Background: Vancomycin resistant *enterococcus* (VRE) is the most common gram-positive bacteria isolated from febrile neutropenic patients and those with pre-engraftment bacteremia after allogenic stem cell transplant SCT. Treatment of invasive infections due to this organism is challenging , no drugs have received FDA approval for treatment of VRE bacteremia. Daptomycin is commonly used to treat VRE infections but non -suspectibiltiy to this drug is a growing problem. Oritavancin, a synthetic lipopeptide has shown an in-vitro activity against VRE. The goal of this study is to test in-vitro susceptibilities of oritavancin against VRE blood isolates with a daptomycin MIC of ≥ 4 mcg/mL.**Methods:** Susceptibility testing on 50 VREF blood isolates from patients who developed bacteremia at MSKCC between 2009-2013 were included in the study. Testing by broth microdilution was simultaneously performed for the following drugs: vancomycin, range: 0.25 to 16 mcg/mL; linezolid, range: 0.5 to 8 mcg/mL; daptomycin, range: 0.12 to 4 mcg/mL; teicoplanin, range: 0.12 to 16 mcg/mL; oritavancin, range: 0.004 to 4 mcg/mL; high-level gentamicin, 500 mcg/mL; high-level streptomycin, 500 to 1,000 mcg/mL; penicillin, range: 0.12 to 8 mcg/mL. Testing was performed in duplicate according to CLSI M07-A10 and CLSI M100-S25 standards for broth microdilution method and interpretation. The project was supported by a research grant from the Medicine Company.**Results:** 18/50 (36%) isolates had daptomycin MIC 90 of > 4 mcg/mL. Median oritavancin MIC 90 was 0.25 mcg/mL (range: 0.06-0.5). Median linezolid MIC 90 was 4 mcg/mL (range 1->8), 50 (100%) of isolates had vancomycin and teicoplanin MIC 90 >16 mcg/mL, penicillin MIC 90 > 8 mcg/mL; 31(62%) had high-level gentamicin MIC 90 >500; and 30 (60%) had high-level streptomycin MIC 90 >1,000 mcg/mL.**Conclusions:** For VRE isolates with high MIC to daptomycin, oritavancin median MIC 90 was 0.25 mcg/mL. Oritavancin may have a role in management of serious VRE infections with limited treatment options. Further data are needed to evaluate oritavancin utility in clinical practice.

Evaluation of a New Rapid Tool for Reading Antibiotic Susceptibility Testing by the Disk Diffusion Technique

Author Block:

S. Le Page, G. Dubourg, J-M. Rolain; IHU Méditerranée Infection; Aix-Marseille Université, Marseille, France

Abstract Body:

Background: In clinical microbiology, some instruments are able to automatically read inhibition zone diameters for Antibiotic Susceptibility Testing (AST) performed by the disk diffusion (DD) method but its low quality resolution and the time necessary for results of AST became too long around 18 to 24 hours. High-resolution scanners have been developed to improve measurement of inhibition of growth like the Scan® 1200 (Interscience, Saint Nom, France). We evaluate and compare the reading and interpretation of AST by DD by the Scan® 1200 to validate this new instrument for its implementation in the routine laboratory. Furthermore, we tried to read AST earlier after 6h and 8h of incubation. **Methods:** The validation of the technique was assessed on 3 reference strains, as usually requested by the European Committee on Antimicrobial Susceptibility Testing (EUCAST) and on 211 clinical isolates with 2 instruments: the Scan® 1200 and the Sirscan system (reference method). For the earlier reading of AST, we measured and interpreted reading zone diameters in a series of 121 Gram-negative bacteria with rapid growthafter 6h, 8h and 24 h of incubation. For both, correlation, statistical and medico-economic analyses are realized.**Results:** The correlation between the 2 instruments, assessed using 211 clinical isolates (n= 2439 zones of growth inhibition measured) was excellent, with a correlation of 0.97 and 1.3% of discrepant results. We obtained a correlation of 0.96 with 3% of discrepant results for 6h of incubation and after 8h the correlation was 0.98 with only 1% of discrepant results. No significant difference was found between 6-8h of incubation and 24h (all p value > 0.05).**Conclusions:**The Scan® 1200 with the complete validation of the technique, its small size, the resolution of the camera, the rapidity of use and its cost represents a robust alternate tool for reading AST for routine use in clinical microbiology laboratories. Moreover, the Scan® 1200 could improve results of AST in a very rapid turnaround time (6h to 8h) in Gram-negative bacteria thanks to the high-resolution imaging.

Zone Size Variation of Meropenem Discs Maintained at Four Temperatures

Author Block:

E. L. Rank, Ph.D.; Quest Diagnostics, Inc., Teterboro, NJ

Abstract Body:

Background: We observed a series of resistant meropenem (M) disc zone (DZ) sizes when tested against a strain of *Haemophilus parainfluenzae*. We retested the organism using fresh M discs. The observed DZ sizes indicated sensitivity. Storage directions for M discs state that discs can be maintained from -20°C to 8°C. Discs routinely are returned to the refrigerator until the next usage. Thus, we systematically investigated whether specific holding temperatures can lead to decreased performance over time for discs with M and other antimicrobials (OA).**Methods:** A 6-month study measured DZ for M and OA against 4 microorganisms: *Escherichia coli* ATCC 25922 (Ec), *Haemophilus influenzae* ATCC 49247 (Hi), *H. parainfluenzae* (Hp), and *Staphylococcus aureus* ATCC 25923 (Sa). OA were: amoxicillin/clavulanate (AC), ampicillin (Amp), ampicillin/sulbactam (AS), aztreonam (Azt), ceftriaxone (Cef), clarithromycin (C), levofloxacin (L), tetracycline (T), and sulfamethoxazole-trimethoprim (ST). Four sets of antimicrobials were opened and stored at 37°C, 22°C to 25°C, 2°C to 8°C, and -20°C. Standard Bauer-Kirby (BK) methodology was employed. Testing was performed once per week. Ec and Sa were grown on BD Mueller-Hinton II agar media in ambient air. Hi and Hp were grown on BD HTM agar media under CO_2. Measured DZ were averaged and compared.**Results:** The percent variation in M DZ size increased as storage temperature increased (Table). DZ variation for OA was also evident. AC, Amp, and AS for Ec and Hi had the greatest average DZ percentage variations. Azt, Cef, L, T, and ST had the least DZ size variation. Average measured DZ sizes were largest for M and OA held at -20°C but decreased as the temperature increased to 37°C. Antimicrobial deterioration was not scientifically confirmed but erratic DZ measurements were photographed along with happenstance patient findings.**Conclusion:** Our study suggests that M discs specifically, but OA as well, should be held at -20°C to ensure consistent performance.

