Signatures Associated with Influenza A/H1n1-Specific Igg Memory-Like B Cell Response in Older Individuals

Author Block:

I. Haralambieva, I. Ovsyannikova, R. Kennedy, M. Zimmermann, K. Goergen, D. Grill, A. Oberg, G. Poland; Mayo Clinic, Rochester, MN

Abstract Body:

Background. Studies suggest that the predominantly recall-based humoral immune response to influenza A/H1N1 originates from activated memory B cells. The aim of this study was to identify blood transcriptional signatures associated with memory B cell immune response measures following influenza vaccination.**Methods**. We used pre- and post-vaccination (Day 3, early and Day 28, late) mRNA-Seq transcriptional profiling on PBMC samples from 159 subjects (50-74 years old) following the receipt of trivalent influenza vaccine containing the A/California/7/2009/H1N1-like virus, penalized-regression methods, and network modeling to identify associations of genes and pathways with peak (Day 28 - Day 0) memory B cell ELISPOT response after vaccination.**Results**. We observed significant genes (p-value range 7.92E-08 to 0.00018, q-value range 0.00019 to 0.039) with baseline, early or late gene expression associated with peak memory B cell response after influenza vaccination. Genes and genesets exhibiting significant associations with memory B cell response included metabolic (cholesterol and lipid metabolism-related), cell migration/adhesion, MAP kinase and NF-kB cell signaling (chemokine/cytokine signaling), and transcriptional regulation signatures correlated with the development of memory B cell response after influenza vaccination.**Conclusion**. Through an unbiased transcriptome-wide profiling approach, our study identified gene signatures of memory B cell response following influenza vaccination, highlighting the underappreciated role of metabolic changes (among the other immune function-related events) in the regulation of vaccine-induced immune memory.

Micro-RNAs in Regulation of Early Host Responses to Hepatitis E Virus Infection

Author Block:

S. K. Panda, S. P. k. Varma, P. Joshi, D. Paliwal; All India Inst. of Med. Sci., New Delhi, India

Abstract Body:

Hepatitis E virus (HEV) is a 7.2kb plus stranded RNA virus and a globally prevalent cause of acute hepatitis. Micro-RNAs (miRNA) are known to regulate host responses in various viral infections. The role of host miRNAs in Hepatitis E virus (HEV) infection is unexplored.We performed mRNA and miRNA profiling of HEV replicon transfected Huh7 cells in biological duplicates at two time points (24hours and 72hours) post transfection and compared with time matched non-transfected controls on next generation sequencing platform (Ion Proton). Data analysis was done using Partek Flow and Partek Genomics Suite and genes with ≥ 2 fold change and p-value <0.05 were considered differentially expressed (DE). Correlations within DE mRNA-miRNA datasets were determined by Pearson's correlation coefficient using 7 databases for *in silico* miRNA target prediction (TargetScan v7.0, miRDB, miRANDA, PITA, microcosm, miRTarbase and miRecords). Biologically relevant 7 miRNAs and 8 mRNAs were validated by real time PCR.A total of 148 and 121 mRNAs were differentially expressed in 24hr and 72hr samples respectively with 15 common genes. A high representation of interferon and immune related genes was observed. While 27 miRNAs were found to be DE at 24 hrs, there were only 3 altered miRNAs in the 72hr samples. *In-silico* correlation analysis in the 24hr samples predicted 46 miRNA–mRNA pairs ($-0.95 > \rho > +0.95$, p-value < 0.05) formed by 10 miRNAs, of which 2 pairs exhibited inverse fold changes and the rest 44 showed a positive correlation. The miRNAs identified were hsa-miR-556-3p, hsa-miR-921, hsa-miR-142-3p, hsa-miR-520c-3p, hsa-miR-202-5p, hsa-miR-6844, hsa-miR-1302, hsa-miR-4798-3p, hsa-miR-548ap-3p and hsa-miR-190a-5p, all of which were upregulated (fold-change range +2 to +4.12) while the upregulated target mRNAs represented diverse pathways such as interferon (IFI6, IFIT5, IRF9), chemokines (CCL5, CXCL10), apoptosis (BIRC3, XAF1) and anti-viral responses (TRIM22, RSAD2, OASL). Downregulated target mRNAs represented cell surface molecules (HS6ST3, DENND1C).We report that micro-RNAs may regulate early host responses in HEV infection. However, with time this miRNA mediated regulation appears to be curtailed.

Ebp1 Negatively Regulates Hepatitis C Virus Replication and Translation

Author Block:

P. Mishra, U. Dixit, A. Pandey, V. N. Pandey; Rutgers Sch. of BioMed. Sci., Newark, NJ

Abstract Body:

HCV infection is the leading cause of chronic liver diseases, which, with time, progress to liver cirrhosis, hepatocellular carcinoma, and liver failure. The majority of liver failure patients requiring liver transplant have a history of CHC. The HCV genome is a positive-stranded RNA with conserved and highly structured untranslated 5' and 3’ terminal regions having multiple regulatory elements that are essential for viral replication and translation. Recently, using a novel affinity probe, we have captured the replicating HCV RNA *in situ* and identified 83 cell factors that are associated with the viral RNA. ErbB3binding protein (Ebp1) was one of them. Here we show that the shorter isoform that lacks the N terminal 54 amino acid sequences is capable of inhibiting HCV replication. We found that overexpression of p42 could inhibit viral protein expression level whereas p48 had no significant effect. By transient expression of each isoform in Ebp1 kd cells, we found that p42 could restore the effect of knock down whereas p48 could not. We confirmed these observations through exogenously added which p42 inhibits in vitro endogenous HCV replication in cell free replicative lysate. We saw inverse correlation between p42 and HCV replication. Ebp1 immunoprecipitate also co-precipitated HCV non structural proteins, NS5A and NS5B. Thus through knock down and overexpression studies we have identified that the shorter isoform negatively regulates HCV replication. p42 functions as host defense molecule (protein) by suppressing viral protein expression. Although the clear mechanism through which the shorter isoform mediates its effect is still to be deciphered, our findings suggest that p42 may have therapeutic role in HCV infection.

Endocrine-disrupting Chemicals Affect Mosquito Development and Mosquito-borne Virus Replication

Author Block:

J. R. Anderson, A. M. Tingle; Radford Univ., Radford, VA

Abstract Body:

Endocrine-disrupting chemicals (EDCs) are found in numerous manmade products and can interfere with normal metabolic processes regulated by hormones and other steroids. Numerous studies have described these detrimental effects in both vertebrate and invertebrate organisms. Our goal was to determine whether EDCs can affect the likelihood of mosquito-borne virus transmission. Toward that end, we exposed developing mosquito larvae to varying concentrations of three EDCs and assessed larval mortality and emergent adult body size and fecundity. All EDCs resulted in significant increases in mortality, while the effects on body size varied by EDC, sex, and species. Females exposed to EDCs deposited more eggs than those reared in water only. We also investigated the effects of EDC exposure on virus replication in cultured cells. EDC exposure tended to result in higher levels of virus replication during the first cell passage, while replication was hindered early in the second passage before again producing more virus. Mosquitoes breeding in plastic or other containers made with EDCs may alter the dynamics of mosquito-borne virus transmission. Important factors in such transmission include the number of mosquitoes in a population, the size of the mosquito, and the ability of the virus to replicate in the mosquito. Our results indicate that all three of these factors can be affected, although how they affect transmission vary based on the EDC and the mosquito studied. Future studies will aim to investigate whether EDCs can directly affect the likelihood of virus transmission by mosquitoes.

Roles of Catecholamines of Enterovirus 71 Infection in Mice Models

Author Block:

S-M. Wang; Natl. Cheng Kung Univ. and Hosp., Tainan, Taiwan

Abstract Body:

Background: Enterovirus 71 (EV71) has been recognized as highly neurotropic and associated with a diverse range of neurological complications. Brainstem encephalitis (BE) was the cardinal feature of EV71 CNS involvement. The plasma concentration of norepinephrine (NE) in EV71-infected patients with autonomic nervous system (ANS) dysregulation and pulmonary edema (PE) were significantly higher than those with BE.**Methods:**Seven-day-old ICR mice were infected with LD_{50} of MP4 by intraperitoneal injection. Norepinephrine, epinephrine, and dopamine were detected by a commercial immunoassay kit (Labor Diagnostika Nord GmbH & Co. KG, Germany). 6-hydroxydopamine (6-OHDA) (Sigma, St. Louis, Mo., USA) was dissolved in sterile saline containing 0.01% (w/v) ascorbic acid (vehicle) and was injected intraperitoneally (i.p.) at a concentration of 25-100 μg/g. Control mice received i.p. injections of an equal volume of vehicle alone.**Results:** Norepinephrine and epinephrin increased at day 2 post infection by EV71. The survival rate of infected mice treated with 6-OHDA (78%) was higher than vehicle-treated mice (50%). The clinical scores of EV71-infected and treated with 6-OHDA group were markedly lower than EV71-infected and vehicle group at day 8 to 12 post infection. The plasma levels of norepinephrine and epinephrine in EV71-infected and treated with 6-OHDA group were significantly lower than EV71-infected and vehicle group.**Conclusions:** EV71 infection induced sympathetic over activity plays an important role in the pathogenesis of neurological complications.

Sybr Green I Real-Time Pcr versus Taqman Probe Techniques in Detection of Hepatitis C Virus RNA in Infected Patients

Author Block:

D. E. Metwally[1], A. N. Amer[2], H. M. Mostafa[1], G. E. A. El Sawaf[1], O. A. Kader[1]; [1]Med. Res. Inst. - Alexandria Univ., Alexandria, Egypt, [2]Faculty of Pharmacy - Univ. of Pharous, Alexandria, Egypt

Abstract Body:

Background: The prevalence of hepatitis C virus (HCV) is highest in Egypt compared to other countries. Nucleic acid amplification test (NAT) may provide an accurate and sensitive method to quantify HCV- RNA . The routine use of NAT as a screening tool for blood products or in clinical practice is quite limited due to its cost. The aim of this study was to compare two common RT-PCR methods, TaqMan probe technique and SYBR Green method in quantitative detection of HCV RNA for diagnosis and follow up of HCV patients. **Methods:** Blood samples were collected from 220 HCV patients and subjected to RNA extraction using a QIAamp viral RNA kit (QIAGEN, Valencia, CA), determination of viral load by TaqMan technique using HCV Qiagen kit (Artus) and detection of HCV RNA by SYBR Green technique using Sigma-Fermentas one step RT PCR kit. Real-time PCR was performed by using the Mx3000P Stratagene real-time PCR system. The PCR products were identified by melting curve analysis. Standard sera with known concentrations of HCV RNA were used to validate our assays.**Results:** Among the recruited 220 HCV patients, 154 (70%) were HCV-RNA positive by both the techniques, while 24 (10.9%) were negative by both techniques. On the other hand, 40 (18.2%) cases were HCV RNA positive only by SYBR Green technique, and 2 (0.9%) only by TaqMan probe technique. Forty (20.4%) of the 196 chronic HCV cases were HCV-RNA positive by SYBR Green but negative by TaqMan probe technique.**Conclusions:** SYBR Green assay is perfectly suitable for both routine clinical use and large-scale screening of donated blood due to its good level of sensitivity and specificity, ease of handling, relatively low cost, and low contamination rate.

Persistent Nontypeable *H. influenzae* Isolates from the Airways of Adults with Copd: Novel Vaccine Candidates and Mechanisms of Diversity

Author Block:

C. P. Ahearn[1], C. Kirkham[1], A. Brauer[1], A. Johnson[1], Y. Kong[2], M. M. Pettigrew[3], T. F. Murphy[1]; [1]Univ. at Buffalo, Buffalo, NY, [2]Yale Sch. of Med., New Haven, CT, [3]Yale Sch. of Publ. Hlth., New Haven, CT

Abstract Body:

Nontypeable *Haemophilus influenzae* (NTHi) is a human restricted pathogen. NTHi colonizes the airways of adults with chronic obstructive pulmonary diseases (COPD) inducing airway inflammation and causes acute otitis media in children. There is no vaccine against NTHi licensed in the US. A 15 year prospective study collected 101 persistent NTHi strains from sputum samples of 78 adults with COPD. The genome sequences of the first and final isolates of persistent strains have been determined to evaluate the genomic changes that occurred during persistence.We hypothesize that NTHi expresses conserved antigens that are surface exposed and immunogenic. Using Reverse Vaccinology methods we identified 30 potential vaccine antigens based on predicted surface exposure and antigenicity. Reverse transcriptase PCR showed that two novel uncharacterized hypothetical genes are expressed. Sequence analyses showed that the genes are conserved and stable during persistent COPD infection. We will determine surface exposure and protective ability of recombinant forms of the antigens *in vivo*.We hypothesize that surface antigens change during persistence due to varying abilities to repair DNA damage. We determined that 4 previously described candidate vaccine antigens in select strains show marked sequence variations during persistence. To test the capacity of strains that change with persistence to resist DNA damage, we subjected selected strains to sublethal DNA damaging treatments and assessed growth characteristics. The results showed differential resistance among strains, with some strains being resistant and some strains susceptible. Genomic comparisons of resistant versus susceptible strains will divulge the sequence variations in repair mechanisms responsible for sequence diversity and antigenic variation.We have identified NTHi antigens to investigate their ability as protective vaccine antigens. We have defined NTHi strains that are differentially resistant to sublethal DNA damage treatment, which provides the foundation to investigate the mechanisms of antigenic variation during persistent NTHi infection.

Comparative Genomics of Foot and Mouth Disease Virus Type O Circulating in Bangladesh

Author Block:

H. Ullah, M. Siddique, R. Chakrabarty, M. Ali, M. Sultana, M. Hossain; Univ. of Dhaka, Dhaka, Bangladesh

Abstract Body:

Background: The causative agent of Foot-and-mouth disease (FMD), FMD virus (FMDV), is a positive sense RNA virus and belongs to the genus *Aphthovirus* within the family *Picornaviridae*. There are seven immunogenically distinct serotypes, i.e. O, A, C, Asia-1 and South African Territories (SAT) 1-3 and vaccine protect against one serotype to another are limited. Here we report isolation and genome wide analysis of FMDV type O from Bangladesh. **Methods:** Virus from infected blister tissue was cultured in BHK-21 cell line followed by nucleic acid extraction. Serotype O [BAN/NA/Ha-156/2013] virus was selected for complete genome analysis. **Results:** The genome was found 8131 nt. in length, which includes a 1020 nt. 5´ un-translated region (UTR), a 6999 nt. length open reading frame (ORF) encoding a polyprotein of 2332 (excluding stop codon) amino acids or 2304 amino acid residues due to two alternative initiation sites and 91nt 3´-UTR plus 21nt poly(A) tail. 5'-UTR contains a short S-fragment, poly C tract, multiple pseudoknots of unknown function, *cis* acting replication element and internal ribosome entry sites (IRES) which directs the initiation of poly protein synthesis. The genome sequence has been deposited in to the NCBI Genbank database with Accession Number KF985189. Regarding to coding region, the sequence of non-structural proteins is much more conserved than that of the structural proteins in the FMDV genome. Among all the compared regions, 5´-UTR, VP1 and 3A were found lowest conservative. Comparative genome wide analysis with reference sequence (RefSeq) revealed that an 82 nt. deletion in S-fragment and 43 nt. consecutive insertion in 5´untranslated region (UTR) was evident introducing an extra pseudoknot (PK) structure. Comparison of structural protein VP1 indicated variation in B-C loop (40~60), G-H loop (133~160) and C-terminal linear epitope amino acid segment (200~211) whereas non-structural protein 3A showed that a 10 amino acid insertion (position 92~101) in the 3A protein.**Conclusions:** The genomic structure of serotype O [BAN/NA/Ha-156/2013] differed from Refseq of the virus. The functional implication of this altered genomic structure needed to be further elucidation.

Quantification Of Rotavirus Particles In Ht29.F8 Cells Treated With T-A3

Author Block:

C. Witcher[1], H. Lockwood[1], M. Mattila[1], R. Havner[1], J. Taylor[1], F. Medina-Bolivar[2], J. Ball[3], R. Parr[1]; [1]Stephen F Austin State Univ., Nacogdoches, TX, [2]Arkansas State Univ., Jonesboro, AR, [3]Texas A&M Univ., College Station, TX

Abstract Body:

Rotaviruses (RV) causes severe life threatening diarrhea in young children. Several effective vaccines have been developed that are protective against specific strains of RV but not all known strains of RV. To discovery new strategies to use against RV infections, it is important to understand the mechanisms of RV pathogenesis and how the host responds to RV infections. Previously, our laboratory has shown that a natural product from peanuts, trans-arachidin- 3 (t-A3), significantly inhibits simian RV replication. Although the molecular mechanism(s) of action for t-A3 on RV infections are not known, the decrease in infectious virus particles suggests that one effect is on RV maturation. The objective of this study is to characterize a human RV strain virions during an infection with/without t-A3. Three methods were used; 1) Virus plaque assays to quantify infectious virus particles, 2) Tunable resistive pulse sensing technology using the qNano instrument to quantify and determine the size distribution of all the virus particles, and 3) Transmission electron microscopy (TEM) to observe the gross distribution of the virus particles and the effects on cell structures. The results with a human RV strain and t-A3 obtained from this study indicates: 1) at least a 50 fold decrease of infectious virus particles with t-A3; 2) the qNano system data shows a distribution of virus particles size between 80-115nm for both treatments; and 3) TEM data displays both mature and immature virus particles. This data confirms that the human RV strain replication is effected by t-A3. Furthermore, the size distribution of virus particles was consistent when observed with both the qNano system and TEM. Also, the TEM micrographs indicate that the structures of the cells with RV alone showed signs of apoptosis at 18 hours post infection, whereas the cells with RV and t-A3 appeared to have more normal ultrastructural appearance. This suggests t-A3 may have a protective effect on the host cells. Thus, these natural products are promising anti-RV therapeutic agents.

Host-Pathogen Interaction Network Among *Sulfolobus islandicus* And Its Viruses

Author Block:

J. A. Black, M. A. Bautista, R. J. Whitaker; Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract Body:

Viruses that infect hyperthermophilic archaea of the genus *Sulfolobus* and other organisms from the order Sulfolobales often show distinct, novel morphologies as compared to viruses that infect eukaryotes or bacteria [1]. The co-evolution and pathogenic interactions between these strains and their Archaeal hosts will provide great insight into the diversity and ancient origins of viral defense, and are prime targets for further exploration. To further our understanding of evolutionary ecology and local adaptation between viruses and their microbial hosts in this system, we have focused our research on two geographically isolated populations of *Sulfolobus islandicus* from Yellowstone National Park, USA, and the Mutnovsky Volcano region of the Kamchatka peninsula, Russia [2]. Using 31 strains of *S. islandicus* and viruses isolated from multiple hot springs in both YNP and Kamchatka, we have performed cross-infections of panels of 12 host and 19 virus strains. The patterns of host-virus interactions are determined experimentally by crossing standardized concentrations of both cells and viruses for each host-virus pair using traditional spot-on-lawn assays. The challenged lawns are monitored for plaque formation, size, as well as an increase in plaque turbidity over time that may indicate recovery of an immune host population, or presence of a resistant host minority. To date, a network of host-pathogen interactions between genetically and geographically distinct *S. islandicus* hosts has not been described. Our data shows that some virus strains produce different infective patterns and plaque morphologies across different host strains. These patterns of host-virus interactions may be influenced by the varying sequences of CRISPR-Cas repeat-spacer arrays [3] across individual host strains on the panel, and these experimentally derived patterns can be compared to expected patterns of immunity as predicted by CRISPR-Cas sequence data. By assembling networks of host-pathogen interactions both experimentally and through sequence data, we can resolve a clearer picture of the co-evolutionary process in this extreme environment and uncover novel mechanisms of virus defense.

Armiñanzas Castillo[1]; [1]Infectious Disease Unit. Hosp. Univ.rio Marqués de Valdecilla, Santander, Spain, [2]Neurology Dept.. Hosp. Univ.rio Marqués de Valdecilla, Santander, Spain

Abstract Body:

Background: The aim of this study was to determine whether patients with HIV infection have higher prevalence of endothelial dysfunction than healthy individuals **Methods:** Case-control study, which included 23 non-smoker patients with HIV infection, with intermediate or low cardiovascular risk calculated according to Framingham risk scale and with more of 5 years after diagnosis, compared with a control group of 23 healthy subjects matched by age and sex. Analytical and ultrasound parameters were analyzed.**Results:** Eleven women and 12 men with HIV infection were enrolled; the mean age was 48.9 years [37-62].All patients had a viral load <20 copies/mL and the median CD4+ T-cell was 733 / mm3 [235-2055]. Patient´s average body mass index (BMI) and waist circumference were respectively 26.18 kg / m^2 [20-32] and 95.33 cm [79-111] without differences in BMI or waist circumference when patients were compared to controls. Cases have mean total cholesterol of 175 mg/dL [120-245], mean LDL cholesterol of 92 mg / dl [91-151], while in the control group mean total cholesterol was 187 mg/dL and mean LDL cholesterol was 114,6 mg/dL, the differences were not statistically significant (p >0.05). The mean intima media thickness (IMT) of the control group was 0.86 cm in both of the common carotid arteries, higher than IMT observed in patients, which had an average IMT of 0.66 cm in the right common carotid and 0.68 cm in the left common carotid (p>0.05). Two patients presented atherosclerotic plaques in the carotid versus none in the control group (p <0.01). Breath holding index (BHI) was higher in the patients with HIV infection than in the control group, 1.1% and 1.05% respectively (p>0.05). The endothelium-dependent vasodilation was significantly higher in the control group (11%) than in the group of HIV patients (9.5%) (p= 0.01).**Conclusions:** Patients with HIV infection present impaired endothelial function, as measured by the rate of endothelium-dependent vasodilation and BHI, as a marker of early vascular damage, compared to normal subjects. These findings suggest that the HIV infection itself acts as risk factor for the development of atherosclerosis.

Regulation of the Transcriptome of Rotavirus-Infected HT29.F8 Cells by Trans-Arachidin-3

Author Block:

H. Lockwood[1], C. Witcher[1], R. Havner[1], F. Medina-Bolivar[2], B. Clack[1], J. Taylor[1], J. Ball[3], R. Parr[1]; [1]Stephen F. Austin State Univ., Nacogdoches, TX, [2]Arkansas State Univ., Jonesboro, AR, [3]Texas A&M Univ., College Station, TX

Abstract Body:

The leading cause of severe diarrhea in infants and young children worldwide is rotavirus (RV) infections that can lead to dehydration and death. Although vaccines are available, some are cost prohibitive in emerging countries, and the efficacies are dependent on timing of vaccination and RV strain specificity. Continuing surveillance for newly emerging RV strains, assessment of vaccine efficacies, and development of cost effective antiviral drugs remain important strategies for the prevention of RV pathology. Previously, our laboratory has determined the antiviral activity of a stilbenoid, trans-arachidin-3 (t-A3), on inhibiting RV replication. The objective of this study was to determine host genes that are regulated in a RV-infected human intestinal cell line (HT29.f8) treated with t-A3. Microarray analyses provided insights into the regulation of the transcriptome of HT29.f8 cells at eight hours post RV/RV+t-A3 infections, and quantitative real-time PCR (qRT-PCR) validated the microarray experiments. One of the findings of this study demonstrates that the apoptotic pathway that leads to cell death is activated with a RV infection. Quantitative RT-PCR confirmed that the transcripts for caspase 7 and 9 are significantly upregulated while caspase 3, 8 and 10 remain relatively constant. This suggests that the intrinsic pathway involving mitochondria dysfunction leading to apoptosis is involved during a RV infection. Additionally, transmission electron microscopy (TEM) was used to observe the ultrastructure of cells with the addition of RV alone or RV+t-A3. The data showed an increase in number of mitochondria around the viroplasms with RV alone than with RV+t-A3. Taken together the data presented in this study implies a mechanism of action by t-A3 that interferes with viral replication, and supports the development of t-A3 as an antiviral agent.

Repression of Aflatoxin Biosynthesis and Elicitation of Conidiation Regulatory Genes in *Aspergillus flavus* by Molasses

Author Block:

S. T. Hua[1], P-K. Chang[2], S. B. L Sarreal and C. H. Tam; [1]USDA-ARS, Western Regional Res. Ctr., Albany, CA, [2]USDA-ARS, Southern Regional Res. Ctr., New Orleans, CA

Abstract Body:

Background: Aflatoxin (AF) B_1 is very toxic to humans and animals and the most potent natural carcinogens known. The toxin is often detected in agricultural crops, dried fruits and spices. AF contamination is a serious and recurrent problem and causes substantial economic losses. We observed that when toxigenic strains of *A. flavus* grown in 8% molasses medium, aflatoxin production was non-detectable by HPLC analysis, and the amount of fungal sclerotia was significantly reduced with concurrent increase of conidiophores and spores. The goal of this project was to examine the mechanism of molasses inhibition. **Methods:** Molasses liquid medium (MB) and agar (MA), potato dextrose agar (PDA) and broth (PDB) were used as growth media. Total RNA from fungal hyphae were extracted and used for cDNAs synthesis followed by Real Time PCR. Dual vitality fluorescent stains were also applied to probe the physiological conditions of fungal hyphae grown in molasses. **Results:** Eight genes, *aflR, aflJ, norA, omtA, omtB, ordB, pksA, vbs* and *ver-1*in the aflatoxin biosynthetic pathway were all suppressed ranging from several to 10,000 fold in fungal cultures grown in MB compared to PDB. The expression levels of conidiation regulatory genes, *brlA, abaA* and *wetA* were significantly increased in MB compared to those in PDB. Consistent with the observed difference in the expression levels of *brlA, abaA* and *wetA* in MB and PDB, microscopic observation showed more conidiophores were produced on MA than on PDA at 48 h. The conidiophores on the former also showed much more conidia, yielding larger heads as evidenced by yellowish green conidial chains. **Conclusion:** Although the underlying mechanism(s) of molasses on the inhibition of AF production and effect on fungal development remains to be elucidated, an early-scheduled increase in conidiation activities may result in a delay or even switching off of secondary metabolism of aflatoxin biosynthesis. Molasses may provide a tool for new findings in aflatoxin control.

Characterization of the Cpx-Dependent Regulation in *Klebsiella pneumoniae*

Author Block:

C-J. Liu[1], T-Y. Liu[1], Z-C. Wang[2], W-F. Lin[3], H-L. Peng[1]; [1]Natl. Chiao Tung Univ., HsinChu, Taiwan, [2]Academia Sinica, Taipei, Taiwan, [3]Linkou Chang Gung Mem. Hosp., Taoyuan, Taiwan

Abstract Body:

The envelope stress two component system Cpx is composed of a sensor kinase CpxA and the cognate response regulator CpxR. We have previously found that deleting *cpxAR* genes from *Klebsiella pneumponiae* CG43S3 significantly enhanced the expression of both type 1 and type 3 fimbriae. The mutation also affected the production of outermembrane proteins, cellulose and capsular polysaccharides. When compared to the parental strain CG43S3, the Δ*cpxAR* mutant was more sensitive to paraquat, SDS and deoxycholate. To investigate how the Cpx-dependent regulation works, a comparative transcriptomic analysis of CG43S3, CG43S3Δ*cpxAR*, CG43S3Δ*cpxR* using RNA sequencing and qRT-PCR was employed and analyzed. Specifically, the transcript levels of *fimA* and *mrkA*, respectively coding for the major subunit of type 1 and type 3 fimbriae, *mrkH*, coding for the c-di-GMP binding protein were significantly increased, while that of RcsA, the major regulator for the capsular polysaccharides synthesis and Fur were reduced by the *cpxAR* or *cpxR* deletion. In addition, expression of the outermembrane protein, iron homeostasis system, oxidative stress responsive enzymes SodA and SodB, and the c-di-GMP synthesis enzyme YfiN are all differentially affected. If CpxAR participates in regulating the intracellular c-di-GMP levels or the biosynthesis of the envelope components thereby affects the expression of type 1 and type 3 fimbriae is being investigated and the results will be reported.

Identification of Virulence Genes in the Regulon of a New Lysr-Type Transcriptional Regulator in the Bacterium *Burkholderia thailandensis*

Author Block:

S. Le Guillouzer, M-C. Groleau, F. Mauffrey, R. Villemur, E. Déziel; INRS - Inst. Armand-Frappier, Laval, QC, Canada

Abstract Body:

Quorum sensing (QS) is a global regulatory mechanism of gene expression depending on bacterial density. QS involves intercellular signaling molecules that are synthesized and secreted by all bacteria in a population. These signals modulate, synchronously throughout the bacterial population, the expression of specific genes resulting in the coordination of microbial activities. Burkholderia pseudomallei is a human pathogenic bacterium responsible for melioidosis, a potentially fatal septicemic infection, and is considered as a probable bioterrorism weapon. Its pathogenicity is attributed to multiple virulence factors which are mostly under QS control through N-acyl-L-homoserine lactones (AHLs) molecular signaling. This pathogen also produces putative signaling molecules belonging to the 4-hydroxy-3-methyl-2-alkylquinolines (HMAQs) family. These molecules, likewise AHLs, are possibly involved in virulence gene regulation. Our investigations on the regulatory mechanism of HMAQs biosynthesis revealed a novel LysR-type transcriptional regulator called HmqR, which is ubiquitous in species belonging to the Burkholderia genus. In order to identify targets of HmqR, and in particular those associated with virulence, we conducted a comparative transcriptomic analysis by RNA sequencing of the wild-type and its hmqR- mutant using the non-pathogenic bacterium Burkholderia thailandensis strain E264, which constitutes a model system for the study of B. pseudomallei. We determined that HmqR acts as a global activator of gene expression in B. thailandensis and that numerous genes controlled by HmqR are potentially involved in host-pathogen interactions. These genes, including several encoding multiple B. thailandensis secretion systems, could play a role in bacterial virulence. Accordingly, infection assays in the model host Drosophila melanogaster showed that HmqR affects the pathogenicity of B. thailandensis. HmqR might represent a potential target for the development of new therapeutic strategies.

Activity-linked Supply and Demand of the Type Vi Secretion System Components

Author Block:

F. Caro, J. J. Mekalanos; Harvard Med. Sch., Boston, MA

Abstract Body:

Background: The type VI secretion system (T6SS) is a molecular puncturing device that transports toxic protein effectors from the bacteria cytoplasm to the extracellular environment or directly into target cells. How bacteria control recycling and replenishment of the T6SS components remains poorly understood. This work details experiments aimed at describing the regulatory network that allows *Vibrio cholerae* to link the firing of the T6SS apparatus to the transcription of its components. **Materials**: The *V. cholerae* isolate 2740-80 with a constitutively active T6SS, a ΔvipA mutant of this strain with an inactive T6SS, and a complemented strain, were grown *in vitro* to extract RNA for transcriptome sequencing. Genetic suppressor screens were used to pinpoint candidates that act as inhibitors of T6SS gene expression in these strains. **Results**: A comparison of the transcriptomes of the three strains showed that T6SS activity positively influences the expression of its own components. The genetic suppressor screen yielded three candidate genes encoding for transcriptional regulators. **Conclusion**: The *V. cholerae* type VI secretion system (T6SS) functions like a weapon; to restore the T6SS following a round of firing, the T6SS substrates have to be re-charged while the structural components can be recycled. The data obtained shows that T6SS firing of the system dictates the generation of more substrates, which could be mediated by a transcriptional feedback mechanism, linking T6SS activity to T6SS gene expression. A deeper understanding of T6SS gene control will reveal the mechanism by which *V. cholerae* strains maintain homeostasis of a ubiquitous virulence factor in diverse environments. It will also enable therapeutic approaches for disrupting T6SS homeostasis during pathogenesis in the human host.

The Landscape Of Rnap Polymerase-Associated Proteins

Author Block:

C. P. Garcia[1], N. Verdini[1], K. Barrasso[1], A. Hochschild[2], P. Deighan[1]; [1]Emmanuel Coll., Boston, MA, [2]Harvard Med. Sch., Boston, MA

Abstract Body:

A plethora of transcription factors interact with RNA polymerase (RNAP) and regulate its activities during all stages of the transcription cycle, including initiation, elongation and termination. Although many transcription factors are sequence-specific DNA-binding proteins that recruit RNAP to specific promoters via a direct protein-protein interaction with RNAP, others bind to RNAP without binding the DNA and influence its behavior at steps other than promoter recognition. In this study we have used a bacterial two-hybrid assay to discover and characterize the precise protein-protein interactions that occur between E. coli RNAP and its associated proteins. Specifically, we have assembled a library of 30+ surface-exposed independently folded RNAP fragments, and tested these individually for interaction with 40 previously identified candidate RNAP-associated proteins. Using this systematic approach we have uncovered and characterized the RNAP-binding determinants for numerous transcription factors and have begun to assemble a landscape interaction map for all RNAP-associated proteins.

Proteomic Analysis of a *Candida albicans Pga1* Null Strain

Author Block:

R. A. Khalaf, A. Awad, P. El Khoury, I. El Khatib; Lebanese American Univ., Byblos, Lebanon

Abstract Body:

Background: The opportunistic fungal pathogen *Candida albicans* is one of the leading agents causing death in immunocompromised individuals. In a pathogen the cell wall in general and cell wall proteins in particular are antigenic determinants as they are the first elements to contact the host. Cell wall proteins have been shown to be involved in adhesion, virulence, response to host oxidative stress among other functions. We have previously characterized Pga1, a cell wall protein that we found to be involved in virulence, adhesion, biofilm formation, chitin deposition, and resistance to oxidative stress. In this study we investigated differential proteomic expression of a *pga1 null* mutant strain compared to the wild-type strain to determine protein expression patterns that explain the above mentioned phenotypes **Methods:** This was accomplished through an advanced protein sequencing technique that combines liquid chromatography and MS/MS analysis. First, cell wall proteins from mutant and wild type parental strains were extracted and subjected to tryptic digestion. The peptides were separated by NanoLC and analysed using MALDI TOF mass spectrometry. The resulting MS/MS data was searched using Protein Pilot Software and MASCOT Server to identify the proteins. In MS/MS Ion Search, Swissprot and NCBI databases were searched and unidentified peptide sequences were blasted on NCBI and Candidagenome.org. **Results:** Under filamentous conditions several proteins such as Dor14, Ssr1, Als7, Skn1 were exclusively expressed in the wild type parental strain, whilst Pga60, pir1, and Bmt6 were present only in the wild type under non filamentous conditions. ALs7 and Pga60 are adhesins and their absence in the mutant might explain the decrease in adhesion, and biofilm formation. Dor14 has been found to be strongly antigenic in mice and its absence in the mutant is reflected as a decrease in virulence. The decrease in resistance to oxidative stress, and decrease in chitin deposition might be due to the absence of Ssr1, Skn1, Pir1, and Bmt6 that are involved in cell wall structure, 1,6-β glucan synthesis, 1-3-β glucan linkage, and β-1,2 mannosylation of cell wall phospholipomannans resulting in a less rigid less resistant cell surface **Conclusions:** MALDI TOF analysis provides a precise and rapid method to analyze cell surface proteome differences in yeast

A. BRIONES[1], C. CABEZAS[1], C. PARDO-ESTÉ[1], J. CASTRO-SEVERYN[1], C. SALINAS[1], C. AGUIRRE[1], S. BAQUEDANO[1], E. H. MORALES[2], E. CASTRO-NALLAR[1], **C. P. SAAVEDRA**[1]; [1]Univ. Andrés Bello, Santiago, Chile, [2]Univ. de Santiago de Chile, Santiago, Chile

Abstract Body:

Salmonella Typhimurium is an intracellular pathogen capable of generating systemic fever in the murine model. During infection of the host, *Salmonella* faces different kinds of stresses, among which Reactive Oxygen Species (ROS) are the most harmful ones. However, *Salmonella* is able to survive this stress and complete a successful infective process, given that it is equipped with different defense mechanisms whose expression is finely tuned by different transcription factors, including OxyR and SoxRS. Another transcription factor involved in the response to oxidative stress and invasion of murine macrophages is SlyA. In our laboratory we evaluated the role of SlyA in the response to H_2O_2 and HOCl, finding that the expression of SlyA increases when it is exposed to these toxics. However, the target genes and the molecular mechanisms by which SlyA is involved in the infective process are unknown. We analyzed changes at the transcriptional level (RNA-seq) of a wild type and Δ*slyA* strain exposed to these toxics, and determined the genes regulated by SlyA in response to the toxics. Among the genes that change their expression, we found some related with protection against ROS (*spy, katG*), virulence (*sopD*), central metabolism (*kgtP, fruK, glpA*), outer membrane permeability (*ompW*), among others. Experiments with transcriptional fusions (GFP) further confirmed that SlyA regulates the expression of these genes, and a direct interaction of SlyA with the promoter regions of several of these genes was confirmed by EMSA. Furthermore, *in-vitro* assays showed that the same genes are also regulated by SlyA in *Salmonella* when infects macrophages and neutrophils. Therefore, the expression of several genes in *Salmonella* is similarly regulated by the transcription factor SlyA in response to ROS and in bacteria residing in immune cells capable of generating ROS, namely macrophages and neutrophils.

Understanding the Regulation and Mechanisms Involved in Multiple Antibiotic Resistance

Author Block:

P. Sharma, D. C. Grainger; Univ. of Birmingham, Birmingham, United Kingdom

Abstract Body:

Antibiotic resistance in bacteria is a serious problem. Such pathogens cause difficult to treat diseases world-wide. Multiple antibiotic resistance in bacteria can be driven by the transcriptional regulators in AraC-XylS family. The *Escherichia coli* '*mar'* regulon is considered a paradigm for such systems. The mar locus consists of 3 genes; *marRAB*. MarA, a transcriptional activator that activates drug efflux pump expression. Transcriptional activation is mediated by binding of MarA to "marbox" sequences at target promoters. The marbox is conserved in many gram negative pathogens. We identified 64 new targets by ChIP-Seq analysis in Enterotoxigenic *E.coli* (ETEC). All targets were enriched for marbox motifs. Few of the 64 new targets of marA were characterised previously. This research provides new insights into understanding of antibiotic resistance at molecular level.

Mining Transcriptional Expression Data to Identify Genes Responsible for Enhanced Alkane and Lipid Droplet Production in Cyanobacteria

Author Block:

D. B. Arias[1], A. Peramuna[2], A. Solomon[3], M. L. Summers[1]; [1]California State Univ., Northridge, Northridge, CA, [2]Univ. of Copenhagen, Copenhagen, Denmark, [3]Massachusetts Inst. of Technology, Cambridge, MA

Abstract Body:

Cyanobacteria have the ability to produce lipid droplets (LDs). These LDs are enriched with alpha-tocopherol and hydrophobic energy-dense compounds such as triacylglycerides and alkanes with biotechnological potential. Previous work from our lab has shown that introducing extrachromosomal copies of two genes (*aar*, *adc)* into *N. punctiforme* caused enhanced production of heptadecane. LDs also increase in number, likely as an adaptation to detoxify excess alkane production. A putative lipase that when over-expressed alone increased alkane production was identified to be associated with purified LDs by Western blotting. Over-expression of this lipase in conjunction with *aar* and *adc* further increased LDs and heptadecanes compared to the over-expression of *aar*/*adc*. The addition of extra copies of the putative lipase also repaired a growth defect observed in the *aar/adc* over-expressor strain. To identify transcriptional changes associated with increased heptadecane and LD production, and complementation of the growth phenotype in the 2-gene over-production strain, RNA from wild-type and over-expresser strains were extracted and subjected to RNA Seq analysis. Genes that showed a >1.5-fold statistically significant change in the 2 and 3-gene over-expressor strains relative to a plasmid-only control were hypothesized to enhance or cope with over-production of LDs and alkanes. Up and down regulated genes encode different sets of proteins including sigma factors, transcriptional regulators, sugar modifying proteins, and stress proteins. A different subset of genes were found to change expression only in the 2-gene samples and returned to wild-type levels in the 3-gene overexpression samples. These included down-regulated genes in the 2-gene over-expressor strain associated with growth, and up-regulated genes including general stress proteins, indicating the lipase may alleviate stress when over-expressed. Genes showing up-regulation have been transformed back into the wild-type strain on a multi-copy plasmid to test the hypothesis that increased gene copy number can mimic the increased LD phenotype. This work is important for using LDs in biotechnological applications.

Gatase1-Like Arac-Family Transcriptional Regulators (Gatrs) in *Burkholderia thailandensi*s

Author Block:

A. M. NOCK, M. J. Wargo; Univ. of Vermont, Burlington, VT

Abstract Body:

GATase1-like AraC-family Transcriptional Regulators (GATRs) are a subgroup of AraCs that are widely distributed among Proteobacteria with an N-terminal class-1 glutamine amidotrasferase-like domain. Based on functions of other GATase1 superfamily members and inferences from our previous studies, we hypothesized that this domain is likely to be used to identify various amine-containing small molecules, particularly those present when microbes are in close association with eukaryotic organisms. The few characterized GATRs are involved with metabolism of eukaryotic-derived amines, and two have links to bacterial virulence.*Burkholderia thailandensis* encodes thirteen GATRs, more than most other sequenced Proteobacteria. The genetic tractability of *B. thailandensis* combined with the high number of GATRs makes it an excellent model organism in which to investigate this family of transcriptional regulators. We generated knockouts of each GATR and are screening each mutant against custom set of amine-containing compounds to assess the metabolic pathways within which these GATRs may play regulatory roles. Based on homology to known regulators in *Pseudomonas aeruginosa*, here we describe the roles of *gbdR1*, *gbdR1*, and *souR* in choline catabolism; *argR* in arginine metabolism; and *cdhR* in carnitine catabolism. These validated orthologs provide valuable comparators for bioinformatic analysis to identify resides involved in ligand specificity and to characterize those GATRs without predicted orthologs. Intriguingly, amongst the eight uncharacterized GATRs is one that appears to be associated with one of the capsule operons shared by *B. thailandensis* and *Burkholderia pseudomallei*. Our goal is to use this data to enable us to infer GATR functions in other Proteobacteria and extend our knowledge of this regulatory family.

A Spectrum of Cody Activities Drives Metabolic Reorganization and Virulence Gene Expression in *Staphylococcus aureus*

Author Block:

N. R. Waters[1], D. J. Samuels[1], J. Livny[2], K. Y. Rhee[3], **S. R. Brinsmade**[1]; [1]Georgetown Univ., Washington, DC, [2]Broad Inst. of MIT and Harvard, Cambridge, MA, [3]Weill Cornell Med. Coll., New York, NY

Abstract Body:

CodY is a global regulator that controls the expression of dozens of genes in many Firmicutes and is known to link nutrient availability and virulence in pathogenic species like *Staphylococcus aureus* by sensing branched-chain amino acids (BCAAs) and GTP. We previously reported that CodY-dependent genes in *Bacillus subtilis* are controlled in a hierarchical manner. While there is overlap between the *B. subtilis* and *S. aureus* CodY regulons (i.e., metabolic genes), *S. aureus'* regulon includes nearly all of the known virulence genes and nothing is known regarding the threshold activities of CodY required to regulate these genes. To test the hypothesis that *S. aureus* uses CodY to grade metabolic and virulence gene expression as a function of BCAA availability, we constructed *S. aureus* strains that produce mutant CodY proteins with varying regulatory activity due to reduced sensitivity to intracellular pools of BCAAs. Using RNA-Seq and LC-MS analysis, we profiled the transcriptome and metabolome to determine the response of *S. aureus* to nutrient depletion. We measured > 1.5-fold increases in steady-state pools of amino acids as CodY activity was reduced ($p < 0.05$, Cuzick's test for trend). Cells lacking CodY activity produce a PIA-dependent biofilm, but development is restricted in strains with moderate CodY activity ($p < 0.05$, Games-Howell test). Relative to *codY* cells, *codY*$^+$ cells repress the production of secreted nuclease >10-fold in an *sae*- and nutrient-dependent manner, revealing cascading virulence regulation. Using *k*-means clustering, genes encoding proteins that mediate the host-pathogen interaction and subvert the immune response are shut off at intermediate levels of CodY activity, while genes coding for proteins that extract nutrients from tissue, that kill host cells, and that synthesize amino acids are the last genes to be turned on. We conclude that *S. aureus* uses CodY to limit host damage to the most severe starvation conditions, providing insight into one potential mechanism by which *S. aureus* transitions from a commensal bacterium to an invasive pathogen.

Crosstalk Between Fimbrial and Flagellar Gene Expression in Uropathogenic *Escherichia coli* is Linked Through Regulation of *papx*

Author Block:

C. Luterbach, H. L. T. Mobley; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Uropathogenic *Escherichia coli* (UPEC) are the main cause of uncomplicated urinary tract infections (UTIs). During a UTI, expression of adherence structures, called fimbriae, promote binding of UPEC to host cell receptors and can thereby aid in colonization of the urinary tract. P fimbriae, encoded by the *pap* operon, bind to the P-blood group antigen found on kidney epithelium, and *E. coli* strains that carry the *pap* operon are more likely to colonize the kidneys during infection, resulting in pyelonephritis. P fimbriae have been confirmed by Molecular Koch's postulates as a virulence factor for CFT073, a pyelonephritis isolate, in the murine model of UTI. Unlike the majority of other fimbrial operons, the 3' end of the *pap* operon encodes a MarR-like transcription factor, PapX. Using SELEX and high-throughput sequencing, our lab has shown that PapX binds to a 29-bp sequence upstream of *flhDC*, the master regulator of flagellar gene expression, and represses motility. We hypothesize that PapX assists in the coordinated regulation of fimbrial and flagellar gene expression observed during UTI. Our lab has previously shown by quantitative PCR that *papX* is transcribed with the *pap* operon. However, using 5' RACE we identified an additional promoter for *papX*. Also, our lab has shown by RNAseq on a clinical UTI *E. coli* isolate, HM69, that *papX* transcription compared to *papA*, which encodes the major fimbrial subunit, is elevated during growth in urine and during UTI compared to growth in LB, suggesting that regulation of *papX* differs from the *pap* operon. To test the regulation of *papX* we constructed transcriptional *lacZ* fusions of the *papX* and *papA* promoters and plan to investigate the impact on regulation of *papX* in strains lacking known regulators of *pap* expression and under different environmental conditions. *E. coli* CFT073 also carries the *foc* operon, which encodes F1C fimbriae and the transcription factor, FocX, which shares 96.7% amino acid sequence identity to PapX. We have tested that FocX and PapX are both capable of repressing motility by soft agar motility assay, and we have constructed transcriptional *lacZ* fusions with the *focX* and *focA* promoters to evaluate regulation of *focX* and cooperation between FocX and PapX. This approach will allow us to determine the impact of encoding multiple "X" proteins on the crosstalk between adherence and motility during UPEC pathogenesis.

The Expression of Virulence Genes of *H. pylori* in the Presence of Reuterin

Author Block:

V. H. Urrutia Baca, M. A. De la Garza Ramos, R. A. Gomez Flores, E. Escamilla Garcia; Univ. Autonoma de Nuevo León, Monterrey, Mexico

Abstract Body:

Background: *Helicobacter pylori* is the pathogen most often associated with diseases of the gastrointestinal tract, about 50% of the world population is infected. *H. pylori* has many virulence factors that allow establishment, colonization and damage in the gastric epithelium Actually, is widely described the use of probiotics and their benefits for the treatment against this infection, however, the antimicrobial activity that may have its metabolites has not been fully tested. In addition, these compounds have shown the ability to inhibit expression of virulence factors in other pathogens. In this study, a metabolite called reuterin produced by *Lactobacillus reuteri* was evaluated. The objective of this investigation was to determine whether reuterin is capable of inhibit the growth or reduce the expression of virulence genes in *H. pylori*.**Methods:** The minimum inhibitory concentration (MIC) was assessed using microdilution method in 96-well plate. The relative expression of virulence genes of *H. pylori* in the presence of 100 µM reuterin was carry out by RT-qPCR.**Results:** The MIC for reuterin against *H. pylori* was 50 mM and a dose-dependent effect was observed. Otherwise, A significant decrease of expression was observed mainly on *flaA*, *vacA* and *luxS* genes at 3 h post-treatment (Figure 1). **Conclusions:** Reuterin has a moderate antimicrobial activity against *H. pylori* in *in vitro* assays and low doses can inhibit the expression of virulence genes. The modulation of virulence genes shown in this study opens the possibility for new approaches about of the mechanisms of interaction of probiotics with gastric pathogens.

Transcriptomic Analysis of *Pichia anomala* WRL-076 in Dual Culture with *Aspergillus flavus*

Author Block:

S. T. Hua[1], G. Wu[2], S. L. Sarreal[1], P-K. Chang[3], J. Yu[2], R. W. Li[2]; [1]USDA-ARS, Western Regional Res. Ctr., Albany, CA, [2]USDA-ARS, Beltsville Agricultural Res. Ctr., Beltsville, MD, [3]USDA-ARS, Southern Regional Res. Ctr., New Orleans, LA

Abstract Body:

Background: *Pichia anomala* (*Wickerhamomyces anomalus*) WRL-076 is a biocontrol yeast which has been shown to inhibit growth and aflatoxin production of *Aspergillus flavus*. The molecular mechanism of biological control was further characterized by the temporal transcriptome response of *P. anomala* to *A. flavus* in a liquid growth medium at ratio of 1:1 during 72h experimental period. **Methods:** Total RNA was extracted and processed using an Illumina TruSeq RNA Sample Prep kit. RNA-seq reads were mapped to the *W. anomalus* genome using tophat2 with default settings. Differential expression analysis was performed using edgeR. Gene ontology (GO) annotation of *P. anomala* was retrieved from http://genome.jgi.doe.gov/. Enrichment of GO categories in differentially regulated genes was determined using Fisher's exact test in the R environment. **Results:** Comparison of yeast gene expression with and without *A. flavus*, a large number of genes were differentially expressed. At 24 h, 662 genes and 679 genes out of a total of 6,423 genes were up- and down-regulated respectively. Specifically, genes involved in protein phosphorylation, protein kinase, DNA-templated regulation of transcription, and microtubule-based movement. They were enriched in the down-regulated genes at 24 h, but in up-regulation at later time points. This suggests that *P. anomala* was recuperating from the competition of *A. flavus*. Transport was enriched in up-regulated genes at 48 h, which implies that *P. anomala* was actively utilizing nutrients from the environment to build its biocontrol activities. **Conclusion:** *A. flavus* has a significant influence on *P. anomala* gene expression. We applied GO annotations to identify major categories of genes that were involved in biological control processes. A group of genes in defense function, such as signal transduction were up-regulated. The lytic enzymes, exo-beta-1,3-glucanase 1 and 2 were slightly higher at 48 and 72 h. Further analysis is warranted for a better understanding on biocontrol efficacy.

Molecular and Structural Considerations of the TF-DNA Binding for the Generation of Biologically Meaningful and Accurate Phylogenetic Footprinting Analysis in Proteobacteria. The LysR-Type Transcription Regulatory Family as a Study Model

Author Block:

M. Peralta-Gil[1], P. Oliver[2], M. L. Tabche[2], T. Romero[1], V. H. Perez-España[1], E. Merino-Pérez[2]; [1]ESAp-UAEH, Apan, Mexico, [2]IBt-UNAM, Cuernavaca, Mexico

Abstract Body:

The in silico identification of Transcription Factor Binding Sites (TFBSs) is a key issue for many Molecular Biology studies aimed to characterize the regulatory elements in sequence genomes. The goal of many algorithms developed to find TFBSs has been the identification of discrete sequence motifs that are overrepresented in a statistically significant manner of a given set of sequences where a TF is expected to bind. Despite their extensive use, the accuracies reached with these methods are still low. In many cases, the true TFBSs are excluded from the identification process or imprecisely identified, especially in those cases when the TFBS correspond to a low affinity. Here we present a new computational protocol named PProCoM (Phylogenetic Profile of Consensus Motifs) to identify in a very precise way, all of the TFBSs in a regulatory sequence, including those with a low conserved sequence or degenerated TFBSs. Our protocol is based on the construction of non-conventional Phylogenetic Profiles consistent of increasing sequence lengths of a set of consensus motifs, obtained by canonical phylogenetic footprinting technique. In this sense, we analyzed the regulatory regions of six members of the LysR-Type Transcriptional Regulator (LTTR) family in Proteobacteria. We have divided these members in three groups according to their regulatory activity, considering predicted TFBSs positions regarding to the promoter sequences of regulated genes. The first group is composed by MetR and GcvA regulatory systems, both of them showed two conserved TFBSs in the intergenic regulatory region shared between the TF and its target gene, while the second group composed by OxyR, IlvY and CynR, have three conserved TFBSs, two of them are spliced. The last is composed by the single regulatory system LysR. We were able to infer the evolutionary change of TFBSs between different organisms and have elucidated possible activation-repression TFBSs roles in accordance of the presence/absence of their corresponding inducers. The in all these information, we have proposed new Molecular Regulatory Models for each one of the LTTR considered in our study.

Improving Crispr Interference (Crispri) to Achieve Finely-tuned Transcriptional Repression of *Escherichia coli* Genes

Author Block:

N. J. Backes, G. J. Phillips; Iowa State Univ., Ames, IA

Abstract Body:

Background: The application of Clustered Regularly Interspaced Short Palindromic Repeats Interference (CRISPRi) has been shown to enable repression of selected genes in *E. coli* (Qi, et al. 2013. Cell. 52:1173-83). This approach has significant potential to allow interrogation of gene function in multiple bacterial species. To more fully utilize the potential of this technology, we have developed a CRISPRi system that allows for sufficiently tight regulation of targeted genes to allow essential genes to be conditionally expressed. We have further modified the nuclease-defective Cas9 protein from *Steptococcus pyogenes* (dCas9) to allow for visualization of specific regions of the bacterial chromosome and episomes. **Methods:** To maximize efficiency of dCas9 expression in *Enterobacteriaceae*, we synthesized a codon-optimized variant of the *S. pyogenes* gene and placed it under regulation of multiple promoters, including *tetR, araB* and *lac*. These constructs were integrated into the *E. coli* chromosome for expression in single copy by either site-specific recombination, or by Tn7 transposition. A dCas-GFP variant was also constructed and expressed in single copy. Guide RNAs were expressed from ColE1-derivative plasmids. **Results:** We achieved sufficient regulation of the dCas9 to allow reversible genetic switching of expression of multiple essential genes, including those encoding components of the *E. coli* signal recognition particle, as evidenced by conditional growth. Furthermore, we were able to use the CRISPRi system to detect the cellular location of the *lac* operon on both the bacterial chromosome as well as on F' *lac*. **Conclusions:** The CRISPRi system described here represents an easy, efficient system to repress essentially any selected gene for transcriptional repression. In addition, use of dCas9-GFP can allow interrogation of chromosome structure and subcellular location of DNA elements. This system should also be amenable to a broad range of bacterial hosts within the *Enterobacteriaceae* family to better understand gene function.

An RNA-Guided System for Analyzing Genetic Interactions Involving Essential Genes in *Escherichia coli* K-12

Author Block:

X. Yang[1], A. Muto[1], K. M. Esvelt[2], B. L. Wanner[3], H. Mori[1]; [1]Nara Inst. of Sci. and Technology, Ikoma, Japan, [2]Wyss Inst. at Harvard Med. Sch., Boston, MA, [3]Dept. of Microbiol. and Immunobiology, Harvard Med. Sch., Boston, MA

Abstract Body:

Escherichia coli K-12 has served as an outstanding model organism for several decades from the development of traditional forward genetics to the modern era of high-throughput systems approaches. Although *E. coli* K-12 is one of the best-studied organisms, the physiological function of a large number of its genes has yet to be characterized experimentally. Furthermore, physiological network structure, such as genetic interaction, has only recently been started and there is a long way to its complete understanding at a systems level. Defining gene essentiality is not simple because it depends on a variety of physiological properties, such as growth media, temperature, other environmental factors, and the genetic background. Elucidating the physiological functions of essential genes is crucial to full understanding of a cell. Furthermore, essential genes often serve as hubs of functional networks in a cell. The identification of epistatic relationships provides a powerful approach to connect genes to their functional partner genes. For this purpose, we applied the CRISPR-Cas system (clusters of regularly interspaced short palindromic repeats and associate protein), to isolate conditional knockdown mutants of target essential genes. The CRISPR-Cas system, first discovered in *E. coli* nearly 30 years ago (Nakata et al., 1989; PMID2656660), contains small guide RNAs to specify the target DNA fragments and nuclease domain to cleave the DNA. Here, we introduce a system based on the CRISPR-Cas9 platform for controlling the expression of target essential genes in *Escherichia coli*, in which we employed a mutant Cas9 (dCas9) protein lacking endonuclease cleavage activity. To facilitate systematic analysis of genetic interactions between essential gene knockdown and non-essential single-gene knockouts, we developed a self-transferable CRISPR system. With this system, quantification of growth rates of the essential gene knockdown alone and in combination with a non-essential knockout reveals genetic interactions between essential and non-essential genes.

Development of a Crispr-Cas9 Based Gene Knockout System for Bifidobacteria

Author Block:

y. yang, L. Yu, D. J. O'Sullivan; Univ. of Minnesota, Saint Paul, MN

Abstract Body:

Bifidobacteria are recognized as beneficial microbes in the human gastrointestinal tract, and are frequently used as probiotic cultures in foods. However, our understanding of how they interact with the host and its microbiome is still quite limited. One of the main research limitations is the lack of molecular tools for analyzing these bacteria, particularly targeted genome editing. Therefore, it was necessary to develop an efficient and reproducible genome editing system for bifidobacteria. CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats)-Cas systems, which have evolved in bacteria and archaea to impart an acquired immunity to invasive DNA, have been used for genome editing in a wide variety of organisms. In this study we adapted the type II bacterial CRISPR-Cas9 system from Streptococcus pyogenes for site specific gene knockouts in Bifidobacterium longum DJO10A using an efficient conjugation-based gene transfer approach. The CRISPR/Cas9 genome editing plasmid pDOJHR-WD6-Y was designed for site specific mutagenesis of the lanR1 gene and comprises a target-specific guide RNA, a codon-optimized cas9 gene, and an RP4 specific oriT. In order to enhance the gene expression, a modified 16s RNA promoter was constructed upstream of the cas9 gene, as well as for the guide RNA. To increase the efficiency of transcription, a transcriptional terminator was inserted downstream of these unique regions. This novel CRISPR-Cas9 based gene knockout system has now been used for the introduction of a frame-shift mutation into the lanR1 gene of B. longum DJO10A and can be redesigned to target any gene of interest in bifidobacteria.

Cas9 Nickase-Assisted Rna Repression Enables Stable Manipulation Of Essential Genes And Combined Metabolic Engineering In *clostridium Cellulolyticum*

Author Block:

T. Xu, J. Zhou; Univ. of Oklahoma, Norman, OK

Abstract Body:

Clostridium cellulolyticum is an anaerobe with potential use in consolidated bioprocessing; however, increasing its industrial value by diminishing acetate production and conducting combined metabolic engineering in this strain is challenging due to the essentiality of acetate-producing genes. Here, we developed new genetic engineering strategies to overcome these difficulties. Plasmid-based expression of antisense RNA (asRNA) molecules targeting the phosphotransacetylase (*pta*) gene successfully reduced PTA activity by 35% in cellobiose-grown *C. cellulolyticum*, metabolically decreased acetate titer by 15% and 52% in wildtype transformants on cellulose and xylan, respectively. Transformants of the double mutant (LM) of lactate dehydrogenase and malate dehydrogenase reduced acetate titer by more than 33%, concomitant with negligible lactate formation. However, further testing showed that chromosomal integrants created by double-crossover recombination exhibited only very weak repression because DNA integration lessened gene dosage. With the design of a tandem repetitive promoter-driven asRNA module and the use of a new Cas9 nickase genome editing tool, a powerful integrant (LM3P) was generated in a single step and successfully enhanced RNA repression, which reduced acetate titer to 73% of LM on 10 g/L cellulose. From batch fermentation, the LM3P integrant exhibited additional changes in cell growth, cellulose utilization, and other fermentation products especially on 50 g/L cellulose. AsRNA-mediated gene repression performed very well in reducing acetate and enabled co-manipulation of lactate and acetate production in *C. cellulolyticum*. This combinatorial method using the Cas9 nickase genome editing tool to integrate the gene repression module demonstrates easy-to-use and high-efficiency advantages, paving the way for stably manipulating genes, even essential ones, for functional characterization and microbial engineering.

Abstract Body:

Background: *Vibrio vulnificus* causes rapid disseminating septicemia by oral infection in infected individuals who have an underlying disease, especially chronic liver diseases. There have been reported a number of studies about several putative virulence factors, which include a capsular polysaccharide, RTX toxin, cytolytic hemolysin VvhA, metalloprotease VvpE, and iron-sequestering system. Although several virulence factors have been found in this organism, the pathogenic mechanisms of *Vibrio vulnificus* infection still unknown. Because in vitro conditions may not always reflect the complicated in vivo host environments, pathogenic genes expressed only in the infection process could be overlooked. Several screening methods for bacterial virulence genes that were expressed in vivo have been developed. In this study, we attempted to apply signature-tagged mutagenesis (STM) to investigate *Vibrio vulnificus* virulence genes that are active in vivo. **Methods:** *Vibrio vulnificus*CMCP6 was mated with *E. coli* BW19795 harboring pUT miniTn5Km2 labeled with one of the 63 unique signature tags. Each set group was used for as a pooled INPUT culture for mouse injection and for template DNA to prepare an INPUT probe. To estimate attenuated mutants, dot hybridization were performed, and the intensity of hybridization signals with INPUT and OUTPUT probes was compared. If tags were detected with INPUT but not with the corresponding OUTPUT, the transposon inserted gens of these attenuated mutants were amplified by AP-PCR and then sequenced. The genes with the highest identification with the database were predicted as transposon-disrupted genes of the attenuated mutants.**Results:** The genes with the highest identification with the database were predicted as transposon-disrupted genes of the attenuated mutants. Ferric vulnibactin receptor VuuA, polysaccharide export protein Wza, and lipid A core-O-antigen ligase were identified as the disrupted genes.**Conclusions:** Some genes which have already known as the putative virulence factor coding gene were identified in the transposon disrupted genes. Thus, we concluded that novel virulence genes could be identified by our STM system.

The *Streptococcus agalactiae* Essential Genome as Determined by Tn-Seq

Author Block:

T. A. Hooven[1], A. J. Catomeris[2], L. J. Tallon[3], S. Ott[3], T. M. Randis[2], H. Tettelin[3], A. J. Ratner[2]; [1]Columbia Univ., New York, NY, [2]New York Univ., New York, NY, [3]Univ. of Maryland, Baltimore, MD

Abstract Body:

Background: *Streptococcus agalactiae* (group B *Streptococcus*; GBS) is the most common cause of early-onset sepsis and a major contributor to neonatal morbidity and mortality. Genome-wide determination of essential GBS genes may help identify new targets for treatment or prevention of GBS. **Methods:** We used next-generation sequencing of transposon-genome junctions (Tn-seq) to define the essential genome of GBS A909 (serotype Ia). A mini-*Himar1* transposon, which inserts without bias at any genomic TA dinucleotide site, was modified to contain MmeI restriction enzyme sites in the termini of its flanking inverted repeat sequences (necessary for Tn-seq) and delivered to GBS on a temperature-sensitive plasmid.Three independent mutant libraries were grown in rich media, and serially sampled. Illumina sequencing of PCR amplified transposon-genome junctions was followed by statistical analysis of insertion frequency using Tn-seq Explorer and ESSENTIALS software. We validated our results by comparison with the essential genome of *Streptococcus pyogenes*—a closely related Gram-positive pathogen—and mapped essential and critical genes onto predicted GBS signal transduction and metabolic pathways.**Results:** Gene fitness data from our mutant libraries were highly correlated ($r > 0.72$, $p < 0.0001$ Pearson correlation), indicating reproducibility between biological and technical replicates. After pooling of sequencing reads, library saturation was 39-45%, with 99.5% of nonessential genes interrupted at three or more TA sites. Our method identified 14.7% of A909 genes as either essential or critical. 93% of GBS gene fitness assignments were concordant with published *S. pyogenes* results. Essential genes mapped to key metabolic pathways such as aminoacyl-tRNA biosynthesis, nucleotide metabolism, and glycolysis. Our fitness data correctly predicted essentiality of the transcriptional regulator CcpA, which is nonessential in close relatives.**Conclusions:** We have developed and tested a reliable system for performing Tn-seq in GBS, and have determined the essential genome of strain A909. This Tn-seq system is flexible and should permit assessment of conditionally essential genes from biological challenge experiments (including *in vivo* systems).

Elucidating Metabolic Networks in Archaeal Species Using Dynamic Control Valves

Author Block:

E. A. Moreb, A. Schmid, M. D. Lynch; Duke Univ., Durham, NC

Abstract Body:

Archaea are some of the least understood but most metabolically and physiologically diverse organisms on earth. *Haloferax volcanii*, a moderate halophile, is relatively simple to culture and has become a model organism for halophilicity and general archaeal biology. Although better characterized than other species, essential and nonessential genes involved in many aspects of metabolism, including carbon utilization and CO_2 fixation, remain unknown in *H. volcanii*. Identifying the metabolic function of uncharacterized enzymes can be difficult, particularly for essential enzymes. Disabling essential genes prevents organisms from growing, making it impossible to determine the genes role in metabolism. Starting with a list of known enzymes in understudied, unusual glycolytic pathway variants in *H. volcanii*, we have developed a dynamic metabolic control strategy to assess the metabolic function of uncharacterized enzymes. This approach involves tagging each enzyme with a small peptide enabling controlled protein degradation. Initially, the cells will be allowed to grow but, following induced proteolysis, the function of tagged enzymes will be removed. This will cause real time alterations in metabolite pools, which can be analyzed by mass spectrometry. Our approach allows for modular, highly scalable, dynamic assessment of essential metabolic enzymes and can be adapted for rapid elucidation of any unknown pathway.

Rapid Identification of Protein-Protein Dimerization Sites Using Modified Error-Prone PCR Mutagenesis Coupled with Bacterial Two-Hybrid Screens

Author Block:

A. M. Ibrahim[1], Y. M. Ragab[2], K. A. Aly[1], M. A. Ramadan[2]; [1]Sinai Univ., North Sinai, Egypt, [2]Cairo Univ., Cairo, Egypt

Abstract Body:

Protein-protein interactions drive many critical events in the microbial cell. This led to recent surge in the quest for rapid methods to identify protein dimerization domains. Here, we took a systematic approach to identify the interaction site between two biomedically important *Staphylococcus aureus* proteins: EsxB and EsxD, which are known to strongly interact. Wild-type *esxD* was PCR-amplified using standard methods, followed by fusion to the C-terminal coding sequence of the *Bordetella pertussis adenylate cyclase* (*cya*) gene on the T25 expression vector (Euromedex). Next, *esxB* was amplified by modified error-prone PCR in the presence of 0.6 mM $MnCl_2$ and 20 mM $MgCl_2$ to create one point mutation per ~250 base pairs. Randomly mutated *esxB* from ten different mutagenesis reactions was consolidated and fused to the N-terminal coding sequence of the *B. pertussis cya* on the T18 vector (Euromedex). The two construct-carrying vectors were co-transformed into the *cya*-deficient *Escherichia coli* DHM1, followed by a blue-white two-hybrid screen. Cells were grown in the presence of antibiotics for vector propagation, IPTG for fusion gene inductions and the chromogenic substrate X-gal. The two-hybrid screen revealed the presence of three different color species: 1- Dark blue (no mutation in the EsxB-EsxD dimerization domain), 2- Light blue (possible mutation in a non-dimerization site that may have rendered EsxB less stable), and 3- White (no EsxB-EsxD interaction). The *esxB* gene from white colonies was subjected to classical PCR, followed by DNA sequencing to identify the point mutation that abolished EsxB-EsxD interaction. A single *esxB* point mutation at position 157 coding for asparagine was identified. N53D substitution had no impact on EsxB stability, but only inhibited EsxB-EsxD interaction as judged by SDS-PAGE of the variant protein. Taken together, this novel combination of error-prone PCR mutagenesis and bacterial two-hybrid screens provides a powerful platform for the rapid and robust identification of protein-protein interaction sites, and opens numerous avenues of future microbial biochemistry research.

Optogenetic Investigation of *Neisseria* Species Motility During the Formation of Microcolonies

Author Block:

I. Eugenis[1], K. Gardner[2], N. Biais[1]; [1]Brooklyn Coll. of the City Univ. of New York, Brooklyn, NY, [2]City Coll. of the City Univ. of New York, New York, NY

Abstract Body:

Bacterial motility plays an important role in the attachment to and colonization of a host. However, the twitching motility of bacteria caused by the retraction of their Type IV pili is an understudied biological phenomenon. Here, an optogenetic system was cloned into the genome of both *Neisseria gonorrhoeae* and *Neisseria elongata* to study both their motility and to assay the role of bacterial movement during the formation of microcolonies, the precursors to biofilms. Optogenetics, a technique commonly used in neurons to regulate the expression of genes with light, was applied to bacteria in this experiment. Using this method, pilT, an ATPase motor protein responsible for the retraction of pili and thus the twitching motility, was put under the control of a promoter responding to blue light. Gibson Assembly, a molecular tool that allows for the joining of DNA fragments, was used to create DNA constructs containing the genes encoding pilT and EL222, a light-sensitive protein that binds to a specific sequence of DNA and allows for the transcription of downstream genes. This tool allows for the precise spatial and temporal control of the motility behavior of the bacteria upon the activation of the pilT gene. The optogenetic control of pilT, and thus of the twitching motility, in *N. gonorrhoeae* and *N. elongata* also allows for the measurement of the dynamics of pili turnover.

FactorsInfluencing In Vitro Transformation Efficiency of *Neisseria lactamica*

Author Block:

J. R. Laver, **Z. C. Pounce**, R. C. Read; Univ. of Southampton, Southampton, United Kingdom

Abstract Body:

Natural competence in the Neisseriaceae is mediated by recognition of DNA uptake sequences (DUS) in extracellular DNA, active translocation of DNA into the cell by Type IV pili and its homologous recombination into the chromosome. Despite being naturally competent, the human commensal *Neisseria lactamica* (Nlac) has, until now, proven refractory to targeted genetic manipulation. The genome of Nlac strain Y92-1009 encodes multiple restriction/modification systems, including NlaIII, which cuts DNA at frequently occurring 5'- CATG – 3' sequences. We posit that Nlac restriction enzymes degrade horizontally acquired genetic material prior to homologous recombination and present the most substantial barrier to targeted mutagenesis.To develop a protocol for the genetic modification of Nlac, we designed gene constructs to incorporate kanamycin resistance gene *aphA3* at specific chromosomal loci of Nlac Y92-1009. Constructs contain at least one DUS and sequences of homology to the Nlac genome. Using a modified plate-based transformation method exploiting the natural competence of Nlac, we recovered kanamycin resistant colonies, demonstrating the targeted mutagenesis of this important commensal for the first time.Transformation efficiency was significantly influenced by the presence of CATG restriction sites in the donor material [$p<0.0001$]. This supports a role for restriction activity in disrupting the horizontal acquisition of genes by Nlac. Using hypermethylated (i.e. restriction resistant) PCR products as donor material, we observed both a 1000-fold increase in transformation efficiency [$p<0.0001$] and ablation of the effect of CATG sequences.Based on studies of other naturally competent bacteria, we hypothesized that a variety of additional factors could influence the efficiency of Nlac transformation. In an attempt to optimize these parameters, we showed that transformation efficiency increases proportionately with the length of sequence homologous to the chromosomal insertion locus [$p<0.0001$] and that transformation efficiency is significantly enhanced when constructs contain more than one DUS [$p=0.002$].In summary we have developed and refined a novel, highly efficient methodology for the targeted mutagenesis of Nlac.

Targeted Genetic Manipulation of *Neisseria lactamica*: A Novel System for Expression of Heterologous Antigen and Potential Therapy

Author Block:

J. R. Laver, Z. C. Pounce, R. C. Read; Univ. of Southampton, Southampton, United Kingdom

Abstract Body:

The human commensal bacterium, *Neisseria lactamica* (Nlac) has approximately 67 % genetic identity with the highly pathogenic *Neisseria meningitidis*. Experimental intranasal inoculation of adult human volunteers results in up to 6 months of asymptomatic nasopharyngeal carriage of Nlac, an event that prevents meningococcal acquisition. Genetic manipulation of Nlac therefore presents an opportunity for microbiome-modifying bacteriotherapy, or novel vaccination. However, despite the natural competence of the Neisseriaceae, attempts to transform Nlac have thus far been unsuccessful, likely due to expression of multiple restriction systems. Using a novel, hypermethylated PCR-based strategy, we demonstrate for the first time the targeted mutagenesis of this important commensal organism.Against a background of Nlac strain Y92-1009 (WT), we have deleted the native β-galactosidase (β-gal) gene (*lacZ*), generating Nlac strain *ΔlacZ* and ablating β-gal Specific Activity ($p<0.0001$ cf. WT). Subsequently, we re-introduced a functional copy of the *lacZ* gene, under the control of the Nlac-derived *porB* promoter, into *Neisseria* Heterologous Construct Insertion Site number 1 (NHCIS1), an intergenic chromosomal locus that minimises disruption to Nlac's existing genetic architecture. With the intention to develop a potential probiotic, the recovery of β-gal activity in strain *ΔlacZ* NHCIS1::*lacZ* indicated that *lacZ* could be used as a marker in antibiotic resistance-free cloning. Using this method, we have successfully introduced the gene encoding the immunodominant meningococcal outer membrane protein, Porin A (*porA*) into NHCIS1, which under the control of its native promoter can be detected on the surface of recombinant Nlac by flow cytometry.The ability to perform targeted mutagenesis of and to introduce heterologous antigen into the Nlac genome has therapeutic potential, both in the development of recombinant outer membrane vesicle (OMV)-based vaccines, and for the derivation of strains suitable for use in either experimental human challenge or as a recombinant commensal prophylactic against diseases of the upper respiratory tract.

A Simple Recombineering-Based Protocol for Rapid Allelic Replacement in *Escherichia albertii,* an Attaching and Effacing Pathogen

Author Block:

M. Egan, J. Ramirez, C. Xander, S. Bhatt, Department of Biology, Department of Mathematics; Saint Joseph's Univ., Philadelphia, PA

Abstract Body:

The genetic engineering technique of recombineering allows bacterial pathogeneticists to rapidly and reliably mutagenize the genomes of pathogens to identify virulence factors. In recombineering, linear double- or single-stranded DNA substrates with two terminal homology arms are transformed into hyperrecombinogenic bacteria that express phage-encoded recombinases. The recombinase catalyzes the replacement of the endogenous allele with the exogenous allele by a double crossover event to generate selectable or screenable recombinants. In particular, lambda red recombinase played a pioneering role in constructing mutants to characterize the virulence factors of the attaching and effacing (A/E) pathogens enteropathogenic *Escherichia coli* (EPEC), enterohemorrhagic *E. coli* (EHEC), and *Citrobacter rodentium. Escherichia albertii* is another member of this group; however, its virulence remains unexplored despite a report from the Centers for Disease Control and Prevention (CDC) that *E. albertii* is an emerging pathogen. Recent studies show that many EPEC and EHEC isolates (~15%), which were previously incriminated in outbreaks, are taxonomically *E. albertii*. Thus, there is urgency to engineer mutations in *E. albertii* and comprehensively characterize its virulence. To date, not a single chromosomal gene has mutagenized in *E. albertii* since it was first isolated almost 25 years ago. This is disconcerting because an *E. albertii* outbreak could have devastating consequences due to our inadequate understanding of its virulence. Herein, we describe a modified lambda red recombineering protocol to mutagenize *E. albertii*. We demonstrate its usefulness by successfully deleting three distinct virulence-associated genetic loci - *ler*, *grlRA*, and *hfq* - and replacing each wild type allele by a mutant allele with an encodable drug resistance cassette bracketed by FRT sites. Subsequently, the FRT-site flanked drug resistance marker was evicted by transient expression of the FLP recombinase to generate excisants containing a solitary FRT site. Our protocol will enable researchers to construct virtually any kind of mutation in the genome of *E. albertii,* which will decipher its pathogenic mechanisms to develop appropriate ways to combat *E. albertii* outbreaks.

Development of Novel *Clostridium difficile* Genetic Tools

Author Block:

K. N. McAllister, J. A. Sorg; Texas A&M Univ., College Station, TX

Abstract Body:

Clostridium difficile is a Gram-positive, anaerobic, spore-forming bacterium and a significant concern as a nosocomial pathogen. The tools available to genetically manipulate this organism are limited, but include: TargeTron (ClosTron) system, Allelic-Coupled Exchange/CodA systems and Mariner transposition. The most widely used system is the TargeTron system which relies on the re-targeting of mobilizable group II introns and the use of retrotransposable activated markers (RAM). Though RAM markers allow for the easy identification of potential mutants, unfortunately, the TargeTron system only creates an insertion mutation which prevents the introduction of more precise mutations into the *C. difficile* genome and can have off-target effects if the preferential site exists elsewhere in the genome. Our own experiences with the allelic exchange systems have been unreliable and time consuming, which prevents the efficient introduction of site-directed, non-polar mutations. Our lab is currently trying to apply other genetic systems to *C. difficile* research with the hope of rapidly introducing markerless, site-directed, non-polar insertions or deletions into the *C. difficile* genome.

Development of an Integratable Vector for G*eobacillus* spp

Author Block:

T. J. Marks[1], P. T. Hamilton[2]; [1]Campbell Univ., Buies Creek, NC, [2]North Carolina State Univ., Raleigh, NC

Abstract Body:

Geobacillus species are gram-positive thermophilic bacteria that have potential for biofuel production because they are capable of fermenting C5 and C6 sugars to mixed acids and ethanol. Some species are also able to produce enzymes of industrial interest, including amylases, proteases, and lipases and some have demonstrated the ability to degrade hydrocarbons and cellulose. Unfortunately, there is a need for additional genetic tools for these organisms due to a lack of gene transfer and protein expression vectors that are useful in *Geobacillus*. The diversity among bacteriophages represents a vast set of potential tools that can be developed to exchange, alter and express genes and gene products from an organism of interest. We have characterized two bacteriophages, designated GBK1 and GBK2, that infect *G. kaustophilus* (ATCC #8005) and have the potential to enhance the tools available to study and modify *Geobacillus* species for various industrial applications. GBK2 is a lytic phage with a circularly permuted dsDNA genome containing 39,078 bp and 64 identified ORFs. Of note are ORFs 39 and 40, which encode proteins with homology to RecE and RecT proteins from *B. subtilis* phage SPP1. RecE/RecT have been used to develop recombineering systems in other bacteria. GBK1 is a temperate phage with a linear dsDNA genome containing 45,439 bp and 63 identified ORFs. A 40 bp attP/attB site was identified in GBK1/*G. kaustophilus.* Slightly downstream of the attP site in GBK1 is ORF 47 which has homology to tyrosine integrase/recombinase. We have shown that the integrase is active by isolating GBK1 lysogens inserted into *G. kaustophilus*. Our current studies involve the development of a suicide plasmid, pUCG5.2INT, that replicates in *E. coli*, confers kanamycin resistance in both *E. coli* and *Geobacillus* spp., and acts as an integratable vector in potentially four different *Geobacillus* species. The development of pUCG5.2INT involved the cloning of the attP/integrase from GBK1 into an existing shuttle plasmid (pUCG18) and removal of the origin of replication for geobacilli. Future studies will involve the integration of the recE and recT genes from GBK2 into a host strain by way of the pUCG5.2INT plasmid to explore the possibility of a functional recombineering system in geobacilli.

The IntXO-*PSL* Recombination System is a Key Component of the Second Maintenance System for *Bacillus anthracis* Plasmid pXOA1

Author Block:

A. P. Pomerantsev, C. Rappole, Z. Chang, S. H. Leppla; NIH/NIAID, Bethesda, MD

Abstract Body:

Background: We previously identified three noncontiguous regions on *Bacillus anthracis* plasmid pXO1 that comprise a system for accurate plasmid partition and maintenance. However, deletion of these regions did not decrease retention of the certain shortened pXO1 plasmids during vegetative growth. **Methods:** Using two genetic tools developed for DNA manipulation in *B. anthracis* (Cre-*loxP* and Flp-*FRT* systems), we found two other noncontiguous pXO1 regions that together are sufficient for plasmid stability.**Results:** This second pXO1 maintenance system includes the *tubZ* and *tubR* genes, characteristic of a type III partition system, and the *intXO* gene (GBAA_RS29165), encoding a tyrosine recombinase, along with its adjacent 37-bp *PSL* (perfect stem-loop) target. Insertion of either the *tubZ* and *tubR* genes or the IntXO-*PSL* system into an unstable mini-pXO1 plasmid did not restore plasmid stability. The need for the two components of the second pXO1-maintenance system follows from the sequential roles of IntXO-*PSL* in generating monomeric circular daughter pXO1 molecules (thereby presumably preventing dimer catastrophe), and of TubZ/TubR in partitioning the monomers during cell division. We show that the IntXO recombinase deletes DNA fragments located between two *PSL* sites in a manner similar to the actions of the Cre-*loxP* and Flp-*FRT* systems.**Conclusions:** These results demonstrate that tyrosine recombinases used in this study provide an approach for genome editing that may be preferred in some cases to alternative methods (e.g., CRISPR/Cas systems).

Generation and *In Vivo* Characterization of an Unmarked *Hemo* Cluster Deletion Mutant of *Acinetobacter baumannii* Lac-4

Author Block:

P. J. Ewing[1], J. A. Garcia[1], W. Chen[2], H. Xu[1]; [1]California State Univ., Los Angeles, Los Angeles, CA, [2]Natl. Res. Council, Ottawa, ON, Canada

Abstract Body:

Background: *Acinetobacter baumannii* is one of the most problematic bacterial pathogens due to its emergence and spread of multi-drug resistance (MDR). We previously showed that a hospital outbreak MDR strain (LAC-4) of *A. baumannii* is hypervirulent in mice, exhibits high serum resistance and expresses a highly efficient heme utilization system. We also found that all *A. baumannii* strains possess a heme utilization gene cluster, while only some strains, including LAC-4, harbor a second gene cluster that contains a gene encoding for heme oxygenase (termed hemO cluster, HOC). However, systematic investigations of MDR *A. baumannii* have been hindered by a lack of facile genetic tools. Here we describe generation and in vivo characterization of an unmarked knockout (KO) mutant of LAC-4 in which the 9.5-kb eight-gene HOC was deleted.**Methods:** The HOC mutant was constructed via homologous recombination of the KO cassette cloned into the suicide vector pMo130. An apramycin (Apr) resistant gene was linked outside to two fused flanking regions of HOC via overlap extension PCR. After the initial transformant was isolated via single cross-over of the suicide plasmid, unmarked HOC mutant was obtained via second homologous recombination achieved by *sacB* counter selection and the use of *xylE* reporter gene. The virulence of the HOC mutant was evaluated in an established mouse model of bacterial pneumonia. **Results:** LAC-4 strain was found to be susceptible to Apr. Consequently, the Apr resistant gene was used for selection in genetic manipulations in this MDR strain. The *xylE* reporter gene was useful both in selection of co-integrants after initial transformation of LAC-4 with KO construct, and in screening for eventual HOC deletion mutant clones which have lost the plasmid backbone which contains *xylE* and *sacB* genes. Sequence-confirmed HOC mutant was found to be less virulent than LAC-4 strain with significantly lower bacterial burdens in the lung and spleen and milder bacteremia ($P<0.001$).**Conclusions:** Our findings indicate the use of *SacB* and *XylE* in conjunction with a construct design for unmarked deletion is an effective strategy to generate unmarked mutants. The hemO cluster appears to contribute to LAC-4's hypervirulence in mice.