Meropenem Percent Variation in Zone Size				
Temperature	*E.coli*	*H. influenzae*	*H. parainfluenzae*	*S. aureus*
37°C	14.8	25.5	13.0	29.8
22-25°C	9.3	25.0	7.6	19.2
2-8°C	4.6	1.2	5.1	8.6
-20°C	0.0	0.0	0.0	0.0

WCK 4282 (Cefepime-Tazobactam) Disk Diffusion Quality Control Ranges Using a Multi-Laboratory Study Design

Author Block:

J. E. Ross, R. K. Flamm, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: We conducted a study to establish disk diffusion (DD) quality control (QC) ranges for WCK 4282 (cefepime-tazobactam) using a 30/20-µg disk (2 manufacturers) and the reference DD method. WCK 4282 is under clinical development for the treatment of serious Gram-negative infections.**Methods**: An eight laboratory study design followed CLSI M23-A3 guidelines. Five QC strains were tested (*Escherichia coli* ATCC 25922 [EC25922], *E. coli* NCTC 13353 [EC13353], *Klebsiella pneumoniae* ATCC 700603 [KPN700603], *Pseudomonas aeruginosa* ATCC 27853 [PSA27853], and *Staphylococcus aureus* ATCC 25923 [SA25923]), using three agar lots (three manufacturers). Ten replicate tests/disk lot/media lot/site were performed for each QC organism generating 480 zone diameters/QC strain (2,400 total results). Cefepime and piperacillin-tazobactam were used as control agents.**Results**: The zone diameter QC range for cefepime-tazobactam disk test from eight laboratories when testing EC25922 was 32 - 37 mm which included 97.9% of the reported results. (See Table). EC13353 is a CTX-M-15 producer and was included to properly evaluate tazobactam inhibition effect. The proposed zone diameter QC range of 27 - 31 mm for EC13353 included 96.7% of results. The KPN700603 strain, a SHV-18 producer, provided a six mm QC range of 25 - 30 mm with 99.4% of the results included. Another narrow range was proposed for PSA27853 of 27 - 31 mm which included 97.3% of all reported zone diameters. The SA25923 QC strain demonstrated a range of 24 - 30 mm which included 99.0% of reported results. Using Range Finder statistical program, there were no laboratories or mediums identified as an outlier. All cefepime and piperacillin-tazobactam disk zones generated for the internal controls were within the CLSI published QC ranges.**Conclusions:** These disk QC ranges for WCK 4282 (cefepime-tazobactam) should accurately guide clinical or reference laboratories participating in the testing of clinical trial isolates, and facilitate the regulatory review process for this investigational antimicrobial combination.

QC organism (Reference no.)	**WCK 4282a zone diameter (mm) QC ranges (% of results in range):**
E. coli (ATCC 25922)	32 - 37 (97.9)
E. coli (NCTC 13353)	27 - 31 (96.7)

K. pneumoniae (ATCC 700603)	25 - 30 (99.4)
P. aeruginosa (ATCC 27853)	27 - 31 (97.3)
S. aureus (ATCC 25923)	24- 30 (99.0)
a. Cefepime-tazobactam disk concentration 30/20-µg

Rapid Growth-Based Detection of Carbapenem-Resistant Gram-Negative Bacteria Using the Real-Time Light-Scattering Method

Author Block:

E. A. Idelevich[1], M. Hoy[1], M. Borowski[2], D. Görlich[2], B. Grünastel[1], D. Knaack[1], G. Peters[1], K. Becker[1]; [1]Univ. Hosp. Münster, Münster, Germany, [2]Univ. of Münster, Münster, Germany

Abstract Body:

Background: The prevalence of multidrug resistant Gram-negative bacteria is increasing worldwide. Therefore, rapid detection of carbapenem resistance is critical for early initiation of an appropriate antimicrobial treatment. **Methods:** Growth-based detection of meropenem resistance was performed by the light-scattering method using BacterioScan^{TM}216R device for real-time monitoring of microbial growth (BacterioScan Inc., St. Louis, MO). Ten meropenem-resistant and ten meropenem-susceptible clinical isolates of Gram-negative rods (seven *Pseudomonas aeruginosa* and three *Klebsiella pneumoniae* isolates in each group) were used. The inoculum of $5x10^5$ cfu/ml was prepared in cation-adjusted Mueller-Hinton broth. The samples were incubated in the BacterioScan instrument for 6 hours at 35°C with and without meropenem in breakpoint concentration 2 µg/ml. Each sample was automatically measured every 3 minutes. ROC analyses were performed considering the ratio of bacterial growth trends (bacteria without antibiotic vs. corresponding sample with antibiotic) for all time points, where growth trends were estimated using a recently developed moving window regression procedure. Broth microdilution method was performed for determination of meropenem minimum inhibitory concentrations (MIC).**Results:** The estimated sensitivity and specificity for detection of meropenem-resistant Gram-negative bacteria achieved both 100% after 200 minutes of incubation. Due to the particularly early response of susceptible *K. pneumoniae* isolates to meropenem, the differentiation of resistant vs. susceptible isolates was possible already after 80 minutes for this species. According to the broth microdilution, MIC_{50}/MIC_{90} were 16/16 µg/ml and 0.25/0.5 µg/ml for meropenem-resistant and meropenem-susceptible isolates, respectively.**Conclusions:** The light-scattering method is promising for the early detection of carbapenem-resistant Gram-negative bacteria. The time to result seems to be particularly short for *Enterobacteriaceae*. The performance of this method warrants further investigation on large number of isolates.