A New Drug Selectable Marker For Rodent Malaria Parasites

Author Block:

A. C. Reese, E. E. Munoz, S. E. Lindner; Pennsylvania State Univ., University Park, PA

Abstract Body:

Sequential and conditional gene knockout approaches are valuable tools for reverse genetics in model species. However, studies of rodent malaria parasites (e.g. Plasmodium yoelii) suffer from having only one drug-selectable marker, a variant of dihydrofolate reductase (DHFR), which is used to select for transgenic parasites in the presence of pyrimethamine. We predict that variants of dihydropterotate synthase (DHPS), another enzyme in the folate pathway, can be used to convey resistance to the drug sulfadiazine as they have conferred resistance in field isolates of human-infectious Plasmodium species. The purpose of this experiment is two-fold. First, to determine which variant of the DHPS sequence will provide the best resistance to sulfadiazine. Second, to determine if DHPS alone can confer resistance, as previous publications have utilized this cassette either with DHFR or with PPPK, the enzyme before DHPS in the folate pathway. To test the effectiveness of DHPS in conferring drug resistance, parasites were transfected with a plasmid that expresses a field variant of DHPS and GFP separately, and were selected by administering sulfadiazine via drinking water. Preliminary data indicates that the bifunctional PPPK-DHPS protein is sufficient to select for transgenic parasites at a dose of 1 mg/L sulfadiazine. Our ongoing experiments will determine at what concentrations of pyrimethamine and sulfadiazine it is possible to simultaneously select for parasites that possess both the DHFR and DHPS cassettes, if the DHPS domain alone is sufficient, and what field variant of DHPS confers the best therapeutic window. Once optimized, this system will provide an efficient means by which doubly transgenic parasites can be selected for by a drug cocktail.

Standardization of a Multifunctional Halotag Reporter System in Tritrichomonas Foetus

Author Block:

A. Kucknoor, **K. Arriola**, S. Ganguly; Lamar Univ., Beaumont, TX

Abstract Body:

The aim of this study is to standardize the multifunctional HaloTag reporter system in *Tritrichomonas foetus*, a cattle pathogen. Protein targeting and localization in trichomonad species is not well studied. Being extracellular parasites, trichomonads establish residence on host epithelial cells, and proteins that are necessary for the adherence of parasites are necessary for pathogenesis. In order to understand the functional role of proteins and how they interact within and outside of the cell it is very crucial to have a flexible reporter system, which will enable us to purify the protein, analyze its expression and localization, and perform further functional analyses. We have constructed an expression plasmid with HaloTag as the reporter gene, and standardized the transfection procedures in *T. foetus*. Following successful detection of HaloTag expression, we have constructed a fusion protein of Ferredoxin-HaloTag and verified the organelle specific localization of Ferredoxin gene using Halotag ligand system. Results from this study indicate that HaloTag system can be used for protein expression and localization studies in trichomonad species. Analyses of surface proteins that are important for host-pathogen interactions of *T. foetus* using the HaloTag system are underway.

Construction of Stable and Unstable Vectors for Use in Sphingomonads

Author Block:

S. S. Eleya, G. J. Zylstra; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Sphingomonads are of a great interest in the bioremediation field due to their unusual capabilities to biodegrade and metabolize a wide range of monocyclic and polycyclic aromatic compounds including benzene, toluene, xylenes, phenols, biphenyl, naphthalene, phenanthrene, carbazole, dibenzofurans, and dibenzo-*p*-dioxins. *Sphingomonas yanoikuyae* strain B1 is one of the most interesting *Sphingomonas* strains because of its capability to degrade both monocyclic and polycyclic aromatic hydrocarbons such as biphenyl, naphthalene, phenanthrene, toluene, and *m*- and *p*-xylene as the sole source of carbon and energy. The complete sequence of the 32 kb *Sphingomonas yanoikuyae* B1 cryptic plasmid pKG2 revealed an origin of replication sequence (*oriR*) and two essential genes encoding for replication and partitioning components of the plasmid, named *repA* and *parA* respectively. We hypothesized that the *repA* gene along with the origin of replication (*oriR*) is the minimum required for replication of pKG2. We also hypothesized that *parA* is required for stability of the plasmid and proper partitioning during cell division. We designed and constructed two *Sphingomonas* shuttle vectors, one containing *repA* and *oriR* from pKG2 and the other containing *repA*, *oriR*, and *parA* from pkG2. Additionally the plasmids contained a tetracycline resistance gene, an origin of conjugal transfer (*oriT)*, the *E. coli* pMB1 *oriR*, and a *lacZ* gene with a multiple cloning site from pGEM5Z (f-). The newly constructed vectors were then examined for their ability to be maintained in *Sphingomonas* strains. Upon introduction into *S. yanoikuyae* B1 with tetracycline selection both new vectors caused the loss of plasmid pKG2 confirming the expected incompatability due to the identical *oriR* in both plasmids. Plasmid stability tests showed that the *repA*-*oriR*-*parA* vector was completely stable (0% loss) over six days of subculture without antibiotic selection. In contrast, the *repA*-*oriR* vector was lost at the rate of 10% for every 24 hr subculture. Our work demonstrates that the *repA*-*oriR* region is sufficient for replication and that *parA* is absolutely required for plasmid stability. These two cloning vectors in both a stable and unstable version are useful genetic tools for the manipulation of *Sphingomonas* strains.

Assembly and Comparison of Whole Genomes from Single-Molecule Sequencing

Author Block:

A. Phillippy[1], S. Koren[1], B. Walenz[1], B. Ondov[2], T. Treangen[2]; [1]Natl. Human Genome Res. Inst., Bethesda, MD, [2]Natl. Biodefense Analysis and Countermeasures Ctr., Frederick, MD

Abstract Body:

Single-molecule sequencing with PacBio technology is now routinely used to assemble complete, high-quality microbial genomes, revealing population-scale structural variation. The newly released Oxford Nanopore MinION instrument provides a similar data type, but with a pay-per-run price model that eliminates instrument cost. This will enable small labs to generate their own genome sequences, in-house, and will demand efficient, usable software for the analysis of whole genomes. We have developed several methods aimed at assembling and comparing whole genomes derived from these data types.For genome assembly, we have developed a new whole-genome assembler, named Canu, that is specifically optimized for single-molecule sequencing. Canu represents a complete refactorization of the Celera Assembler that introduces support for Oxford Nanopore reads, lowers coverage requirements, and improves runtime. We have demonstrated that Canu can efficiently generate complete assemblies of microbial genomes using ~30X coverage of either PacBio or Nanopore data.For whole-genome comparisons, identifying closely related genomes is often the first step after sequencing a new genome. However, given a massive collection of sequences, pairwise alignment becomes infeasible for this task. To address this problem, we have developed a new tool, Mash, that reduces large genomes and metagenomes to small, representative sketches, from which pairwise genomic distances can be rapidly estimated. Mash distances correlate well with established metrics like Average Nucleotide Identity, and can be used to cluster thousands of genomes by species, cluster metagenomes by composition, reconstruct approximate phylogenies, and search large reference databases. For example, using Mash we were able to compress all 54,118 NCBI RefSeq genomes into a 93 MB sketch database, and using this reference database, correctly identify Ebola virus from 200 kb of MinION nanopore reads in just one second.Canu and Mash, as well as additional tools for metagenomics, genome assembly, and core-genome alignment, are freely available from https://github.com/marbl.

Integrative Analysis Pipeline for Bacteria Genome Assembly and Methylation Analysis Using Smrt Sequencing and Hybrid Approach

Author Block:

h. nguyen, S. Leopold, L. R. Coy, S. Lek, B. Hanson, E. Sodergren, G. Weinstock; The Jackson Lab. for Genomic Med., Farmington, CT

Abstract Body:

With the rapid progress of Single-molecule real-time (SMRT®) DNA sequencing and computational methods, we can improve *de novo* genome assembly, and discover DNA modifications including N6-methyladenine, 5-methylcytosine and N4-methylcytosine at single-nucleotide resolution. We present an integrative analysis pipeline dedicated to bacterial genome assembly and methylation analysis using PacBio Sequencing and heterogeneous NGS bioinformatics resources (SMRTANALTYSIS, QUIVER, PILON, Celera). The pipeline contains four main iterative steps: (1) *de-novo* assembly using PacBio long reads, and PBcR and HGAP assembler, (2) error correction and gap filling of the draft assembly with high-quality of Illumina short reads, (3) utilization of GEPARD dotplots and illumina paired-reads mapped on PacBio contigs for assembly quality checks and circular validation, and (4) implementation of the draft reference genome and SMRT movie data for detecting the methylase motif including Dam GATC that plays a role in the initiation of bacterial replication. The ratio of the GATC motif detection in the movie data compared to the draft reference genome can also be used for validating the quality of raw data and of genome assembly. We have successfully applied this integrative pipeline for dozens of bacteria strains including *Klebsiella pneumoniae* carbapenemase, *Staphylococcus aureus*, and *Escherichia coli*.. Finally, we show that the combination of *de-novo* assembly processes and methylation analysis can help address a variety of biological questions concerning antibiotic resistance by bacterial pathogens.

Absence of Cytomegalovirus in Transcriptome and High-Coverage DNA Sequencing Argues against Antiviral Treatment of Human Glioblastoma Multiforme

Author Block:

K-W. Tang; Univ. of Gothenburg, Gothenburg, Sweden

Abstract Body:

Viruses cause 10-15% of all human cancers. Massively parallel sequencing has recently proved effective for uncovering novel viruses and virus-tumour associations. We screened a diverse landscape of human cancer, encompassing 4,433 tumours and 19 cancer types, for known and novel expressed viruses based on >700 billion transcriptome sequencing reads from The Cancer Genome Atlas Research Network. The resulting map confirms and extends current knowledge. Our analysis argues strongly against viral aetiology in several cancers where this has frequently been proposed. For example were we unable to detect any cytomegalovirus (CMV) in 22.8 billion sequencing reads of mRNA from 167 glioblastoma multiforme tumors. We also utilized deep-coverage whole-genome sequencing data to detect latent CMV DNA and to assess the relative proportions of viral and human DNA. We did not find traces of CMV in 52.6 billion DNA sequencing reads from 34 glioblastomas. By statistical analysis, we conclude that should the virus be present in these tumors, the average CMV level does not exceed one virus per 240,000 tumor cells (99% CI). These findings together strongly argues against current antiviral treatment of glioblastoma multiforme.

C. Zhang, A. Phillips, R. Whitaker; Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract Body:

Sulfolobus islandicus, an aerobic hyperthermophilic crenarchaeon which grows optimally at 80°C and pH 2 in terrestrial solfataric springs distributed around the world, has been developed as a novel model microorganism to study the unique biology of Crenarchaea. Here, a comprehensive genome-scale analysis of gene function by transposon mutagenesis coupled with deep sequencing methodology has been developed successfully in *S. islandicus*. Three independent transposon insertion libraries with around 100,000 colonies in total were collected, sequenced and then mapped to the reference genome. As a result, about 90,000 unique insertions (reads >3) were identified, allowing us to classify about 17% of the genome (~460 genes) as possible essential genes. The differences noted between our data with those predictors of essentiality led to several surprisingly discoveries. For example, the reverse gyrase-encoding gene, which is considered as a hallmark of hyperthermophiles and a prerequisite for hyperthermophilic life, is dispensable for cell survival as a couple of transposon insertions were found. This result was further confirmed by a successful disruption of the reverse gyrase gene via reverse genetics, suggesting that S. islandicus does not require reverse gyrase. Our investigation of essentiality of every gene will serve as a valuable resource to reveal unexplored genetic determinants and the underlying mechanisms of various biological processes especially the DNA repair, replication and recombination in the *S. islandicus*.

Dissecting the Genetic Basis of Species-Specific Essential Genes in Yeast

Author Block:

M. Sanchez[1], C. Payen[1], F. Cheong[1], B. Hovde[1], J. Skerker[2], R. Brem[2], A. Caudy[3], M. Dunham[1]; [1]Univ. of Washington, Seattle, WA, [2]Univ. of California Berkeley, Berkeley, CA, [3]Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

To understand how complex genetic networks perform and regulate diverse cellular processes, the function of each individual component must be defined. One powerful approach to defining gene function is via genetics: phenotypes conferred by mutant alleles can be used to determine what processes depend on the normal function of a gene. This approach has been wildly successful in model organisms, in which comprehensive studies have been performed. These results are often translated to the increasing number of newly sequenced genomes by using sequence homology. However, sequence similarity does not always mean identical function or phenotype, suggesting that new methods are required to functionally annotate newly sequenced species. We have implemented comparative functional analysis by high-throughput experimental testing of gene function in a sequenced, but otherwise understudied species of yeast, *Saccharomyces uvarum*, a sister species of *S. cerevisiae.* We created a haploid and heterozygous diploid library containing Tn7 transposon insertions in *S. uvarum* to identify species-specific essential genes. Using deep sequencing, we identified 50,193 and 37,022 independent insertion sites found in 80% and 63% of orthologous coding sequences in the diploid and haploid libraries respectively. We predict 809 genes to be essential in *S. uvarum*, with 444 of those genes also known to be essential in *S. cerevisiae*. We predict 115 genes to be *S. cerevisiae*-specific essential genes (non-essential in *S. uvarum),* and confirmed 5 highly ranked genes. However, these genes are capable of cross-species complementation, demonstrating that differences in genetic background must contribute to differential gene essentiality. We are now mapping these genetic background elements to determine the molecular explanation for these differences. This data set provides direct experimental evidence of gene function across species, which can inform comparative genomic analyses, improve gene annotation and be applied across a diverse set of microorganisms to further our understanding of gene function evolution.

Targeting Self-Resistance for Genomics-Based Discovery of Novel Antibiotics

Author Block:

X. Tang, J. Li, N. Millán-Aguiñaga, J. J. Zhang, E. C. O'Neill, J. A. Ugalde, P. R. Jensen, S. M. Mantovani, B. S. Moore; Scripps Inst. of Oceanography, UCSD, La Jolla, CA

Abstract Body:

Recent genome sequencing efforts have led to the rapid accumulation of uncharacterized or "orphaned" secondary metabolic biosynthesis gene clusters (BGCs) in public databases. This increase in DNA-sequenced big data has given rise to significant challenges in the applied field of natural product genome mining, including (*i*) how to prioritize the characterization of orphan BGCs, and (*ii*) how to rapidly connect genes to biosynthesized small molecules. Here we propose a new genomics-based strategy that by correlating putative antibiotic resistance genes with orphan biosynthetic gene clusters, we can predict the biological function of pathway specific small molecules before they have been revealed in a process we call target-directed genome mining. Combined with an approach based on transformation-associated recombination in yeast to directly assemble complete gene sets from genomic DNA, we can prioritize, capture, and express potential antibiotic producing biosynthetic gene clusters to identify antibiotic leads, their resistance genes, and their targets. To validate this approach, we queried the pan-genome of 86 *Salinispora* genomes for duplicated house-keeping genes co-localized with natural product biosynthetic gene clusters (BGCs) and prioritized an orphan polyketide synthase-nonribosomal peptide synthetase hybrid BGC (*tlm*) with a putative fatty acid synthase resistance gene. We then directly cloned *tlm* and the related *ttm* BGCs directly from genomic DNA and to heterologously express them in *Streptomyces* hosts. We show the production of a group of unusual thiotetronic acid natural products, including the well-known fatty acid synthase inhibitor thiolactomycin that was first described over 30 years ago, yet never at the genetic level in regards to biosynthesis and auto-resistance. This finding validates the target-directed genome mining strategy for the discovery of antibiotic producing gene clusters without *a priori* knowledge of the molecule synthesized and highlights a streamlined method for the coordinated discovery of antibiotics, their resistance genes, and their targets

Characterization of a Unique Gamma-Glutamylase Dependent Pathway for Ethanolamine Catabolism

Author Block:

B. San Francisco, X. Zhang, J. T. Bouvier, J. E. Cronan, J. A. Gerlt; Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract Body:

Ethanolamine is abundant in nature as a component of phosphatidylethanolamine found in the cell membranes of eukaryotes and bacteria. Many species of bacteria derive carbon and/or nitrogen from ethanolamine via the well-characterized ethanolamine utilization (EUT) pathway. The central enzyme in the EUT pathway is the adenosylcobalamin-dependent ethanolamine ammonia-lyase, which cleaves ethanolamine to release ammonia and acetaldehyde. Here, we report functional and phylogenomic characterization of a new, gamma-glutamylase dependent pathway (termed EOA) for ethanolamine catabolism in bacteria. We use enzymology and microbiology guided by large-scale analyses of sequence-function relationships and genome context to delineate this four-enzyme pathway for ethanolamine catabolism that terminates in glycine, a source of cellular nitrogen. Analysis of the taxonomic distribution of the EOA pathway revealed that the pathway is found almost exclusively in Proteobacteria and Actinobacteria. Interestingly, the pathway in each phylum differs by the enzyme that catalyzes the final step. Proteobacteria utilize a previously uncharacterized hydrolase from the amidohydrolase superfamily while Actinobacteria utilize a member of the peptidase C26 enzyme family to catalyze the final step of the pathway. In total, the characterization of this pathway enabled the assignment of function to enzymes and proteins from at least ten different Pfam families encoded in the genomes of nearly 400 distinct species. We found that some species encode enzyme homologues of both the EUT and EOA pathways, and we provide evidence to suggest that organisms may prefer one pathway depending on microhabitat. We discuss possible modes of regulation and environmental pressures that may have been involved in pathway selection.

Single Molecule Real Time (SMRT) Sequencing of the *Prevotella intermedia* Methylome to Overcome the Restriction-Modification Barrier Using a Host Mimicking Strategy

Author Block:

C. D. Johnston, S. R. Rittling; The Forsyth Inst., Cambridge, MA

Abstract Body:

Prevotella intermedia is a major oral pathogen associated with periodontitis, endodontic infections and oro-facial gangrene. Additionally, *P. intermedia* is increasingly found in association with respiratory infections such as cystic fibrosis, a progressive and frequently fatal genetic disease. We previously identified a new virulence mechanism utilized by *P. intermedia* capable of efficiently disabling and killing neutrophils allowing persistent infections to become established. However, there is currently no system available for genetic manipulation of *P. intermedia,* so in order to elucidate this mechanism we attempted to use functional plasmids from related bacterial species (*Bacteroides*/*Porphyromonas/Prevotella*) but none of these conferred antibiotic resistance. The failure of these plasmids despite compatible replicative machinery led us to consider that restriction-modification (R-M) systems, which allow bacteria to distinguish between their own DNA and any foreign DNA, were inhibiting transformation. We demonstrate that *P. intermedia* genomic DNA (gDNA) is highly resistant to restriction endonucleases that recognize the short commonly occurring sequence $^{5'}$-GATC-$^{3'}$ (*Sau*3AI, *Mbo*I, *Dpn*I, and *Dpn*II), suggesting the presence of an active R-M system specific for the cytosine residue of this sequence (GAT^{m-}C). We hypothesize that this and other R-M systems are the root cause of the transformation-barrier in *P. intermedia* and that circumvention of these R-M systems is a prerequisite for the development of its genetic system. Fortunately, an innovative technology, Single Molecule Real-Time (SMRT) sequencing, has recently become available which allows rapid and sensitive detection of each methylation site, with single-base resolution, across an entire bacterial genome (i.e. the bacterial methylome). Here we utilize SMRT sequencing to define the complete methylomes of *P. intermedia* ATCC25611 and the clinical isolate strain-17 to identify specifically the cognate recognition sequences used by each of their R-M systems. Methylome analysis and the subsequent use of a host-mimicking plasmid (codon optimized *de-novo* synthesized plasmid DNA lacking each recognition sequence) represents an entirely novel and innovative approach to developing a genetic system for *P. intermedia*.

The Isolation of DNA from the Oral Metagenome Using Entrapment Vectors

Author Block:

S. Tansirichaiya, N. Antou, P. Mullany, A. P. Roberts; UCL Eastman Dental Inst., London, United Kingdom

Abstract Body:

Antibiotic resistance genes are often associated with transposable elements (TEs). TEs are segments of DNA capable of movement within a genome. By detecting TEs, we may discover associated resistance genes.Entrapment vectors are plasmids capable of capturing TEs based on their movement. They have previously been used to capture TEs within single bacterial isolates. As more than 99% of bacteria are not yet culturable, we constructed entrapment vectors for the direct isolation of TEs from human oral metagenomic DNA. Therefore, TEs from both culturable and not yet culturable could theoretically be captured by this system.Three entrapment vectors were used, each differing in their characteristics. We designed a small insert-high copy number (pUCpAK) and a large insert-low copy (but inducible to high copy) number (BACpAK) vectors based on the pAK1 entrapment vector. These vectors contain a *cI-tetA* positive selection cartridge. The *cI* gene encodes a repressor that inhibits the expression of *tetA*. Therefore, if there is disruption of *cI* gene by insertion of TE, it will allow *tetA* to be expressed and result in a tetracycline resistant phenotype, providing positive selection for insertional inactivation by a TE.The oral metagenome was either directly transformed into *Escherichia coli* competent cells containing an entrapment vector, or a library constructed in the vectors followed by transformation into *E. coli* and selection on tetracycline-containing media. Most of the tetracycline resistant clones contain different types of background mutation in *cI-tetA* (point mutation, deletion, and duplication) and some showed the insertion of TEs from the chromosome of the *E. coli* host. We also found the insertion of *Veillonella parvula* DNA and three different human DNAs at the same position between *cI* and *tetA*. These insertions are not likely to be a result of classical transposition and might represent a new mechanism of DNA recombination.

A Novel Method for a More Complete Microbial Community Profile

Author Block:

C. L. Wright, M. Band, M. A. Mikel, A. G. Hernandez; Univ. of Illinois, Urbana, IL

Abstract Body:

Utilizing next generation sequencing (NGS) on 16S amplicons, one can classify all bacteria in a defined location and compare that community across different time-points, locations, treatments, or other conditions. Here, we present a novel approach to this common method that leverages NGS with microfluidics PCR to allow simultaneous amplification of multiple samples with not just the 16S bacterial locus, but also eukaryotic, archaeal, fungal, as well as functional-gene specific targets. The procedure takes less than 1 week with output ready for NGS sequencing.DNA samples are quantified and diluted to 2 ng/µl. A master mix is prepared using the Roche High Fidelity Fast Start Kit and 20x Access Array (AA) loading reagent according to Fluidigm AA protocol. Master mix, 1 µl DNA and 1 µl Fluidigm Illumina barcoded linkers are added to each sample well of a Fluidigm 48.48 AA IFC. Selected primer pairs are aliquoted separately. The AX controller (Fluidigm) performs microfluidic loading of all primer/sample combinations in the IFC followed by amplification on the Fluidigm Biomark HD. Following amplification, harvested products are quantified and run on a Fragment Analyzer (Advanced Analytics, Ames, IA) to confirm sizes. Samples are pooled, gel-size selected, and again checked on an Agilent Bioanalyzer. Up to 1536 barcoded samples can be combined into one pool for sequencing.The pool is quantitated by qPCR, denatured and diluted to 6 pM and spiked with 15% non-indexed PhiX. Sequencing is done on the Illumina MiSeq or V2 Rapid HiSeq based on the number of samples and primer-sets within each pool to target at least 20k sequencing reads per sample per primer. The fragments are sequenced for 250nt from each end.Cluster density averages ~700k/mm2 with ~90% of clusters passing filter. Raw .bcl files are run through the Illumina bcl2fastq pipeline using a custom pipeline to generate data by primer set and by index so that final data is ready to be analyzed in QIIME, mothur, IM-tornado, or other analysis software packages.This novel microbial profiling system is a fast, cost-effective, multi-targeted metagenomic approach for whole microbial community analysis. Surveying the entire microbial community gives an enhanced understanding of the complex nature of these communities. Here we share details with the broader research community to help raise microbial community studies to the next level.

The Impact of DNA Extraction and Selected 16S Primers on the Results of Gut Microbiota Composition Analysis

Author Block:

A. Rintala[1], E. Munukka[1], S. Pietilä[2], E. Eerola[1], J-P. Pursiheimo[1], A. Laiho[2], P. Huovinen[1]; [1]Turku Univ., Turku, Finland, [2]Turku Ctr. for Biotechnology, Turku, Finland

Abstract Body:

Next generation sequencing (NGS) has recently become the most popular method for investigating the gut microbiota composition. As the number of available methods is extensive, the comparability of different study results is often not guaranteed. In this study, we analyzed the impact of DNA extraction and selected 16S primers on the gut microbiota NGS results.Bacterial DNA from four fresh stool specimens was extracted with five commercial DNA extraction kits: QIAamp DNA Stool Mini Kit (Qiagen), QIAamp Fast DNA Stool Mini Kit (Qiagen), PowerFecal DNA Isolation Kit (MO BIO), GXT Stool Extraction Kit (Hain Lifescience), and MagNA Pure 96 DNA and Viral NA Large Volume Kit (Roche). The microbial composition was analyzed with two distinct protocols, one detecting the V3-V4 and the other detecting the V4-V5 area of the bacterial 16S rRNA gene. The V3-V4 area was amplified by following the Illumina 16S Metagenomic Sequencing Library Preparation Quide, while the V4-V5 area was amplified with indexed primers modified from Caporaso *et al.* (2011). NGS was performed with Illumina Miseq system, and the data were analysed with QIIME 1.9 pipeline (Caporaso *et al.* 2010).The DNA yield was highest with GXT Stool Extraction Kit, but the quantity and quality of the DNA was sufficient for 16S library preparation with all tested methods. The number of recognized operational taxonomic units (OTUs) in NGS did not significantly differ between the extraction methods, and no significant differences were found in the abundances of different bacterial phyla. Yet, the abundance of certain bacterial genera varied between the extraction protocols. The V3-V4 and V4-V5 sequencing results differed significantly from each other. The total OTU count was clearly higher in V4-V5 sequencing, but the average diversity of the samples was higher in the V3-V4 sequencing. The abundance of all bacterial phyla and several genera varied significantly between the protocols. The results indicate that the influence of the DNA extraction on the gut microbiota NGS analysis is relatively low, while the primers targeting the 16S rRNA gene have a huge impact on the gained results.

Minimization of Chimera Formation and Substitution Errors in Full-Length 16s Pcr Amplification

Author Block:

S. Oh, R. Hall, L. Hon, **C. Heiner**; Pacific BioSci.s, Menlo Park, CA

Abstract Body:

The constituents and intra-communal interactions of microbial populations have garnered increasing interest in areas such as water remediation, agriculture and human health. Amplification and sequencing of the evolutionarily conserved 16S rRNA gene is an efficient method of profiling communities. Currently, most targeted amplification focuses on short, hypervariable regions of the 16S sequence. Distinguishing information not spanned by the targeted region is lost, and species-level classification is often not possible. PacBio SMRT® Sequencing easily spans the entire 1.5 kb 16S gene in a single read, producing highly accurate single-molecule sequences that can improve the identification of individual species in a metapopulation.However, this process still relies upon PCR amplification from a mixture of similar sequences, which may result in chimeras, or recombinant molecules, at rates upwards of 20%. These PCR artifacts make it difficult to identify novel species, and reduce the amount of informative sequences. We investigated multiple factors that may contribute to chimera formation, such as template damage, denaturation time before and during thermocycling, polymerase extension time, and reaction volume. We found two related factors that contribute to chimera formation: the amount of input template into the PCR reaction, and the number of PCR cycles.A second problem that can confound analysis is sequence errors generated during amplification and sequencing. With the updated algorithm for circular consensus sequencing (CCS2), single-molecule reads can be filtered to 99.99% predicted accuracy. Substitution errors in these highly filtered reads may be dominated by mis-incorporations during amplification. Sequence differences in full-length 16S amplicons from several commercial high-fidelity PCR kits were compared.We show results of our experiments and describe our optimized protocol for full-length 16S amplification for SMRT Sequencing. These optimizations have broader implications for other applications that use PCR amplification to phase variations across targeted regions and generate highly accurate reference sequences.

Development of a Metagenomics-Based Tool for Detection of Pathogens on Environmental and Clinical Samples

Author Block:

J. C. Castro[1], L. M. Rodriguez[1], J. K. Hatt[1], M. Carter[2], K. T. Konstantinidis[1]; [1]Georgia Inst. of Technology, Atlanta, GA, [2]United States Depertment of Agriculture, Albany, CA

Abstract Body:

Accurate detection of pathogenic bacteria plays a key role in the prevention of outbreak and spread of disease. Fresh produce and clinical isolates are commonplace for microorganisms, and in these conditions is crucial to be able to determine pathogen presence, in order to diminish the associated risks in our food supply and clinical environments. We aimed to develop a tool that allows for the detection of bacteria in metagenomic samples. In order to do this, we first determined the regions of the genome that had significant matches in another species; these "noisy" regions were flagged and discarded. We then created different sets of *in*-silico metagenomes, with variable amounts of reads generated from the E. coli genome. This served us to create a null model for the presence and absence of E. coli in the metagenome. Our tool uses a logistic model to estimate the probability of presence; based on the percentage of the genome that is recovered (sequencing breadth) and the number of times each region is sequences (sequencing depth). To test our model, we inoculated spinach leaves with different cell concentrations of this strain (80 to $8*10^5$ cells), and sequenced the resulting samples using the Illumina MiSEQ platform. Thus we achieved a simple yet effective bioinformatics approach and the associated wet-lab protocol to detect pathogen species based on metagenomics. Our methodology can easily be extended t other pathogens that may be present in fresh produce or clinical samples.

An Effect Size Meta-Analysis across Microbiome Studies

Author Block:

P. Vangay, D. Knights, 55455; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Microbial communities are critical contributors to maintaining balance in a variety of environments, such as deep-sea water vents, nutrient-rich farm soils, and throughout the human body. Despite large differences in microbiome studies, similar metrics are used for hypothesis testing throughout microbial ecology, including those such as alpha diversity, beta diversity, taxonomic differences, and functional pathway differences. Although many studies have calculated effect sizes for the purpose of power analysis when designing studies, these results typically include only one or two datasets and are not commonly published. There currently has not been an in depth meta-analysis of effect sizes across a large variety of microbiome studies. We present an analysis of effect sizes based on several well-known and newly published datasets in the microbiome field, and also take into account how factors such as data transformations, data filtering, rarefaction, and choice of statistical test influence the effect size of different group comparisons within a dataset. With this paper, we have also included access to an open-source R package with a public web interface for users to directly interact with, enabling reproduction of our results, the addition of new datasets, and direct use for their own studies.

Multiplexing Strategies for Microbial Whole Genome Smrt® Sequencing

Author Block:

C. Lambert, W. Lee, J. Harting, P. Baybayan; PacBio, Menlo Park, CA

Abstract Body:

The increased throughput of the PacBio® RS II and Sequel Systems enables multiple microbes to be sequenced on a single SMRT® Cell. This multiplexing can be readily achieved by incorporating a unique barcode for each microbe into the SMRTbell™ adapters after shearing genomic DNA using a stream-lined library construction process. Incorporating a barcode without the requirement for PCR amplification prevents the loss of epigenetic information (e.g., methylation signatures), and the generation of chimeric sequences, while the modified protocol eliminates the need to build several individual SMRTbell libraries.We multiplexed up to 8 unique strains of *H. pylori*. Each strain was sheared, and processed through adapter ligation in a single, addition only reaction. The barcoded strains were then pooled in equimolar quantities, and processed through the remainder of the library preparation and purification steps.We demonstrate successful *de novo* microbial assembly and epigenetic analysis from all multiplexes (2 through 8-plex) using standard tools within SMRT Link Analysis using data generated from a single SMRTbell library, run on a single SMRT Cell. This process facilitates the sequencing of multiple microbial genomes in a single day, greatly increasing throughput and reducing costs per genome assembly.

Complete Microbial Community Representation by Next-Generation Sequencing

Author Block:

M. Hymes, K. Cunningham; Swift BioSci.s, Inc., Ann Arbor, MI

Abstract Body:

Next generation sequencing (NGS) provides a powerful tool for metagenomics, however, multiple methods and are required in order to identify both single-stranded (ssDNA) and double-stranded DNA (dsDNA) organisms from a single sample. Here, we address a new method for NGS library preparation which utilizes a single preparation to analyze all microbial members in a metagenomic sample.In order to demonstrate the potential of capturing DNA from both ssDNA and dsDNA in a single NGS library preparation, we created a simplified phage community model comprised of ssDNA phage, PhiX174 and M13 mixed with dsDNA phage. A total of 10 different phage were pooled together in varying ratios across multiple samples in order to understand the impact of combining these organisms. In all cases, the abundance level as detected by NGS analysis aligned within 10% of the theoretical inputs. In a separate evaluation, harsh extraction methods of DNA were tested to determine the effects of the library preparation method on difficult to extract genomes. Two species, *Eggerthella sp* HPP0013 and *Facklamia sp.* HGF4, were subjected separately to either bead beating or NaOH boiling for DNA extraction followed by a ssDNA NGS library preparation. The *Eggerthella* samples produced comparable results with either method while the *Facklamia* samples provided a 30x increase in yield from using NaOH boiling for extraction. The experiment was repeated with a dsDNA library preparation method and resulted yields from the bead beating samples but not the NaOH boiled samples due to denaturing of DNA. The results of these studies demonstrate that the method used to extract and prepare the DNA library for sequencing influences the genomes which will be represented in the sample and must be carefully considered when designing NGS based experiments.

Profiling of Metagenomic Communities with Long Reads

Author Block:

A. Hernandez, C. Wright; Univ. of Illinois, Urbana, IL

Abstract Body:

Background: Next-generation DNA sequencing has allowed massive gains in microbial studies. Assembly of individual genomes and metagenomes and the characterization of metabolic pathways is an important step for elucidating the structure and function of these communities and in evaluating how they change in response to physiological, pathological or environmental conditions. However, this is still a daunting task using short-read sequencing technologies.The aim of this project is the optimization of tools for assembling and profiling metagenomic communities in a timely and cost-effective manner. In this regard, we have beta tested and optimized a novel application that produces long sequence reads with high coverage from short Illumina reads. These *in-silico* long reads enable the accurate reconstruction of individual genomes allowing more comprehensive profiling of the strains that compose the community as well as characterization of the genes present. The application, known as TruSeq Synthetic Long Reads (Illumina, CA) is the only existing method for production of contiguous long reads with very low error rate.**Methods:**To start, 500ng of DNA from a metagenomic community were sheared to an average size of 8kb with a g-Tube (Covaris). The fragments were blunt-ended, 3'-end A tailed, ligated to adaptors, size selected on a 0.8% agarose gel and quantitated by qPCR. 1,500fg of fragments were robotically dispensed on a 384-well plate, which results in ~ 300 fragments per well. Fragments were amplified with long-range PCR, tagmented and amplified with one barcoded primer per well. The products were pooled, quantitated by qPCR and sequenced on one lane on a HiSeq 2500 with paired-reads 150nt in length. The reads were assembled with the TSLR application in the BaseSpace cloud environment (Illumina).**Results:**The sequencing produced over 288 million reads (43 Gbases), which resulted in 541 Mbases of assembled reads with an N50 read length of 7.8kb and a distribution from 1.4kb to 11kb.**Conclusions:**Utilizing the TSLR library preparation method produced long reads up to 11kb in length with very high depth of short reads with no associated bioinformatics cost or labor. Efforts are underway to integrate these reads into assemblies done from shotgun and mate-pair library sequencing. We present our work on this novel application to help move this field forward and enhance researcher efforts in metagenomic studies.

Workflow for Processing High-throughput, Single Molecule, Real-time Sequencing Data, for Analyzing the Microbiome of Patients Undergoing Fecal Microbiota Transplantation

Author Block:

R. Hall[1], C. Heiner[1], S. Oh[1], C. Staley[2], M. Hamilton[2], A. Khoruts[3], C. Kelly[4], L. Brandt[5], M. Sadowsky[3]; [1]Pacific BioSci.s, Menlo Park, CA, [2]BioTechnology Inst., St Paul, MN, [3]Univ. of Minnesota, St Paul, MN, [4]The Warren Alpert Med. Sch. of Brown Univ., Providence, RI, [5]Albert Einstein Coll. of Med., New York, CA

Abstract Body:

There are many sequencing-based approaches to understanding complex metagenomic communities, the most common employing either targeted amplification (e.g., multiple 16S regions) or whole-sample shotgun sequencing. While targeted approaches provide valuable data at low sequencing depth, they are limited by primer design and PCR. Traditionally, whole-sample shotgun experiments have relied on high-throughput, short-read sequencing, which results in data processing difficulties. For example, reads less than 500 bp in length will rarely cover a complete gene or region of interest, and will require assembly. In complex communities comprised of many similar organisms, this not only introduces the possibility of incorrectly combining sequence from different community members, it requires a high depth of coverage. As such, rare community members may not be represented in the resulting assembly. Circular-consensus, single molecule, real-time (SMRT®) Sequencing reads in the 1-3 kb range, with >99% accuracy can be efficiently generated. For reads >1 kb at >99% accuracy, it is reasonable to expect a high percentage to include gene fragments useful for analysis without the need for *de novo* assembly. Recent improvements in instrumentation in the Sequel System, have resulted in a 7x increase in the data generated per run compared with the previous generation PacBio RS II. Samples from a blinded, placebo-controlled trial have been sequenced on the Sequel System and include those from pre-FMT patients, post-placebo patients at 2 and 8 weeks, post-open-label patients at 2 and 8 weeks, and the donor control. We demonstrate that our workflow allows a high resolution analysis of the differences between microbial communities, at the level of both abundance and function.

Publishing Title:

Vgrg and Paar Proteins Define Distinct Versions of a Functional Type VI Secretion System

Author Block:

F. R. Cianfanelli, M. Guo, M. Trost, S. J. Coulthurst; Univ. of Dundee, Dundee, United Kingdom

Abstract Body:

The Type VI secretion system (T6SS) is a macromolecular machinery, widespread in Gram negative bacteria, which is used to deliver toxic proteins ("effectors") into target eukaryotic or prokaryotic cells. As a result, this system plays a crucial role both in direct pathogenicity and in interbacterial interactions, including polymicrobial infections. T6SS are encoded within large gene clusters containing, at least, fourteen conserved core components. These form a large trans-envelope machinery including an expelled puncturing device consisting of a tube formed by hexameric rings of Hcp, topped by a VgrG trimer and further sharpened by a PAAR-repeat protein. Anti-bacterial T6SS can deliver a variety of effectors targeting different compartments of the recipient cell, such as the peptidoglycan cell wall, the cell membrane and nucleic acid. Current models suggest that a variety of effectors can be injected in one single lethal shot, each either non-covalently associated or directly fused with one of the proteins forming the puncturing device. *Serratia marcescens* is an opportunistic pathogen that possesses a potent anti-bacterial T6SS. This T6SS is encoded by a large cluster in addition to several other loci encoding non-essential components and multiple effectors. Two different VgrG homologues and three PAAR-repeat proteins are encoded in the genome of *S. marcescens* Db10. Here, we used a combination of genetic, proteomic and phenotypic approaches to determine the role of the two VgrG and the three PAAR-repeat proteins in the functionality of the T6SS. We identified specific VgrG-PAAR combinations able to mediate active secretion and displaying different anti-bacterial activity, and we further showed that this latter difference could be due to delivery of specific subsets of antibacterial effectors.

Transformation of *Chlamydia trachomatis* with a Plasmid Containing Epitope-tagged Translocator and Chaperone Protein

Author Block:

D. Bulir, S. Liang, J. B. Mahony; McMaster Univ., Hamilton, ON, Canada

Abstract Body:

Background: *Chlamydia trachomatis* is the leading cause of preventable blindness worldwide, and the most common bacterial sexually transmitted infection in North America. Undiagnosed infections can lead to pelvic inflammatory disease (PID) and infertility. *C. trachomatis* is believed to utilize a type III secretion system (T3SS) to infect the host cell. The translocator proteins of the T3SS, *Chlamydia* outer protein (Cop) B and D are believed to be essential for infection of host cells. To examine the possible function of the translocator proteins, epitope-tagged translocator proteins and their putative chaperone, LcrH_1, were transformed into a plasmidless strain of *C. trachomatis* using the recently developed transformation system of *C. trachomatis*.**Methods:** Using overlapping PCR, restriction sites and epitope tags were added to LcrH_1, CopB, and CopD for cloning into the shuttle vector pGFP::SW2, generating pGFP-LBD. Prior to transformation into *C. trachomatis*, protein expression was first confirmed in E. Coli. Transformation of *C. trachomatis* L2 was performed as described by Barta *et. al.* (2015). Immunofluorescence and western blot analysis was performed to examine the production, and localization of the epitope-tagged proteins throughout the chlamydial life cycle.**Results:** Cloning into pGFP::SW2 produced a plasmid containing 6xHis-LcrH_1, 3xFLAG-CopB, HA-CopD, as well as the native transcription start site for the operon containing LcrH_1, CopB, CopD. Using western blot analysis, expression of the tagged proteins were confirmed in *E. coli*. We successfully transformed *C. trachomatis* L2 with the pGFP-LBD vector, as western blot and immunofluorescence confirmed the expression of the epitope-tagged translocator and chaperone proteins.**Conclusion:** *Chlamydiae* are obligate intracellular pathogens requiring the T3SS to infect the host. The translocator proteins are believed to be an essential component of the infection machinery, yet, there is limited information regarding the localization and function of the translocators within an infected cell. In the absence of techniques to knock genes out and propagate *Chlamydia* in the absence of cells, transformation of *Chlamydia* with epitope-tagged fusion proteins allows for better understanding of the function of chlamydial proteins in the life cycle of *C. trachomatis* infections.

The C-Terminus of the *Staphylococcus aureus* Esat-6 Virulence Component Esxc Is a Calcium-Dependent Homodimerization Domain

Author Block:

R. M. Abd El-Fatah[1], N. M. Mesbah[2], D. M. Abo-elmatty[2], K. A. Aly[1]; [1]Sinai Univ., North Sinai, Egypt, [2]Suez Canal Univ., Ismailia, Egypt

Abstract Body:

The human pathogen *Staphylococcus aureus* poses a serious threat to the global healthcare system. It recruits a specialized pathway, termed the ESAT-6 Secretion System (Ess), for full virulence. The Ess pathway is a membrane-spanning complex that coordinates the secretion of 4 non-canonical substrates: EsxA, EsxB, EsxC and EsxD into the extracellular environment. EsxC is a 17 kDa homodimer that lacks a classical topogenic sequence. Previous studies have shown that EsxC is required for the secretion of all 4 substrates, thereby revealing its biomedical importance. Here, a modified bacterial two-hybrid screen (BTH) shows that EsxC homodimerization is abolished in the presence of EDTA. Homodimer restoration was tried using several cations, and was found to be successful in the presence of the divalent calcium, suggesting that EsxC dimerization is calcium-dependent. To gain insights into the nature of EsxC homodimerization, N- and C-terminal truncations were constructed in blocks of 5 amino acids each, followed by BTH analysis of the EsxC homodimerization pattern. Results show that the last 5 amino acids of EsxC are required for self-association. To further validate the BTH data, N-terminal 6x-His-tagged wild-type (WT) EsxC and an EsxC variant lacking the last 5 amino acids (EsxCΔ5C) were purified by immobilized metal affinity chromatography (IMAC) over an FPLC-operated HisTrap column. Ultrapure proteins were subjected to chemical crosslinking using the homobifunctional crosslinker disuccinimidyl suberate. SDS-PAGE of the cross-linked WT EsxC shows monomeric and dimeric bands at 17 kDa and 34 kDa, respectively. In contrast, EsxCΔ5C revealed only a monomeric signal, validating the importance of the EsxC C-terminus in homodimerization. We are currently studying the role of the calcium-dependent C-terminal homodimerization domain of EsxC in Ess substrate secretion, the outcome of which will have a profound impact in the areas of microbial biochemistry and drug discovery.