CLSI M23 Tier 2 Study to Establish Disk Diffusion Quality Control Ranges for S-649266

Author Block:

M. Hackel[1], D. Dressel[1], M. Tsuji[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Shionogi and Co., Ltd., Osaka, Japan

Abstract Body:

Background: S-649226 is a novel parenteral siderophore cephalosporin with potent activity against Gram-negative pathogens including carbapenem-resistant isolates and is currently in clinical development with Shionogi & Co., Ltd. This study was performed to establish quality control (QC) disk diffusion ranges for S-649266 against specific ATCC QC organisms utilized by the Clinical and Laboratory Standards Institute (CLSI).**Methods:** Two ATCC QC organisms within the spectrum of S-649266 activity were tested: *Escherichia coli* ATCC 25922 and *Pseudomonas aeruginosa* ATCC 27853. S-649266 and a control agent (cefepime) were tested against both QC strains following CLSI guidelines for disk diffusion. This study design met the CLSI M23-A3 requirements for Tier 2 QC studies: seven laboratories/independent sites; three media lots (different manufacturers); two disk lots; 10 replicates of each QC strain per laboratory (at least 70 total test points per medium lot); and at least 210 test points per QC strain/drug combination. Calculation of the proposed QC ranges was based on the Gavan statistic.**Results:** Greater than 95% of all test values reported from nine laboratories were within the ranges shown in the table. All cefepime results were within the established CLSI ranges.**Summary of Proposed CLSI M23 Tier 2 Quality Control Ranges for S-649266**

Organism	**Gavan Statistic Proposed QC Range (mm)**	**Size of range**	**(%) in Range**
E. coli ATCC 25922, All 3 media	23-31	9	95.3 (515/540)
P. aeruginosa ATCC 27853, All 3 media	19-31	13	95.0 (513/540)
P. aeruginosa ATCC 27853, Media A & B only	19-28	10	96.3 (347/360)

Conclusions: Using M23-A3 criteria, a nine millimeter range of 23 - 31 mm included 95.3% of all reported results for *E. coli* ATCC 25922. The Gavan statistic calculated a 13 millimeter range of 19 - 31 mm for *P. aeruginosa* ATCC 27853, which included 95.0% of all reported results. It was noted that a significant number of test results for *P. aeruginosa* ATCC 27853 on Media C

were at the higher end (larger zones) of the calculated range, therefore the analysis was repeated including data from Media A and Media B only, yielding a 10 mm range of 19-28 mm.

Validation of the Check-MDR 103XL Assay Utilizing the CDC/FDA Antimicrobial Resistance Isolate Bank Gram-Negative Carbapenemase Detection Panel

Author Block:

E. Powell, **J. Mortensen**; Cincinnati Children's Hosp., Cincinnati, OH

Abstract Body:

Background: Multi-drug resistant Gram-negative bacilli are being reported more frequently worldwide. The challenge to the clinical microbiology laboratory is how to best detect and monitor these isolates. Including a genotypic component along with the traditional phenotypic antimicrobial resistance testing may add clarity for isolates that are highly resistant or have unclear or difficult to interpret antimicrobial resistance patterns. One such genotypic testing platform is the Check-points system using the CT103XL panel (CPXL). This platform involves a multiplex PCR to amplify resistance genes followed by a microarray for detection. The purpose of this study was to begin the validation process for the CPXL for use in the clinical microbiology laboratory using the CDC-FDA Antimicrobial Resistant Isolate Bank: Gram-Negative Carbapenemase Detection Panel. **Methods:** The panel consists of eighty Gram-negative bacilli with reduced susceptibility to carbapenems via a variety of previously identified mechanisms. DNA was isolated using the NucliSENS easyMAG extractor and the presence of various beta-lactamases—including penicillinases, AmpCs, extended spectrum beta-lactamases, and carbapenemases—was determined using the CPXL test.**Results:** The CPXL detected most reported resistance genes that were included in the CPXL (73 genes in 64 isolates). 6 isolates without reported resistance markers were negative by CPXL. 4 reported genes were not detected by Check-points: chromosomal AmpC genes were not detected in 2 isolates of *Enterobacter aerogenes*, only OXA-24 was detected in 1 isolate with OXA-23 and 24, and the OXA-23 was misidentified as OXA-58 in a second isolate. Additionally, 4 isolates in which there were no reported resistance genes were positive on CPXL: 1 isolate with a wild-type TEM penicillinase, 1 isolate with SHV with 238S and 240K point mutations, 1 isolate with OXA-24, and 1 isolate with NDM and CTX-M-1, group 15 like.**Conclusions:** As clinical microbiology laboratories incorporate more molecular based methods for the determination of antibiotic resistance, the challenges of validating these systems compared to traditional phenotypic systems will be many. Discrepant results may need further phenotypic characterization. Overall, The CPXL performed well in this first trial and warrants further study.

Multi-site Evaluation of Dalbavancin and Vancomycin Mic Test Strip Compared to Broth Microdilution Mic

Author Block:

L. M. Koeth[1], D. J. Hardy[2], T. R. Walsh[3]; [1]Lab. Specialists, Inc., Westlake, OH, [2]Univ. of Rochester Med. Ctr., Rochester, NY, [3]Cardiff Univ., Cardiff, United Kingdom

Abstract Body:

Background: Dalbavancin and vancomycin are antibiotics used for treatment of acute bacterial skin and skin structure infections caused by Gram-positive organisms. This study was performed to evaluate the performance of the dalbavancin and vancomycin MIC test strips (MTS) from Liofilchem, Roseto degli Abruzzi, Italy compared to a broth microdilution method (BMD) for a FDA 510(k) submission.**Methods:** Clinical and challenge isolates were tested by BMD with frozen panels and by MTS. For dalbavancin, 311 *S. aureus* from recent clinical sources were collected and tested at 3 sites, 76 *S. aureus* challenge isolates were tested at 1 site, and for reproducibility 10 *S. aureus* were tested 10 times at 3 sites. For vancomycin, 312 *S. aureus*, 20 *S. epidermidis*, 378 *E. faecalis*, and 62 *E. faecium* from recent clinical sources were collected and tested at 3 sites, 76 challenge isolates (41 *S. aureus*, 5 *S. epidermidis*, 11 *E. faecalis* and 24 *E. faecium*) were tested at 1 site, and for reproducibility 10 isolates were tested 10 times at 3 sites. QC strains (*S. aureus* ATCC 29213, *E. faecalis* ATCC 29212) were tested a minimum of 20 times by each site.**Results:** As shown in the table, dalbavancin and vancomycin MTS MIC results for consolidated clinical and challenge organisms were within +/- one doubling dilution (essential agreement) of BMD MIC results for all isolates with only one exception.

Agent	Organism	N	% Essential Agreement	% Category Agreement
Dalbavancin	*S. aureus*	387	100%	99.7%
Vancomycin	*S. aureus*	353	99.7	98.6
Vancomycin	*S. epidermidis*	65	100	98.5
Vancomycin	*E. faecalis*	389	100	99.7
Vancomycin	*E. faecium*	81	100	97.5

For reproducibility strains, 100% of dalbavancin and 98.1% of vancomycin MTS results were within a doubling dilution of BMD results. All dalbavancin and vancomycin QC results were within CLSI ranges**Conclusions:** The dalbavancin MTS against *S. aureus* and the vancomycin

MTS against *S. aureus, S. epidermidis, E. faecalis* and *E. faecium* performs similar to the reference broth microdilution method.

Abstract Body:

Background: Interlaboratory reproducibility of antimicrobial susceptibility results has been identified by CLSI and CAP as a significant challenge. In this multi-center study, we evaluated the reproducibility of a novel integrated ID and AST system that can provide molecular-based ID and automated microscopy-based phenotypic AST results directly from positive blood cultures.**Methods:** Five bacterial isolates (*S. aureus*, *E. faecalis*, *K. pneumoniae*, *A. baumannii*, and *P. aeruginosa*) were tested at 9 clinical sites. Isolates were seeded into BACT/Alert SA Standard Aerobic, BACTEC Plus Aerobic/F Medium or VersaTREK Redox 1 Aerobic Media with healthy donor blood, incubated until positivity, and run on the Accelerate ID/AST System. ID agreement and AST reproducibility for 24 antibiotics (amikacin, ampicillin, ampicillin-sulbactam, aztreonam, cefazolin, cefepime, ceftaroline, ceftazidime, ceftriaxone, ciprofloxacin, colistin, daptomycin, doxycycline, ertapenem, erythromycin, gentamicin, imipenem, linezolid, meropenem, minocycline, piperacillin-tazobactam, tobramycin, trimethoprim-sulfamethoxazole and vancomycin) and 4 resistance phenotypes (MRSA/MSA, MLSb, high-level gentamicin and streptomycin) were determined.**Results:** Overall ID sensitivity and specificity were 97.8% (44/45) and 100% (765/765), respectively, with 1 false-negative *S. aureus* result. Interlaboratory AST reproducibility (MIC values within 1 dilution of the mode) was 98.4% (443/450).**Conclusions:** The Accelerate ID/AST Blood Culture Assay produced highly reproducible ID and AST results between all clinical laboratory sites using several types of blood culture systems.

Rapid Antibiotic Susceptibility Tests by Mass on 96-Well Plates

Author Block:

C. Schneider, P. Harris, K. Babcock, S. Strenn, S. Markakis; Affinity Biosensors, Santa Barbara, CA

Abstract Body:

A rapid phenotype-based antibiotic susceptibility test (AST) would positively impact medical outcomes and antibiotic stewardship, provided that it is amenable to clinical workflow. This work was carried out using a recently-developed resonant mass method, (Burg), in which a mechanically resonant microchannel is used to monitor microbial growth in broth microdilutions by detecting and measuring the mass of individual microbes at high throughput. This technique has been automated and applied to standard 96 well plates so as to provide rapid testing against numerous antibiotics, using sample preparation nearly identical to the CLSI broth microdilution reference method. We tested this rapid AST for repeatability and reproducibility on Gram negative quality control (QC) strains, and assessed its ability to determine the correct minimum inhibitory concentration (MIC) in three hours or less.Gram negative QC strains *Escherichia coli* ATCC 25922, *Escherichia coli* ATCC 35218, *Klebsiella pneumoniae* ATCC 700603, and *Pseudomonas aeruginosa* ATCC 27853 were used to inoculate standard MIC well plates (Thermo Scientific Sensititre GN2F, GN3F, and GN4F). Each well plate contains between 20 and 24 antibiotics at various concentrations. Additional testing was carried out using manual dilutions of a subset of antibiotics. In all cases well plates were inoculated at a microbe concentration of $2x10^5$/ml and incubated for two to three hours, then measured. Wells that showed less than 10x growth from the inoculation concentration were labelled as not growing (susceptible) at that antibiotic concentration. For this study, each microbe/well plate combination was tested three times on each of two instruments.All results obtained with the Sensititre plates were within quality control MIC ranges. Repeated tests and instrument comparisons were in agreement in 95% of the cases, and within a single 2-fold dilution for the remainder. For the manual dilutions, MICs were within the QC range in 90% of the cases, and within a single 2-fold dilution for the remainder.The results indicate that a rapid AST based on microbe mass detection produces the correct and repeatable AST result on Gram negative strains in standard antibiotic panels in under 3 hours. Ongoing work seeks to expand these results to Gram positive strains and to validate the method on clinical samples from positive blood cultures.