Identification of the Regulators of the Type Vi Secretion System *In Vibrio Harveyi*

Author Block:

S. G. Olney, J. van Kessel; Indiana Univ., Bloomington, IN

Abstract Body:

Quorum sensing is a bacterial communication mechanism that controls the switch between individual and group behaviors in response to changes in cell density. Quorum sensing enables bacteria to synchronously alter expression of genes that produce many different behaviors such as biofilm formation, bioluminescence, and virulence factor production. The type VI secretion system (T6SS) in *Vibrio harveyi* is controlled by the master regulator LuxR. T6SS is a virulence factor and defense mechanism that delivers effector proteins via an injector complex to both bacterial and phagocytic eukaryotic cells. In *V. harveyi*, LuxR binds to the three T6SS promoter regions to directly activate transcription of five gene operons. However, recent work has suggested that other proteins likely work together with LuxR to drive transcription activation. Thus our goals were to (1) identify other novel regulators of this system and (2) examine the link between T6SS and the quorum sensing regulation pathway. A reporter plasmid was constructed with the T6SS promoter and downstream gene *tssD* transcriptionally fused to *lacZ* (P_{tssD}-*tssD*-*lacZ*) to measure expression. We generated a transposon library in wild-type *V. harveyi*, and the reporter plasmid was subsequently introduced into this library. We screened for mutants with either higher or lower levels of β-galactosidase activity compared to wild-type *V. harveyi*. We identified several novel regulators which will be further characterized to elucidate their roles in regulation of the T6SS genes.

Differential Regulation and Functional Redundancy of *esxb* Duplications in *M. marinum*

Author Block:

R. E. Bosserman, M. M. Champion, P. A. Champion; Univ. of Notre Dame, Notre Dame, IN

Abstract Body:

Mycobacterium marinum is a widely used model organism for studying Esx-1 (ESAT-6 System 1), a protein export system required for virulence in pathogenic mycobacteria. Two major substrates of the Esx-1 system are EsxB and EsxA, a pair of tightly interacting proteins. EsxB and EsxA are encoded by *esxBA* within the *esx-1* locus. Interestingly, the *M. marinum* genome has two duplications of *esxBA* outside of the *esx-1* locus. *esx* gene duplications are widespread in *M. marinum* and *M. tuberculosis (M. tb)* genomes, but the role of these genes remain unknown. This study examines an *esxBA* duplication in *M. marinum,* which is not conserved in *M. tb,* and its involvement with the Esx-1 system. The duplicate locus encodes for an EsxB paralog, EsxB_1, which is 100% identical to EsxB at the amino acid level. Because EsxB_1 is identical to a major virulence factor in mycobacteria, we sought to understand why *M. marinum* has two *esxB* genes and whether EsxB_1 contributes to Esx-1-mediated virulence. To study this locus, we created a clean deletion of *esxB_1* and employed molecular techniques, genetics, and mass spectrometry. We found that the *esxB_1* gene is transcribed and translated however at levels lower than the *esxB* locus. Deletion of *esxB* results in a loss of Esx-1-mediated export and virulence despite the presence of an intact *esxB_1* locus. Although deletion of *esxB* abrogates Esx-1 function, we found that deletion of *esxB_1* does not, indicating distinct roles. Yet, our data show that over-expression of the *esxB_1* locus can functionally complement Esx-1 function in the Δ*esxBA* strain. These data show that the two loci can substitute for each other when regulation is decoupled. We therefore hypothesize that the two loci are differentially regulated. Future work will focus on transcriptional regulation of the *esxB_1* locus. We conclude that EsxB_1 and its putative partner EsxA_1 can be secreted by Esx-1 in *M. marinum*. Moreover, the *esxB_1* locus is functionally redundant to the Esx-1 locus, *esxBA*, when over-expressed. However, the *esxBA* locus, not *esxB_1*, is the primary contributor to Esx-1 function and virulence. This study shows that by considering *esx*- gene duplications, Esx-1 secretion may be more complex than previously thought.

The Conjugative Relaxase Trwc Delivers DNA into Human Cells and Promotes Its Integration in the Human Genome

Author Block:

c. gonzalez, M. Llosa; Univ. of Cantabria, Santander, Spain

Abstract Body:

Bacterial conjugation consists on the transfer of relaxase-DNA complexes between bacteria through a Type IV secretion system (T4SS). These systems stand out for their plasticity in terms of translocated substrates (proteins and/or DNA) and secretion target (prokaryotic or eukaryotic cells). We exploited this versatility to secrete a conjugative T4SS substrate through a T4SS required for effector translocation into human cells, resulting in efficient translocation of the relaxase-DNA into human cells through the VirB/D4 T4SS of *Bartonella henselae* (Fernández-González *et al*., 2011). This accomplishment suggests that natural transkingdom DNA transfer may occur through T4SS of human pathogens (Llosa *et al.*, 2012).The DNA introduced in the human cell is led by TrwC, the conjugative relaxase of plasmid R388, responsible for DNA processing during bacterial conjugation. Apart from its role in conjugation, TrwC is also a site-specific integrase being able to catalyse integration of the mobilized DNA into a copy of its target sequence (*oriT*) present in the recipient cell (Agúndez *et al*., 2012). We have characterized integration of TrwC-driven DNA molecules into the recipient genome when a target oriT copy is not available, both in bacterial and in human genomes.We have selected stable integration events of the mobilized DNA into the human genome. TrwC was found to facilitate such integration by more than 3 logs. We have characterized the integration pattern mediated by TrwC using linear amplification-mediated PCR. We have identified at least one site-specific integration event mediated by TrwC, implying TrwC is active in human cells; however, the vast majority of integrants represent random integration events of recircularized plasmid. Our results suggest that TrwC stabilizes the incoming DNA molecules, probably by protecting both ends, favouring their long-term presence and subsequent genomic integration through host-mediated mechanisms. Due to that, TrwC could be used in conjunction with a site-specific nuclease to accomplish targeted genomic modification of human cells.Agúndez, L., González-Prieto, C., Machón, C. & Llosa, M. 2012. Characterization of a Spore-associated Protein to Study Assembly of *Streptomyces* Spores

Author Block:

Z. J. Resko, M. Kocher, C. Moore, J. R. McCormick; Duquesne Univ., Pittsburgh, PA

Abstract Body:

Streptomyces coelicolor is a model non-pathogenic, filamentous bacterium that produces chains of spores from aerial hyphae. Linear plasmid SCP1 contains *sapC*, *sapE*, and *sapD*, which are genes that code for spore-associated proteins. Spore-associated protein SapC (17 kDa, no putative conserved domains) does not contain a normal secretion signal nor is the mechanism of secretion known. Sap proteins were identified because they can be extracted from the spore surface using a non-lethal detergent wash and analyzed via SDS-PAGE, Coomassie blue staining and/or by Western Blot. In our preliminary studies, our strategy to study secretion was to use recombineering to fuse a passenger protein to the C-terminus of a spore-coat protein, SapC. We chose a passenger protein that we could detect with an antibody, the β subunit of the *E. coli* heat labile toxin (LTB). Results characterizing this fusion suggest that SapC-LTB was secreted and assembled on the spore surface. A current goal of this ongoing project is to analyze several constructed C-terminal truncations of SapC (SapC'-LTB) to locate the secretion and/or spore surface assembly signals of SapC. To further characterize SapC protein secretion, an N-terminal fusion of LTB to SapC was also constructed and LTB-SapC secretion is being analyzed. Finally, N-terminal truncations of SapC (LTB-`SapC) are being constructed to complement the C-terminal truncation study to potentially locate and understand the nature of the secretion signal. In the future, the use of Sap protein fusions to passenger proteins might lead to an additional method for vaccine delivery by assembling recombinant *Streptomyces* spores with epitopes displayed on the spore surface.

Cooperation of Two Key Virulence Factors in Bordetella

Author Block:

Z. Nash, P. Cotter; Univ. of North Carolina - Chapel Hill, Chapel Hill, NC

Abstract Body:

Pertussis is a human respiratory illness caused by the Gram-negative bacterium *Bordetella pertussis*. Two main virulence factors of *B. pertussis* are filamentous hemagglutinin (FHA) and adenylate cyclase toxin (ACT). FHA is an adhesin and immunomodulator formed from FhaB after regulated cleavage of its C-terminal prodomain (PD). Before removal from FhaB, the PD appears to function in protein folding and prevention of bacterial clearance by the immune system. Bacteria lacking the extreme C-terminus of the PD rapidly convert all FhaB to FHA and can adhere *in vivo* but cannot persist. Alternatively, processing of FhaB that lacks the PD N-terminus results in FHA with a misfolded and non-functional mature C-terminal domain (MCD), the domain necessary for bacterial adherence to host cells. Recent work has shown that the MCD can bind purified ACT, a toxin that inserts into membranes of phagocytes to create pores and inhibit host signaling. Additionally, *fhaB*-null cultures have reduced bacteria-localized adenylate cyclase activity in comparison to wild type. Instead, activity is mostly detected in the supernatant, suggesting that FHA promotes retention of ACT to the bacterial surface. Because FHA is an adhesin with a role in immunomodulation and ACT requires bacteria-host adherence to transfer the toxin, this implies a role for ACT-FHA association in delivery of ACT to host cells *in vivo*.We sought to explore ACT and FHA *in vitro* localization in wild type and *fhaB*-null bacteria using immunoblotting techniques. We initially degraded bacterial surface proteins with Proteinase K then examined ACT and FHA production and localization over time. We found minimal membrane-localized ACT in *fhaB*-null bacteria. Instead, most of the ACT was located in supernatant. Additionally, the appearance of supernatant-localized ACT was delayed in wild type bacteria, occurring only after membrane-bound FHA was saturated with bound ACT. These data indicate that ACT preferentially binds to FHA following export instead of releasing into the supernatant. We propose a model in which ACT binds to the MCD of FHA in order to gain proximity to the host cell. This suggests that two well-studied virulence factors work together to enhance pathogenesis.

Mapping the Sorting Signals of the Cytoplasmic Domain of Atg27

Author Block:

M. A. Trujillo; High Point Univ., High Point, NC

Abstract Body:

Proteins perform different cellular functions such as structural support and transport of solutes. It is essential that these proteins be delivered to where they are needed. Membrane trafficking is an important process that allows for the distribution of specific macromolecules, such as proteins, throughout the cell. Protein transport is carried out with the help of sorting signals, which are short stretches of amino acids that mediate the transport of proteins to their designated compartment or organelle. Autophagy is a specialized type of membrane trafficking during which unneeded or damaged cytoplasmic components are taken to the degradative organelle of the cell for recycling. Irregularities in autophagy can lead to human diseases like cancer and neurodegenerative disease. In addition, certain pathogenic bacteria are known to escape targeting by harnessing autophagy. Because autophagy is highly conserved in eukaryotes, the eukaryotic microbe *Saccharomyces cerevisiae* (baker's yeast) has been a great model system to better understand autophagy and its connection to human diseases. One of the key trafficked proteins in autophagy is Atg27, a membrane protein with a single cytoplasmic domain. In order to map the sorting signals of this protein, we have generated multiple fluorescent Atg27 cytoplasmic domain deletion mutants. Our current work is focused on dissecting the effects of these mutations on Atg27 localization and function during autophagy.

Development of Vacuole Targeted-delivery System by Signal Peptide Sequence of Lysosomal Proteins in Yeast

Author Block:

D. Park, Y-H. Kim, J. Min; Chonbuk Natl. Univ., Jeonju, Korea, Republic of

Abstract Body:

All of the proteins consists one or more long chains of amino acid residues with signal peptide sequence. They have different delivery mechanism according to bind what kinds of signal sequence. It is important to delivery proteins to the organelles in eukaryotes for mass transfer. In our study we focused on vacuole which consists single membrane and have several of hydrolytic enzymes to discompose macromolecule from the outside of the cells in yeast. Those vacuole proteins also have signal peptide sequence in protein residue. We tried to transport cytosolic protein to vacuole by developing two type of vacuole targeted-delivery vector using signal sequence of vacuole proteins, respectably. First type of signal peptide exists in front of vacuole proteins and other type is in the middle of the protein. Thus our result indicated that development of vacuole targeted delivery system is useful tool that specific proteins are able to transport organelles by signal peptide sequence in eukaryotic cells. This work was carried out with the support of "Cooperative Research Program for agriculture Science & Technology Development (Project title: Development of Target-specific Antimicrobial and Neutralizing Agents for Livestock Biological Hazardous Factors, Project No:PJ01052701)' Rural Development Administration, Republic of Korea. The authors are grateful for their support.

Who Will Be My Next Host? New Approach to Determine Possible Hosts of Unknown Mobile Plasmids

Author Block:

J. Zrimec[1], T. Rijavec[2], A. Lapanje[3]; [1]Faculty of Hlth.Sci., Univ. of Primorska, Izola, Slovenia, [2]Inst. of Metagenomics and Microbial Tehcnologies, Ljubljana, Slovenia, [3]Saratov state Univ., Saratov, Russian Federation

Abstract Body:

Increased incidence of antimicrobial resistance (AMR) in bacteria has raised global awareness and will continue to do so, due to the decreased rate of introduction of new antibiotics. One approach to treat AMR infections is to use the most appropriate antibiotic combinations that inhibit the transfer of AMR genes, since inappropriate treatments increase AMR incidence. In human pathogens, AMR genes spread frequently by transfer of mobile conjugative plasmids from the large environmental AMR pool. Each plasmid can be hosted in a particular repertoire of appropriate bacterial hosts, characterized by the plasmid's MOB group. Currently to determine the MOB group, a mobile plasmid must be sequenced, the sequence of its relaxase must be determined and conjugation experiments must performed. We have presently considered the following. The most important components for plasmid transfer are oriT regions and conjugative relaxases. The oriT site is a substrate for the relaxase, which nicks the DNA and initiates transfer. Since each relaxase is specific to one type of oriT, DNA in each oriT region must have specific physicochemical properties that most efficiently attract and enable activity of the particular relaxase. We thus developed a bioinformatic framework, incorporating prediction of DNA physicochemical properties of oriT regions according to current models and machine learning algorithms. Based on our computational analysis of physicochemical properties of oriT regions, we were able to successfully sort 64 mobile plasmids into their corresponding MOB groups (classification accuracy of 99%). By using this method we only needed to obtain the identity of a DNA sequence up to 240 bp long, with which the most probable hosts can be determined. In the future, this approach will help clinicians determine the right antibiotic treatment based on the present mobile elements and their host ranges, as well as develop new approaches for inhibition of horizontal AMR gene transfer within polymicrobial infections.

Toxin-Antitoxin Systems Inside the Antibiotic Resistance Plasmid World

Author Block:

P. Bustamante[1], J. Iredell[2]; [1]The Westmead Inst. for Med. Res., Sydney, Australia, [2]The Westmead Inst. for Med. Res., Westmead Hosp., The Univ. of Sydney, Sydney, Australia

Abstract Body:

Plasmids are key players in the current antibiotic resistance (AbR) emergency, especially within Enterobacteriaceae. They have the ability to acquire and spread either single or multiple AbR genes, which has become a problem and an obstacle to successful therapeutic treatment. The factors that allow certain plasmid types to maintain AbR genes, to remain stable in bacterial populations and to successfully spread to different bacterial strains remain unclear. However, successful stability has been attributed to the presence of toxin-antitoxin (TA) systems (along with multimer resolution systems and partition systems) and their role in plasmid maintenance. TA systems are small genetic elements composed of a toxin gene and its cognate antitoxin and are both in bacterial plasmids and chromosomes. They are diverse both in the nature of their constituents (protein or RNA) and attributed functions. Historically, a role in plasmid maintenance has been attributed to plasmidial TA systems, but there are indications that their role could be more complex. The real contribution and the diversity of TA systems to the success of AbR dissemination have not yet been fully explored, and it is not known whether specific TA systems are associated with any particular type of plasmid. Our main aim is to elucidate the diversity of TA systems encoded in AbR plasmids in *E. coli* and *K. pneumoniae*, and specifically to characterize a novel putative TA system encoded on an IncX4 plasmid. Using bioinformatic tools a novel putative TA system was identified in pJIE143, an IncX4 plasmid carrying $bla_{\text{CTX-M-15}}$ from an *E. coli* ST131 isolate. We analyzed its genetic and molecular characteristics and the effect of its expression on *E. coli* growth, as well as its contribution to plasmid maintenance. Bioinformatic analysis revealed that it is exclusively present in IncX plasmids. According to bacterial two-hybrid and co-purification assays, the toxin and the antitoxin do not form a protein complex. Toxin overexpression affected the density of *E. coli* cultures and induced cell elongation, which was associated with diminish FtsZ levels. Overall, our results show that AbR plasmids could contain an underappreciated diversity of TA systems, some of them with novel characteristics, toxin targets and functions.

High Level of Resistance to Ciprofloxacin Conferred by a Plasmid Carrying a *qnrS1* Gene from an *Escherichia coli* Clinical Isolate

Author Block:

I. Anacarso[1], **M. M. Tavío**[2]; [1]Modena and Reggio Emilia Univ., Modena, Italy, [2]Las Palmas G. C. Univ., Las Palmas G.C., Spain

Abstract Body:

It has been described that QnrS1 confers a low level of resistance to fluoroquinolones, and is able to increase 12.3-fold the MIC of ciprofloxacin, and 24- to 49-fold under induced expression.[1] We studied the ciprofloxacin resistance conferred by plasmids carrying *qnr* genes, extracted from *Enterobacteriaceae* strains that had been isolated from urine samples of patients in an Italian hospital.Twenty clinical isolates of *E. coli* and 15 of *Proteus mirabilis* were studied. The presence of *qnr* (A, B, C, D, S) and *aac(6´)-Ib-cr* genes was assessed by PCR and sequencing. The antibiotic MICs were determined by the microdilution method. The resistance conferred by plasmids carrying *qnr* genes was determined by conjugation assays, using *E. coli* J53 rifampicin-resistant as recipient strain. The transcript levels of *qnr* genes were studied by reverse transcription of RNA.The MIC50, MIC90 and Range of ciprofloxacin MICs in the 35 studied strains were respectively 2 µg/ml, 32 µg/ml and 0.625 - 128 µg/ml. Plasmids with *qnr* genes were only detected in eight *E. coli* strains, 6 *qnrS1*-positive, 1 *qnrB1*-positive and a plasmid with *qnrS1* and *qnrB1* genes. No other type of *qnr* gene was detected. The *qnrS1* and *qnrB1*- positive plasmid increased 32-fold ciprofloxacin MIC in J53 strain. Furthermore, the increase in ciprofloxacin MICs in the recipient strain that were conferred by either *qnrS1*-positive or *qnrB1*-positive plasmids ranged 16- to 32-fold, with the exception of the plasmid 27-MD that only carried *qnrS1* and increased 128-fold the ciprofloxacin MIC in J53 strain (from 1 to 128 µg/ml). The ciprofloxacin MIC in the donor strain 27-MD was 32 µg/ml and the plasmid 27-MD that was extracted from the same strain, was not found to carry *aac(6´)-Ib-cr* gene. In addition, the transcript level of *qnrS1* in the plasmid 27-MD in the transconjugant was 15- to 21-fold higher than those of the *qnrS1* genes in the remaining plasmids when they were expressed in J53 strain.The increased transcript level of *qnrS1* gene in a native *E. coli* plasmid was responsible for a high level of resistance to ciprofloxacin in a susceptible recipient strain.

IncA/C_2 plasmids Act as Suppressor of Cyclic-Di-GMP Dependent Biofilm Formation in S*almonella enterica* Serovar Typhimurium

Author Block:

S. F. Rouf, S. Rodrigue, V. Burrus; Université de Sherbrooke, Sherbrooke, QC, Canada

Abstract Body:

Background: Conjugative plasmids of the A/C incompatibility group (IncA/C) are well known for spreading multidrug resistance among pathogenic *Enterobacteriaceae*. Bacterial biofilm formation has been broadly studied in *S.*Typhimurium (ST). While conjugative plasmids have often been correlated with enhanced biofilm production, the influence of IncA/C plasmids on biofilm formation is still unclear. Here we report that the type 2 IncA/C_2 plasmid pVCR94 subdues the biofilm formation in ST by depleting the cellular secondary messenger c-di-GMP.**Methods:** ST SR11 was used as the wildtype strain. For biofilm analyses in solid/liquid state, ST was grown in saltless Luria agar or broth (LB) at 28ºC & followed for 3 days. For red dry and rough (*rdar*) morphotype and cellulose detection, Luria agar was supplemented with congo red and calcofluor, respectively. Biofilms on liquid-air interphase from static LB culture were stained with crystal violet to examine the adherent cellulose on glass tubes.**Results:** On saltless Luria agar, pVCR94-bearing ST produced a brown dry and rough (*bdar*) morphotype distinct from the wildtype strain which produced a *rdar* morphotype. On calcofluor plates, the presence of pVCR94 resulted in weak cellulose production when analyzed under UV light. Crystal violet staining revealed that pVCR94-bearing ST produced less adherent cellulose on air-liquid interface than the wildtype strain in LB culture favoring biofilm formation. Interestingly, all pVCR94 driven biofilm phenotypes in ST vanished upon deletion of the master activator *acaCD*, which controls conjugative transfer of IncA/C plasmids, reverting to the wildtype level. Deletion of the conserved predicted c-di-GMP phosphodiesterase gene, *pdeAC*, which is embedded in one of the four clusters of transfer genes of IncA/C_2 plasmids, also abolished pVCR94 driven biofilm phenotypes.**Conclusions:** Loss of rugoseness and *rdar* morphotype in the presence of pVCR94 and subsequent restoration of these phenotypes after *acaCD* deletion suggested that the suppression of biofilm in *S.* Typhimurium was solely pVCR94 driven. These findings unveil a direct association between IncA/C_2 plasmids and c-di-GMP-regulated biofilm formation, thereby suggesting a possible role of IncA/C_2 plasmids in the virulence of pathogenic *Enterobacteriaceae*.

The *Salmonella* Genomic Island 1 Reshapes the Conjugative Apparatus Encoded by IncA/C Plasmids

Author Block:

N. Carraro, **R. Durand**, N. Rivard, C. Anquetil, V. Burrus; Lab. of bacterial molecular genetics, Université de Sherbrooke, Sherbrooke, QC, Canada

Abstract Body:

IncA/C conjugative plasmids (ACPs) and the *Salmonella* genomic island 1 (SGI1) or its variants are frequently associated with multidrug resistance in clinical isolates of pathogenic *Enterobacteriaceae*. SGI1 is not self-transmissible and has been shown to be specifically mobilized in *trans* by ACPs[1]. Excision of SGI1 from the chromosome is triggered by the transcriptional activator complex AcaCD that is encoded by ACPs[2]. Seven genes of SGI1 are preceded by predicted AcaCD boxes. Three of these genes, namely *trhN*, *trhH* and *trhG*, code for distant orthologues of the ACP-encoded proteins TraN, TraH and TraG, respectively, which are putative mating pore subunits. We engineered a mini-SGI1 element that only contains the conserved sequences shared by all SGI1-like elements, including the orthologous *tra* genes, and confirmed its functionality. Using combinations of deletion mutants of mini-SGI1 and the helper ACP pVCR94, we explored the role of each Tra and Trh subunit in conjugative transfer and the complex interactions between mini-SGI1 and pVCR94. We found that TraN/G/H are essential for ACP conjugative transfer and that TrhN/G/H are functional proteins, which are expressed under the control of AcaCD. Complementation assays of individual *tra*/*trh* mutants revealed that not only do TrhN/G/H replace TraN/G/H in the mating pore encoded by ACPs but also that *trhG* is required for mini-SGI1 transfer whereas *trhH* strongly improves mini-SGI1 transfer. TraN and TrhN were found to be equivalent *vis-à-vis* pVCR94 or SGI1 transfer efficiency. These results indicate that SGI1 alters the mating pore encoded by ACPs to selectively enhance its own transfer by a mechanism that remains to be determined. Known mobilizable genomic islands rarely code for mating pore components; instead they usually hijack the mating pore encoded by their helper conjugative element. Whether this strategy of mating pore alteration confers a competitive advantage to SGI1 over ACPs for dissemination in clinical population of enteric pathogens remains to be determined.

Unusual Class 1 Integrons Located on Plasmids of Canine *Escherichia coli*

Author Block:

A. K. Siqueira[1], G. B. Michael[1], M. G. Ferraz[2], M. G. Ribeiro[3], S. Schwarz[1], **D. S. Leite**[2];
[1]Friedrich-Loeffler-Inst., Neustadt-Mariensee, Germany, [2]UNICAMP, Campinas, Brazil,
[3]UNESP, Botucatu, Brazil

Abstract Body:

Escherichia coli is a common cause of canine urinary tract infections. There is a growing number of studies that report unusual class 1 integrons lacking the 3´-conserved segment and displaying a genetic linkage with the sulphonamide resistance gene *sul3*. The aim of this study was to investigate the presence of such integrons among clinical and non-clinical *E. coli* isolated from dogs (n=158). PCRs were performed for the detection of class 1 integron-integrase gene (*intI1)*, *sul3*, *sul1*, truncated quaternary ammonium resistance gene (*qacE1)* and for the variable region of usual class 1 integrons. Two isolates, the 16C from faeces from an apparently healthy dog and 87U from a canine urinary tract infection, were *intI1*- and *sul3*-positive but showed negative results for *qacE1*, *sul1* and the variable region of usual integrons. Based on the antimicrobial susceptibility testing and reference sequences, linkage PCRs between *intI1* and *dfrA12*, *dfrA12* and *cmlA*, *cmlA* and *qacH* as well as *qacH* and *sul3* were performed. They were positive and the sequence analysis confirmed that both unusual class 1 integrons carried the gene cassette array *dfrA12*-orfF-*aadA2*-*cmlA1*-*aadA1*. Plasmid profiling was done by S1-PFGE and one 35-kb plasmid was found in each isolate. The isolate 87U carried an additional 220-kb plasmid. After electrotransformation, PCRs and sequence analysis the location of the *intI1* and *sul3* and their linkage to the gene cassette array *dfrA12*-orfF-*aadA2*-*cmlA1*-*aadA1* on the 35-kb transformed plasmids was confirmed. Electrotransformants displayed also the same antimicrobial multi-resistance pattern (chloramphenicol, streptomycin, sulfonamide and trimethoprim). According to the replicon typing, the 35-kb plasmids belonged to the incompatibility groups IncF+IncFIC. Similar restriction patterns were seen with the PstI and HindIII-digested plasmids. However, XbaI-PFGE of the isolates 16C and 87U revealed distinctly different patterns. In this study, unusual class 1 integrons were located on similar plasmids of unrelated isolates which may indicate a horizontal dissemination of such multi-resistance plasmids among apparently healthy and diseased dogs.

Publishing Title:

New Small Plasmid Harboring *bla*$_{kpc-2}$ in Two Different *Pseudomonas aeruginosa*

Author Block:

R. Galetti[1], L. N. Andrade[1], M. Chandler[2], A. M. Varani[3], A. L. C. Darini[1]; [1]Univ. of Sao Paulo, Ribeirao Preto, Brazil, [2]Ctr. Natl. de la Recherche Scientifique, Ramonville, France, [3]Univ.e Estadual Paulista "Julio de Mesquita Filho", Jaboticabal, Brazil

Abstract Body:

First report of KPC-producing *Pseudomonas aeruginosa* was 10 years ago, in Colombia, and *bla*$_{KPC-2}$ gene was chromosomal localized, with subsequent worldwide reports on plasmid and in chromosomal genetic contexts. In Brazil, the first KPC-producing *P. aeruginosa* was reported in 2012, however, up to date, there are no data regarding genetic localization. The aim of this study was to characterize the genetic context of *bla*$_{KPC-2}$ in two *P. aeruginosa* (BH6 and BH9 isolates) from Brazil. These bacteria were isolated from inpatients in Belo Horizonte city, in 2011, and the isolates were characterized as KPC-2 producers multidrug-resistant (MDR) and belonged to ST244 (BH6) and to ST381 (BH9). Furthermore, genomic localization of *bla*$_{KPC-2}$ gene was determined by hybridization after I-*Ceu*-I-PFGE using *bla*$_{KPC-2}$ probe as well as *S1*-PFGE using 16S rDNA probe. In addition, plasmids were searched following the PCR-based replicon typing (PBRT) scheme targeting replicons of the major incompatibility (Inc) groups of plasmids occurring in *Enterobacteriaceae*, however no Inc group was detected. Besides, the investigation of plasmids DNA content was carry out using Midiprep Kit, according to the manufacturer's protocol, and the plasmid DNA purified was completely sequenced using Ion PGM™ procedures. The set of experiments mentioned above confirmed that *bla*$_{KPC-2}$ was harbored in a single small plasmid in BH6 isolate and there is no copy of this carbapenemase-encoding gene in its chromosome. The complete sequencing revealed a new plasmid, characterized here as pBH6, of 3,642 bp including an IS*Swi1* resolvase, *bla*$_{KPC-2}$ gene, a partial IS*Kpn6* and an origin of replication (*ori*). No *rep* gene was present in the pBH6. However, in BH9 isolate, *bla*$_{KPC-2}$ was detected inserted in the chromosomal DNA. Thus, the entire genomic DNA of BH9 isolate was sequenced using Ion Proton™ procedure. Analyzes of genomic content of BH9 showed that the same genetic element, pBH6, was totally inserted in its chromosomal DNA. The genetic context of *bla*$_{KPC-2}$ gene here evaluated is different from those already described. In our study, *bla*$_{KPC-2}$ was harbored in a new small plasmid, living as a "free" element in BH6 isolate and inserted in the chromosomal DNA of BH9 isolate.

A New Family of Multidrug Resistance Islands Found Among Clinical *Vibrio cholerae* non-O1/non-O139 in Haiti are Mobilizable by IncA/C Conjugative Plasmids

Author Block:

N. Rivard[1], N. Carraro[1], D. Ceccarelli[2], R. R. Colwell[3], V. Burrus[1]; [1]Lab. of bacterial molecular genetics, Université de Sherbrooke, Sherbrooke, QC, Canada, [2]Central Vet. Inst. of Wageningen UR, Lelystad, Lelystad, Netherlands, [3]Maryland Pathogen Res. Inst., Univ. of Maryland, Coll. Park, College Park, MD

Abstract Body:

IncA/C conjugative plasmids (ACPs) are efficient vehicles for dissemination of multidrug resistance genes in modern pathogenic bacteria. Mobility of ACPs ultimately depends on the expression of multiple ACP-borne operons activated by the master activator AcaCD[1]. Beyond ACP transfer, AcaCD also activates the expression of genes located in the unrelated mobilizable genomic islands MGI*Vmi1* of *Vibrio mimicus* and SGI1 of *Salmonella enterica*.While ACPs have been rarely reported in *Vibrio cholerae*, a recent study[2] described their presence in a 2012 clinical O1 isolate from Haiti. Here we investigated the presence of ACP-activated genomic islands in Haitian *V. cholerae* and discovered MGI*Vch*Hai6, a novel genomic island integrated into the 3' end of *trmE* in the genome of non-O1/non-O139 clinical isolates recovered in 2010. MGI*Vch*Hai6 contains the mercury resistance transposon Tn*5053* and an In104-like multidrug resistance element similar to the one inserted in SGI1. MGI*Vch*Hai6 carries *mobI*- and *xis*-like genes preceded by an AcaCD box. *mobI* and *xis* genes code for a putative auxiliary protein required for the transfer of several conjugative elements and a recombination directionality factor, respectively. We showed that MGI*Vch*Hai6 excises from the chromosome, transfers at high frequency in an ACP-dependent manner and confers resistance to β-lactams, sulfamethoxazole, trimethoprim, tetracycline, chloramphenicol, streptomycin and spectinomycin. *In silico* analyses revealed that MGI*Vch*Hai6-like elements are also found in environmental and clinical strains recovered from North and South America, and from the Indian subcontinent.ACPs have influenced the evolution of Haitian *V. cholerae* strains by propagating genomic islands bearing AcaCD-activated genes. ACP-driven circulation of MGI*Vch*Hai6-like elements should be carefully monitored as they serve as a potential reservoir of transmissible multidrug resistance genes.

Toxin-Antitoxin ParE/ParD of Conjugative Plasmid Controls Plasmid Copy Number in *Pseudoalteromonas rubra*

Author Block:

Baiyuan Li, Jianyun Yao, Pengxia Wang, **X. Wang**; South China Sea Inst. of Oceanology, Guangzhou, China

Abstract Body:

The toxin-antitoxin systems were originally identified as plasmid maintenance or stability modules, and can eliminate plasmid-free cells due to a mechanism known as post-segragational killing. Here we characterized a type II toxin/antitoxin pair ParE/ParD on a low-copy-number conjugative plasmid in marine bacteria *Pseudoalteromonas rubra*. The size of the conjugative plasmid is 69.9 kb, containing genes that are responsible for plasmid replication, partition and conjugative transfer. The copy number of the conjugative plasmid is maintained at one copy per cell. Deletion of the toxin/antitoxin pair from the plasmid greatly increased the copy number of plasmid, reaching up to 60 copies per cell. However, deletion of the toxin alone did not affect the copy number, indicating a possible role of antitoxin in controlling the copy number. Bioinformatics analysis showed that the toxin belongs to the ParE family, and overproduction of the toxin caused filamentous growth in *E. coli* host, and caused cell inflation and cell lysis in *Pseudoalteromonas rubra* host. The antitoxin contains a CopG-like domain. Co-production of the antitoxin neutralized the toxic effect of the toxin, and toxin and antitoxin interact directly at the protein level. Toxin is very stable but the antitoxin is labile. Thus they consists of a typical type II toxin/antitoxin system. Our EMSA results showed that the antitoxin can bind to its own promoter and autoregulate the expression of the toxin/antitoxin operon. Additionally, it can also bind and shift the promoter the replication gene *repA* of the plasmid. Further investigation on how this toxin/antitoxin pair affects plasmid stability, segregation and dissemination is needed.

A Large Ciprofloxacin-Resistant Plasmid from Nigeria Confers Resistance to Multiple Antibacterials without a Carrying Cost

Author Block:

R. Monárrez[1], M. Braun[1], O. Coburn-Flynn[1], B. W. Odeotyin[2], A. O. Aboderin[2], I. N. Okeke[3]; [1]Haverford Coll., Haverford, PA, [2]Obafemi Awolowo Univ., Ile-Ife, Nigeria, [3]Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Antimicrobial resistance is a large and growing global problem. We screened 97 fecal fluoroquinolone resistant *Escherichia* isolates from Nigeria for plasmid-mediated quinolone resistance genes. Sixteen of the isolates harbored at least one of these genes and three were positive for *aac(6′)-Ib-cr*. In one strain, *aac(6′)-Ib-cr* was mapped to a self-transmissible 125-kb IncFII plasmid, pMB2, which also bears CTX-M-15 and seven other resistance genes. We hypothesized that pMB2 had been selected by antimicrobials and that its large size would confer a growth disadvantage. **Methods**: We studied growth rates of laboratory strains carrying pMB2 and found they grew as fast as, or faster than, isogenic strains lacking the plasmid in both rich and minimal media. We excised a 32-kb fragment, not including most resistance or conjugative genes, and studied growth and nutrient utilization of the resultant 93-kb mini-plasmid. **Results**: There was a carrying cost for the 93-kb mini-plasmid in all tested media and phenotypic microarrays revealed that utilization of certain amino acids was slower in the deletion. The deleted region included *sitABCD* genes, *nikM* and several open-reading frames of unknown function. Complementation of growth defects with the excised portion on a separate plasmid was unsuccessful, potentially due to copy-number effects. However, trans-complementation with the cloned *sitABCD* genes alone confirmed that these genes account for the growth advantage conferred by pMB2 in iron-depleted media. **Conclusion**: Nutritional factors encoded on a large and transmissible multiresistance plasmid allow it to be maintained successfully without a carrying cost, worsening the trajectory for antimicrobial resistance.

Single-cell (Meta-)genomics of a Dimorphic Candidatus Thiomargarita Nelsonii Reveals Extraordinary Genomic Plasticity and a Mite Bearing Group I Intron

Author Block:

B. E. FLOOD[1], P. Fliss[1], D. S. Jones[1], G. J. Dick[2], S. Jain[2], A-K. Kastor[3], M. Winkel[4], M. Mußmann[5], J. V. Bailey[1]; [1]Univ. of Minnesota, Minneapolis, MN, [2]Univ. of Michigan, Ann Harbor, MI, [3]Leibniz Inst. DSMZ, Braunschweig, Germany, [4]GFZ German Res. Ctr. for GeoSci.s, Potsdam, Germany, [5]Max Planck Inst. for Marine Microbiol., Bremen, Germany

Abstract Body:

The genus *Thiomargarita* includes the world's largest bacteria. But as uncultured organisms, their physiology, metabolism, and basis for their gigantism are not well understood. Thus a genomics approach, applied to a single *Candidatus* Thiomargarita nelsonii cell was employed to explore the genetic potential of one of these enigmatic giant bacteria. The *Thiomargarita* cell was obtained from an assemblage of budding *Ca.* T. nelsonii attached to a provannid gastropod shell from Hydrate Ridge, a methane seep offshore of Oregon, USA. Here we present a manually curated genome of Bud S10 resulting from a hybrid assembly of long Pacific Biosciences and short Illumina sequencing reads. Surprisingly, the genome included the largest number of metacaspases and introns ever reported in a bacterium. In eukaryotes, metacaspases are involved with programmed cell death, but in bacteria they are poorly understood. Both group I and group II introns have been previously observed in the rRNA genes of giant vacuolated sulfur bacteria, but never in protein-coding genes. In the Bud S10 genome we observed a high number of these introns and other repetitive and palindromic elements, such as transposons and miniature inverted-repeat transposable elements (MITEs). In some cases, mobile genetic elements disrupt key genes in metabolic pathways. For example, a MITE interrupts *hupL*, the key gene in hydrogen oxidation. Moreover, we detected a group I intron in one of the most critical genes in the sulfur oxidation pathway, *dsrA.* Group I introns in bacteria are extremely rare and hardly ever disrupt protein encoding genes. This group I intron also carries a MITE sequence found throughout the genome. We hypothesize that the Group I intron plays a role in dispersal of the MITE sequences and is a new form of molecular symbiosis. The presence of a high degree of mobile elements in genes central to *Thiomargarita*'s core metabolism has not been previously reported in bacteria and suggests a highly mutable genome where the transcription of introns and other mobile elements may mediate cellular responses.

Application of a Plasmid Classification System to Determine Prevalence of Replicon Familiesamong Multidrug Resistant *Enterococci*

Author Block:

C. R. Jackson[1], J. B. Barrett[1], L. M. Hiott[1], T. A. Woodley[1], S. Cho[2], J. G. Frye[1]; [1]USDA-ARS, Athens, GA, [2]Univ. of Georgia, Athens, GA

Abstract Body:

Background: The presence and transfer of plasmids from commensal bacteria to more pathogenic bacteria may contribute to dissemination of antimicrobial resistance. However, prevalence of plasmids from commensal bacteria in food animals such as the enterococci remains largely unknown. In this study, the prevalence of plasmid families from multidrug resistant (MDR; resistance to three or more antimicrobials) enterococci from poultry carcasses was determined. Plasmid positive MDR enterococci were also tested for the ability to transfer plasmids and resistance to other enterococci. **Methods:** *Enterococcus faecalis* (n=98) and *Enterococcus faecium* (n=702) used in this study were isolated from poultry carcass rinsates between 2004 and 2011. Isolates were identified to species and analyzed for antimicrobial susceptibility as part of the animal arm of the National Antimicrobial Resistance Monitoring System (NARMS)—Enteric Bacteria at the US Department of Agriculture—Agricultural Research Service (USDA-ARS), Athens, GA. MDR enterococci were tested for the presence of 19 plasmid replicon (*rep*) families using multiplex PCR. Transfer of plasmids and antimicrobial resistance was determined by filter mating.**Results:** Approximately 48% of *E. faecalis* (47/98) and 17% of *E. faecium* (116/702) were positive for at least one *rep*-family. Fourteen *rep*-families were detected indicating the presence of 14 different plasmids among the isolates. The most common MDR pattern among the isolates was GenKanLinTet and LinNitTet. The *rep*-family 9 (rep_9) was predominant among both *E. faecalis* and *E. faecium* for all years tested. Host range for *E. faecalis* and *E. faecium* was different as 13 *rep*-families were found among *E. faecalis* and 12 among *E. faecium*. The rep_7 and rep_{17} family were unique to *E. faecalis*, while the rep_5 family was unique to *E. faecium*. The most number of *rep*-families detected was in 2005 (n=10) and the least in 2009 (n=1). No transfer of tetracycline or erythromycin resistance was detected among selected isolates.**Conclusion:** Results from this study show that *E. faecalis* and *E. faecium* from poultry carcasses contain numerous and diverse *rep*-families. Additional conjugation studies are ongoing to determine if the plasmids can transfer into other enterococci.