Publishing Title:

Value of Beckman Coulter Microscan Antimicrobial Susceptibility Panels to Detect Resistance to Carbapenems in *Enterobacteriaceae* in South Africa, Report from National Antimicrobial Reference Laboratory

Author Block:

O. Perovic, A. Singh-Moodley; Natl. Inst. for Communicable Diseases, Johannesburg, South Africa

Abstract Body:

Background: Since the first case of carbapenemases producing Enterobacteriaceae (CPE) in 2010, the Antimicrobial Resistance Laboratory at the National Institute for Communicable Diseases has received isolates for confirmatory antimicrobial susceptibility testing (AST) and molecular analysis. We aimed to validate AST panels in estimating resistance to carbapenems. **Methods:** Confirmatory identification was done on MALDI-TOF. AST was performed by the MicroScan® automated Walkaway system (Beckman Coulter, USA) using Gram-negative MIC Panel Type 44 (ertapenem 0.5-1µg/mL; doripenem 1-4µg/mL; imipenem 1-8 µg/mL; meropenem 1-8 µg/mL), the interpretation was based on the Clinical and Laboratory Standards Institute (CLSI) guidelines. DNA was extracted from the phenotypically confirmed CPEs by a crude boiling method. The supernatant was screened for bla_{NDM}, bla_{KPC}, $bla_{\text{OXA-48}}$ and its variants, $bla_{\text{GES,}}$ bla_{IMP} and bla_{VIM} using real-time polymerase chain reaction (PCR) (Light Cycler 480 II, Roche Applied Science, Light Cycler 480 Probes Master kit and the individual LightMix Modular kits (Roche Diagnostics, IN, USA). Validity of the panels was analysed using STATA. **Results:** A total of 1621 carbapenem non-susceptible isolates from various specimen types were received. MicroScan panels confirmed non-susceptibility to carbapenems in 88% from a total of 1241 Enterobacteriaceae and 90% in 746 *Klebsiella pneumoniae*. By PCR (gold standard) we confirmed CPEs in 1082 (67%) isolates. Sensitivity of ertapenem was 93.7%; specificity, 28.6%; positive predictive value (PPV), 71% and negative predictive value (NPV), 63%. For imipenem/meropenem and doripenem, the sensitivity was 75% and 76%, retrospectively; specificity was 69 and 72%, PPV 83 and 87% and NPV 57 and 55%. *Klebsiella pneumoniae* was the predominant organism 1114 (61%) and carbapenemases were detected in 721 (72%) isolates which included 442 (42%) NDM as the most predominate gene with a substantial increase in the positivity rate from 33% in 2014 to 52% in 2015. **Conclusions:** MicroScan panel showed excellent sensitivity with ertapenem and good specificity with the other three carbapenems. It can be recommended for screening and confirmation of CPE when molecular tests are not available.

Antibiograms in Five Pipetting Steps: Precise Dilution Assays in Sub Microliter Volumes with a Conventional Pipette

Author Block:

L. Derszi[1], T. S. Kaminski[2], **P. Garstecki**[2]; [1]Univ. of Padova, Dept. of Physics and Astronomy, Padova, Italy, [2]Inst. of Physical Chemistry, Polish Academy of Sci., Warsaw, Poland

Abstract Body:

Here we demonstrate a microfluidic chip that allows to execute an antibiotic susceptibility assay in an array of nanoliter droplets with the use of a standard automatic pipette, requiring only five pipetting steps. The system passively prepares a series of dilutions of a chemical compound and mixes them with portions of the sample and all the liquid handling operations are hard-wired into the geometry of the microfluidic chip. The precision of metering, merging, mixing, and splitting of discrete portions of liquid samples roots in the passive capillary action in microfluidic traps and not in the precision of dosing with a pipette. We demonstrate exemplary use of the system in determination of minimum inhibitory concentration (MIC) of ampicillin against *E. coli* ATCC 25922. The technology may significantly lessen the manual work load required to execute the most commonly performed assay in clinical microbiology.

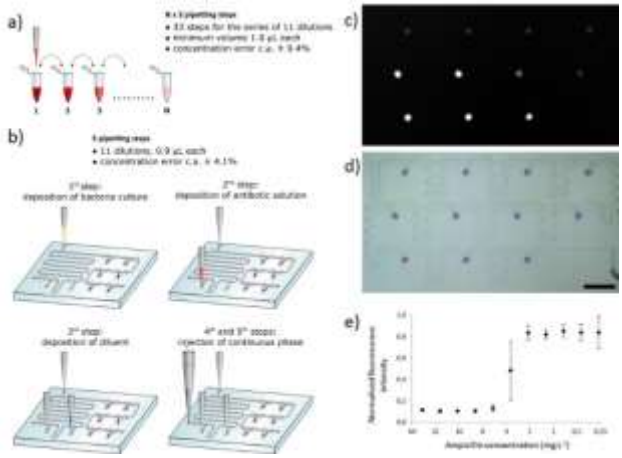

Fig. 1. a) Classic MIC assay requires 3N pipetting steps: aliquoting of pure broth, dilution of antibiotic, addition of bacteria, **b)** microfluidic chip requires 5 pipetting steps, regardless of the total number of dilutions. Fluorescent **(c)** brightfield **(d)** image show conversion of resazurin to resorufin in test-droplets after incubation, **e)** the MIC plot for ampicillin against ATCC 25922.

Discrepant Susceptibility to Gentamicin by Vitek 2 in *Klebsiella pneumoniae* Induced by *Arma*

Author Block:

J. H. Ko[1], **J. Y. Baek**[2], K. R. Peck[1], S. H. Kim[2], H. Seok[1], G. E. Park[1], S. Y. Cho[1], Y. E. Ha[1], C-I. Kang[1], D. R. Chung[1], H. J. Huh[1], N. Y. Lee[1], J. H. Song[2]; [1]Samsung Med. Ctr., Sungkyunkwan Univ. Sch. of Med., Seoul, Korea, Republic of, [2]Asia Pacific Fndn. for Infectious Diseases, Seoul, Korea, Republic of

Abstract Body:

Background: In the era of increasing beta-lactam resistance of *Enterobacteriaceae*, aminoglycoside antibiotics become important treatment option for multi-drug resistant *Enterobacteriaceae.* Although VITEK 2 automated system plays major role in clinical practice measuring antibiotics susceptibility, there were reports that high-level resistance to aminoglycosides could be falsely reported as susceptible. We evaluated true antibiotics susceptibility and presence of 16S rRNA methylase gene in *K. pneumoniae* with this unique aminoglycoside susceptibility pattern presented by VITEK 2. **Methods:** We screened *K. pneumoniae* blood isolates from January 2015 to December 2015 at a 1950-bed tertiary care center. MIC values and interpretations reported by VITEK 2 system were reviewed and isolates with gentamicin non-resistance despite amikacin resistance were selected. We substantiated MICs of selected isolates by broth microdilution method. Presence of 16S rRNA methylase genes including *armA, rmtB, rmtC, rmtE,* and *rmtF* were investigated by PCR. **Results:** A total of 564 blood isolates of *K. pneumoniae* was identified, 550 isolates (97.3%) were susceptible, 2 (0.4%) were intermediate, and 12 (2.1%) were resistant to amikacin by VITEK 2 system. Among 12 amikacin resistant isolates, 9 (75%) were susceptible (4 isolates) or intermediate (5 isolates) to gentamicin, all of which were tested for MIC and 16S rRNA methylase genes. All of gentamicin intermediate isolates (100%) and 3 of gentamicin susceptible isolates (75%) showed high-level resistance to both amikacin and gentamicin (MIC > 128μg/ml and ≥ 256μg/ml, respectively) by broth microdilution method and were positive to *armA* gene. **Conclusion:** Discrepant susceptibility to gentamicin despite amikacin resistance in *K. pneumoniae* by VITEK 2 was related with false susceptibility induced by *armA*. This finding presents important information in selecting antibiotics especially for multi-drug resistant pathogens, and gentamicin susceptibility of *K. pneumoniae* isolates with discrepant aminoglycoside susceptibility pattern presented by VITEK system should be confirmed by alternative susceptibility testing.

S-649266 Mic Quality Control Ranges In Iron-Depleted Cation-Adjusted Mueller-Hinton Broth Using A Multi-Laboratory Study Design

Author Block:

J. E. Ross[1], A. Ito[2], M. Tsuji[2], R. K. Flamm[1], R. N. Jones[1], H. S. Sader[1]; [1]JMI Lab., North Liberty, IA, [2]Shionogi & Co., Ltd., Toyonaka, Osaka, Japan

Abstract Body:

Background: We conducted a study to establish MIC quality control (QC) ranges for S-649266, a siderophore cephalosporin, in iron-depleted cation-adjusted Mueller-Hinton broth (MHB). Chelex treatment depletes iron from the medium and enhances the uptake of S-649266, which can enter the bacterial cell through iron transport mechanisms in Gram-negative (GN) bacteria. S-649266 exhibits potent efficacy against various GN bacteria including carbapenem-resistant strains.**Methods:** An eight laboratory study design followed CLSI M23-A3 guidelines. Two QC strains were tested (*Escherichia coli* ATCC 25922 [EC25922] and *Pseudomonas aeruginosa* ATCC 27853 [PSA27853], using four media lots (three manufacturers) of MHB treated with a chelating agent. MHB was treated for 2 hours with Chelex, filtered, pH adjusted, and levels of calcium and magnesium were adjusted to CLSI specifications. Zinc was adjusted to 0.5 mg/mL; 10µM. Ten replicate tests were performed for each QC organism generating 320 broth microdilution values/QC strain. Cefepime was used as a control agent.**Results:** S-649266 MIC QC range of 0.06 - 0.5 µg/mL was proposed for EC25922, which included 99.7% of results and a mode at 0.25 µg/mL. A MIC "shoulder" at 0.12 µg/mL included 53.1% of the number of MIC results compared to the number of MIC values at the modal 0.25 µg/mL, thus causing a need for a four $\log_2$ dilution range. PSA27853 also needed a four $\log_2$ dilution range of 0.06 - 0.5 µg/mL to include 95.0% of all reported results for S-649266. This distribution had a modal value at 0.25 µg/mL with a "shoulder" at 0.12 µg/mL which included 83.2% of the number of MICs compared to the modal value. One medium lot was identified as an outlier when tested against EC25922 with S-649266 having a modal MIC value of two $\log_2$ dilutions (0.06 µg/mL) lower than the other three lots (0.25 µg/mL). Medium variations occurred with the S-649266 compound only. All MIC values generated for cefepime were within the CLSI published QC range.**Conclusions:** These proposed MIC QC ranges for S-649266 when tested in MHB (iron depleted by Chelex treatment) should accurately guide clinical or reference laboratories participating in the testing of clinical trial isolates, and facilitate the regulatory review process for this investigational antimicrobial agent.

Performance Of Two Methods For Detection Of Carbapenem Resistance Mechanism Among Enterobacteriaceae

Author Block:

S. Miller[1], T. Wagner[2], **R. M. Humphries**[1]; [1]UCLA, Los Angeles, CA, [2]OpGen, Gaithersburg, MD

Abstract Body:

Background: Carbapenem resistance is conferred by the presence of extended spectrum beta-lactamases (ESBL), AmpC enzymes and/or carbapenemases, often in combination with a permeability defect. Knowledge of the resistance mechanism is critical to epidemiological studies, but few laboratories have the capacity to routinely evaluate for mechanisms of resistance among carbapenem resistant Enterobacteriaceae (CRE).**Methods:** The performance of the OpGen Acuitas® Resistome Test (Opgen Inc. Gaithersburg, MD) was compared to a laboratory-developed TaqMan real-time polymerase chain reaction (RT-PCR) that detects the presence of *bla*$_{KPC}$, *bla*$_{NDM}$, *bla*$_{IMP}$, *bla*$_{VIM}$, *bla*$_{SME}$ and *bla*$_{OXA-48-like}$ carbapenemase genes, for a collection of 20 clinical isolates. All isolates had imipenem and/or meropenem MICs >1 μg/ml. The Acuitas Resistome Test applies a microfluidic PCR array that analyzes isolates of Gram-negative bacilli for approximately 50 resistance mechanisms, including carbapenemases, ESBLs, and AmpC.**Results:** 18/20 isolates yielded concordant carbapenemase results by the Acuitas Resistome Test and RT- PCR. These included 1 KPC, 2 IMP, 2 NDM and 2 OXA-48-like enzymes, and 11 isolates negative for carbapenemase genes targeted in the RT-PCR. A *Providencia rettgeri* was positive for KPC, NDM, SHV ESBL and TEM by the Acuitas Resistome Test, but NDM alone by the RT-PCR. Repeat testing yielded NDM alone by both tests. A *Citrobacter freundii* was positive for VIM, CTX-M-1, SHV, TEM and CMY/MOX by the Acuitas Resistome Test and negative by the RT-PCR. Upon repeat testing, only CTX-M-1 and CMY/MOX AmpC were detected by Acuitas Resistome Test and the RT-PCR was negative. We hypothesize these 2 discrepancies may be due to plasmid loss and/or heterogeneous populations of the cultured isolates. For the carbapenemase-negative isolates by the RT-PCR, plasmid AmpC was detected in 5, ESBL in 3, OXA-23 and OXA-51 in 1 and no beta-lactamases in 2, by the Acuitas Resistome Test.**Conclusion:** The Acuitas Resistome Test performed comparably to RT-PCR for the detection of carbapenemase genes. Laboratories must be aware that discordant results might be observed in CRE, one possibility being due to plasmid loss. Furthermore, this test provides data on resistance mechanisms outside the presence of carbapenemases.

Using a Novel Atp Bioluminescence Assay (Atpb) with Elimination of Extracellular (Ec) Atp to Predict Quantitative Counts in Time-Kill Studies (Tks) within 15 Minutes Against Extensively Drug Resistant (Xdr) Gram Negative Bacteria (Gnb)

Author Block:

Y. Cai[1], J. Ng[2], L. Hui[1], S-X. Tan[1], T-P. Lim[1], J. Teo[1], W. Lee[1], T-T. Tan[1], T-H. Koh[1], A-L. Kwa[1]; [1]Singapore Gen. Hosp., SG, Singapore, [2]Natl. Univ. of Singapore, SG, Singapore

Abstract Body:

TKS is commonly employed to determine bactericidal antibiotic (abx) combinations (combi) for XDR GNB. However, bacterial count quantification in TKS is laborious & requires 24h incubation. Bacterial ATP has been proposed as a surrogate for viable count, but its utility is confounded by EC-ATP released upon exposure to abx. We developed a novel ATPB assay with EC-ATP elimination & demonstrated its use in quantifying kill in TKS within 15min. **Methods:** 6 clinical XDR GNB [2 *A. baumannii* (AB), 2 *K. pneumoniae* (KP), 2 *P. aeruginosa* (PA)] were used. 24hTKS were conducted with 5log CFU/mL at baseline with clinical concentrations of amikacin (65), levofloxacin (8), meropenem (20) tigecycline, polymyxin B (2) & aztreonam (24) singly & in 2-abx combi. At each timepoint (0, 2, 4 6, 8, 24h), the following samples were obtained: 1) direct measurement of total ATP; 2) elimination of EC-ATP using apyrase (1U/mL) for 15min at 37°C with repeated washings & ATP measurement; 3) filtration with ATP measurement to determine EC-ATP. Bacterial counts by viable plating was determined. Correlation (r^2) between counts (CFU/mL) & ATP measurements (RLU/100uL) were determined. **Results:** Moderate correlation ($r^2 = 0.62$) was observed between viable counts & direct ATP measurements when all XDR GNB were collectively analyzed (operating range of 10^2 to 10^8 CFU/mL). When correlation between viable counts & direct ATP measurements was determined for each species, correlation was highest for KP & lowest for PA (KP $r^2 = 0.71$, AB $r^2 = 0.69$, PA $r^2 = 0.48$). Significantly higher correlation of ATP measurements to viable counts was observed in apyrase-treated samples ($r^2 = 0.82$) when all XDR GNB were collectively analyzed. Improved correlation was also seen in each species (KP $r^2 = 0.90$, AB $r^2 = 0.84$, PA $r^2 = 0.74$). Measurements of EC-ATP showed that the amount EC-ATP varied widely upon abx exposure, accounting for the high variability in direct ATP measurements. **Conclusions:** Our ATPB assay with EC-ATP removal can accurately predict bacterial counts to determine killing in TKS within 15min. This short turn-around time allows TKS to be employed to guide the timely selection of abx combi for clinical use.

Evaluation of Antibiotic Susceptibility by Headspace Gas Analysis

Author Block:

J. D. S. Newman, E. M. Becker, M. Krause, **J. L. Lucas**, J. A. Trimboli; MRIGlobal, Rockville, MD

Abstract Body:

Recent analyses of bacterial headspace samples have demonstrated that microorganisms can be identified by profiling a range of volatile organic compounds (VOCs), including distinguishing between antibiotic susceptible and resistant sub-strains of *Staphylococcus aureus* (Bean et al, 2014). We have identified the VOC profiles of two strains of *Bacillus anthracis*, the causative agent of anthrax, using a non-invasive, micro-extraction technique. *B. anthracis* Sterne 1:6 is resistant to ciprofloxacin, while the parent strain, Sterne, is susceptible. Our approach involves culturing the *B. anthracis* strains in the presence and absence of ciprofloxacin, the primary treatment for anthrax. The culture's headspace is then sampled with solid-phase microextraction (SPME), and the chemical constituents analyzed with gas chromatography-mass spectrometry (GC-MS). To date, we have characterized the signatures associated with *B. anthracis* Sterne and *B. anthracis* Sterne 1:6 (AMR). Two fiber compositions (PDMS/Carboxen and PDMS/Carboxen/Divinylbenzene) have been tested as well as three culture media (tryptic soy broth (TSB), Mueller-Hinton (MH) and LB broth). Our study identified compounds unique to the *B. anthracis* AMR strain, either in the presence or absence of ciprofloxacin. One fiber-media combination (PDMS/Carboxen and TSB) resulted in the discovery of a single compound, 3-hydroxy-2-butanone, which was only present in the AMR strain. This compound is capable of differentiating the AMR strain from the susceptible strain in both the presence and absence of ciprofloxacin. These results support the further development of VOC profiles in bacteria species as a novel approach for antibiotic susceptibility testing.