Increase in IS*256* Transposition in Different *S. aureus* Lineages after Antibiotic Selective Pressure

Author Block:

S. Di Gregorio[1], M. Herrera[2], S. Fernandez[1], J. Di Conza[1], Á. Famiglietti[1], M. Mollerach[1]; [1]UBA, BA, Argentina, [2]UAP, ER, Argentina

Abstract Body:

Background: In *S. aureus*, transposition of IS*256* has been described to play an important role in biofilm formation and antibiotic resistance. Previously, we reported an augment in IS*256* transposition associated with the selection of hVISA/VISA strains, both in vivo and in vitro, indicating that VAN pressure could enhance IS256 transposition, and eventually the loss of *agr* function. In this study we aim to characterize the effect of antibiotic selective pressure in IS*256* transposition of *S. aureus* isolates belonging to different lineages.**Methods:** Mutant strains were independently selected on increasing concentrations of vancomycin (ST8, ST100) and tigecycline (ST5, ST239). Isolates were genotypically characterized by PFGE, MLST, *spa*, SCC*mec*, *agr*, and southern hybridization using IS*256* and *agr*AC specific probes. The *agr* locus functionality was determined by delta-heamolysis assay. The *sig*B and *rsb*U regulatory genes were mapped by PCR. Additionally, the transcription of IS*256* transposase (*tnp*) gene was evaluated by RTqPCR for ST5 and ST239 strains. Data was expressed as normalized relative quantities (NRQ) using *gyr*B and *pta* as reference genes. All experiments were performed by triplicate. Statistical analysis of the data was accomplished using Student t test (*alfa*=0.05).**Results:** Isogenicity between mutant and parental strains was confirmed by PFGE. An increase in IS*256* copies was demonstrated in mutants selected with vancomycin (MRSA-ST100-IV_{nv}-t*002-agrII*, and MSSA-ST8-t*008-agrI*), and tigecycline (MRSA-ST239-III-t*654-agrI*) by southern blot hybridization. No copy of IS*256* was inserted into *sig*B and *rsb*U genes. NRQ values of *tnp* gene were significantly higher in ST239 mutant strain when compared to parental strain ($p<0.0082$). On the other hand, an increase was also detected for MRSA-ST5-IV-t*002-agr*II mutant strain but it was no significantly different ($p=0.2616$).A loss of *agr* function was determined for ST5, ST100 and ST8 mutant strains but it could not be correlated to IS*256* transposition.**Conclusions:** Selective pressure of vancomycin and tigecycline produce an increase in IS*256* transposition in strains belonging to ST100, ST8 and ST239. This phenomenon could generate diverse genetic rearrangements, which may contribute to the flexibility and evolution of different lineages of this pathogen

Analysis of Mobile Genetic Elements Encoding Macrolide Resistance in *Streptococcus suis*

Author Block:

J. Huang, Y. Liang, L. Wang; Nanjing Agricultural Univ., Nanjing, China

Abstract Body:

Streptococcus suis is a major pathogen of pigs and is responsible for a variety of diseases including meningitis, arthritis and pneumonia. Macrolide resistance emerged globally during the 1990's in streptococci including *S. suis*. The mechanism to macrolide resistance is mainly due to modification of the methylase-mediated target site by the product of *erm*(B) and followed by drug efflux by products of *mef*(A) and *msr*(D). To better understand the mobile genetic elements (MGEs) response for macrolide resistance, a total of 80 clinical isolates of *S. suis* and 22 complete genome sequenced strains from NCBI database were analyzed by comparative genomics followed by PCR, sequencing, and epidemiological analysis. ICE*Sa*2603-like integrative and conjugative elements (ICEs) and Φm46.1-like phages were the main elements carrying *erm*(B) and *mef*(A), respectively. The *erm*(B)-carrying ICE*Sa*2603-like ICEs specifically recognized a 15-bp *att* sites at the 3'-end of *rplL*, which was highly conserved in genus *Streptococcus*. Although *mef*(A)-carrying Φm46.1-like phages have been described in *Streptococcus pyogenes* and *Streptococcus pneumoniae*, here we first reported it in *S. suis*. Further, a novel ICE-phage composite MGEs was identified to disseminating macrolide, tetracycline, and aminoglycoside resistance in China. Fitness assay of the clinical isolates of MGEs and non-MGEs showed little or no fitness cost which may explain why those MGEs-carrying isolates emerge and disseminate. The data indicate that *erm*(B) and *mef*(A) is widely disseminated in streptococci through ICEs and phages, respectively, and the elements are undergo recombination to form new composite elements. Thus *S. suis* is an important antibiotic resistance reservoir that can contribute to the spread of macrolide resistance genes to the streptococci.

Characterization of Two Novel Composite Staphylococcal Cassette Chromosome *mec* Elements of Methicillin-Resistant *Staphylococcus lugdunenesis*

Author Block:

S-C. Chang, C-F. Yeh, C-W. Cheng, T-P. Liu, J-F. Lin, M-C. Ge, Y-T. Chou, M-H. Lee, J-J. Lu; Chang Gung Mem. Hosp. at Linkou, Taoyuan, Taiwan

Abstract Body:

Methicillin resistance in staphylococci is mediated by the acquisition of *mecA* gene, which is carried by mobile genetic element staphylococcal cassette chromosome *mec* (SCC*mec*). SCC*mec* elements in coagulase-negative staphylococci (CoNS) are highly diverse and may act as a reservoir of SCC*mec* for *Staphylococcus aureus* to form methicillin resistance. However, little is known about the SCC*mec* structure of methicillin-resistant CoNs. Here, we used whole-genome sequencing to determine the composite SCC structures of two clinical *Staphylococcus lugdunenesis* isolates CMUH-SL22 and CMUH-SL25, which were assigned to SCC*mec* type Vt and V, respectively, as the common methicillin-resistant *Staphylococcus lugdunenesis* clones prevalent in Taiwan by multiplex PCR. Each of these elements had a unique mosaic structure but shared the common feature of integration at an identical integration site within the 3' end of *orfx* gene flanked by direct and inverted repeats. Although sequences located between *orfx* and IS*Sau4*-like transposase of both elements were similar to those found in *Staphylococcus aureus* PM1, sequences of CMUH-SL25 harbored a novel *ccrC* complex, and a C2-like *mec* complex in opposite orientation similar to that in *Staphylococcus aureus* WIS. Besides, a *ccrA4B4* gene, and parts of sequences within J1 and J2 regions of CMUH-SL25 were similar to those elements found in *Staphylococcus haemolyticu*s. In contrast, J1 region of CMUH-SL22 contained several regions that were highly similar to *Staphylococcus epidermidis* or *Staphylococcus aureus.* These observations suggested that elements found in CMUH-SL25 and CMUH-SL22 evolved separately and assembled through independent recombination events or horizontal gene transfer between staphylococcal species.

Whole Genome Sequencing Reveals an Insertional Mutation Disrupting A*grc* in a Methicillin Resistant *Staphylococcus aureus* Isolate of St239 Lineage

Author Block:

A. M. N. Botelho[1], M. Nicolás[2], A. M. S. Figueiredo[1]; [1]Inst. of Microbiol., Rio de Janeiro, Brazil, [2]Natl. Lab. for Scientific Computing, Petropolis, Brazil

Abstract Body:

Background: Multiresistant isolates of the ST239-SCC*mec*III lineage are the most frequently detected methicillin-resistant *Staphylococcus aureus* (MRSA) in hospital infections. The balance between fitness and virulence capability could be a key factor in the MRSA clonal shift resulting from the success of one specific clone over another. The accessory gene regulator (Agr) is the major staphylococcal quorum sensing system, and it plays an important role in the global regulation of virulence factors. In this study, Agr-dysfunctional isolates were investigated. **Methods:** Agr activity was assessed using MALDI-TOF in a collection of ST239 clinical isolates (n=100). Whole-genome sequencing (WGS) was carried out using Roche 454 for four isolates displaying natural Agr attenuation. PCR was used to detect specific DNA sequences in the bacterial genomes, whereas real time qRT-PCR was used for transcript quantification. Finally, biofilm was tested using a microplate-based method. **Results:** A percentage of 30% of Agr dysfunction was detected. The WGS revealed one isolate (HC1335) carried a transposase element inserted in the *agrC*, resulting in complete Agr inactivation. This same insertion was found in 13% of all Agr-dysfunctional isolates. No mutation was found in the *agr* locus of other sequenced genomes, indicating the defect was upstream *agr*. In fact, these ST239 isolates displayed low *sarA* transcripts (n=2) or increased *saeRS* expression (n=1), which are positive or negative regulators of *agr*, respectively. Additionally, a greater number of Agr-functional isolates was collected from infection than from colonization ($p<0.001$). Also, the amount of biofilm accumulated positively correlated with Agr function ($p<0.05$). **Conclusion:** These results demonstrate that an IS*256* element can quickly re-edit the bacterial global regulation by inactivating the master regulator RNAIII. The importance of the *agr* on/off mechanism in ST239 isolates remains unclear. However, recent studies associated Agr dysfunction with fitness improvement and persistent bacteremia. Thus, it is possible that this switch represents a significant mechanism of genetic variability in the adaptation of this MRSA as a successful hospital pathogen.

Gene Transfer Agents in *Heliconia phytotelmata* and Microbial Mats

Author Block:

M. De Jesus-Cruz, C. Rios-Velazquez; Univ. of Puerto Rico at Mayaguez, Mayaguez, PR

Abstract Body:

Microbial mats and heliconia phytotelmata are micro-ecosystem which fosters a highly diverse microbiota and present a complex nutrient cycle, in which horizontal gene transfer mechanisms should be playing an important role regulating the ecological structure and dynamics. Besides conjugation and transformation, an important and novel genetic exchange process carried out through constitutive transduction by a phage-like element is called gene transfer agents (GTAs). The function and importance of GTAs in the population structure and maintenance of the metabolic capabilities in microbial mats and heliconia phytotelmata is poorly understood. The purpose of this research is to determine the presence of GTAs elements in Purple Non Sulfur Bacteria (PNSBs) isolated from these two aquatic environments. To test the presence of GTAs in our environmental collection of PNSBs, a PCR using GTA *gp5*-specific primers was performed and further analyzed *in silico*. Amplicons from the isolates were obtained using specific primers for the major capsid protein *gp*5. The putative presence of the transduction-like gene transfer agent (GTA) were observed in genome sequences of four out of eight isolates from heliconia phytotelmata and in several isolates from microbial mats. *In silico* analysis suggests the presence of *gp*5 sequences derived from genome-sequenced Rhodobacterales. The presence of the GTA in our samples will allow the development of new research questions about the physiological and ecological roles that the GTA-mediated gene exchange may have to these microbial groups in adaptation to transient environments like microbial mats and phytothelmata.

Chromosomal Location of the *Bla*$_{\text{ctx-M-55}}$ Gene in a Multidrug Resistant *Escherichia coli* ST167 Isolated from Healthy Chicken in China

Author Block:

C-W. Lei, B-H. Liu, H-N. Wang, A-Y. Zhang; Sichuan Univ., Chengdu, China

Abstract Body:

Background: CTX-M-55 extended-spectrum beta-lactamase (ESBL), like CTX-M-15, mediates resistance to the third-generation cephalosporins and enhances the hydrolytic activity against ceftazidime. It is generally carried by IncI2 plasmids and has become one of the most prevalent ESBLs in China. Here we first characterized the chromosomal location of *bla*$_{\text{CTX-M-55}}$ gene in a multidrug resistant *Escherichia coli* isolated from healthy chicken in China.**Methods:** *E. coli* strain ECwhn14 was isolated from a healthy chicken in Hebei province. Antimicrobial susceptibility test and conjugation experiments were performed. Whole genome sequencing was performed on the Illumina MiSeq using a 400-bp paired-end library with 210-fold average coverage. The paired-end reads were assembled de novo and the gaps among contigs were filled in by PCR-linkage.**Results:** Strain ECwhn14 displayed multidrug resistant profile. The Sequence Type of ECwhn14 was ST167. An amikacin-resistant plasmid, named pECwhn14, could be transferred to *E. coli* EC600 with 5.5×10^{-4} frequency. However, the ceftazidime-resistant determinant could not be transferred. Sequence analysis showed the *bla*$_{\text{CTX-M-55}}$ was integrated into the chromosomal gene *ttdR* encoding LysR family transcriptional regulator (Fig. 1a). The 4482-bp IS*Ecp1*-mediated transposition unit might come from the IncI2 plasmid. The 1331-bp insertion sequence IS*2* that contained *orfA* and *orfB* transposase genes was inserted into the IS*Ecp1*. The 185134-bp plasmid pECwhn14, which belonged to F36:A4:B1 and carried eleven resistance genes, was also characterized (Fig. 1b).**Conclusions:** This is the first report of the chromosomal location of *bla*$_{\text{CTX-M-55}}$ and IS*Ecp1-bla*$_{\text{CTX-M-55}}$ region disrupted by IS*2*.

Mycobacterial Sufb Intein as Environmental Sensor

Author Block:

C. Green, N. Topilina, M. Belfort; Univ. at Albany, SUNY, Albany, NY

Abstract Body:

Inteins are mobile genetic elements that self-splice at the protein level from their flanking extein fragments. Mycobacteria have inteins inserted into several important genes, including those corresponding to the iron-sulfur cluster assembly protein SufB. Curiously, the SufB inteins are found primarily in mycobacterial species that are potential human pathogens. Experiments with an *Escherichia coli*-derived reporter system and the *Mycobacterium tuberculosis* SufB precursor revealed that reactive oxygen species and reactive nitrogen species inhibit SufB extein ligation. Such exceptional sensitivity of SufB intein splicing to oxidative and nitrosative stresses is a result of predisposition of the intein's catalytic cysteine residues to oxidative modification. Our data suggest that reactive oxygen and reactive nitrogen species interference with SufB splicing is a dynamic process, where the concentration of these species affects the extent of splicing inhibition and the outcome of precursor processing. These dynamics depend on whether the catalytic cysteine residues participate in splicing before they become modified through oxidative reactions. We suggest that oxidative modifications inhibit the splicing pathway and diminish activity of the iron-sulfur cluster assembly machinery. We propose that splicing inhibition is an immediate, post-translational regulatory response that can be either reversible, by inducing precursor accumulation, or irreversible, by inducing N-terminal cleavage, which may potentially channel mycobacteria into dormancy under extreme oxidative and nitrosative stresses.

Characterization of pHeBE7, an IncFII Type Virulence-Resistance Plasmid Carrying *bla*$_{\text{ctx-M-98b}}$, *bla*$_{\text{tem-1}}$ and *rmtb* Gene in *Escherichia coli* from Chicken in China

Author Block:

A. Zhang, Y. Yang, H. Wang; Sichuan Univ., Chengdu, China

Abstract Body:

Background: Recentely, a novel variant of the CTX-M enzyme, CTX-M-98, was detected in *Escherichia coli* isolates from food animals in China. Notably, the *bla*CTX-M-98 gene was also found in *E. coli* strains from patients and healthy individuals in China, which indicated the blaCTX-M-98 gene might spread between *E. coli* strains from food animals and human beings. **Methods:** An *E. coli* HeB7 strain, positive for A *bla*$_{\text{CTX-M-98b}}$, *bla*$_{\text{TEM-1}}$, *rmtB* and *traT* gene, was isolated from a diseased chicken. Whole-genome sequencing was performed with Illumina MiSeq using a 350-bp paired-end library. Sequence reads for the plasmid were assembled by using the GS De Novo Assembler v2.8. The contigs were closed by PCR with specific primers. The transferability of pHeBE7 was investigated by mating-out assays. Genetic stability tests and growth competition experiments were conducted as previously described.**Results:** The assembled plasmid, named pHeBE7, belonged to F2:A-:B-, is a complete molecule of 86,015-bp with a GC content of 51.9% and 84 open reading frames (ORFs).The pHeBE7 can be divided into two parts consisting of a -67.2 kb backbone structure and a -18.8 kb mosaic region. The backbone structure contains replication operon (4 ORFs of *repA2-repA3-repA1-repA4*) and coding regions that are involved in the plasmid stability (17 ORFs) and plasmid transfer (33 ORFs). The mosaic regions of pHeBE7, which only part related to several other plasmid sequenced so far, consist of two specific transposon units that are associated with antimicrobial resistance. The first unit is the Tn*3* transposon haboring *bla*$_{\text{TEM-1}}$ and 16S rRNA methylases *rmtB* gene. BLASTn searches revealed that a similar structure was found in some other IncFII type plasmids, such as pMC-NDM and pXZ. The other unit is a typical (IS*Ecp1-bla*$_{\text{CTX-M}}$-IS*903*) transposition unit inserted into a Tn*1721* haboring *bla*$_{\text{CTX-M-98b}}$ gene,which shows a great genetic diversity in other plasmids due to carrying different resistance genes. Conjugation and growth competition experiments indicated that pHeBE7 could be transmitted effectively with low fitness cost. **Conclusions:** This is the first completely resolved sequence of plasmid carrying *bla*$_{\text{CTX-M-98.}}$ The genetic characteristion of pHeBE7 may help to better understand the dissemination of resistance and virulence genes in enterobacter.

YhgA-Like Proteins of *Escherichia coli* K-12 and Their Contribution to RecA-Independent Horizontal Transfer

Author Block:

A. W. Kingston; New England Biolabs, Ipswich, MA

Abstract Body:

In bacteria, mechanisms that incorporate DNA into a genome without strand-transfer proteins such as RecA play a major role in generating novelty by horizontal gene transfer. We have developed a conjugal DNA transfer system in *Escherichia coli* to identify, compare, and analyze novel gene acquisition mechanisms. Using this system, we identified an unexpected RecA-independent recombination mechanism in which a large segment of the recipient chromosome is replaced with genomic DNA from the donor. This process occurs at low frequency (~10^{-10}/recipient/h) and a single event can exchange over two megabases of continuous DNA.We then used this conjugal system to investigate YhgA-like proteins, which were predicted to contribute to horizontal gene transfer based on their distribution patterns among bacteria. The *E. coli* K-12 genome encodes five YhgA-like paralogs (YjiP, YfcI, YadD, YhgA and YfaD). When overexpressed in the recipient of our conjugal system, all but the last of these increased the frequency of RecA-independent recombination events, were toxic to the cell, and induced expression of a reporter of DNA damage. Mutagenesis of predicted active site residues in YhgA abolished or diminished these effects. Purified YhgA exhibits endonuclease activity *in vitro* as well. We propose a working model in which YhgA-like proteins promote RecA-independent recombination by cleaving genomic DNA *in vivo*, and help connect one end to a strand of foreign DNA via sequence microhomology.

High Incidence of *lux* Merodiploids Indicates Frequent Horizontal Gene Transfer in Vibrios

Author Block:

K. Venkler, C. F. Wimpee; Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract Body:

This laboratory has been carrying out a long-term study of bacterial bioluminescence as a model system for bacterial molecular evolution and interspecific gene mobility. In a diversity study of bioluminescent bacteria from Puerto Rico, we encountered a surprising number of Vibrio isolates possessing two copies of *luxA*. These merodiploids were initially detected by restriction endonuclease fingerprinting of *luxA* PCR products, in which the restriction fragments generated from certain strains added up to twice the size of the *luxA* amplicon. In addition, sequencing of amplified *luxA* from these strains revealed numerous mixed sites. Fingerprinting of multiple single colonies from each of these strains demonstrates that the two copies are not a result of contaminating single-copy lux strains. These merodiploids are not identical. Among 96 isolates from 2 ml of seawater, the diversity of *luxA* restriction patterns indicates that there are five different strain types carrying two copies. Merodiploids might arise by either gene duplication or by horizontal gene transfer (HGT). To distinguish between these two possibilities, PCR-amplified *luxA* genes from each merodiploid type were cloned, and multiple separate clones were fingerprinted and sequenced. Phylogenetic analysis of the cloned *luxA* sequences indicates that the merodiploids did not arise by gene duplication, but rather by import of *luxA* from other strains (HGT). Furthermore, we have identified the closest relatives for the individual *luxA* genes of the merodiploids, and find them among the single-copy lux strains we have isolated in the same water sample. These merodiploids thus represent intermediates in the process of HGT. The diversity of merodiploids that we find in only 2 ml of seawater supports the hypothesis that horizontal transfer of *lux* genes is a frequent and ongoing process in Vibrios. It is therefore likely that many other Vibrio genes that are less easily detected undergo frequent horizontal transfer, as well.

Transfer of Plasmids from *Escherichia coli* to *Clostridium difficile* is Sensitive to DNAse

Author Block:

L. Khodadoost, P. Mullany; UCL Eastman Dental Inst., London, United Kingdom

Abstract Body:

Background: Horizontal gene transfer (HGT) between bacterial cells is an important mediator of bacterial evolution and adaptation to various environments. Three mechanisms of HGT in bacteria are known: conjugation, transduction and transformation. HGT is also used to transfer genetic constructs made in organisms that have relatively advanced genetic technologies, such as *Escherichia coli*, to organisms that are not as amenable to genetic manipulation. Commonly plasmid RK2 is used to mobilise plasmids having a compatible origin of transfer *oriT*. This system is used for genetically modifying the important human pathogen *Clostridium difficile.* In this work we demonstrated *oriT* is not required for transfer between *E. coli* and *C. difficile* and that transfer is abolished in the presence of DNase indicating that a possible cell-to-cell transformation-like mechanism is responsible for transfer. **Objectives:** To investigate the mechanisms of transfer of plasmids between *E. coli* and *C. difficile.* **Methods:** *E. coli* donor strain CA434 (HB101 carrying the IncPß conjugative plasmid, R702) was transformed with pMTL9301 or pMTL9301Δ*oriT*. *E. coli* donors containing the plasmids was mixed with *C. difficile* CD37 and incubated anaerobically without selection for 18 hours then transferred onto selective plates, supplemented with the antibiotic to select for the plasmid-encoded resistance, with counter-selection against the *E. coli* donor. **Conclusions:** Deletion of *oriT* lowered the transfer frequency of pMTL9301 but did not stop it indicating that pMTL9301 can be transferred by a mechanism different from conjugation. In support of this pMTL9301Δ*oriT* could not transfer to *C. difficile* in the presence of DNase. We hypothesize that an unknown and undefined DNA uptake system, possibly a cell-to-cell transformation-like mechanism is involved.

Htra1 Functions to Induce *Comga* Transcription and Increase Transformation Efficiency in *Staphylococcus aureus*

Author Block:

K. L. Maliszewski, **P. Roy**, P. D. Fey; Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract Body:

Natural bacterial transformation, which occurs during a physiological state called competence, is responsible for a major proportion of horizontal gene transfer and evolution in certain species. *Staphylococcus aureus*, thought to evolve primarily through point mutation and acquisition of mobile genetic elements via conjugation and transduction, has never been considered a naturally transformable species until recently. The DNA binding and uptake apparatus, encoded by *com* genes, are conserved in *S. aureus*. Moreover, competence regulation in *S. aureus* have been found to be dependent on the alternative sigma factor σ^H, its overexpression facilitating the uptake of both plasmid and chromosomal DNA. However, the genes that function with σ^H are unknown. Hence this study was designed to identify genes that function with σ^H to regulate *comGA* transcription and induce competent state in *S. aureu*s.The Nebraska Transposon Mutant Library was utilized to identify genes that regulate transcription of *comGA*. The phage library was transduced into *S. aureus* RN4220 *PcomGA::lacZ* reporter strain. β-galactosidase activity of the mutants with enhanced *comGA* transcriptional activity was confirmed by the modified Miller assay. qRT-PCR was performed to evaluate *sigH* and *comGA* expression and select for mutants of interest. Lastly, to determine the function of *htrA1* and *htrA2* in transformation frequency, σ^H was overexpressed and transformation experiments were performed on N315, N315 *htrA1*, N315 *htrA2*, and N315 *htrA1 htrA2* with or without the *sigH* overexpressed plasmid (pNF285).The screen identified 117 genes that induced transcription of *comGA* including *htrA1* and *htrA2* encoding serine proteases previously linked to competence induction in *S. pneumoniae.* A transformation frequency of ~10^{-6} was detected in N315/pNF285, while the transformation frequency was increased two orders of magnitude (10^{-4}) in N315 *htrA1*/pNF285 and N315 *htrA1 htrA2*/pNF285; no change was observed in N315 *htrA2*/pNF285. Complementation with plasmid encoded *htrA1* decreased N315 htrA1/pNF285 transformation frequency, suggesting a function for HtrA1 in regulating competence induction in *S. aureus.*In conclusion, our data suggests that HtrA1 functions to regulate σ^H activity, and subsequently *comGA* transcription, thus regulating transformation efficiency in *S. aureus*.

Hyper Efficient Horizontal Genome Transfer Between *Streptomyces* Strains by Insertion of Conjugative Transfer Genes on the Chromosome

Author Block:

M. Kataoka, T. Miyatake, J. Kim, K. Murabata; Shinshu Univ., Fac. Engineering, Nagano, Japan

Abstract Body:

In the nature, lateral gene transfer (LGT) was thought to take an important role in bacterial evolution. Little is known about the mechanism how the large DNA fragment could be transferred in bacterial genome evolution. The case of Hfr of the F factor in *Escherichia coli* is exceptionally well known mechanism of genome level transfer where the whole genome is transferred with high frequency. We proposed that Hfr like mechanism would be working in bacterial evolution. *Streptomyces* is major soil bacteria and known as a major antibiotic producer. They have frequent small conjugative circular plasmids. We have studied the conjugation mechanism of the pSN22, a small conjugative plasmid replicated via rolling circle mechanism, from *S. nigrifaciens* (*S. flavovirens*). pSN22 transfer depends on the tra genes consisted of *traR, traA, traB* and *spdB*, and the *cis*-element *clt*. The pSN22 transfer is accompanied with chromosomal mobilization. After conjugation between *S. lividans*, the pSN22 derivatives transferred nearly 100% recipient cells in donor excess condition, and up to 10^{-3} recipients were chromosome recombinants. To test the Hfr like behavior of the pSN22 *tra* system, the DNA fragment encoded the *traR, traA, traB* genes and *clt* locus was inserted *S. lividans* TK21 genome using phiC31 integration system with Neomycin resistant gene. The resultant strain was crossed with *S.lividans* TK24 derivative (Sm^r). Surprisingly over 10% recipient cells showed Neomycin resistant, indicating that chromosomal transfer from donor cell occurred with very high frequency. This Chromosomal Mobilizing Activity (CMA) was lost by mutations within *traB* or in the absence of the *clt* region. The lack of *traA* resulted in the decrease of CMA to 10^{-4} likely in the case of plasmid transfer. To test the application possibility of this system in genomic engineering in *Streptomyces*, we tested the inter-species genome transfer from *S. lividans* to the other *Streptomyces* strains. Although the frequency was decreased, enough chromosomal recombinants were obtained. The potential of this technique in genome engineering will be discussed.

Detecting Lateral Gene Transfer Events in Host-associated Microbial Communities

Author Block:

T. Y. Hsu[1], E. A. Franzosa[1], C. Luo[2], D. H. Wong[3], M. G. I. Langille[3], R. G. Beiko[3], C. Huttenhower[1]; [1]Harvard T.H. Chan Sch. of Publ. Hlth., Boston, MA, [2]Broad Inst., Cambridge, MA, [3]Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Background: Lateral gene transfer (LGT) is a key mechanism for adaptation and maintenance of gene diversity in microbial communities. Currently, methods to detect LGT are time consuming and optimized for whole genomes. However, many microbial communities are profiled using metagenomic shotgun sequencing, which generates short, fragmentary assemblies. **Methods:** Here, we present a new method to detect recent LGTs in shotgun metagenomes, titled WAAFLE (Workflow for Annotating Assemblies and Finding LGT Events). Shotgun reads are first assembled into contigs, which are then searched against a reference database consisting of pan-genomes. This can provide a reference-based gene annotation for contigs by grouping overlapping homologous regions. Homology to pangenome elements is then used to assign and score taxa of origin for each gene. We then compute how likely the contig is explained by one taxon versus multiple. Sufficiently high multiple-taxon scores indicate a likely LGT. **Results:** WAAFLE achieved median true positive rates from 86.4-91.2% and maintained median false positive rates from 0-0.6% on a set of 1,000 synthetic contigs containing LGT events spanning 8 phylogenetic levels. To date, we have further analyzed 12 body sites' metagenomes from one female in the Human Microbiome Project (HMP). Genus-level LGT events ranged from 0 events out of 1552 contigs (anterior nares) to 434 events out of 139878 contigs (stool). LGT analyses are ongoing for 265 individuals on 6 major body sites at up to 3 time points in the HMP. **Conclusion:** WAAFLE provides a validated method for identifying recent LGT events, donor and recipient taxa, and transferred functions in shotgun metagenomes.

A Functional Analysis Of The Stator Complex Of The Flagellar Motor From Alkaliphilic Bacillus Trypoxylicola

Author Block:

M. Ito, R. Imazawa, S. Naganawa; TOYO Univ., OURAGUN, Japan

Abstract Body:

Many bacteria swim by rotating their flagella. The flagella are filamentous organelles that extend from the cell surface. A flagellum consists of three parts, the filament (helical propeller), the hook (universal joint), and the basal body (rotary motor). Intensive genetic and biochemical studies of the flagellum have been conducted in *Salmonella* and *Escherichia coli*, and more than 50 gene products are known to be involved in the flagellar assembly and function. The flagellar motor is energized by either a proton (H^+) or sodium ion (Na^+) motive force, and its torque is generated by electrostatic interaction between the rotor (FliG) and stator interface. In general, there are three kinds of stator complexes: MotAB-type stators use protons, while MotPS- and PomAB-type stators use Na^+ as coupling ions. In 2012, we reported that alkaliphilic *Bacillus alcalophilus* AV1934 was first identified as a bacterium which uses Na^+, potassium ion (K^+) and rubidium ion (Rb^+) as coupling ions for flagellar rotation (1). This finding suggested that coupling ions other than H^+ and Na^+ are available to power the bacterial flagellar motor. Recently, we surveyed another example of a bacterium which can use K^+ as a coupling ion for bacterial flagellar rotation. Alkaliphilic *Bacillus trypoxylicola* was selected as a candidate bacterium because this bacterium can grow at high alkaline pH and K^+ rich conditions. In this study, we describe the flagellar stator protein (BT-MotPS) from *B. trypoxylicola* that is coupled to both Na^+ and K^+. In the absence of Na^+ or K^+, no swimming was observed in *B. trypoxylicola*. A stator-free *E. coli* mutant expressing BT-MotPS complemented a deficiency in motility in the presence of Na^+ or K^+. Thus, the operating principles of flagellar motors and molecular mechanisms of ion selectivity are clarified.

Energy And Aerotaxis Receptors In *pseudomonas*: Phylogenetics And Functional Characterization In *p. Pseudoalcaligenes* Kf707

Author Block:

S. C. Booth, R. J. Turner; Univ. of Calgary, Calgary, AB, Canada

Abstract Body:

Energy-, aero- and chemo-taxis allow bacteria to swim towards optimum growth environments. Taxis towards specific chemoattractants has been attributed to their binding to cognate, membrane-bound receptors called Methyl-accepting Chemotaxis Proteins (MCPs). Recently, ligands for many MCPs have been identified in various *Pseudomonas* species, though the majority remain unknown (1). This is partially because energy and aerotaxis have been found to mask the function of some MCPs as they enable cells to swim towards optimum environments for generating energy, be it ideal concentrations of oxygen or metabolizable carbon source (2). The MCPs *aer* (homologous to the MCP in *E. coli)* and *aer-2* were identified in *P. aeruginosa* and have been respectively characterized as energy and aerotaxis receptors (3), though the function of *aer-2* has been disputed (4). Conversely, 3 homologs of *aer* were found in *P. putida* of which only one was functional in energy taxis, with the role of the other homologs remaining unknown (5). No homolog of *aer-2* was found. As taxis is important for the ability of various *Pseudomonas* species to swim towards attractants in pathogenesis, plant-growth promoting and bioremediation scenarios it would be beneficial to understand the function of these genes and their distribution within the genus in order to elucidate whether they are redundant in function or not.Phylogenetic analysis of available *Pseudomonas* genomes has revealed that neither *aer* nor *aer-2* are part of the core genome and that the presence and number of *aer* homologs is widely variable. Despite this variability, the genomic environments of each of the homologs are conserved implying conserved function. There are four homologs of *aer* of which some species possess up to 3. Few species possessed both multiple *aer* homologs and *aer-2*. To investigate possible redundancy or alternative functions for these genes, deletion mutants were constructed in *P. pseudoalcaligenes* KF707 as it possesses 3 *aer* homologs and *aer-2*. Using all possible combinations of single and multiple deletions a semi-redundant function has been revealed for these genes. Swim diameters in soft-agar stab plates showed that the most ancestral homolog of *aer* is responsible for most energy taxis but functions in conjunction with the other homologs and also, surprisingly, with *aer-2*.

Organization of Flim and Fliy in the Flagellar Switch Complex of *Bacillus subtilis*

Author Block:

E. Ward, D. Blair; Univ. of Utah, Salt Lake City, UT

Abstract Body:

The flagellar switch complex is a protein assembly that regulates the direction of rotation of the flagellar filament in response to changes in cellular levels of phospho-CheY, regulated by the chemotaxis pathway. The complex is made up of multiple copies of the proteins FliG and FliM, together with either FliY (in Gram-positive organisms) or FliN (in Gram-negative organisms). Despite the clear homology of the switch proteins in *E. coli* and *Bacillus subtilis,* the switches respond oppositely to phospho-CheY, giving CW rotation in *E. coli* but CCW rotation in *B. subtilis*. Further, FliY has an additional large middle domain that is not present in *E. coli* FliN, suggesting significant differences in subunit organization. In the present work, we used cross-linking, two-hybrid assays of protein interaction, and systematic mutagenesis to examine the organization of FliM and FliY in *Bacillus subtilis.* Two-hybrid and crosslinking data indicate that the middle domain of FliM ($FliM_M$) interacts with itself and is organized similarly to the corresponding domain in *E. coli*. The large $FliY_M$ domain that is not present in Gram-negative organisms also shows a self-interaction in two-hybrid assays, but does not interact with $FliM_M$, and thus appears to form an assembly distinct from the $FliM_M$ array. Disulfide-crosslinking results indicate significant differences in the organization of the bottom (membrane-distal) part of the complex: Whereas in *E. coli* this is formed from an alternating array of $FliM_C$ domains and FliN multimers, in *B. subtilis* the $FliM_C$ and $FliY_C$ domains can form an intertwined dimer, structurally similar to a $FliY_C$ dimer observed in crystal structures (from *Thermotoga maritima*). This intertwining of $FliM_C$ and $FliY_C$ might account for the closer homology of these domains in *B. subtilis* than in *E. coli* or other Gram-negative species, and would imply a 1:1 ratio of FliM and FliY subunits in the switch. Two-hybrid data and switch- biased phenotypes of certain mutations indicate a probable site of interaction for phospho-CheY on the $FliM_M$ domain. The candidate CheY binding site corresponds with that proposed previously on the basis of NMR studies of Dahlquist and co-workers, using proteins of *T. maritima*. Overall, our findings provide a preliminary picture of the organization of the middle and lower parts of the *B. subtilis* switch complex. Future work will aim to extend these results to the upper part, containing FliG.

T. Gao, H. Gao; Zhejiang Univ., Hang Zhou, China

Abstract Body:

Background: *Shewanella oneidensis*, a facultative γ-proteobacterium, is extensively studied for redox transformations. Now it is becoming a research model for many other studies such as biofilm formation, respiration diversity, fatty acid metabolism and motility. *S. oneidensis* is motile by a single polar flagellum. The flagellar genes are organized into a four-tiered transcriptional system. However, it is clear that the whole flagellar system is complex and there may be other regulator elements involved in flagellar transcription, assembly and function.**Methods:**In frame mutant construction and complementation, motility assay, microscope observation, site-directed mutagensis**Results:** In this study, we identified a role of *S. oneidensis* YbgC (*So*YbgC, SO_2752) in flagellar gene expression and motility. YbgC proteins have been proposed to be functionally associated with the Tol-pal system which is critical to division because its coding gene is co-transcribed with *tol-pal* genes. Unlike *tol-pal* mutants, Δ*SoybgC* results in no growth defect but increased motility, which is confirmed by genetic complementation. Promoter activity assay shows that expression of *flgKL*, whose products are hook proteins to which the filament is attached, increases 2-fold. These data indicate *So*YbgC can improve the stability of filament. YbgC proteins from *Helicobacter pylori* (*Hp*YbgC) and *Haemophilus influenza* (*Hi*YbgC) have thioesterase activity, and *Hi*YbgC^{D18N} does not show this activity. Our experiments show that *So*YbgC^{D15N} can not decrease motility, indicating that Asp-15 is important for YbgC's function in motility.**Conclusions:***So*YbgC may improve the stability of filament. *So*YbgC^{D15N} can not decrease motility, indicating that Asp-15 is important for YbgC's function in motility.To our knowledge, this is the first report for the role of YbgC in motility. It provides new insights into to our understanding of the bacterial locomotion by flagallar systems.

***Helicobacter pylori* Chemoreceptor Tlpb Mediates Tactic Responses to Acid, Not Urea**

Author Block:

P. S. HOFFMAN, C. Gineste, R. Razzaq, S. Shukla; UNIV OF VIRGINIA, CHARLOTTESVILLE, VA

Abstract Body:

Background: *Helicobacter pylori* utilize natural pH gradients within gastric mucus to direct initial colonization in establishing lifelong infections. Gastric *Helicobacter* species express acid sensing chemoreceptor TlpB (also senses AI-2) that promotes negative chemotactic responses. A recent study reported that TlpB promotes urease-dependent positive chemotactic responses to urea which enables colonization and persistence. We initiated this study to formally test these two competing hypotheses. **Methods:** Chemotactic behavior of *H. pylori* and mutants (*ureAB, ureI*, and carbonic anhydrase, AC) were tracked by video microscopy in flat micro-capillary tubes (population based assays) and by syringe-based tactic assays (bacterial enumeration). Threshold tactic responses were determined over pH ranges from 1 - 8 and for urea from 10 microM to 10 mM. Competition assays (urea + HCl) tested tactic dominance and site-directed mutagenesis was used to identify periplasmic domain mutants defective in taxis.**Results:** Most bacterial species show no chemotactic response to urea and our studies confirmed that *H. pylori* and mutant strains exhibited no chemotactic response to urea. In contrast, *H. pylori* strains and *ureAB, ureI* and *CA* mutants displayed acid avoidance pH taxis. Since CA is primarily responsible for buffering of the periplasm, we determined that these mutants exhibited more robust tactic responses to external acid challenge than did WT strains. Since the urease system maintains a relatively pH-neutral periplasm (pH ~6.1) at external pH below 6.0, we next examined how TlpB responds to small changes in periplasmic pH. Mutation of two conserved histidine residues in the periplasmic domain of TlpB (H72A and H172A) correlated with loss of pH taxis. **Conclusions:** In an integrated model of acid acclimation and pH sensing, we show that TpB responds to strong acid via the PAS domains (<pH 5) and to weak acid by histidine protonation/deprotonation (>pH 5). We show that the urea-taxis phenotype results from urease mediated alkalization of the weakly buffered chemotaxis medium, creating a pH gradient (pH taxis). Our studies confirm that *H. pylori* utilize natural pH gradients to colonize the gastric mucosa and that TlpB competes successfully with the urease-dependent acid acclimation system that buffers the periplasm to mediate pH tactic behavior.

Functional Annotation of Chemoreceptors Using Recombinant Sensor Domain Ligand Screening

Author Block:

D. Martin-Mora[1], V. Garcia[2], J. A. Reyes-Darias[1], A. Ortega[1], B. Morel[1], A. Corral-Lugo[1], M. A. Matilla[1], T. Krell[1]; [1]Estación Experimental del Zaidín - Superior Council for Scientific Res., Granada, Spain, [2]Ctr. for Biomolecular Sci., Nottingham, United Kingdom

Abstract Body:

Many bacterial signal transduction processes are initiated by the recognition of signal molecules by sensor proteins. However, most of the sensor proteins are functionally unannotated and their cognate ligands remain unknown, which represents currently a major bottleneck.To identify ligand that bind to chemoreceptors, we have been using *in vitro* ligand screening approaches using recombinantly produced sensor domains. We report here the functional annotation of two chemoreceptors from the saprophytic bacterium *Pseudomonas putida* KT2440, termed McpP and McpQ. Using isothermal titration calorimetry studies we show that the McpP sensor domain binds acetate, pyruvate, propionate and l-lactate whereas the corresponding domain of McpQ recognizes specifically citrate and citrate/metal complexes. McpQ complements the ligand profile of the previously identified McpQ paralogue McpS, which binds many TCA cycle intermediates but no citrate/metal complexes. Chemotaxis assays showed that the mutation of the *mcpP* and *mcpQ* genes resulted in a strong reduction of the response towards the corresponding ligands identified. McpP is predicted to have a CACHE sensor domain and evidence is presented suggesting that this domain type may be associated with the recognition of pyruvate and acetate. The response to TCA cycle intermediates is thus mediated by the concerted action of two paralogous receptors, McpS and McpQ, that possess a broad and complementing narrow ligand specificity.The approach was successfully used to annotate chemoreceptors but can also be employed to annotate other of sensor proteins.

Physiological and Transcriptomic Characterization of *Mvat mvau osro* Knockout Mutants Devoid of Pf4 Prophage in *Pseudomonas aeruginosa* Pao1

Author Block:

G. Li[1], C-D. Lu[2], L. Yang[3], J-Y. Li[2]; [1]Univ. of Massachusetts Lowell, Lowell, MA, [2]Georgia State Univ., Atlanta, GA, [3]Nanyang Technological Univ., Singapore, Singapore

Abstract Body:

MvaT and MvaU are two redundant xenogeneic silencing proteins of the H-NS family in *Pseudomonas aeruginosa*. Previous studies to investigate the physiological consequences of *mvaT* and *mvaU* depletion were hampered by activation of Pf4 prophage in the resulting mutants. In this study, an *mvaT mvaU* double knockout mutant (PAOΔTU) was constructed in a strain of PAO1 (Δpf4) devoid of the Pf4 prophage on the chromosome. In comparison to its parent strain and the wild type PAO1, PAOΔTU exhibited several distinctive phenotypes including loss of pyocyanin production, retarded motilities in swimming, swarming and twitching, and a slower growth rate in 2YT broth (generation time 15 minutes v.s. 9 minutes of PAO1). Transcriptome analysis by GeneChip (Affymetrix) revealed that over 227 genes were found up-regulated in PAOΔTU, including several multi-gene loci for type III and type VI protein secretion systems, O-antigen, exopolysaccharide, pili assembly, and many others of unknown functions. In addition, a relatively unexplored locus (PA2222-PA2228) including *qsrO* and *vqsM* for quorum sensing and virulence that exists only in PAO1 and some strains of *P. aeruginosa* was found highly induced in PAOΔTU. In comparison, about 54 genes including *rhlLR* and *pqsABCDE-phnAB* in quorum sensing were down-regulated in PAOΔTU. A triple knockout mutant of mvaT/mvaU/qsrO was constructed, and this mutant partly recovered the capability on pyocyanin production and motilities. Transcriptome analysis indicated that the expression levels of *pqsABCDE, phnAB, rhIL/rhIR* and some unknown genes were reverted back to the level as in its parental PAO1. Similar patterns of gene expression were also observed by RNA-seq analysis. Among ncRNA of known functions, only *crcZ* in carbon catabolite repression and *phrS* in PQS were found reduced significantly in PAOΔTU. These results support the global effects of MvaT and MvaU as gene silencers, and provide the evidence to link down-regulation of PQS and pyocyanin synthesis to the strain-specific QsrO protein as part of the MvaT/MvaU regulon.

Strain-Specific Regulation of Flagella Genes in *Helicobacter pylori*: A Complex Interplay Between Csra and Rpon

Author Block:

Y. T. Huang, C. Y. Kao, **J. J. Wu**; Natl. Cheng Kung Univ. Med. Coll., Tainan, Taiwan

Abstract Body:

Helicobacter pylori infects 50% of the population worldwide, and increases the risk for developing peptic and duodenal ulcer, gastric adenocarcinoma and mucosa-associated lymphoid tissue lymphoma (MALToma). Previous studies indicated that carbon storage regulator A (CsrA) is necessary for *H. pylori* full motility and infection ability. Moreover, CsrA controls *H. pylori* motility through regulating *rpoN* expression and flagella formation. In the present study, we further demonstrated the strain-specific regulation of flagellar-related genes expression, especially focused on the interplay between CsrA and RpoN. The results showed that both *csrA* mutant J99 and 26695c8 displayed deficient motility compared to the wild-type. Transmission electron micrographs showed that no flagella were observed in the *csrA* mutant J99 and 26695c8 compared to the wild-type strains. Only 57% *flaA*, 29% *flaB*, and 57% *rpoN* mRNA expression in the *csrA* mutant J99 determined by RT-qPCR ($p < 0.001$, < 0.001 and < 0.01, respectively). Interestingly, 210% *flaA*, 57% *flaB*, and 59% *rpoN* mRNA expression were determined in the *csrA* mutant 26695c8 compared to its wild-type ($p < 0.01$, < 0.05 and < 0.01, respectively). In addition, the FlaA and FlaB proteins were decreased in the *csrA* mutant J99 determined by western blotting, whereas the FlaA protein was no such change in the *csrA* mutant 26695c8. Furthermore, RT-qPCR results showed that the *flaA* mRNA expression was decreased more prominent in the *rpoN* mutant J99 compared to the wild-type, whereas *flaA* mRNA expression dramatically increased in the *rpoN* mutant 26695c8. These results suggest that the regulation of flagella/motility is strain-specific in *H. pylori*.

Altered Swarming Motility and Quorum-sensing Exhibited by a Mutant Lacking *lrp* in *Pseudomonas aeruginosa*

Author Block:

B. L. Moses, M. C. Griffin; Kennesaw State Univ., Kennesaw, GA

Abstract Body:

The leucine responsive regulatory protein, Lrp, has been widely characterized in the intestinal bacterium, *Escherichia coli*. Lrp belongs to the feast or famine protein family, responsible for gene repression and regulation based on the presence or absence of amino acid co-factors. Through extensive mutant and microarray analysis, it is projected to regulate up to 10% of the *E. coli* genome. Little is known about the Lrp homologue in *Pseudomonas aeruginosa*. Currently, only the *dadAX* operon involved in alanine catabolism has been demonstrated to be regulated by Lrp in *P. aeruginosa* (1). We speculate that Lrp is well-positioned to play a more global role for *P. aeruginosa* as it is found in many diverse environments (ie. water, soil and humans) thus requiring a versatile metabolism. We report here an altered environmental response, swarming motility, by an *lrp* knockout mutant. This complex motility is specifically-adapted for a viscous environment. When grown on swarming agar directly from a rich media, wild-type PAO1 swarms across the surface in an even concentric pattern away from the inoculation site. Conversely, an *lrp* knockout mutant has a ruffled and uneven, advancing margin morphology. Furthermore, when WT is grown side by side with the mutant on the same assay plate, an antagonistic effect is observed against WT. The growth margins of wild-type are repulsed or broken down nearest to the *lrp* mutant. This suggests that the mutant is producing an inhibitory or degradative product that is likely normally suppressed by the wild-type Lrp protein. SDS-PAGE analysis of supernatants from both strains indicates the presence of an extracellular protein present in *lrp*- supernatants only. Identification of this product is underway. The regulation of swarming motility by quorum-sensing (qs) guide bacteria to switch forms of motility (swarming, surface, gliding) in response to environmental conditions. Using a *Chromobacterium violaceum* acyl-homoserine lactones (AHL) signal-deficient mutant, we observed that a *C. violaceum* qs-induced violet pigment could be induced by AHLs from *P. aeruginosa* and an enhanced induction of *C. violaceum* pigment was seen for the *lrp* mutant in comparison to WT. These phenotypes have not been reported for Lrp in *P. aeruginosa* and may indicate more roles for this protein in *P. aeruginosa* than the regulation of alanine as previously reported.

Citrate, an Organic Acid, Increases Biofilm Formation in *Pseudomonas fluorescens* Through the Diguanylate Cyclase, GcbC, and Limiting Adhesin Proteolysis by LapG

Author Block:

D. Giacalone[1], T. Smith[2], L. J. Bergeron[1], G. A. O'Toole[2]; [1]New England Coll., Henniker, NH, [2]Geisel Sch. of Med. at Dartmouth, Hanover, NH

Abstract Body:

The intracellular signaling molecule, cyclic diguanosine monophosphate (c-di-GMP) is a potent modulator that influences a wide range of bacterial processes. High levels of c-di-GMP shift bacteria from a planktonic life style to sessile life style, forming a biofilm. Biofilms are formed in response to environmental cues. These cues are of great medical and industrial interest due to the capability of enhancing antibiotic resistance, biofouling, and bioleaching. *Pseudomonas fluorescens*, a model organism of biofilm formation, requires cell surface localization of the large adhesin, LapA to promote biofilm formation. The level of LapA at the cell surface reflects the amount of c-di-GMP within the cell. In conditions unfavorable for biofilm formation, LapA is cleaved by the calcium-dependent protease, LapG, which inhibits biofilm formation. The mechanism of biofilm formation in *P. fluorescens* is well understood, however the environmental cues regulating this process are unknown. We hypothesized that citrate, an organic acid secreted by plants, is sensed by the diguanylate cyclase, GcbC, to promote biofilm formation. GcbC contains a calcium channel chemotaxis receptor (CACHE) domain, which are known to sense small environmental ligands. The calcium chelator, citrate, was previously shown to increase biofilm formation by inhibiting proteolytic activity of LapG. Here we propose a two-tiered role of citrate 1) enhances biofilm formation through inhibiting LapA proteolysis by LapG and 2) increases GcbC activity, thereby increasing c-di-GMP production and enhancing LapA levels at the cell surface.

Abstract Body:

Background: *P. aeruginosa* is an ubiquitous and metabolic versatile proteobacterium and PA14 is a highly virulent strain with the ability to infect several phylogenetically distinct hosts. The attenuated-in-virulence *kerV* deletion mutant strain displays a pleiotropic phenotype that includes higher production of pyocyanin and impaired motility. *kerV*, which encodes a putative S-adenosyl-L-methionine (SAM) methyltransferase, is located immediately upstream of *rnhA* and *dnaQ*, both related with DNA replication and repair. The organization of this locus is well conserved across several proteobacteria (1), suggesting that its genes products might function in correlate pathways. DnaQ is the ε-subunit of DNA polymerase III that has 3'-->5' exonuclease activity for proofreading in DNA replication and it is important to improve the catalytic efficiency of DNA polymerase III *in vitro* by its association with α-subunit (DnaE). **Methods:** The methods include detection of Transcriptional Start Sites (TSSs) of individual genes by 5'RACE, analysis of gene expression by qRT-PCR, transcriptional *lacZ* fusions and immunoblot detection.Virulence was assessed by using both feeding and pricking *Drosophila* model of infection.**Results:** We detected independent TSSs for each gene of *kerV* locus and we also found that deletion of the *kerV* coding region affects *dnaQ* expression, since *kerV* mutant presented lower levels of both mRNA and DnaQ protein. Levels of *rnhA* mRNA are also affected, but this effect was not observed at the protein level. Attempts to complement *kerV* mutant strain showed that twitching and swarming motility and a feeding *Drosophila* model of infection were rescued not by KerV alone, but only when wild-type levels of DnaQ were restored. The complementation experiments support the conclusion that some phenotypes of *kerV* mutant strain are caused by decreased DnaQ levels and the coordinated expression of three genes of locus are necessary for full rescue of wild-type phenotype.**Conclusions:** Although essential genes are usually overlooked in respect to their role in virulence, a better understanding of their roles and regulation may uncover novel functions that increase the fitness of the pathogen in the environment provided by the host.

Development of a Replicable oriC Plasmid for *Mycoplasma genitalium*

Author Block:

M. Hernandez-Solans, S. Torres-Puig, E. Querol, J. Piñol, O. Q. Pich; Univ. Autònoma de Barcelona, Bellaterra, Spain

Abstract Body:

Over the last two decades, replicative oriC plasmids have been successfully developed for several mollicutes. The oriC region of these shuttle vectors contains DnaA binding sites similar to the *E. coli* consensus sequence 5'-TTATCCACA-3'. Therefore, the presence of conserved DnaA boxes is a hallmark of mycoplasmal oriC sites, which actually facilitates the identification of the replication origin in the chromosome. So far, the identification of the *Mycoplasma genitalium* oriC region (Mge-oriC) has been elusive. The usual locations of the oriC, i.e. flanking the *dnaA* gene (MG_469) or between the *parA* (MG_470) and *dnaN* (MG_001) genes, are devoid of conserved DnaA boxes in this bacterium. In order to identify the Mge-oriC, we used a computational method aimed to predict stress-induced DNA destabilization sites (SIDD). Susceptibility to stress-induced destabilization is closely associated with several classes of DNA regulatory regions, including promoters, terminators or replication origins. Using the SIDD method, we identified a putative oriC region between the *parA* and *dnaN* genes. We found that plasmids containing the putative oriC region were capable to replicate when introduced into *M. genitalium*. Transformation efficiencies obtained with the Mge-oriC plasmid were similar to those obtained with transposons. When the replicative oriC plasmid was introduced into the reference strain G37, it rapidly integrated into the chromosome at a high frequency. In contrast, the plasmid remained episomic when introduced into a *recA* null mutant. The absence of sequences with less than two mismatches with respect to the DnaA box consensus within the identified Mge-oriC indicates that DnaA binding sites of *M. genitalium* are significantly divergent. Of note, the Mge-oriC contains four instances of a 10-bp long palindromic sequence that is only found seven additional times in the chromosome. Deletion of some of these sequences abrogated the self-replicating capacity of the oriC plasmid. This result suggests the existence of novel regulatory sequences controlling replication initiation in *M. genitalium*. Work is in progress to pinpoint the DnaA binding sites and to establish the participation of additional sequences in the replication of the *M. genitalium* chromosome.

Human Cytomegalovirus Localization Pattern of Nascent Viral DNA Along with Replication Proteins in Human Fibroblasts Using Fluorescent Imaging

Author Block:

S. Manska, C. Rossetto, V. Gutierrez; Univ. of Nevada, Reno, NV

Abstract Body:

Human Cytomegalovirus (HCMV), a member of the herpesvirus family, is a highly prevalent pathogen that asymptomatically infects the majority of the population by adulthood. HCMV was originally thought to be an opportunistic infection in immunologically compromised individuals, predominantly in organ transplant recipients and HIV/AIDS patients. Congenital infection with HCMV is the number one viral cause of birth defects and leads to developmental disabilities such as diminished mental capability, deafness, and motor skill deficiencies. As this area of research continues to grow, it has been demonstrated that HCMV can also cause or exacerbate disease in healthy individuals. For HCMV DNA replication to take place, host cell machinery along with viral encoded factors are required for viral replication, leading to production of infectious virions and ultimately establishment of a lifelong latent infection in the host. Therefore, identification of the proteins required for DNA replication is essential towards understanding mechanisms of infection. Preliminary experiments performed using iPOND (identification of Proteins On Nascent DNA) with HCMV infected human fibroblasts followed by mass spectrometry (LC-MS/MS) have identified viral and cellular proteins that are associated with viral DNA synthesis. iPOND experiments identified known viral encoded factors required for viral DNA replication but also identified novel cellular and viral proteins associating with nascent DNA. Although these proteins have proven to be fundamental in viral replication, the details in protein and DNA co-localization were unknown. Using Click-iT® EdU Alexa Fluor® 594 which incorporates a fluorescently labeled nucleoside analog into replicating DNA, we now show nascent DNA synthesis in infected (AD169) vs. non-infected human fibroblasts. Furthermore, we use an Immunofluorescent Assay (IFA) to detect HCMV and cellular replication proteins along with nascent DNA to determine patterns of co-localization.

An Accessory Helicase Pcra and Recombination Proteins Mitigate Replication-Transcription Collisions in *Bacillus subtilis*

Author Block:

P. Yeesin[1], A. Bittner[1], J. Peng[2], A. Medina[2], M. Schmitz[1], J. Wang[1]; [1]Univ. of Wisconsin-Madison, MADISON, WI, [2]Baylor Coll. of Med., Houston, TX

Abstract Body:

Since bacterial DNA replication and transcription concurrently take place on the same DNA template, collisions between replication machineries and RNA polymerase (RNAP) are inevitable and can lead to genome instability. Replication-transcription collisions can occur in either co-directional or head-on manners, depending upon specific gene orientation. Inversion of highly transcribed ribosomal RNA genes (*rrn*) creates strong head-on collisions and impairs DNA replication, which leads to loss of genome integrity and cell inviability in rich medium. Mechanisms by which bacterial cells cope with replication-transcription collisions during rapid growth remain poorly understood. In this work, we determined the roles of protein factors in alleviating replication-transcription conflicts in *Bacillus subtilis*. Using a candidate gene approach and plating efficiency, we identified an accessory helicase PcrA and multiple recombination proteins, namely RecA, RecFOR, and AddAB, which rescue *rrn*-inversion cells in rich medium. We further characterized PcrA ATPase activity and its C-terminus (an RNAP-interacting domain) and showed that both are indispensable for conflict mitigation. Interestingly, the rescue by PcrA is RecA-dependent, suggesting interactions between the two factors *in vivo*. To elucidate such interactions in *B. subtilis* cells, we used time-lapse fluorescence microscopy to monitor RecA dynamics in response to replication-transcription collisions in the presence or absence of PcrA. We found that PcrA promotes RecA-mediate homologous recombination after head-on collisions and prevents persistent RecA that could act as roadblocks to subsequent rounds of DNA replication. However, PcrA does not accelerate RecA disassembly after the homology-directed repair, implying that RecA displacement by PcrA (the mechanism demonstrated *in vitro*) is less likely in this case. Together, we propose a novel model in which PcrA and RecA interact *in vivo* to mitigate head-on replication-transcription collisions.

SSB Recruitment of Exonuclease I Aborts Template-Switch Mutations in Bacteria

Author Block:

L. Laranjo, Stephen Gross, Danna Zeiger, Saie Mogre, Vincent A. Sutera Jr. and Susan T. Lovett; Brandeis Univ., Waltham, MA

Abstract Body:

Quasi-Palindromes (QPs) are short nucleic acid inverted repeats capable of forming hairpins and cruciform structures. Subsequently, these non-canonical nucleic acid structures can stall DNA polymerase and facilitate template switch mutations, double strand breaks and chromosomal rearrangements. Most of QP mutations result from template switching during DNA synthesis and they have been associated with several human diseases. Aiming to further understand the cellular avoidance mechanism of template-switch mutations, we have created QP reporters using a chromosomal QP in the *lacZ* gene. A frameshift mutation was created with the insertion of 4bp in one inverted repeat, causing a $lacZ^-$ phenotype. When a template-switch occurs onto the corresponding inverted repeat, the *lacZ* mutation is reverted and reports a $lacZ^+$ phenotype (blue colonies). In *E.coli*, the avoidance of QP related mutation involves novel genetic factors, including the two major exonucleases Exonuclease I (Exo I) and Exonuclease VII (Exo VII). Our results suggest that template switch mutations are stimulated by exonuclease-deficiency and different rates of mutation between the leading and lagging strand derives from more efficient avoidance of mutation through exonucleolytic degradation of the lagging strand instead of a more frequent occurrence of mutations on the leading strand. This work provides evidence of Exo I predominant role in aborting template-switch mutations and its required interaction with single stranded DNA binding (SSB). In addition we examined the effects of *xonA*-R148A, an Exo I mutant with no interaction with SSB, but with full exonuclease activity. Our results confirm that SSB interaction is absolutely necessary for ExoI to abort QP-associated mutagenesis on the lagging strand. Further studies will use QP reporters in yeast to assess QP mutation rates in eukaryotes.

Evolving Antimutators to Achieve Greater Genetic Stability for Synthetic Biology

Author Block:

D. Leon, D. Deatherage, J. E. Barrick; Univ. of Texas at Austin, Austin, TX

Abstract Body:

Biological systems are difficult to engineer because they are inherently unpredictable. Most synthetic devices that are encoded in the DNA of these "machines" decrease host fitness and are quickly inactivated, resulting in strong selection for mutations that lead to the loss of the designed function. To ensure the long-term reliability of synthetic devices, we must understand the mechanisms involved in genetic instability and engineer more stable host organisms. We propose that the stability of the host genome can be significantly improved by reducing the baseline mutation rate of the host organism, decreasing the probability that random mutations will render a device inactive. We have developed an iterative, universal method called Periodic Reselection for Evolutionarily Reliable Host Variants (PResERV), in which antimutator strains in a pool of mutants are enriched in a population over time by sorting for cells that maintain costly GFP expression. The final population is then sequenced to determine the causative mutations. An initial goal of this study was to address whether antimutator mechanisms are specific to the nature of the synthetic device and/or the strain background. In *Escherichia coli*, we assayed several K-12 derivatives (BW25113, MDS42, BL21, and TOP10) by expressing GFP on a pBR322-origin plasmid (pSKO4) or from a genomically integrated construct under control of T7 RNA polymerase. Our preliminary PResERV results using BW25113 + pSKO4 identified two antimutator mutations, in *polA* and *polB*, that are present in strains in which mutation rates on this plasmid are lower by a factor of 3- and 25-fold, respectively. We predict that the *polA* substitution results in a polymerase with higher fidelity and that the *polB* nonsense mutation leads to an antimutator phenotype by deleting this error-prone polymerase. Our work will provide essential knowledge and resources for engineering biological systems. Understanding the mechanisms involved in genetic stability will allow engineers to more rapidly tackle novel, challenging problems, without the hindrance of frequently inactivated parts.

Polymorphism Associated with Fluoroquinolone Resistance Stabilizes *E. coli* MutM

Author Block:

B. D. Hornstein, A. C. Fluty, N. Sung, S. Lee, L. Zechiedrich; Baylor Coll. of Med., Houston, TX

Abstract Body:

A global problem, antibiotic-resistant bacteria infect 2 million people and kill 23,000 people each year in the U.S. alone. Only eight new antibiotics were approved by the FDA in the last two years, all of them target gram-positive bacteria, yet gram-negative infections are extremely problematic. Our goal is to prolong the use of the antibiotics that target gram-negative bacteria by better understanding resistance mechanisms. Toward this goal, since 1999, our laboratory has collected over 5,000 gram-negative clinical isolates, representing the full spectrum of known antibiotic-resistant phenotypes. Using this collection, we uncovered four single nucleotide polymorphisms (SNP) associated with fluoroquinolone resistance in *E. coli*, each of which encodes a modification in a DNA-binding domain. One of these resulting enzymes, MutM T127A, has an altered helix-capping residue in a helix-turn-helix motif. MutM is a DNA repair enzyme that excises 8-oxoguanine, a consequence of oxidative stress. We hypothesize that the threonine to alanine change in MutM stabilizes the helix-turn-helix motif and improves the ability of MutM to mitigate oxidative damage, which should affect antibiotic resistance. Supporting this hypothesis, a Δ*mutM* mutant strain complemented with *mutM(A127)* survived hydrogen peroxide exposure better than *mutM(T127)*, but *mutM(T127)* better survived UV exposure (1). After purifying both protein variants, we determined the protein stability using a thermofluor assay. We found that the melting temperature of MutM(A127) was consistently higher across 96 difference conditions than MutM(T127), with an average, statistically significant, difference of 1.5°C. DNA binding and catalysis studies are currently underway. The MutM(A127) variant is found in all fluoroquinolone-resistant *E. coli* isolates sequenced to date. The increased stability we detected may improve MutM function, making bacteria with this SNP better able to repair oxidative damage, which is a downstream mechanism of antibiotic activity.

The Role of H-Ns in Nucleoid Compaction in *Escherichia coli*

Author Block:

C. Pina, C. Weitzel, S. T. Lovett; Brandeis Univ., Waltham, MA

Abstract Body:

H-NS is an abundant nucleoid associated protein (NAP) with many functions within the *E. coli* cell. It exists largely as a dimer but is able to oligomerize along DNA. Notably, H-NS has been implicated in DNA structure and organization as well as possible chromosome integrity. Over-expression of H-NS has been shown to produce a condensed toroidal nucleoid. In an attempt to further evaluate the toroidal structure (that has previously been suggested to be "unnatural"), we have re-examined the nucleoid using deconvolution fluorescence microscopy. We illustrate that the toroidal nucleoid is a physiologically relevant structure, appearing during exposure to protein synthesis inhibitors and entry into stationary growth phase. Moderate over-expression of H-NS is required to reproduce nucleoid condensation. We have demonstrated that over-expression of several abundant NAPs are unable to generate the same nucleoid structure produced when H-NS is over-expressed. This compaction is prevented by treatment with rifampicin, suggesting a dependence on transcription. Three individual mutations within *hns* were shown to have differing abilities to produce a toroidal nucleoid when their protein is over-expressed. Future experiments seek to examine H-NS mutants through live cell imaging and evaluate the consequences of mutant H-NS within the cell.

Epigenetic Modification at the *vlha* Locus of *Mycoplasma synoviae* Wvu 1853^{t}

Author Block:

D. R. BROWN[1], G. F. KUTISH[2], M. A. MAY[3]; [1]UNIV OF FLORIDA, GAINESVILLE, FL, [2]UNIV OF CONNECTICUT, STORRS, CT, [3]UNIV OF NEW ENGLAND, BIDDEFORD, ME

Abstract Body:

Modified DNA nucleotides at the 78.5-kb *vlhA* locus of *Mycoplasma synoviae* WVU 1853^{T} were analyzed in an effort to identify candidate factors that control high-frequency unidirectional recombination between the single expression site of its primary adhesin VlhA and a contiguous reservoir of >60 promoterless *vlhA* pseudogenes. Methyl-6-adenine and methyl-4-cytosine residues identified by SMRT Analysis (pacb.com) were displayed using GenomeView (genomeview.org) and filtered for confidence score >30 (P<0.001) across the locus and flanking genes VY93_01145 *nanI* through VY93_01470 *gapDH*. Instances of genome-wide methylation motifs were mapped across the locus using the Insilicase degenerate motif finder (insilicase.co.uk). GC skew was visualized using GView (gview.ca). Motifs in the *vlhA* locus consistent with methylation by N-6 adenine-specific DNA methylases elsewhere throughout the 846-kb genome (GenBank CP011096) included GmATC, GAmAN$_6$TTT, AAmAN$_7$TTC, GAmAN$_5$YYCTTH, CTAmABN$_4$BNTTT and AAmANVN$_4$VTTAG. The locus was strikingly under-modified versus the rest of the genome. For example, only 33 of 208 (16%) sites recognizable by the Dam methylases VY93_01015 and VY93_02585 were modified in the locus versus 86% of 3,840 Dam sites modified genome-wide, and 23 of those 33 (70%) were only hemi-methylated, although the combined frequency of relative under-methylation at specific motifs did not reach statistical significance (Pearson chi-square P=0.0921). Its G+C content is 5.4 mol% higher than the whole genome, but no modifications by the N-4 cytosine-specific DNA methylase VY93_02380 were detected in the locus versus 742 instances found elsewhere. It is thought that *M. synoviae* acquired *vlhA* by horizontal transfer from *Mycoplasma gallisepticum*. If thus separated from species-specific enzymes or other factors necessary for its epigenetic modification, the resulting under-methylation could promote the high-frequency recombination and proliferation of *vlhA* pseudogenes observed in the new genomic context.

Effect of FIS Deficiency on Radiation Survival of *Escherichia Coli*

Author Block:

M. B. Hussain, D. A. Hudman, **N. J. Sargentini**; ATSU/Kirksville Coll. of Osteopathic Med., Kirksville, MO

Abstract Body:

Background: The factor for inversion stimulation (*fis*) gene produces a nucleoid-associated protein (Fis) involved in growth regulation in *Escherichia coli*. Our previous, screening study suggested *fis*-associated radiation sensitivity. Our current study investigates this finding in more depth, and probes the role of Fis in DNA repair after UV- or X-irradiation, and in DNA recombination and in spontaneous and UV-radiation mutagenesis. **Methods:** A *fis779*::kan deletion mutation was introduced into *E. coli* K-12 AB1157 and related DNA repair-deficient strains (*uvrA, recA, recB, recC, recF*). Cells were grown in LB broth at 37^{o}C with aeration to log or stationary phase. Cell survival studies relied on plating assays after cells were treated with UV- (254 nm) or X- (160 kV) radiation. DNA recombination studies relied on an Hfr-dependent conjugation assay. Mutagenesis studies relied on an *argE3* (base-substitution) reversion assay. Statistical analysis was performed by interpreting radiation doses yielding 1% cell survival from triplicate, multi-dose survival curves, and t test was used to determine if differences were significant at $P \leq 0.05$. **Results:** Wild-type and *fis* mutant strains were compared for UV radiation survival in multi-dose studies. At 1% cell survival (for the wild-type strain), the *fis* mutation sensitized cells by 8 to 25-fold, if grown to log- or stationary-phase, respectively. After X-irradiation (stationary-phase only), *fis*-sensitization was much greater, i.e., 125-fold. To probe the *fis*-effect on specific DNA repair pathways, we compared the cell survival of stationary-phase cells (control vs. *fis* strain at 1% survival) after UV-irradiation. The *fis* mutation sensitized *uvrA* cells 7-fold ($P<0.001$). The *recF* strain was sensitized only 2-fold ($P=0.019$). However, *fis* did not sensitize the other *rec* strains tested, in fact *fis* protected the *recB* ($P=0.007$) and *recC* ($P=0.023$) strains about 2-fold. The *recA* strain was not protected ($P=0.069$). In associated studies, the *fis* mutant was 67% deficient in DNA recombination ability, normal for spontaneous mutagenesis, and 45% more susceptible to UV-radiation mutagenesis. **Conclusion:** Fis plays a greater role in the survival of X-irradiated vs. UV-irradiated cells, and its role in DNA repair most likely impacts recombinational repair (especially for DNA double-strand breaks) rather than nucleotide excision repair.

Rec220 and Rec534 Are Two Novel Regulators of RecA Function in the Human Pathogen *Mycoplasma genitalium*

Author Block:

S. Torres-Puig, C. Martínez-Torró, I. Granero-Moya, E. Querol, J. Pinyol, O. Q. Pich; Univ. Autònoma de Barcelona, Bellaterra, Spain

Abstract Body:

RecA is a highly conserved recombinase functioning in recombinational DNA repair and genome maintenance. It promotes the central steps of homologous recombination in bacteria, aligning and pairing two DNA molecules, and then promoting a strand switch by branch migration. To this end, RecA binds in long clusters to ssDNA to form a nucleoprotein filament. Both RecA loading onto DNA and filament extension are typically modulated by a broad network of accessory proteins, which can inhibit, promote or stabilize targeted assembly of recombinase filaments. Remarkably, the pathways that facilitate RecA loading onto ssDNA in many bacteria, e.g. RecBCD and RecFOR, seem to be missing in the streamlined bacterium *Mycoplasma genitalium.* In a recent study, we demonstrated that the alternative sigma factor MG428 is a master regulator of recombination. In addition to RecA and the Holliday junction resolvases, two previously uncharacterized proteins under the control of the MG428 regulator, MG_RS01295 and MG_RS02200 (hereinafter Rec220 and Rec534), were found to be necessary for homologous recombination in *M. genitalium*. In the present work, we analyzed the expression of a RecA-fluorescent protein fusion under the control of a constitutive strong promoter. Most of the cells of the isogenic mutant analyzed exhibited a diffuse fluorescence, but some mycoplasmas displaying a distinctive sharp fluorescence were also observed. These results are in agreement with the formation of RecA foci in a small subset of cells. Further analyses revealed that RecA foci formation required the expression of the Rec220 and Rec534 proteins. Additionally, we created mutants carrying Rec220- or Rec534-fluorescent protein fusions at their respective native loci. Of note, deletion of the *rec220* gene completely abrogated the presence of Rec534-fluorescent cells. In contrast, Rec220-fluorescent cells were still observed in *rec534* mutants, though the percentage of fluorescent cells was significantly reduced. Altogether, our data indicate that RecA, Rec220 and Rec534 interact *in vivo*, and that Rec220 and Rec534 have different roles in the regulation of RecA function. A model depicting the interplay of these three proteins to target RecA filamentation to specific sites is presented.

Inactivation of Sos System Reduces Atp Production and Membrane Integrity in Quinolone-resistant *Escherichia coli*

Author Block:

J-M. Rodriguez-Martinez[1], E. Recacha[2], J. Machuca[2], P. Diaz de Alba[2], M. Ramos Güelfo[2], F. Docobo Perez[1], J. Rodriguez Beltran[3], J. Blazquez[3], A. Pascual[1]; [1]Univ. of Seville, Seville, Spain, [2]Univ. Hosp. Virgen Macarena, Seville, Spain, [3]Inst. of Biomedicine of Seville, Seville, Spain

Abstract Body:

Background: SOS system has been postulated as target with potential impact in both quinolone resistance and mutant development. The aim of this study was to evaluate the impact of SOS system in resistance suppression in an isogenic collection of quinolone-resistant *Escherichia coli* strains using biochemical techniques. **Materials/methods**: Six isogenic strains were used: ATCC 25922 (wild-type), EC02 (*E. coli* ATCC 25922 plus Ser83Leu substitution in GyrA), EC04 (EC02 plus Ser80Arg substitution in ParC), EC08 (EC04 plus Asp87Asn substitution in GyrA), EC09 (EC08 plus deletion in *marR*) and EC59 (EC09 expressing QnrS1). To switch-off the SOS system, *recA* gene was inactivated (all strains) and *lexA* was replaced by *lexA1* (wild-type, EC04 and EC09). Ciprofloxacin concentrations assayed were: 1 mg/L (breakpoint for reduced susceptibility), 2.5 mg/L (human serum Cmax), 1xMIC for each isogenic group (on/off SOS system) and 0.5xMIC of the wild-type for SOS system for each isogenic group. Metabolic activity and viability were assayed by using the Luminescent BacTiter-Glo Microbial Cell Viability Assay (Promega) (ATP production) and LIVE/DEAD® BacLight™ Bacterial Viability Kit (Life Technologies) (membrane integrity), respectively. Fluorescence microscopy and *recA* reporter vector were also used. **Results**: *recA* reporter vector evidenced the lack of activation of SOS system in *recA* knockouts or *lexA1* mutants (at least 10-folds drop compared to wild-type SOS system). SOS inactivation produced a clear reduction in ATP production (about 100-folds after 24 hours) in all conditions assayed. Monitoring the viability of bacterial populations as a function of the membrane integrity of the cell showed a clear reduction (up to 95-folds after 4 hours of antimicrobial exposition) of surviving bacteria when SOS system was inactivated. These data were evidenced by fluorescent microscopy. **Conclusions**: This approach showed the sensitization of quinolone resistant *E. coli* (including both low level and high level resistant strains) by targeting *recA* or *lexA* genes. This strategy might have a potential role as adjuvant of antimicrobial treatment.

Characterization of Mutations in *Acinetobacter baylyi* Adp1 *yqgf* Reveals an Unexpected Role in Enhancing Susceptibility to Dna Damage

Author Block:

D. J. McClung[1], **A. Calixto**[2], M. N. Mosera[2], S. J. Patel[2], E. L. Neidle[3], K. T. Elliott[2]; [1]Univ. of California Berkeley, Berkeley, CA, [2]The Coll. of New Jersey, Ewing, NJ, [3]Univ. of Georgia, Athens, GA

Abstract Body:

The gene *yqgF* is nearly ubiquitous in bacteria, and yet represents one of only 13 remaining essential genes of unknown function in *Escherichia coli*. We used the naturally transformable soil bacterium *Acinetobacter baylyi* ADP1 to begin to characterize *yqgF*, a predicted Holliday junction resolvase. Using deletion mutants and site-directed mutations in codons for predicted catalytic amino acids, we assessed the role of *yqgF* in comparison with *ruvC*, which encodes a known resolvase. Mutant strains were tested for effects on recombination-dependent phenotypes including the efficiency of allelic replacement by natural transformation, resistance to DNA damaging agents, and frequency of large spontaneous chromosomal deletions. We also surveyed sequences of novel DNA junctions resulting from spontaneous chromosomal deletions in these genetic backgrounds. Unexpectedly, Δ*yqgF* and Δ*ruvC* had opposite effects on each phenotype assessed. In addition, we found that the presence of a functional copy of *yqgF* resulted in increased susceptibility to DNA damage due to nalidixic acid or UV radiation. Despite the striking differences in phenotype between the Δ*yqgF* and Δ*ruvC* mutants, the amino acids predicted, based on similarity to RuvC, to participate in catalysis by YqgF were required for YqgF function. Taken together, these findings raise questions about the predicted function of YqgF as a Holliday junction resolvase. Further, our results establish *A. baylyi* ADP1 as a tractable system for molecular studies of this highly conserved but poorly characterized gene.

Does Recombineering Require a Replicating Dna Target?

Author Block:

L. C. Thomason[1], N. Costantino[2], D. L. Court[2]; [1]Leidos BioMed. Inc., Frederick Natl. Lab. for Cancer Res., Frederick, MD, [2]Natl. Cancer Inst. at Frederick, Frederick, MD

Abstract Body:

Recombineering, *in vivo* genetic engineering using bacteriophage recombination systems, is a powerful technique for making genetic modifications in bacteria. Two systems widely used in *Escherichia coli* are phage Red and the Rac prophage RecET. Both systems have a single-strand annealing protein and a 5'->3' double-strand DNA (dsDNA) exonuclease. Some experimental evidence suggests that recombineering requires a DNA target proficient for DNA replication. We further investigated the *in vivo* dependence of recombineering on DNA replication of recombining substrates. For the Red system, when replication of a target plasmid is prevented, Beta-mediated recombination with single-strand DNA (ssDNA) oligonucleotides is reduced nearly 1000-fold. The RecT recombination frequency is substantially less robust than that of Beta, but only when DNA replication is allowed. The Red Beta and Rac RecT recombination frequencies converge to similar levels when the plasmid target is not replicating. A very low level of plasmid by ssDNA recombination is observed in the absence of any phage functions and is independent of DNA replication. In contrast to these results, both the Red and RecET systems efficiently recombine a non-replicating linear dimer plasmid to yield a circular monomer. Our experiments show that for the Red system the requirement for DNA replication is substrate-dependent and consistent with Red recombination occurring primarily by single-strand annealing rather than by strand invasion.

Sequence Analysis and Functional Studies of Xer Site-Specific Recombination Sites in *Klebsiella pneumoniae* Plasmids

Author Block:

M. Babayan[1], D. J. Sherratt[1], M. E. Tolmasky[2]; [1]Univ. of Oxford, Oxford, United Kingdom, [2]California State Univ. Fullerton, Fullerton, CA

Abstract Body:

Background: *Klebsiella pneumoniae* (Kp) has gained in importance as a hospital pathogen due to its acquired multidrug resistance. The sequencing of complete genomes of clinical isolates showed that Kp usually includes multiple plasmids that carry resistance genes, frequently as part of transposons. Most of these plasmids are poorly characterized despite their impact on the ability of the host strains to resist antibiotic treatment. An analysis of plasmids from two clinical isolates that were recently sequenced showed that most included regions highly related to Xer site-specific recombination (XSR) targets, which are essential for stable inheritance in several plasmids. **Methods:** Functionality of target sites was determined by dimer-resolution in vivo assays. *Escherichia coli* was transformed with dimers of recombinant clones harboring the sites. Dimers were prepared by transformation of the hyper-recombinogenic *E. coli* JC8679 followed by plasmid extraction and dimer purification. Site-directed mutagenesis was carried out using a commercial kit. **Results:** Inspection of the nucleotide sequences of XSR sites showed that many possess accessory sequences with a faulty ARG box, a locus that facilitates binding of one of the architectural proteins that help establishing the synaptic complex necessary for recombination. Others include variations in the distance between the core recombination site (crs) and accessory sequences, or in the lengths of the central region of the crs. Dimer resolution assays showed that these sites mediated resolution levels well below those necessary to stabilize the plasmids under laboratory conditions. In particular, mutagenesis of the ARG box indicated that the presence of the adequate nucleotides is essential for the mediation of recombination at high levels. **Conclusions:** We conclude that while XSR sites are present in most Kp plasmids, they are usually unable to mediate high levels of multimer resolution. It is therefore possible that they are essential only under specific growth conditions or that they mutated after becoming redundant, following the acquisition of replicative transposons that act as stabilizers through their own site-specific cointegrate resolution site. It is also possible that these sites have other still unknown functions.

Brujita Integrase: A Simple, Armless, Promiscuous Tyrosine Integrase System

Author Block:

B. L. Lunt, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

In most temperate phages lysogeny and immunity to superinfection are determined prior to integration into the host chromosome. However, mycobacteriophage Brujita is an unusual temperate phage in which establishment of immunity is dependent on chromosomal integration. Brujita integration is mediated by a non-canonical tyrosine integrase lacking an N-terminal domain typically associated with binding to arm-type sites within the phage attachment site (*attP*). This raises the questions of how these integrases (Ints) bind their DNA substrates, if they form higher order protein DNA complexes, and how site selection and recombinational directionality is determined. We used *in vivo* recombination and *in vitro* binding assays to explore these questions. Here we show that Brujita Integrase is a simple tyrosine recombinase, whose properties more closely resemble those of recombinases FLP and Cre than it does the canonical phage tyrosine integrases. Brujita Int uses relatively small DNA substrates, fails to discriminate between phage and bacterial attachment sites (*attP* and *attB*), cleaves attachment site DNA to form a 6-base overlap region, and lacks directional control. Brujita Int also has an unusual pattern of binding to its DNA substrates. It binds to two half sites (B and B') in *attB*, although binding to the B half site is strongly dependent on occupancy of B'. In contrast, binding to the P half site is not observed, even when Int is bound at P'. However, an additional Int binding site (P1) is displaced to the left of the crossover site in *attP*, is required for recombination, and is predicted to facilitate binding of Int to the P half site during synapsis. This simple tyrosine phage integrase system may reflect ancestral states of phage evolution with the complexities of higher-order complex formation and directional control representing subsequent adaptations.

Mimicking *In Vivo* Stress Conditions Elicit Differential Responses from Several Strains of *M. tuberculosis* (*mtb*)

Author Block:

A. V. Veatch[1], J. Caskey[2], S. Mehra[3], D. Kaushal[1]; [1]Tulane Natl. Primate Res. Ctr., Covington, LA, [2]LSU Sch. of Vet. Med., Baton Rouge, LA, [3]LSU Sch. of Vetinary Med., Baton Rouge, LA

Abstract Body:

~1/3 of the human population is infected with *Mtb*, the causative agent of tuberculosis (TB). While most infections are latently controlled, 1.3M people die due to TB per year. *Mtb* is able to evade killing by phagocytes, survive in a dormant state within the granuloma, and able to re-activate to infect the next host. Phagocytes attempt to kill *Mtb* by using a variety of methods such as low pH, antimicrobial peptides, and oxidative stress. Appropriate response to stress is key to *Mtb*'s survival. Thus, *Mtb* must contend with hypoxia for its intra granulomatous survival. Of the major *Mtb* lineages, East Asian is associated with hyper virulence and lower immune responses. We hypothesized that variable virulence in *Mtb* strains may be due to differences in stress response. We therefore studied responses of *Mtb* strains CDC1551 (low virulence Euro Am), Erdman (high virulence Euro Am) and HN878 (high virulence East Asian) to hypoxia and oxidative stress using RNAseq. These strains are differentially susceptible to hypoxia and oxidative stress, correlating with virulence. Thus, high virulence strains Erdman and HN878 exhibit greater fitness in hypoxia, being able to replicate significantly better relative to CDC1551 in an *in-vitro* model of reactivation. During hypoxia the expression of i) a higher than expected number of tRNAs were induced in all strains, pointing to an interesting role for these genes in stress management; ii) greater than expected PE/PPE genes was down regulated in high relative to low virulence *Mtb* and iii) lipid biosynthesis genes was not enriched in the induced bin in the high relative to the low virulence strains. Reactivation to a higher magnitude may lead to a greater transmission, and thus higher virulence. Our results show that increased fitness in response to hypoxia imparts a greater magnitude of reactivation on high virulence *Mtb* and this response may explain the higher virulence of Erdman and HN878. In contrast, CDC1551 is highly susceptible to thiol oxidative stress while Erdman is resistant, with HN878 exhibiting an intermediate phenotype. Efficient phagocyte mediated killing of low virulence *Mtb* CDC1551 can explain its lower virulence as well as higher immunogenicity.

Selective Activation of the Rv1625c Adenylyl Cyclase in *Mycobacterium tuberculosis*

Author Block:

R. Johnson[1], G. Bai[2], B. VanderVen[3], K. McDonough[1]; [1]SUNY Albany Sch. of Publ. Hlth., Albany, NY, [2]Albany Med. Coll., Albany, NY, [3]Cornell Univ., Ithaca, NY

Abstract Body:

Mycobacterium tuberculosis (Mtb) uses the 3'-5'-cyclic AMP (cAMP) second messenger to modulate expression of genes important to intracellular survival and pathogenesis in response to changing environmental conditions. cAMP signaling in Mtb is complex, potentially involving the activity of 15-17 adenylyl cyclases (ACs) and 10 putative cNMP binding effector proteins. The presence of many ACs has complicated the characterization of any individual cyclase within viable mycobacteria, and therefore most of our understanding of these enzymes is limited to biochemical characterization of purified recombinant proteins. Recently, a chemically diverse set of small molecules was found that inhibit mycobacterial growth both within macrophages and on cholesterol as a sole carbon source. Inhibition of Mtb growth was correlated with the production of high levels of cAMP, and multiple independent transposon insertions in *Rv1625c*, encoding a class III AC, conferred resistance to these drugs. Rv1625c has been of interest due to its homology to mammalian transmembrane ACs at both the sequence and structural levels. Here show that one of these compounds, V12-007958, specifically activates Rv1625c to convert ATP into cAMP, providing the first tool to selectively stimulate a single AC in live Mtb. We use both knock out and knock-in approaches to show that Rv1625c is necessary and sufficient for the compound to induce cAMP production in Mtb, *M. bovis* BCG and *M. smegmatis*. We rule out the potential for indirect effects mediated by Rv1625c on other mycobacterial ACs by expressing Rv1625c in *cya* deficient *E. coli*, showing that Rv1625c is responsible for producing the excess cAMP following V12-007958 treatment. cAMP was measured using a specific radioimmunoassay. In addition to their potential as therapeutics, V12-007958 and related compounds are the first small molecules identified capable of selectively activating a single AC in Mtb, and are powerful tools for studying cAMP signaling in this pathogen.

Publishing Title:

Characterization of a Third Transketolase in *Salmonella enterica*

Author Block:

J. A. Shaw, T. J. Bourret; Creighton Univ., Omaha, NE

Abstract Body:

Salmonella enterica serovar Typhimurium is a facultative intracellular pathogen that is a major cause of food-borne illness throughout the world. During infection of its host, *S.* Typhimurium must adapt to rapidly changing environments with fluxes in pH, nutrient availability, and osmolarity, as well as innate host defenses that include reactive oxygen species (ROS) and reactive nitrogen species (RNS). The pentose phosphate pathway (PPP) is notable for its contribution in maintaining cellular reducing power through the reduction of NADP+ to NADPH in the oxidative branch of the PPP (oxPPP), which enables *S.* Typhimurium to defend itself against ROS and RNS produced during infection. Downstream in the non-oxidative branch of the PPP (non-oxPPP), transketolases and transaldolases can either channel metabolites generated in the oxPPP to glycolysis, or divert carbon from glycolysis to generate precursors for nucleotide and aromatic amino acid biosynthesis. The *S.* Typhimurium genome encodes two transketolases that have been identified and characterized (TktA and TktB), along with third, putative transketolase (referred to here as TktC). TktC is hypothesized to be the product of two genes (*STM2340* and *STM2341*) that together form a functional transketolase enzyme. This study aims to explore the functional role of TktC in the PPP of *S.* Typhimurium. Analysis of growth in rich media revealed no major defects in strains lacking only one or two transketolases, while growth in the transketolase-deficient (Δ*tktA* Δ*tktB* Δ*tktC*) mutant was severely attenuated. Additionally, the transketolase-deficient strain was able to grow in minimal media with glucose as the sole carbon source, but failed to grow with ribose as the sole carbon source. This finding was indicative that the non-oxPPP was defective in the transketolase-deficient strain. These data suggest that not only are each of the enzymes able to compensate for the loss of the others, but also that TktC is capable of performing the transketolase reaction. This was supported by observations that 1) the expression of *STM2340* and *STM2341* is induced in strains lacking both *tktA* and *tktB*, 2) transketolase activity in the Δ*tktA* Δ*tktB* strain was similar to wild-type controls, and 3) that transketolase activity was absent in the strain lacking all three transketolases. Taken together, these data support the hypothesis that STM2340 and STM2341 produce a third functional transketolase in *S.* Typhimurium.

New Approach to Monitor Gamma-rays Effects on Different Bacteria in the Environment

Author Block:

A. Margaryan, D. Soghomonyan, S. Astanyan, K. Ohanyan, H. Badalyan, **A. Trchounian**; Yerevan State Univ., Yerevan, Armenia

Abstract Body:

Background: Development of mining of heavy metals and atomic technology lead to increasing of high-level radioactive wastes impacting on environment and can be dangerous for living organisms including bacteria. They are a basic part of biosphere having mechanisms to maintain cell integrity and activity upon environmental stress. Bacteria can be employed as sensors for monitoring of the environmental radiotoxicity.**Methods:** *Escherichia coli* M17 and *Pseudomonas aeruginosa* GRP3 wild types and accepted methods were used. Comparison analysis of bacterial cell morphology was carried out utilizing computational approach, using light and polarization microscopy and computer programs NOVA and LabView. As γ-rays source Cs^{137} with dose ranging from 30-35 μSv/h was emplyed.**Results:** The bacterial growth rate decreased 2-fold after 30 min γ-irradiation compared to control. The growth stationary phase of 30 min irradiated cells started 3 h later compared with non-irradiated cells. CFU of *P. aeruginosa* irradiated for 15 and 30 min with γ-rays decreased significantly by 10^1 and 10^4 times, respectively. It was found that γ-rays affected ATPase activity of *E. coli*: 15 min irradiation stimulated the *N,N'*-dicyclohexilcarbodiimide (DCCD) sensitive ATPase activity in 1.2-fold but 30 min irradiation had no effects. For *P. aeruginosa* the total H^+ efflux decreased on ~15% and ~30 % and the DCCD sensitive H^+ efflux suppressed on ~40 and ~50%, respectively, when compared with non-irradiated cells. Therefore, the F_0F_1-ATPase (for which DCCD is an inhibitor) could be a target for γ-rays, as for different environmental factors.Morphological alterations of *E. coli* and *P. aeroginosa* caused by γ-rays have been also detected using computational analysis. The average cell surface area decreased on 8% and 70% (15 min irradiated) and 3% and 50% (30 min irradiated), respectively, and bacterial cell perimeter (i.e. 2D projection of bacterial cell perimeter in photo image) - on 6% and 45% (15 min) and 2% and 35% (30 min), respectively. These changes were sensitive and statistically valid. They are stronger with *P. aeroginosa,* which could be used as a test strain.**Conclusions:** The comparison analysis points out γ-rays effects on different bacteria. As a rapid approach, computational analysis can be highly useful in monitoring of γ-rays effects on bacteria in the environment.

Dinb is Structurally and Functionally Altered Upon Interaction with Reca

Author Block:

T. F. Tashjian, I. Lin, V. Belt, V. G. Godoy; Northeastern Univ., Boston, MA

Abstract Body:

Evolutionarily conserved translesion synthesis (TLS) DNA polymerases (pols) accommodate DNA lesions that otherwise cause replication-fork stalling and cell death. Consequently, TLS pols have an ample active site and relatively low fidelity. In *Escherichia* coli TLS pols' expression is regulated by the well-understood SOS response. However, the mechanisms underlying DNA Pol IV or DinB interaction with the cell's main recombinase, RecA, which increases DinB's fidelity, are unknown.Under non-damaging conditions DinB is approximately 10-fold more abundant than the replicative DNA pol III. It is possible that DinB could compete with pol III for access to RNA primers, which are readily available on the lagging strand. Because of DinB's relative low fidelity, this would result in high mutagenesis during normal DNA replication. The inherent ability of DinB to polymerize at RNA primers has not been previously studied.We purified both DinB and RecA in strains lacking the *dinB* and *recA* genes and separated the products of the DinB-RecA interaction by size exclusion chromatography. These were characterized by western blot, mass spectrometry, trypsin proteolysis, and circular dichroism spectroscopy. The activity of DinB upon interaction with RecA was tested by primer extension assays, where DinB incorporated nucleotides from a fluorescently labeled DNA or RNA primer, and compared to DinB alone.Remarkably, we find that DinB's secondary structure and trypsin proteolysis pattern is altered upon interaction with RecA. Moreover, DinB alone has a 2-fold preference to synthesize from a DNA primer compared to an RNA primer, which increases to a 20-fold preference upon interaction with RecA.In summary, DinB undergoes a structural change upon interaction with RecA. This change could be responsible for our previous observation of lowered DinB mutagenesis upon RecA interaction. RecA drastically increases DinB's preference for DNA primers, which could represent a regulatory mechanism for preventing DinB from synthesizing from RNA primers on the lagging strand during non-damaging conditions.

Molecular Mechanism of *Pseudomonas Aeruginosa* Responses to Spermine Stress

Author Block:

Y-C. Peng[1], C-D. Lu[2]; [1]Georgia State Univ., Atlanta, GA, [2]Univ. of Massachusetts Lowell, Lowell, MA

Abstract Body:

Pseudomonas aeruginosa can grow efficiently on biogenic polyamines via the gamma-glutamylpolyamine synthetase (GPS) pathway. There are six GSP homologues encoded by *pauA1-pauA6* genes (polyamine utilization) scattered on the chromosome, and growth on spermine and spermidine was abolished completely in the *pauA2* knockout mutant. Without a functional PauA2, exogenous spermine exerts an adverse effect on growth as reflected on MIC measurements. Suppressors of the *pauA2* mutant against 10mM of spermine at pH 8.0 were isolated from the selection plates. These suppressors shared common changes on various phenotypes including delayed growth rate, retarded swarming motility, and pyocyanin overproduction. Transcriptome analysis of one such suppressor representative by GeneChip (Affymetrix) reveals that phosphate transporter genes (*pstS-pstCAB-phoU*) were highly induced over 5-20 fold. In addition, genome resequencing (Illumina) revealed that a unique C to T mutation at the *phoU* gene results in Ser to Leu amino acid substitution. Polyphosphate (polyP) accumulation can be visualized by Neisser stain. The reduction of polyP by the trans-acting polyphosphate phosphatase (PPX) increased the spermine susceptibility in the *pauA2* suppressor. Identical phenotypes were also observed in a Δ*pauA2*Δ*phoU* double knockout mutant. This study demonstrated polyphosphate accumulation as the potential protection mechanism against spermine toxicity in *P. aeruginosa*.

Cell Envelope Stress Response Regulons & Adaptation to *n*-Butanol Stress in *Bacillus subtilis* 168

Author Block:

G. Mahipant[1], A. S. Vangnai[1], J. D. Helmann[2]; [1]Chulalongkorn Univ., Bangkok, Thailand, [2]Cornell Univ., Ithaca, NY

Abstract Body:

Biofuels such as *n*-butanol can be produced in appropriately engineered microbial hosts, but product toxicity remains a major obstacle. *Bacillus subtilis* 168 has a higher butanol tolerance than many other production strains. Here, we demonstrate that growth in the presence of 1%(v/v) butanol allows *B. subtilis* to better tolerate and grow in higher concentrations such as 1.6%. This suggests that *B. subtilis* may adapt to solvent stress, presumably by altering gene expression. The adapted cells are morphologically altered and have a much broader distribution of cell lengths compared to unstressed cells. We therefore hypothesized that *B. subtilis* adapts to butanol by activating the expression of one or more cell envelope stress responses (CESR). In *B. subtilis*, CESRs are regulated by extracytoplasmic function (ECF) σ factors and two-component systems (e.g. LiaRS, CssRS). Cell envelope homeostasis is also affected by other global regulators including σ^B, σ^D, σ^H, and σ^I. By monitoring the growth of various mutant strains in the presence of butanol, we have demonstrated that ECF σ factors are not the major regulators of adaptation. In fact, activity of σ^W, σ^X, and σ^M is decreased during growth in the presence of butanol, and mutants lacking these sigma factors are not impaired growth in butanol-containing medium. In contrast, mutants lacking σ^I (a positive regulator of *bcrC*, *mreBH*, and *lytE*) is more sensitive to butanol stress. These results are providing a picture of those genes and pathways that are most critical for adaptation of *B. subtilis* to *n*-butanol stress.

A Novel Universal Compatible Solute of Halophilic and Halotolerant Bacteria: Trans-4-Hydroxy-L-Proline

Author Block:

K. Kim, H. Jeong, B. Jia, C. Jeon; Chung-Ang Univ., Seoul, Korea, Republic of

Abstract Body:

Halobacillus halophilus (*H. halophilus*), a moderate halophilic bacterium, has a capability to grow at a wide range of salinities. The strategy that accumulates compatible solutes to cope with osmotic stress in high salt environments has been well studied in *H.halophilus*, and glutamate, glutamine, and proline have been well known as compatible solutes. In this study, the accumulation of trans-4-hydroxy-L-proline (T4HP) was additionally identified from *H. halophilus* cells in the course of the analysis of osmolytes using ^{1}H-NMR. Accumulation of T4HP increased with the increase of salinity concentration in culture media. A gene that was annotated as multidrug DMT transporter permease (HBHAL_RS11735) in *H. halophilus* genome of GenBank was selected as a putative proline 4-hydroxylase (P4H) catalyzing the formation of T4PH by BLAST searches. To confirm the function of the putative P4H gene, the HBHAL_RS11735 gene was over-expressed in *E.coli* BL21(DE3) strain and the resulting recombinant strain showed the proline 4-hydroxylase enzyme activity, suggesting that the HBHAL_RS11735 gene is the P4H-coding gene in *H. halophilus*. RT-qPCR analysis showed that transcription levels of the HBHAL_RS11735 gene increased 80 times under 3M NaCl conditions compared to 0.4M NaCl. In addition, to confirm the presence of T4HP as a ubiquitous compatible solute, we analyzed T4HP from cell extracts of other halophilic or halotolerant bacteria that were cultivated at high salt conditions, which suggested that T4HP may be a novel universal compatible solute in halophilic or halotolerant bacteria.

Analyzing the Mechanism of Dipicolinic Acid Release during C*lostridium difficile* Spore Germination

Author Block:

M. B. Francis, J. A. Sorg; Texas A&M Univ., College Station, TX

Abstract Body:

Clostridium difficile is an anaerobic, spore forming bacterium that infects antibiotic-treated hosts. The vegetative form of *C. difficile* produces toxins that elicit the primary symptoms of disease but it is the spore form that is necessary for host to host transmission. Spores are metabolically dormant forms of bacteria that are resistant to harsh environmental conditions, including antibiotics. Spores sense changes in environmental conditions and begin the transition from dormancy to vegetative growth (germination) upon sensing appropriate signals (germinants). In *B. subtilis*, the initiation of germinant receptor-mediated spore germination is divided into two genetically separable stages. Stage I is characterized by the release of dipicolinic acid (DPA) from the spore core. Stage II is characterized by cortex degradation, and stage II is activated by the DPA released during stage I (DPA release precedes cortex hydrolysis during *B. subtilis* spore germination). We demonstrated previously that these stages I & II of germination are flipped during *C. difficile* spore germination (cortex hydrolysis precedes DPA release). To understand of the mechanism of DPA release, we investigated 3 proteins associated with the packaging and release of DPA in *B. subtilis*: SpoVAC, SpoVAD and SpoVAE. By creating in-frame deletions in the genes encoding these proteins and by using *B. subtilis* as a heterologous host, we hope to better understand how DPA is released from the *C. difficile* spore.

Mitochondrial Activity and Cyr1 are Key Regulators of Ras1 Activation of *C. albicans* Virulence Pathways

Author Block:

N. Grahl[1], E. G. Demers[1], A. K. Lindsay[1], C. E. Harty[1], S. D. Willger[1], A. E. Piispanen[2], D. A. Hogan[1]; [1]Geisel Sch. of Med. at Dartmouth, Hanover, NH, [2]Franklin Pierce Univ., Rindge, NH

Abstract Body:

The human commensal and fungal pathogen *Candida albicans* is a major health concern and new therapies are desperately needed. Its morphological switch from yeast to hypha is associated with disease and the Ras1-Cyr1-PKA pathway is a major regulator of *C. albicans* morphogenesis as well as biofilm formation. Our previous studies of microbe-microbe interactions showed that bacterial phenazines and the analog methylene blue inhibit the yeast-to-hypha switch. Here, we show that mitochondrial inhibition by these compounds strongly decreased Ras1 GTP-binding and activity in *C. albicans* and other *Candida* species. Consistent with there being a connection between respiratory activity and GTP-Ras1 binding, mutants lacking complex I or complex IV grew as yeast in hypha-inducing conditions, had lower levels of GTP-Ras1, and Ras1 GTP-binding was unaffected by respiratory inhibitors. Mitochondria-perturbing agents decreased intracellular ATP concentrations and metabolomics analyses of cells grown with different respiratory inhibitors found consistent perturbation of pyruvate metabolism and the TCA cycle, changes in redox state, increased catabolism of lipids, and decreased sterol content which suggested increased AMP kinase activity. Biochemical and genetic experiments provide strong evidence for a model in which the activation of Ras1 is controlled by ATP levels in an AMP kinase independent manner. The Ras1 GTPase activating protein, Ira2, was required for the reduction of Ras1-GTP in response to inhibitor-mediated reduction of ATP levels. Furthermore, Cyr1, a well-characterized Ras1 effector, participated in the control of Ras1-GTP binding in response to decreased mitochondrial activity suggesting a revised model for Ras1 and Cyr1 signaling in which Cyr1 and Ras1 influence each other and, together with Ira2, seem to form a master-regulatory complex necessary to integrate different environmental and intracellular signals, including metabolic status, to decide the fate of cellular morphology. Future studies will show if this knowledge can be used to develop therapies that would favor benign host-*Candida* interactions by promoting low Ras1 activity.

***Saccharomyces cerevisiae* as a Model for Screening Volatile Organic Compounds**

Author Block:

S. U. Morath, C. E. Boland, J. W. Bennett; Rutgers Univ., New Brunswick, NJ

Abstract Body:

In indoor environments, volatile organic compounds (VOCs) are gaseous at room temperature, readily dissipate throughout the environment, and may be of anthropogenic or biogenic origin. VOCs, particularly those produced by microbes, have been correlated with "building related illness," a diagnosis with symptoms including fatigue and headache that resolve upon exiting the offending space. Additionally, the built environment provides a relatively closed ecosystem in which microbial VOCs may be present at increased concentrations and maintain their normal function as signaling molecules that alter population dynamics and behavior of the receiving organism, whose growth may be enhanced or inhibited. In this study, we used *Saccharomyces cerevisiae* to investigate the response to VOC exposure and the accompanying basic response mechanisms, which are often conserved in eukaryotes, from fungi to humans. We determined the sensitivity of *S. cerevisiae* in response to exposure to twenty-seven VOCs, collectively or singularly produced by bacteria, fungi, plants, and in industrial processes, and containing various chemical functional groups. Using a serial dilution spot assay with a wild-type yeast strain, the compounds were screened at 10ppm for 48hr in a shaking incubator maintained at 30°C to determine their impact on yeast growth. Mean relative growth of yeast was compared to the control after exposure. We found that the common industrial VOCs toluene and xylene had little effect on yeast growth, while gas-phase formaldehyde, three microbial VOCs, 1-octanol, 1-octen-3-one, and trans-2-octenal, and a common plant VOC, trans-2-hexen-1-al, completely inhibited yeast growth at 10 ppm. Several other compounds were significantly inhibitory: 1-octen-3-ol, benzene, and isobutyraldehyde. We also identified 2 common microbial VOCs, 3-methyl-1-butanol and 3-octanone, that significantly increased yeast growth. These results indicate that neither means of production nor chemical structure is indicative of the impact of these VOCs at the tested concentration on yeast growth. This study is the first study using yeast to screen the effects of VOCs in the gas-phase, and provides the basis for future studies to reveal whether there is a common mechanism of action of VOCs within the cell.

Comparison of the Chemical Signaling of the Two Life Stages in the Coccolithophore *Emiliania huxley* Exposed to Visible Light Stress

Author Block:

L. E. Valentin-Alvarado[1], S. Strom[2]; [1]Univ. of Puerto Rico at Humacao, Santa Isabel, PR, [2]Western Washington Univ., Anacortes, WA

Abstract Body:

The cosmopolitan marine phytoplankton species *Emiliania huxleyi* presents a digenetic heteromorphic life cycle, with the non-motile diploid phase bearing coccoliths and the flagellated haploid phase being non-calcified. *E. huxleyi* contains high concentrations of dimethylsulphoniopropionate (DMSP), the precursor of dimethylsulphide (DMS). DMSP is a multifactorial compound; it acts as a compatible solute in cell metabolism and as a chemical signal influencing bacterial and protist behavior. In the atmosphere DMS enhances cloud formation influencing climate. However, little has been documented on *E. huxleyi* chemical signal responses to high light stress, and how this relates to the heteromorphic life cycle. To this end, low light acclimated cultures of both haploid and diploid *E. huxleyi* were exposed to high light for 2 hr and allowed to recover in low light for 2 hr. During and after these treatments, growth, photosynthetic efficiency (Fv/Fm), DMSP (intracellular and released) and cell chlorophyll content were measured. Our preliminary results suggest that presence of high light decreased Fv/Fm to a greater extent in haploid than in diploid (calcified) cells, while recovery of Fv/Fm was rapid in both life stages. The chlorophyll content and intracellular DMSP was not different in both life stages. However, the dissolved DMSP increased after light stress in diploid cells suggesting a possible advantage serves as antioxidant protection or another cellular function, such as grazing protection in this life stage.

The Effects of Stress on Protein Translation in *Entamoeba histolytica*

Author Block:

M. A. Hapstack, H. M. Hendrick, B. H. Welter, L. A. Temesvari; Clemson Univ., Clemson, SC

Abstract Body:

Entamoeba histolytica is an intestinal parasite that is known to cause amoebic dysentery and liver abscess, resulting in 100,000 annual deaths worldwide. During infection, *E. histolytica* encounters a number of different stresses in the tissues of its host. Other eukaryotic organisms use a conserved response to stress, involving the phosphorylation of a serine residue (S59) on the alpha subunit of eukaryotic initiation factor2 (eIF2α). The result of this is down-regulation of global protein translation to conserve energy for the stress response. Although genomic data has revealed that *E. histolytica* possesses the components of this system, translational-control of stress has never been examined in this parasite. To better understand how *E. histolytica* counters stress, global protein translation after stress was analyzed by polyribosome profiling. Cells were stressed (long-term serum starvation, glucose deprivation, heat shock), and then cell lysates were resolved using continuous sucrose gradient fractionation. Fractions were taken and analyzed by spectroscopy (254 nm) to detect relative polyribosome abundance. Only long-term serum starvation showed a significant decrease in polyribosome abundance, indicating that *E. histolytica* utilizes the eIF2α phosphorylation pathway to survive this stress. This is the first example of translational control in *E. histolytica*. The data are consistent with other data that show a significant increase in the level of phospho-eIF2α during serum starvation in this pathogen. Experimentation with cell lines expressing phosphomimetic and non-phosphorylatable mutants of eIF2-α in *E. histolytica* will promote further understanding of stress response in this parasite, as well as in eukaryotic systems as a whole.

Career Needs of Students and Recent Graduates in the Field of Microbiology

Author Block:

S. Gadwal; American Society for Microbiol., Washington, DC

Abstract Body:

With the rising number of young scientists electing to pursue non-academic careers, universities and professional societies are increasingly concerned with how they can better serve the professional development needs of these individuals. To accommodate this shift in career choice, there is also increased focus on improving biomedical training for students in master's and doctoral programs. To better understand the skills and career resources young microbiologists are seeking in the current market, an online survey was conducted. Students, postdocs, and early-career microbiologists from various organizations around the world were invited to participate and approximately 940 surveys were collected. When asked what resources would be most helpful with regards to professional development, 48% of the respondents cited a mentorship program based on their career interests, 36% wanted information on applying and interviewing for academic positions, and 31% wanted more internship opportunities. Survey participants were also asked to explain the communication, managerial, and interpersonal skills they wanted to develop or improve. A majority of respondents indicated that the communication skills they seek are in writing scientific papers (57%) and grants (52%); for managerial skills, the top two responses were project management (34%) and leadership (32%); and for interpersonal skills, a majority identified negotiation skills (63%) and conflict resolution (51%). Participants were also asked to indicate the type of organization they wanted to work in. As predicted, the majority (60%) were interested in non-academic careers, such as industry, government, and hospitals or clinical settings, while 40% of the participants remain interested in working in academia. Some survey respondents felt a lack of information regarding non-academic careers and how to pursue them. Overall, our findings indicate that a significant percentage of students, postdocs, and early-career scientists are considering non-academic careers and seek better preparation for such career paths. The information gained from this study can be used to assist in planning of future programming activities and educational training programs to better prepare young scientists for a non-academic career.

A Survey of Microbiology Education in Nursing Practice

Author Block:

R. J. Durrant, J. P. Fenn, R. L. Buxton, A. R. Brooks, A. K. Doig; Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: Nurses must have sufficient education and training in microbiology to perform many roles within clinical nursing practice (e.g. administering antibiotics, collecting specimens, preparing specimens for transport and delivery, education of patients and families, communicating results to the healthcare team, and developing care plans based on results of microbiology studies and patient immunological status). It is unclear whether current microbiology courses in the United States focus on the topics that are most relevant to nursing practice. We sought to utilize an internet-based survey to inquire about educational background in microbiology and related topics, as well as nurses' use of microbiology knowledge in their current duties in order to gauge the relevance of their microbiology education to nursing practice. Our goal was to formulate suggestions on specific topics to improve the quality and applicability of microbiology education for nursing students.**Methods:** Three hundred and twenty six Registered Nurses completed a confidential, web-based survey that inquired about the participant's past microbiology education, types of microbiology specimens collected, nursing duties that require microbiology knowledge, and frequency of infectious diseases encountered in practice.**Results:** The topics deemed most relevant to current practice were infection control, hospital acquired infections, disease transmission, and collection and handling of patient specimens. Topics of least interest included the Gram stain procedure and using a microscope. Surprisingly, there was little interest in molecular testing methods. This may highlight a gap in understanding molecular microbiological test utilization that could be partially bridged in a microbiology course.**Conclusions:** We now have data supporting anecdotal evidence that nurses are most engaged in learning about microbiological topics that have the greatest impact to patient care. Information collected from this survey will be used to adapt the focus and emphasis of microbiology courses to focus on relevant topics for nursing practice.

Wadsworth Center Master's Degree in Laboratory Science: 4 Years Strong

Author Block:

L. Mingle, K. Chou, D. Kay, A. Fayo, K. Musser, M. Perry, C. Egan; Wadsworth Ctr., New York State Dept. of Hlth., Albany, NY

Abstract Body:

The New York State Department of Health's Wadsworth Center Master of Science in Laboratory Sciences (MLS) Program is designed to train the next generation of public health laboratory (PHL) scientists and supervisors. The program provides a comprehensive overview of PHL fundamentals and allows development of advanced technical and analytical skills, combining didactic lecture-based coursework with lab training. Students gain hands-on practical experience and training in the major PHL areas, including infectious disease, environmental health, genetics, clinical biochemistry, clinical/diagnostic immunology, biodefense/emergency preparedness, translational medicine and lab quality certification. The 2-year, 6-semester (60-credit) curriculum includes 9 core courses, 4 special topics courses, lab rotations, and culminates with a capstone project. By addressing a practical challenge in the PHL, the capstone project provides essential lab training and strengthens analytic, interpretive and writing skills. Unique aspects of the program include extensive development of communication skills; exposure to lab operations and management, including best practices, financial operations, and human resource management; hands-on experience with outbreak investigations and new assay development and validation; and access to core facilities using state-of-the-art instrumentation and technology. The MLS program is in its 4th year with 5 current matriculated students. Six graduates have worked in grant-funded positions at Wadsworth Center's newborn screening, biodefense, bacteriology/mycobacteriology, virology and bloodborne viruses labs. Several have earned competitive Emerging Infectious Diseases (EID), Oak Ridge Institute for Science and Education (ORISE) and Advanced Molecular Diagnostics Emerging Infections Program (AMD-EIP) fellowships sponsored by the Centers for Disease Control and Prevention (CDC) and Association of Public Health Laboratories (APHL). Graduates of the MLS program are well-equipped to conduct lab analysis with cutting-edge tools and technology, investigate complex public health questions and respond to everyday challenges in public health.

Teaching Matters: Making the Most of Teaching Training for Everyone's Benefit

Author Block:

B. Fahnert; Cardiff Univ., Cardiff, United Kingdom

Abstract Body:

Teaching professionalism benefits academic career establishment/advancement even though most developed economies do not yet require pedagogic training for Higher Education teachers. Many Higher Education Institutions encourage and offer teaching training, and demands for compulsory training have become stronger. For example a European Commission High Level Group recommended that everyone teaching in Higher Education needs to be trained by 2020, combined with mandatory continuing professional development and linking recruitment and promotion to teaching performance. Teaching skills can be developed e.g. in formal university courses, staff development programmes and through learned societies. Training teachers is perceived as valuable by students. Staff certainly benefit from being supported when developing their personal philosophy of teaching based on educational theory, analysing their teaching practice and attempting teaching innovation. Yet, ensuring long-term benefit of generic teaching training for all stakeholders depends on successfully making it part of individual continuing professional development and local departmental academic culture. A stakeholder and discourse analysis and a mixed method study were conducted, qualitatively analysing experiences of teaching training participants and non-participating colleagues in a biosciences department. Emerging important aspects were e.g. relevance and accessibility of pedagogy as a discipline new to quantitative scientists, not being trained by peers, and issues around accepting and learning how to use qualitative methodology and its findings. Presented outcomes of the study outline opportunities that help every academic to engage with pedagogic learning and to embed it in their professional identity in light of such challenges as high workload, local disciplinary contexts and issues of recognition, and that help managers and institutions to support it. Understanding the opportunities and challenges crucially informs provision of training and tailoring communication with all stakeholders in order to optimally implement teaching training initiatives and to generally relate training of individuals to organisational learning, and to manage the respective change.

Insights Into the Academic Interests of Undergraduates Identified During Undergraduate Initiation of an Asm Student Chapter

Author Block:

J. A. Lucci, G. Tollefson; Univ. of Rhode Island, Kingston, RI

Abstract Body:

Background: In the fall of 2012, the University of Rhode Island consolidated its Microbiology, Biotechnology, and Biochemistry majors into an all-encompassing Cell & Molecular Biology (CMB) major. The the previously separate majors were organized into subcategories of this collective CMB major. To help students to reap the benefits of this departmental consolidation, a hand selected group of CMB students worked together to organize a student chapter of the American Society for Microbiology (ASM) to encourage increased unity and cooperation between a diverse group of students in the combined CMB program. At the inaugural meeting, the chapter took a poll to determine the greatest areas of interest for CMB students. This information could be used as valuable feedback to aid faculty in providing resources and coursework that is more closely aligned with our student population. **Methods:** To identify the groups interests, copies of the 'Scientific Areas' section from the *Scientific Background* section of the Directory Profile of the ASM website were provided at the next meeting. Chapter members indicated areas of interest on these sheets which were collected and analyzed by the chapter board. **Results:** Significant findings include that 11 of 18 (61%) members expressed interest in viruses and 10 out of 18 (55%) expressed interest in biodefense. 8 out of 18 (44%) members indicated interest in Immunology as well as Cell Biology. Fortunately for our undergraduates, these topics are explored in the new CMB curriculum. **Conclusions:** The variable nature of recorded areas of interest exemplifies the many focuses and applications of cell and molecular biology to industry, health, and academic research. We aim to share this data with the faculty of the University of Rhode Island CMB department to encourage personalized course material. We will also use this data to help us plan meeting content that will be helpful and interesting to our ASM student chapter.Data

Cybernetic Girls Can Be Pinky: Empowering Biologists into Computational Fields

Author Block:

L. Casillas, L. Casillas-Santiago; UPR-Humacao, Humacao, Puerto Rico

Abstract Body:

Recent studies by the National Science Foundation indicate that women's participation in certain areas such as Computational Sciences (CS) is less than 18%. This number is lower in Latinas, with only 4.9% participation. A problem alluring Hispanics females to join careers in CS is that femininity and achievements in men-dominated careers are opposed. Consequently, we have engaged in a **Teaching to Increase Diversity and Equity in Science** (TIDES) initiative to increase the number of Latinas entering into CS. More specifically, our empowering program "*Cybernetic Girls can be Pinky*" is alluring Latinas into Computational Biology. Our program consist of changes at the curricular level revamping three Biology core courses with more quantitative analysis experiments, the offering of R and Phyton programming workshops to Biology students, and gender-related conferences for undergraduates. Comparison of the pre and post-tests that measures critical-thinking skills in the revamped courses indicated Hake's Gain up to 66% in five of the nine skills tested. In the Molecular and Cell Biology Course we implemented the Small World Initiative and students were able to identify to the molecular level more than 25 unique isolates with antibiotic activities. Students also had an active participation in oral reports, class discussions and final poster preparations. Overall evaluation of the programming workshops was 4.3 (with 5 as excellent), students only faced problems making graphs using ggplot2 and in how to simulate different distributions in a study. To fully empower our students we provided a Women in Science Course that emphasize the accomplishments of Latinas in Science. In all courses we provided students with a pre and post questionnaire named: What do you think about quantitative analysis and computational biology? We asked students perception toward female scientists specifically in Computational Biology. Interestingly, most students were not aware of the salary differences, masculine environments and how motherhood was considered an obstacle for success. We observed changes in male perceptions, for example, in the post tests male students reported stronger disagreement with the idea that one of the basic responsibilities of a professional woman is to raise her children. We plan to incorporate the changes, surveys and programming and gender workshops as part of our curriculum.

Gram Stain Workshop Improves Technique Comprehension and Interpretation

Author Block:

M. S. Delfiner, Luis R. Martinez, Charles S. Pavia; NYIT Coll. of Osteopathic Med., Old Westbury, NY

Abstract Body:

Introduction: Laboratory diagnostic tests have an essential role in patient care, and the increasing number of medical schools that teach laboratory medicine reflect this importance. However, it has not been shown if pedagogical method influences competency in comprehension and interpretation of these tests. The Gram stain is a frequently used diagnostic test that helps categorize bacteria based on cell wall structure. Here, a randomized control study is used to determine if there is a difference when students learn Gram staining via a hands-on workshop, a small group discussion, or a lecture.**Methods:** Twenty-seven volunteers, selected from the first-year class at NYIT College of Osteopathic Medicine (COM), were randomly placed into three groups: a lecture group, a workshop group, and a discussion group. All participants attended a lecture where they were instructed on the structure of bacterial cell walls and the basic principles of the Gram stain procedure**.** Additionally, the workshop participants performed the Gram stain procedure and observed their stained slides under a light microscope. The discussion group participants interpreted pre-stained slides and discussed their findings. One week later, all participants took a multiple-choice quiz, which assessed understanding of staining procedure, importance, and interpretation. Mean scores were calculated and compared with analysis of variance (ANOVA) and the Bonferonni test. Chi-square analysis was used for categorical variables. One outlier was removed since it fell over two standard deviations from the mean.**Results:** Ten participants each were assigned to the workshop and the lecture groups, while seven were assigned to the discussion group. There was no significant difference between groups in regards to age, gender, and race. The mean quiz score for the workshop group was 13.1 out of 15 (SD=1.76), for the discussion group was 10.29 (1.98), and for the lecture group was 9.2 (2.44). There were significant differences between the workshop and lecture groups ($p=0.04$) and between the workshop and discussion groups ($p=0.002$). There was no difference between the discussion and lecture groups.**Conclusion:** This study shows that there is an improvement in Gram stain interpretation when students have hands-on experience. These results suggest importance in including a laboratory component in medical school curricula.

International Workshop and Evaluation of Science in Countries of the Caucasus Region

Author Block:

F. Perler[1], **E. Becraft**[2], J. Bird[3], D. McCrimmon[4], D. Polosukhina[5], R. Ramaley[6], J. Spear[7], W. Swingley[8], L. Ziolkowski[4], T. A. Vishnivetskaya[3]; [1]Perls of Wisdom Biotech Consulting, Brookline, MA, [2]Bigelow Lab. for Ocean Sci., East Boothbay, ME, [3]Univ. of Tennessee, Knoxville, TN, [4]Univ. of South Carolina, Columbia, SC, [5]Vanderbilt Univ., Nashville, TN, [6]Univ. of Nebraska Med. Ctr., Omaha, NE, [7]Colorado Sch. of Mines, Golden, CO, [8]Northern Illinois Univ., DeKalb, IL

Abstract Body:

The Caucasus Mountains provide a unique opportunity for investigating microbial diversity and microbial processes in non-volcanic thermal regions. Though numerous hot springs are found in the Caucasus, their biology is just beginning to be tapped. The natural mineral waters contain indigenous microorganisms with valuable characteristics involved in biosynthetic and biodegradative pathways, heavy metal resistance, and bioremediation of toxic metals and explosives. In 2015 an international workshop was held in Georgia and Armenia for the purpose of discussing the potential for establishing beneficial new collaborations, as well as opportunities for expanding educational interchange. The workshop format was similar in both countries with a symposium comprising local and U.S. speakers, visits to local scientific institutions, field trips to natural environments, and cultural components. The NSF expert panel consisted of ten U.S. scientists, mostly with basic science backgrounds, running the gamut from graduate students to professors to retired personnel. The Armenian participants mirrored the composition of the U.S. panel with the addition of high level institutional and government representatives, while the Georgian participants consisted of distinguished senior scientists and government officials. The NSF expert panel evaluated (i) existing collections of thermophilic microorganisms, (ii) thermal natural resources, and (iii) basic or applied thermophilic microbiology research programs with respect to biotechnology. The workshop materials will be published as NSF report. This one-week workshop developed strong international networks among scientists from participating countries, establishing a new niche for innovative collaborative research on Caucasus natural resources amongst faculty and students from U.S. and Armenian or Georgian universities. It provides a blueprint for establishing similar connections within other countries.

Hiv Outbreak in Scott County, Indiana: The Laboratory Response

Author Block:

J. Madlem, S. Dalenberg, J. Gentry, M. Cruz, E. Vecchio, M. Cross, S. Matheson, M. Glazier; Indiana State Dept. of Hlth., Indianapolis, IN

Abstract Body:

Background: In late 2015, cases of Hepatitis C and HIV increased to outbreak levels in a small southern Indiana county. A state of emergency was declared, and all available resources from the Indiana State Department of Health (ISDH) HIV, Preparedness, Laboratory and other divisions were mobilized to Scott County. In a matter of days, a Community Outreach Center was opened, providing services to residents of Scott and surrounding counties. Services included immunizations, drivers' licenses, birth certificates, needle exchange, and HIV testing. **Methods:**The ISDH Laboratory increased surge capacity for HIV and Hepatitis B/C testing, and provided emergency on-site phlebotomy training to disease investigators from the Centers for Disease Control and Prevention (CDC) and other state health departments. These investigators responded to the call for assistance in controlling this outbreak. **Results:** Phlebotomy is becoming an essential service of public health during outbreak situations. Rapid collection of serology specimens is critical to confirming and controlling disease outbreaks. Disease investigators, public health nurses, and other essential personnel have been called upon to perform phlebotomy more often in recent years. Unfortunately, a majority of these personnel have not had proper training to perform this function. The ISDH Laboratories Outreach and Training Team developed a single-day phlebotomy refresher course to meet this critical need. During eight training sessions in Scott County, 48 disease investigators were trained. Using the Kirkpatrick Model of evaluation, there was a 66% increase in the post test scores. Evaluations from this training indicated the highest level of satisfaction with this course. **Conclusions:** The ISDH Laboratory tested a total of 1681 specimens from Scott and surrounding counties. Of those, 181 (11%) tested positive for HIV, 618 (38%) tested positive for Hepatitis C, and 30 (3%) tested positive for Hepatitis B. Furthermore, the ISDH HIV Program initiated an HIV Testing Blitz in November 2015 in an effort to test associates of known positive cases. 152 additional specimens were received, and of those, 150 were tested. The November testing blitz detected 5 (3%) cases of HIV, along with 83 (55%) cases of Hepatitis C.

Forgotten: The Spanish Influenza Pandemic of 1918

Author Block:

S. C. Pal; Univ. of California at Davis, Davis, CA

Abstract Body:

The Spanish Influenza pandemic of 1918 killed more individuals globally than World War I, yet it is often mentioned as a corollary to the war, rather than its own event. The disease played a part during the First World War, but it also affected civilians and baffled medical professionals. Despite this, the pandemic gathered little popular attention and failed to leave a literary or scientific mark, causing its near erasure in the American collective memory. The virus was strange because of its virulence and atypical patterns of infection. While soldiers struggled to define the flu and keep it from spreading, medical professionals tried to quell the rapidly growing public health crisis caused by outbreaks. Privately, doctors and nurses wrote of the disease, but publicly published little, even years after the pandemic ended. This research extensively uses primary sources to show that the pandemic of 1918 was largely forgotten because dying in war due to influenza or any other disease was seen as less honorable than dying due to combat, as evidenced by the lack of memorials for flu victims. The violent military deaths in combat overshadowed the death of soldiers dying of influenza. Consequently, those mourning felt guilty for their sorrows in juxtaposition to the War and placed less importance on the pandemic and more importance on "worthier" causes, such as the war effort. The pandemic wasn't written on in scientific publications until the late 1900s because there wasn't an understanding to address it. In 1918, the scientific advancements just weren't advanced enough to explain the virus. Disease is often seen as an inevitable and natural. This, although true, does not merit the dismissive attitude that much of history has placed on the Spanish Influenza pandemic of 1918. How a population views a pandemic after its occurrence says much about how disease is viewed in society and in memory.

The Practice of Smallpox Inoculation in Colonial Boston and the Response from the Medical and Religious Communities in the Colonies and Britain, 1721-30

Author Block:

S. M. Richart; Azusa Pacific Univ., Azusa, CA

Abstract Body:

Centuries prior to Jenner's cowpox vaccination, the Chinese practiced inoculation of smallpox material on healthy people as a means of preventing smallpox disease. As this practice spread to India, Turkey, and parts of Africa, it came to the attention of the European world in the early 18th century. Enlisting the aid of local Boston physician Zebediah Boylston, famous Puritan minister Cotton Mather championed the implementation of the smallpox inoculation following an epidemic in Boston starting in 1721 that resulted in about 50% of the city's inhabitants developing smallpox disease. Boylston's practice of inoculation sparked an intense public debate that played out from the newspapers to the pulpit. While ultimately a compelling pragmatic argument arose in support of inoculation when data showed lowered smallpox death rates in people who had been inoculated, many other ethical considerations and concerns were raised within both the medical and religious communities before inoculation became more widely embraced. Here, using primary documents from Boston and Britain written between 1721-30, we examine some of the major ethical concerns to inoculation raised during this pivotal time period. While many of these concerns illustrate a pre-Germ theory conception of disease, some are recognizable in the current vaccination debate.

Stockhausen's Review of Beijerinck's Work: Valuable Thoughts from 1907 Concerning the Niche, Enrichments and Microbial Ecology

Author Block:

D. KLEIN; COLORADO STATE Univ., FORT COLLINS, CO

Abstract Body:

In 1907, Ferdinand Stockhausen published a summary of M. W. Beijerinck's work, entitled "Ecology, enrichments according to Beijerinck," or in German, "Ökoligie, Anhäufungen nach Beijerinck." This brief book contains many insights concerning the nature of enrichments and their use to better understand the characteristics of the microbial niche. The book begins with a discussion of different approaches that can be used to obtain "pure" cultures. Pasteur's approach was considered to be "mechanical," while that of Delbrueck was based on natural enrichments, the approach that was further developed by Beijerinck. Following this introduction, there is an extended discussion concerning the niveau (niche). A niche can be developed based on a series of factors: this can involve physical separation (for motile organisms) the formation of gradients, as well as niche creation through symbiotic processes, light, and negative factors. A major emphasis was placed in the role of nutrients, oxygen and temperature (p. 42) as determinants of niche characteristics over space and time . He also noted that niches could shift their physical location, appear and also disappear. The use of carefully designed enrichments for a wide range of microbes, especially concerned with the nitrogen and sulfur cycles, made it possible for him to draw out valuable general ecological principles. One of the most valuable was his observation (p. 177) that the slightest changes in environmental conditions can lead to differences in microbes ;that become dominant in a specific environment, and that it is possible to predict outcomes of varied environmental manipulations, in essence allowing the description of the niche for a specific microbe. In spite of the centrality of ecology to the book, the word ecology, itself, only appears to be used in the title, along with the word enrichment. The message? All enrichments, whether created in the laboratory or as they occur in nature, are ecological, involving in situ active, interacting microbes. The foundational concepts provided by Beijerinck, as summarized by Ferdinand Stockhausen, provide valuable insights, for understanding how the field of microbial ecology developed to the present, and to assist in shaping the future.

"Sir Almost Right": The Prodigious but Colorful Career of Sir Almroth Wright (1861-1947)

Author Block:

B. J. Freij[1], J. B. Freij[2]; [1]Beaumont Children's Hosp., ROYAL OAK, MI, [2]Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD

Abstract Body:

Almroth Wright (AR), "brought up in scholastic surroundings and comparative poverty", graduated at 22 years with degrees in literature and medicine. AR eschewed clinical practice for medical science. Early research was on coagulation, citration of blood, and diabetes. In 1892, he became Chair of Pathology at the Army Medical School, Netley. He developed an agglutination test for Malta fever. From the bacteriologist Haffkine AR learned of live/killed bacteria use as vaccines. He made a Malta fever killed vaccine, injected himself, and was then inoculated with a live culture. It failed and AR suffered from Malta fever for weeks. AR focused on typhoid fever, a major killer of British soldiers. He injected himself and "surgeons-on-probation" with killed typhoid bacilli and showed that blood's killing power against live bacteria increased 50-fold. The Boer War allowed for a limited field study in volunteers. AR pushed for vaccinating all soldiers. A heated debate arose with Karl Pearson in the *BMJ* pages. Pearson wanted a controlled trial, but AR was unwilling to wait. The War Office was pondering vaccinating all soldiers, before definitive proof of efficacy. AR was young and not well known. He was knighted to shore up his standing to push for the vaccine! AR moved to St. Mary's Hospital in 1902 where he worked on opsonization and the "opsonic index", paving the way for use of therapeutic vaccines; this failed. Because of lack of funds, AR financed vaccine production by collaborating with Parke Davis for 40 years. He raised the ire of medical practitioners with attacks on Harley Street and views on the "bankruptcy of medicine". Critics dubbed him "Sir Almost Right". Later research included saline treatment of wounds and pneumococcal vaccination of miners. AR was a fierce critic of the suffragette movement. He believed in "an illimitable gulf between men and women" and that diacritical judgment was "notoriously lacking in women". An anti-suffragette letter in the *The Times* (March 28, 1912) espoused views such as "the mind of woman is always threatened with danger from the reverberations of her physiologic emergencies" and "there is mixed up with the woman's movement much mental disorder". *The Unexpurgated Case Against Woman Suffrage* followed, a book justifying his opinions. By the time of his death, AR had published about 150 books and papers.

The History And Use Of The Terms Endospore And Spore

Author Block:

R. Wolff; South Univ., Columbia, SC

Abstract Body:

‘Spore’ is a word with a great history and includes both reproductive structures and structures which are able to survive by resistance to environmental conditions. Organisms considered to have ‘spores’ include protozoa, fungi, plants, algae and bacteria. In 1876 the term endospore was coined for the highly resistant structures found in some bacteria. The usage of endospore has varied over the years, but they are generally regarded as occurring only in some bacteria, and they must contain dipicolinic acid to be a true endospore. Most of the true endospores occur in the Phylum Firmicutes, in medically important genera such as *Bacillus* and *Clostridium*. There are other spore types in bacteria including myxospores, but these are reproductive. Some misuses of the term endospore are attributed to Cyanobacteria and Algae. The more general term ‘spore’ is used for various structures in a wide variety of organisms. In the fungi there are many types of spores and their use is very specific (Based on structure are sporangiospores, zygospores, ascospores, basidiospores, aeciospores, urediniospores, teliospores, oospores, carpospores and tetraspores; or function such as chlamydospores; or life cycle including meiospores and mitospores; or by mobility are zoospores, autospores, and ballistospores). The term cyst is also confusing as it has been defined as a protective capsule and/or resting stage in some animals, plants and protozoa, as well as bacteria. The bacteria *Azotobacter* is described as forming a cyst of dormant cells with thickened cell walls. The history of ‘spore’ usage for bacteriology needs to be clarified, and most importantly, in the age of computer searches it is critical that the term ‘endospore’ be used whenever research papers are published on endospores so that that proper retrieval of articles may be accomplished. Endospore is a very useful and precise term and proper usage needs to be encouraged.

Activity of Omadacycline against Clinical Isolates of *Neisseria gonorrhoeae*, Including Ciprofloxacin-Resistant Isolates

Author Block:

D. Sweeney, D. Hall, D. Shinabarger, **C. Pillar**; Micromyx, Kalamazoo, MI

Abstract Body:

Background: The prevalence and ease of transmission of gonococcal infection coupled with the high degree of resistance among *N. gonorrhoeae* (GC) to former front-line therapies (penicillin, tetracycline, and ciprofloxacin) and recent emergence of cephalosporin resistance has caused concern about gonorrhea control going forward. Omadacycline (OMC), a new once daily oral and intravenous aminomethylcycline currently in phase 3 development for the treatment of skin and respiratory infections, retains potent *in vitro* activity against bacteria resistant to legacy tetracyclines. In this study, the *in vitro* activity of OMC against recent clinical isolates of GC including ciprofloxacin-resistant (CIP-R) isolates was evaluated.**Methods:** MICs of OMC, CIP, and ceftriaxone (CRO) were determined by agar dilution in accordance with CLSI guidelines (CLSI M7 and M100) against 52 clinical isolates of GC, 24 of which were CIP-R. In addition, the impact of testing susceptibility by agar dilution relative to broth microdilution using GC medium was evaluated using concurrent inocula of *N. gonorrhoeae* ATCC 49226.**Results:** The activity (µg/mL) of OMC and comparators against GC is shown in the table below.

Test Agent	Overall (n=52)		CIP-S (n=28)		CIP-R (n=28)	
	MIC range	MIC_{50}/MIC_{90}	MIC range	MIC_{50}/MIC_{90}	MIC range	MIC_{50}/MIC_{90}
OMC	0.25-4	2/4	0.25-2	1/2	1-4	4/4
CIP	0.002->8	0.008/>8	0.002-0.015	0.004/0.008	2->8	>8/>8
CRO	0.002-0.12	0.008/0.06	0.002-0.015	0.004/0.008	0.004-0.12	0.03/0.06

OMC had an overall $MIC_{50/90}$ of 2/4 µg/mL and maintained activity against CIP-R GC with an MIC_{90} within 2-fold that observed for CIP-S GC. CRO also maintained activity against CIP-R GC, though the MIC_{90} was reduced 8-fold relative to CIP-S GC. The OMC agar dilution MIC against *N. gonorrhoeae* ATCC 49226 (2 µg/mL) was 4-fold higher than the OMC broth microdilution MIC (0.5 µg/mL).**Conclusions:** OMC exhibited *in vitro* activity against the evaluated GC isolates and maintained potency against CIP-R isolates which are commonly encountered clinically. The variation in potency of OMC against GC by broth microdilution relative to agar dilution suggests variability in activity by test method.

***In Vitro* Activity of Two New Topoisomerase Inhibitors Against Biodefense Pathogens**

Author Block:

S. Demons[1], L. Miller[1], S. Halasohoris[1], B. Somerville[1], F. Danel[2], B. Gaucher[2], M. Page[2]; [1]United States Army Med. Res. Inst. of Infectious Diseases, Frederick, MD, [2]Basilea Pharmaceutica Intl. Ltd, Postfach, Switzerland

Abstract Body:

Background: BAL1 and BAL2 are novel tricyclic topoisomerase inhibitors with potent activity against multi-drug resistant bacteria causing life-threatening infections. They were evaluated *in vitro* at the United States Army Medical Research Institute of Infectious Diseases against 30 isolates of geographically and genetically diverse sets of each of the following Tier 1 bacteria: *Bacillus anthracis*, the causative agent of anthrax, *Francisella tularensis*, the causative agent of tularemia, *Yersinia pestis*, the causative agent of plague, *Burkholderia mallei*, the causative agent of glanders, and *Burkholderia pseudomallei*, the causative agent of melioidosis.**Methods:** Minimum inhibitory concentrations (MICs) were determined according to Clinical and Laboratory Standards Institute microtiter-based methods. BAL1, BAL2, and comparator antibiotics were serially diluted in cation-adjusted Mueller-Hinton broth. The antibiotic range tested for both compounds was 0.015 - 32 µg/ml, with a final well volume of 100 µl. Plates were incubated for 18-48 h, depending on the organism. Quality control of antibiotic stocks was established using *E. coli* ATCC 25922, *P. aeruginosa* ATCC 27853, and *S. aureus* ATCC 29213.**Results:** BAL2 was active against *B. anthracis*, *F. tularensis*, *Y. pestis*, *B. mallei*, and *B. pseudomallei* with MIC_{90} values of ≤ 2µg/ml. BAL1 had a MIC_{90} of ≤ 2µg/ml against *B. anthracis*, *F. tularensis*, *Y. pestis*, and *B. mallei*. Lesser activity was seen against *B. pseudomallei* with a MIC_{90} of 8µg/ml. The MIC values were generally similar to the clinical comparators ciprofloxacin, azithromycin, and ceftazidime.**Conclusions:** Overall both compounds show potential to expand the armamentarium for treating anthrax, tularemia, plague, glanders, and melioidosis based on the *in vitro* data. Their efficacy should be assessed in murine aerosol models.

Broth Microdilution Testing of S-649266 Against *Acinetobacter baumannii* and Appropriate Interpretation of Mic Endpoints

Author Block:

M. Hackel[1], M. Tsuji[2], R. Echols[3], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Shionogi and Co., Ltd., Osaka, Japan, [3]Shionogi Inc., Florham, NJ

Abstract Body:

Background: S-649266 is a novel parenteral catechol-substituted siderophore cephalosporin that is active against carbapenem-resistant Gram-negative bacteria. Accurate *in vitro* testing of S-649266 by broth microdilution (BMD) requires the use of iron-depleted (ID) conditions to mimic the condition in mammalian hosts. Indistinct MIC endpoints (trailing) have been observed when testing *Acinetobacter baumannii.* This study was designed to ascertain the frequency and reproducibility of trailing endpoints, and to establish proposed guidelines for determining MIC values for S-649266.**Methods**: All MICs were determined by BMD according to CLSI guidelines except cation-adjusted Mueller Hinton broth (CAMHB) was replaced with ID-CAMHB made iron deficient by pretreatment with Chelex-resin (Bio-Rad Laboratories) with replenishment of Ca, Mg and Zn. Technologists were instructed to confirm that there was strong growth control (i.e. a button of > 2 mm) before proceeding to read the MICs. MIC endpoints were defined as the first well in which growth was significantly reduced (i.e. a button of < 1 mm or light/faint turbidity) relative to control. Trailing was noted when present. To determine the frequency of trailing, 240 isolates (200 *A. baumannii*, 20 *P. aeruginosa*, 20 *Enterobacteriaceae*) were tested. In addition, 20 *A. baumannii* were read by 8 technologists, who were instructed to follow the proposed guidelines. Twenty isolates, including *A. baumannii* with some degree of trailing, were retested 10 times over four days using 3 media lots to determine whether trailing was reproducible.**Results**: Trailing was noted in 64/200 (32%) of *A. baumannii* isolates (no trailing was noted in *P. aeruginosa* or *Enterobacteriaceae*), however using the proposed guidelines, it was possible to assign an MIC value for 199/200 (99.5%) isolates. When read by 8 different technologists, 17/20 (85%) *A. baumannii* MICs were within one doubling dilution. When 10 replicates of 20 isolates were read by a single technologist, 94.2% of MICs were +/- 1 doubling dilution, whereas trailing was not consistently reproducible.**Conclusions**: Trailing occurs inconsistently when testing *A. baumannii*, however the proposed interpretive criteria guidelines for reading S-649266 MIC endpoints are effective when trailing is encountered.

Publishing Title:

Activity of Ceftazidime-Avibactam (Ca) and Ceftolozane and Tazobactam (Ct) Against Gram-negative Bacteremic Isolates Exhibiting Various Antimicrobial-resistant Phenotypes

Author Block:

S. Burgio, D. Amsterdam; Erie County Med. Ctr., Buffalo, NY

Abstract Body:

The armamentarium of antimicrobial agents directed against Gram-negative microorganisms is limited and the potency of newly developed agents (CA and CT) against various antimicrobial resistant phenotypes is questionable. We investigated the comparative susceptibility of CA and CT against a variety of Gram-negative antimicrobial resistant phenotypes. Bacterial identification and antimicrobial susceptibility studies were performed with the MicroScan (Beckman Coulter) system using CLSI interpretive guidelines. A total of 94 bacteremic resistant phenotypes recovered from 2011-2015 were evaluated. They comprised: 32 *Klebsiella pneumoniae*; 30. *Escherichia coli*; 5 *Klebsiella oxytoca*; 5 *Enterobacter spp*.; 4 *Citrobacter* spp.; 11 *Acinetobacter baumannii*; 3 *Pseudomonas aeruginosa*; and 4 other *Enterobacteriaceae*. Of the 8 antimicrobial agents initially evaluated for these bacteremic isolates: cefepime, ceftriaxone, doripenem, ertapenem, meropenem, piperacillin/tazobactam, tobramycin, and tigecycline; only tigecycline exhibited near uniform (100%) susceptibility. Based upon most recent CLSI guidelines, all carbapenemase producing organisms were classified as CREs. ESBLs were confirmed with clavulanic acid via MicroScan or manually. E-Test strips were used to determine MICs for CA and CT using manufacturer FDA interpretations for susceptibility(S) and resistance(R). CA interpretations are applicable for *Enterobacteriaceae* and *Pseudomonas* and are the same for both ≤ 8/4 (S) and >16/4 (R). CT interpretations are ≤ 2/4 (S) for *Enterobacteriaceae* and ≤4/4 for *Pseudomonas*. Interpretive guidelines are unavailable for either antibiotic for *Acinetobacter*. Of the 76 *Enterobacteriaceae* tested, all were uniformly susceptible to CA and 56.6% to CT. Among the CA susceptible species were 20 CREs, 47 ESBLS, and 9 CRE/ESBL. CT displayed limited activity, i.e. less than 50%; ESBL resistant phenotypes exhibited greater susceptibility. Resistant phenotypes that were not susceptible to CT included ESBLs and CREs. The addition of CA and CT to the antimicrobial arsenal has been long awaited. It remains to be determined if they can sustain the in vitro potency.

***In Vitro* Activity of Eravacycline and Comparators Against *Enterobacteriaceae*, Including Strains Resistant to Carbapenems Or 3rd/4th Generation Cephalosporins in the US**

Author Block:

Y. Doi[1], G. R. Corey[2], I. Morrissey[3], T. Grossman[4], K. Luepke[4], **P. Scoble**[4], J. Sutcliffe[4]; [1]Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA, [2]Duke Univ. Med. Ctr., Durham, NC, [3]IHMA Europe Sarl, Epalinges, Switzerland, [4]Tetraphase Pharmaceuticals, Inc., Watertown, MA

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity in development for the treatment of serious infections, including those caused by multidrug-resistant (MDR) pathogens. The purpose of this study was to evaluate the *in vitro* activity of ERV and comparators against *Enterobacteriaceae* (ENT), including isolates resistant to carbapenems (CR) or 3rd/4th generation cephalosporins (GC-R) in the US.**Methods:** Clinical isolates were collected from various body sites in patients in US hospitals from 2013-14. MIC results for ERV and comparators against 2,723 ENT isolates were determined by CLSI broth microdilution. Susceptibility was determined with CLSI 2015 breakpoints, except for tigecycline (TGC) where FDA breakpoints were used. GC-R was defined as resistant to ceftriaxone, cefotaxime, ceftazidime, or cefepime (FEP). CR was defined as resistant to imipenem (IPM).**Results**: The ERV $MIC_{50/90}$ for all ENT was 0.5/2 mg/L. The ERV $MIC_{50/90}$ of GC-R and CR isolates were 0.5/2 and 1/2 mg/L, respectively. ERV and comparator MIC results (mg/L) for *Escherichia coli, Klebsiella pneumoniae,* and *Serratia marcescens* are shown in the table below. Most GC-R-resistant ENT were susceptible to TGC (91.8%), however susceptibilities decreased in CR isolates (61.4%).

Organism (N)	**ERV**	**TGC**	**IPM**	**FEP**
	$MIC_{50/90}$	**$MIC_{50/90}$**	**$MIC_{50/90}$**	**$MIC_{50/90}$**
E. coli (349)	0.12/0.25	0.25/0.5	≤0.25/0.5	≤0.25/4
GC-R (50)	0.25/0.5	0.25/0.5	≤0.25/1	16/>16
K. pneumoniae (350)	0.5/1	0.5/2	≤0.25/1	≤0.25/4
GC-R (50)	1/2	1/2	0.5/8	16/>16
CR (20)	0.5/2	1/2	>8/>8	>16/>16
S. marcescens (347)	1/2	2/2	1/2	≤0.25/0.5
GC-R (26)	2/2	2/2	1/4	1/16
CR (6)	1/2	1/2	4/>8	≤0.25/>16

$MIC_{50/90}$, minimum inhibitory concentration required to inhibit growth of 50/90% of isolates (mg/L)**Conclusion:** Overall, ERV MIC_{90} for ENT isolates ranged from 0.25-2 mg/L, and was the same or within two-fold for GC-R and CR isolates. Potency of ERV was comparable to 2-fold greater than TGC. ERV was up to 4-fold and 8-fold greater for IPM for FEP, respectively. ERV shows promising activity against ENT including those with resistant phenotypes isolated from US patients.

Publishing Title:

Susceptibility Survey of Ceftazidime-Avibactam (C-A) Against Multidrug Resistant (Mdr) Gram-negative Clinical Isolates from a Single Academic Medical Center

Author Block:

L. Donohue, H. L. Cox, J. Carroll, A. Cheruvanky, A. J. Mathers; Univ. of Virginia Hlth.System, Charlottesville, VA

Abstract Body:

Background: C-A has in vitro activity against both *Klebsiella pneumoniae* carbapenemase-producing organisms (KPCO) and MDR *Pseudomonas aeruginosa*, but a widely available antimicrobial susceptibility testing (AST) method for clinical use is unestablished. AST is important when both resistant and susceptible clinical isolates exist, but little resistance has been described. We sought to evaluate C-A susceptibility among MDR *Gammaproteobacteria* to assess the importance of AST prior to use. **Methods:** Forty MDR *Gammaproteobacteria* clinical isolates, most KPCO, were selected from those collected at our institution since August 2008. Isolates included: *Enterobacter cloaca*e (n=15), *Klebsiella pneumoniae* (n=7), *K. oxytoca* (n=5), *Serratia marcescens* (n=2), *Aeromonas hydrophila* (n=1), and *P. aeruginosa* (*P*sA, n=10). All but one (an *E. cloacae)* non-*PsA* were KPCO by PCR and all were CB-nonsusceptible (all resistant), as were 90% of *PsA* (8 resistant, 1 intermediate). Thirty-one (78%) isolates were FEP-nonsusceptible (23 resistant, 8 intermediate). VITEK2 was the primary testing modality for CB and FEP susceptibility, with disk diffusion (DD) performed for 2 isolates. AST was performed using manufacturer-supplied E-test strips and disks per manufacturer and CLSI standards. C-A zones and MICs were interpreted by FDA breakpoints.**Results:** In non-*PsA*, all isolates were C-A susceptible by E-test (MIC range 0.5 - 2 µg/mL, MIC_{90} 1.5 µg/mL). One *K. pneumoniae* was resistant by DD (19 mm). Of the 10 *PsA*, 4 were resistant by E-test (MIC range 2 - ≥256 µg/mL, MIC_{90} 64 µg/mL). Zones ranged from 0 - 25 mm, with 3 resistant by DD. DD exhibited 95% categorical agreement to E-test. **Conclusions:** Multiple species of KPCO exhibited *in vitro* susceptibility to C-A. However, the *K. pneumoniae* isolate resistant by DD warrants further investigation. C-A resistant *PsA* isolates likely resulted from mechanisms other than class A or class C β-lactamase overproduction but this requires further study. Given the limited availability and prolonged turnaround time of broth dilution, these results re-iterate the need for reliable and accessible AST methods prior to clinical use.

***In Vitro* Activity of Eravacycline and Comparators Against *Acinetobacter baumannii*, Including Carbapenem-resistant Strains, and *Stenotrophomonas maltophilia* Isolated from Patients in the US**

Author Block:

Y. Doi[1], G. R. Corey[2], I. Morrissey[3], T. Grossman[4], K. Luepke[4], **P. Scoble**[4], J. Sutcliffe[4]; [1]Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA, [2]Duke Univ. Med. Ctr., Durham, NC, [3]IHMA Europe Sarl, Epalinges, Switzerland, [4]Tetraphase Pharmaceuticals, Inc., Watertown, MA

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity in development for the treatment of serious infections, including those caused by multidrug-resistant (MDR) pathogens. The purpose of this study was to evaluate *in vitro* activity of ERV and comparators against *Acinetobacter baumannii* (AB), including strains with a carbapenem-resistant (CR) phenotype, and *Stenotrophomonas maltophilia* (SM) isolated from US patients. **Methods:** Non-duplicate, non-consecutive, single-patient clinical isolates of AB and SM were collected from US patients in 2013-2014. MICs for ERV and comparators against 380 isolates from both species were determined by CLSI broth microdilution. Susceptibility was determined with CLSI 2015 breakpoints, except for tigecycline (TGC) where FDA breakpoints were used. CR in AB (CRAB) was defined as resistant to imipenem.**Results**: ERV *in vitro* activity against AB and SM is shown in the following Table. ERV MIC_{90} for all AB and SM isolates was 1 mg/L, and 2 mg/L for CRAB. TGC, imipenem (IPM), and colistin (CST) MIC_{90} for AB were 4, >8, and 2 mg/L, respectively, and remained consistent for CRAB. Susceptibility to CST for all AB was 95%, while for CRAB was 93%. Susceptibility to IPM for all AB and CRAB was poor (39.4%, 0%, respectively). TGC, IPM, and CST MIC_{90} for SM were 2, >8, and 4 mg/L, respectively. There were no CR SM isolates collected.

Organism (N)	**ERV**	**TGC**	**IPM**	**CST**
	$MIC_{50/90}$	**$MIC_{50/90}$**	**$MIC_{50/90}$**	**$MIC_{50/90}$**
A baumannii (349)	0.5/1	1/4	>8/>8	1/2
CRAB (207)	0.5/2	2/4	>8/>8	1/2
S. maltophilia (31)	0.5/1	1/2	>8/>8	1/4

$MIC_{50/90}$ = minimum inhibitory concentration required to inhibit growth of 50/90% of isolates (mg/L).**Conclusions:** Overall, ERV MIC_{90} for AB and SM was 1 mg/L (2 mg/L for CRAB), and

was 2-4 fold more potent than TGC or CST, and up to 8-fold more potent than IPM. ERV shows promising activity against AB and SM, including CRAB, isolated from US patients.

G. R. Corey[1], Y. Doi[2], I. Morrissey[3], T. Grossman[4], M. Olesky[4], **H. Patel**[4], J. Sutcliffe[4]; [1]Duke Univ. Med. Ctr., Durham, NC, [2]Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA, [3]IHMA Europe Sarl, Epalinges, Switzerland, [4]Tetraphase Pharmaceuticals, Inc., Watertown, MA

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity being developed for the treatment of serious infections, including those caused by multidrug-resistant (MDR) pathogens. ERV has been evaluated in studies for the treatment of complicated intra-abdominal infections (cIAI) and complicated urinary tract infections (cUTI), including pyelonephritis. The purpose of this study was to evaluate the activity of ERV against key pathogens from the US isolated from GU and GI sources.**Methods:** MIC results for ERV and comparator agents were determined by CLSI broth microdilution against 1004 GI and 1199 GU isolates collected from US hospitals in 2013-2014. MDR was defined as resistant to ≥3 from cefepime/ceftazidime/ceftriaxone (any one), gentamicin, imipenem, levofloxacin, piperacillin-tazobactam or tetracycline. **Results:** ERV MIC data for species where N ≥ 30 from each infection type are shown in the Table.

Comparison of Fosfomycin *In Vitro* Susceptibility Testing Methods - Disc Diffusion, Etest and Vitek 2 - Against *Escherichia coli* and *Enterococcus* Urinary Isolates

Author Block:

T. T. Nguyen, D. C. Vinh, T. C. Lee, V. G. Loo; McGill Univ. Hlth.Ctr., Montreal, QC, Canada

Abstract Body:

Background: Fosfomycin (FM) has been reintroduced in many jurisdictions for the treatment of urinary tract infections. Laboratories will need to periodically test and report susceptibility. To determine if the antimicrobial susceptibility testing method influences results, we compared 3 *in Vitro* tests on urinary isolates. **Methods:** Consecutive urinary isolates of *E. coli* and *Enterococcus* were collected from February to August 2015 at our Canadian university-affiliated tertiary care center, targeting 150 samples. FM susceptibility was tested in parallel on both genera using CLSI's disc diffusion (DD) method, by Etest, and for *E. coli*, by VITEK 2 AST-N263. Although FM interpretive criteria for *E. faecium* are not defined by CLSI, those for *E. faecalis* were applied for comparison. Correlation between testing methods was evaluated as rates of categorical agreement (CA) and error rates. **Results:** Fosfomycin susceptibility by method is presented in Table 1. Most isolates of *E. coli* and *E. faecalis* were susceptible to FM. *E. faecium* had lower susceptibility. For *E. coli*, CA of VITEK 2 and Etest relative to DD were 99.3% and 98.6%, with minor errors in 0.7% and 1.4%, respectively. For *Enterococcus*, CA of Etest relative to DD was 93.8%, with minor errors in 6.2%. There were no major or very major errors.

Table 1. Susceptibility to fosfomycin by different methods[a]

Organism (N) / Method	Susceptible [N (%)]	Intermediate [N (%)]	Resistant [N (%)]	$MIC_{50/90}$ (µg/mL)
E. coli (146)				
• DD	141 (96.5%)	2 (1.4%)	3 (2.1%)	N/A
• Etest	140 (95.8%)	3 (2.1%)	3 (2.1%)	0.75/16
• VITEK 2	141 (96.5%)	2 (1.4%)	3 (2.1%)	<16/<16
ESBL *E. coli* (17)				
• DD	16 (94.1%)	0 (0%)	1 (5.9%)	N/A
• Etest	15 (88.2%)	0 (0%)	2 (11.8%)	0.75/48
• VITEK 2	15 (88.2%)	0 (0%)	2 (11.8%)	<16/<16
Enterococcus (145)				
• DD	134 (92.4%)	11 (7.6%)	0 (0%)	N/A
• Etest	126 (86.9%)	18 (12.4%)	1 (0.7%)	32/96
E. faecalis (126)				
• DD	125 (99.2%)	1 (0.8%)	0 (0%)	N/A
• Etest	120 (95.2%)	6 (4.8%)	0 (0%)	32/48
Non-VRE *E. faecium* (9)				
• DD	5 (55.6%)	4 (44.4%)	0 (0%)	N/A
• Etest	3 (33.3%)	6 (66.7%)	0 (0%)	96/196
VRE *E. faecium* (10)				
• DD	4 (40.0%)	6 (60.0%)	0 (0%)	N/A
• Etest	3 (30.0%)	6 (60.0%)	1 (10.0%)	96/196

[a]DD, disc diffusion; $MIC_{50/90}$, MIC that inhibited 50%/90% of isolates (susceptible, ≤64 µg/ml; intermediate, 128 µg/ml; resistant, ≥256 µg/ml); VRE, vancomycin-resistant *Enterococcus*.

Conclusions: For *E. coli*, there was excellent agreement among the 3 methods tested. For *Enterococcus*, there was a higher rate of minor errors, which still falls in the <10% range at which CLSI considers a test adequate. We suggest that any of the three methods of susceptibility testing can be utilized for *E. coli* and *E. faecalis*, but that further evaluation of breakpoints and testing methods for *E. faecium* are warranted.

Fosfomycin Has the Lowest Resistance Rate among Oral Antimicrobial Agents Tested Against Community Uropathogens

Author Block:

S. E. Farhat[1], I. Coelho[1], M. Bhatti[1], G. Lim[1], B. Shingala[1], W. P. Shih[1], M. Pandya[1], B. Shea[1], B. Premraj[1], A. E. Simor[2]; [1]Alpha Lab., Toronto, ON, Canada, [2]Sunnybrook Hlth.Sci. Ctr., Toronto, ON, Canada

Abstract Body:

Background: Fosfomycin (FOS) has recently attracted increasing interest, largely because of its good activity *in vitro* against multidrug-resistant (MDR) pathogens. However, there have been few studies of FOS in North America, mostly with *Escherichia coli*. In light of current antimicrobial resistance (R) in the community, we sought to assess the R rate of FOS among community urinary isolates, in comparison to those of other oral antimicrobial agents commonly used for the treatment of uncomplicated urinary tract infections (UTIs) in non-hospitalized patients.**Methods:** Consecutive isolates were identified by conventional methods from urine cultures processed over a 9 week period ending on January 30, 2015. Organisms not recommended for routine testing (e.g., streptococci) were excluded from the study. Isolates were tested by disk diffusion or the Vitek-2 system (bioMérieux), in accordance with CLSI guidelines, against ampicillin (AM), cefazolin (KZ), ciprofloxacin (CIP), nitrofurantoin (FM), trimethoprim/ sulfamethoxazole (SXT), and FOS. Due to lack of FOS interpretive criteria for all organisms, CLSI *E. coli* and *E. faecalis* breakpoints were applied for all organisms, similar to recently published investigations.**Results:** Of 11,853 urine specimens processed, a total of 2,455 non-duplicate isolates were tested, including *E. coli* (*n* = 1,617), *E. faecalis* (343), *Klebsiella* (192), *Proteus mirabilis* (144), *Citrobacter* (56), *Enterobacter* (39), *Morganella morganii* (35), *Staphylococcus aureus* (17), *Pseudomonas aeruginosa* (4), *Acinetobacter* (3), *Serratia* (3), *Providencia* (1) species, and *E. faecium* (1). R rates for AM, KZ, CIP, FM, SXT, and FOS were 43%, 25%, 12%, 10%, 30%, and 2%, respectively. FOS R rates among MDR isolates that were R to ≥ 3 antimicrobial classes (*n* = 268), and ESBL producing strains (90 *E. coli*, 2 *Klebsiella*), were 6% and 1%, respectively.**Conclusions:** Of the six oral antimicrobial agents reported in this study, FOS had the lowest resistance rate among community urinary isolates. These results provide support for FOS as a useful agent for the treatment of UTIs caused by various organisms.

CLSI M23 Tier 2 Study to Establish Disk Diffusion and Broth Microdilution Quality Control Ranges for Lactone Ketolide Nafithromycin (WCK 4873)

Author Block:

M. Hackel[1], S. Bhagwat[2], M. Patel[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: Nafithromycin (WCK 4873) is a new lactone ketolide discovered at Wockhardt having completed Phase 1 studies in US and Europe. This study was performed to establish quality control (QC) broth microdilution and disk diffusion ranges for WCK 4873 against specific ATCC QC organisms as recommended by the Clinical and Laboratory Standards Institute (CLSI).**Methods**: Five ATCC QC organisms within the spectrum of WCK 4873 activity were tested: *Haemophilus influenzae* ATCC 49247 (disk and broth), *Streptococcus pneumoniae* ATCC 49619 (disk and broth), *Staphylococcus aureus* ATCC 29213 (broth only), *S. aureus* ATCC 25923 (disk only), and *Enterococcus faecalis* ATCC 29212 (broth only). All strains were tested following CLSI guidelines for broth microdilution and disk diffusion. WCK 4873 and a control agent (telithromycin) were tested against all QC strains. This study design met the CLSI M23-A3 requirements for Tier 2 QC studies: seven laboratories/independent sites; three media lots (different manufacturers); two disk lots; 10 replicates of each QC strain per laboratory (70 total test points per medium lot); and 210 test points per QC strain/drug combination.**Results**: Greater than 95% of all MIC values reported from at least seven laboratories were within the ranges shown in the table.**Summary of Approved CLSI Quality Control Ranges for WCK 4873**

	WCK 4873 Approved CLSI Quality Control Range	
Organism	Broth Microdilution (µg/mL)	Disk Diffusion (mm)
S. aureus ATCC 29213	0.06 - 0.25	NA
S. aureus ATCC 25923	NA	25 - 31
E. faecalis ATCC 29212	0.015 - 0.12	NA
S. pneumoniae ATCC 49619	0.008 - 0.03	25 - 31
H. influenzae ATCC 49247	2 - 8	16 - 20

NA- not applicable**Conclusions**: All proposed quality control ranges were accepted by the CLSI at the June 2015 meeting and should be used to monitor the quality control whenever testing WCK 4873 by broth microdilution or disk diffusion.

Publishing Title:

In Vitro Activity Of Wck4873, A Second Generation Ketolide, Against Chlamydia Pneumoniae

Author Block:

S. A. Kohlhoff, M. R. Hammerschlag; SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract Body:

Background: WCK4873 is an advanced generation, lactone ketolide antibiotic currently being evaluated for treatment of community acquired bacterial pneumonia (CABP). WCK 4873 shows potent activity for all the typical and atypical respiratory pathogens including telithromycin-non-susceptible pneumococci. The drug recently received qualified infectious disease product status from the FDA.**Methods:** We tested 10 isolates of *C. pneumoniae* against WCK4873, azithromycin, docycycline and levofloxacin. Isolates tested were: TW 183, AR 39, CM-1, T 2040, and 6 isolates from bronchoalveolar lavage specimens from patients with human immunodeficiency virus infection and pneumonia from the United States (BAL15, BAL16, BAL 18, BAL 19, BAL 37, BAL 62). Susceptibility testing of *C. pneumoniae* was performed in cell culture using HEp-2 cells grown in supplemented DMEM media followed by infection with 10^3 - 10^4 IFU/ml. After incubation at 35C for 72 h, cultures were fixed and stained for inclusions with fluorescein-conjugated antibody to the chlamydial lipopolysaccharide genus-specific antigen. The minimum inhibitory concentration (MIC) was the lowest antibiotic concentration at which no inclusions were seen.**Results:** The MIC_{50} and MIC_{90} for WCK4873 were 0.03 and 0.25 g/ml, respectively (range 0.03-1 g/ml). The MIC_{50} and MIC_{90} for azithromycin were 0.0075- 0.015 (range 0.003-0.03), for doxycycline, 0.06 and 0.125 (range 0.03-0.25), and levofloxacin, 0.25 and 0.25 (range 0.03-25).The in vitro activity of WCK4873 was comparable to that of several antibiotics with proven clinical efficacy for treatment of infections due to *C. pneumoniae*. Activity was also comparable to solithromycin (MIC_{90} 0.25 g/ml), another ketolide that is now in phase 3 clinical trials for CABP. Furthermore, the in vitro susceptibility testing protocol used for this study is the only one that has been shown to correlate with clinical outcome and microbiologic eradication for infections caused by *C. pneumoniae*.**Conclusion:** Based on favourable PK-PD demonstrated for telithromycin-non-susceptible pneumococci and potent intracellular activity (shown against Legionella), WCK4873 is expected to provide therapeutic efficacy for *C. pneumoniae* infections.

A Multicenter Evaluation of *In Vitro* Activity of Ceftazidime-Avibactam Against Selected Isolates from the Chicago Area

Author Block:

A. Harrington, E. Stolar, E. Wenzler, S. Collier, P. Schreckenberger, B. Blumer, M. Costello, K. Singh, D. Schora, P. Patel, R. Thomson, D. Shabib, A. Charnot-Katsikas; Chicago Micro Directors Roundtable Organization (CMDRO), Chicago, IL

Abstract Body:

Background: There are a limited number of antimicrobial agents available for the treatment of carbapenem resistant *Enterobacteriaceae* (CRE) and other carbapenem resistant organisms (CRO). Ceftazidime-avibactam (CTZ) is a new antibiotic recently approved by the FDA to treat adults with complicated intra-abdominal and urinary tract infections. Avibactam is a member of a novel class of non-β-lactam β-lactamase inhibitors that has activity against class A (KPC), class C (AmpC), and some class D (OXA) β-lactamases. It does not have activity against class B (MBL). Although there have been larger evaluations of the *in vitro* activity of CTZ against isolates recovered by clinical microbiology laboratories, the data are not specified by geographic region. The purpose of this study was to gather data specific to the Chicago area. **Methods**: A convenience sample of isolates from 6 clinical microbiology laboratories affiliated with academic medical centers or large hospital networks in the Chicago area was tested using E-test to determine the *in vitro* activity of CTZ. **Results**: A total of 210 isolates were evaluated: 11 *E. coli*; 12 *Pseudomonas spp.* (1 *P. putida*, 11 *P. aeruginosa*); 1 *Acinetobacter baumannii*; 1 *Serratia marcescens*; 4 *Enterobacter cloacae*; 2 *Citrobacter freundii*; 161 *Klebsiella pneumoniae.* The MIC distribution for all isolates ranged from 0.047 to >256 μg/ml. 10 isolates were identified as carrying MBL against which CTZ had no activity. 4 isolates were carrying an OXA mechanism, and the MICs ranged from 1 to 16. For *Pseudomonas* isolates, where the mechanism of resistance was not identified, the MICs ranged from 3 to 24. Overall susceptibility of CTZ to CRO was 96% (192/200) excluding organisms possessing MBLs. 185 isolates were positive by the modified-hodge test or identified as CRE. The MICs for those isolates ranged from 0.047 to 96 (MIC_{90} $\leq$4), where 4 isolates had MIC values considered resistant ($\geq$16). Confirmation of resistance is pending. **Conclusions**: CTZ demonstrated good activity *in vitro* to a large collection of isolates specifically from the Chicago area. Region-specific susceptibility data may impact utilization strategies for these new antimicrobial agents.

Abstract Body:

Background: Ceftazidime/avibactam (CZA) and ceftolozane/tazobactam (C/T) are two new antimicrobial agents with activity against *P. aeruginosa*, including multidrug resistant (MDR) strains. There is limited data regarding activity against strains isolated from cystic fibrosis (CF) patients and no studies directly comparing the activities of these agents. The purpose of this study was to determine the activities of CZA and C/T against resistant *P. aeruginosa* isolated from CF patients.Methods: A total of 54 isolates obtained from the sputum of 24 CF patients aged 9 to 64 years were collected from March to December 2015. Included strains were either resistant to meropenem [n = 41], resistant to two beta-lactams from different classes [n = 50], or resistant to one agent in three different classes (MDR) [n = 47]. Strains resistant to agents in all classes tested were further categorized as extensively drug resistant (XDR) [n = 7]. Both mucoid and non-mucoid phenotypes were included. MICs for CZA and C/T were determined by investigational E-tests provided by the drug manufacturers. Tests were performed in duplicate or triplicate to reconcile discordant results. The MIC_{50}, MIC_{90}, and susceptibility percentages were determined using FDA breakpoints for CZA and C/T. Susceptibility for all other antibiotics was determined with the Trek Sensititre GN3F panel, using current CLSI breakpoints.Results: A summary of the activity of CZA and C/T are provided in the table below. Of 10 resistant isolates, 5 were resistant to CZA, 3 were resistant to C/T, and 2 were resistant to both. No XDR pathogens were resistant to CZA, whereas 3 were resistant to C/T.

Summary of CZA and C/T activity against P. aeruginosa isolates from CF patients

CZA	MIC_{50} (µg/ml)	MIC_{90} (µg/ml)	Range (µg/ml)	%S/%I/%R
All Isolates (n = 54)	4	16	0.5-32	87.0/-/13.0
MDR Strains (n = 47)	4	16	0.5-32	85.1/-/14.9
Mucoid Strains (n = 17)	4	16	0.5-32	82.4/-/17.6
C/T	MIC_{50} (µg/ml)	MIC_{90} (µg/ml)	Range (µg/ml)	%S/%I/%R
All Isolates (n = 54)	2	8	0.5-256	88.9/1.8/9.3
MDR Strains (n = 47)	2	8	0.5-256	87.2/2.1/10.7
Mucoid Strains (n = 17)	1	4	0.5-16	88.2/5.9/5.9

Conclusions: Both agents demonstrated good activity against *P. aeruginosa* strains isolated from CF patients. Fewer isolates were resistant to C/T and MICs were generally lower compared to CZA. C/T was more active against mucoid strains, while CZA was more active against XDR strains.