Evaluation of Ceftolozane-Tazobactam Mic Test Strip Compared to Broth Microdilution Mic for *Enterobacteriaceae* and *Pseudomonas aeruginosa*

Author Block:

L. M. Koeth, J. DiFranco-Fisher; Lab. Specialists, Inc., Westlake, OH

Abstract Body:

Background: Ceftolozane-tazobactam (C-T) is a cephalosporin - beta lactamase inhibitor combination antimicrobial agent that was approved by the Food and Drug Administration (FDA) for the treatment of complicated urinary tract infections (cUTI), including pyelonephritis and in combination with metronidazole for the treatment of complicated intra-abdominal infections (cIAI). This study was performed to evaluate the performance of a newly developed gradient strip, the ceftolozane-tazobactam MIC Test Strip (MTS) from Liofilchem, Roseto degli Abruzzi, Italy compared to a broth microdilution method against indicated Gram negative isolates. **Methods:** The study isolates (50 *Enterobacteriacieae* [21 *E. coli*, 13 *K. pneumoniae*, 9 *E. cloacae*, 4 *P. mirabilis* and 3 *K. oxytoca*] and 50 *P. aeruginosa*) were recent clinical isolates primarily from indicated sources and chosen to include a wide range of C-T MIC results (0.12-4 to >32-4 µg/mL). Each isolate was tested for C-T MIC by broth microdilution (BMD; LSI prepared frozen panels) and by C-T MTS on 100 mm Mueller Hinton agar (MHA) plates (Becton Dickinson, Sparks, MD). QC strains (*E. coli* ATCC 25922, *E. coli* ATCC 35218, *P. aeruginosa* ATCC 27853 and *K. pneumoniae* ATCC 700603) were tested on 9 days with MHA from 2 suppliers (Becton Dickinson and Hardy Diagnostics, Santa Maria, CA) and results compared to CLSI expected ranges. **Results:** As shown in the table, C-T MTS and BMD results were within +/- one doubling dilution (essential agreement) for 94.0% of *Enterobacteriaceae* and 96.2% of *P. aeruginosa*. Quality control results were within CLSI established ranges, with exception of one outlier result for *E. coli* ATCC 35218 on Hardy MHA.

Organism	Dilution difference of ceftolozane-tazobactam MTS-BMD (n)							Total
	-3	-2	-1	0	1	2	OS>	
Enterobacteriaceae	2	1	11	16	14	0	6	50
P. aeruginosa	2		6	12	28		5	53

OS: Off-scale (> highest concentration tested)**Conclusions:** This initial evaluation of the C-T MTS showed good correlation to BMD MIC. Further testing with additional isolates at multiple sites and with media from multiple manufacturers is warranted.

Publishing Title:

Comparison of Modified Hodge Test, Neo-Rapid Carb, and Xpert Carba-R for the Detection of Carbapenemases in the *Enterobacteriaceae*

Author Block:

C. Doern, C. Bender, T. Neal, B. Forbes; Virginia Commonwealth Univ. Hlth.System, Richmond, VA

Abstract Body:

Historically, laboratories have relied on phenotypic methods such as the Modified Hodge Test (MHT) to confirm carbapenemase production. The limitations of this method in both sensitivity and specificity have been well documented and newer methods such as the Neo-Rapid CARB Kit (NRC)) (Rosco Diagnostica) and the Xpert Carba-R (XCR) (Cepheid) promise to improve the accuracy of carbapenemase detection. NRC is a phenotypic test that detects carbapenemase activity through carbapenem hydrolysis in the presence of an indicator. XCR is a multiplex PCR assay that detects genes encoding KPC, VIM, OXA-48, IMP-1, and NDM carbapenemases. The goal of this study was to compare the performance of the XCR and NRC assays to that of MHT for carbapenemase detection in isolates of *Enterobacteriaceae.* Herein we compare the results of meropenem disk diffusion (MDD), MHT, NRC, and the XCR testing for a challenge set of 95 isolates (14 *E. coli*, 19 *Enterobacter* spp., 41 *Klebsiella* spp., 12 *Citrobacter* spp., 3 *Providencia* spp., 2 *Proteus mirabilis*, 2 *Serratia marcesens*, and 2 *Morganella morganii*) with reduced susceptibility to either 3rd generation cephalosporins and/or carbapenems. Forty-seven isolates were obtained from clinical specimens and 48 with known mechanisms of resistance were purchased. Forty-three isolates yielded negative MHT results. Of these, all but 4 were negative by NRC and all were negative by the XCR. MDD using current CLSI breakpoints yielded 9 resistant and 15 intermediate results within this group. Fifty-two isolates were MHT positive. Of these, 32 were positive by XCR (30 KPC, 2 VIM) and 44 were positive by NRC. MDD yielded susceptible results in 8 isolates. When using MHT as the gold standard, these data show that both the XCR and NRC perform with high specificity (only 4 false positives; all by NRC). However, in MHT-positive isolates, significant discrepancies were observed. Eighteen and 8 MHT-positive isolates were negative by XCR and NRC, respectively. Three of these isolates were *Enterobacter* spp. which are known to harbor chromosomal *ampC* genes and four additional isolates were known to harbor ESBLs. These day may suggest that these are actually falsely positive MHT results. Further studies including reference broth microdilution and Check-Direct CPE are currently being performed to resolve these discrepancies.

Publishing Title:

Comparative Performance of the Modified Hodge Test (Mht) with a New Modified Rapid Carbar Kit (Rosco Tabs) for the Detection of Carbapenem Resistant Organisms (Cros)

Author Block:

J. Vedula, A. Clowes, M. Lam, T. Dingle, C. Hamula; Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract Body:

Background: The rise in prevalence of carbapenem resistant organisms (CROs) has precipitated the need for a rapid and accurate method to phenotypically identify these isolates. The CarbaNP and Modified Hodge test (MHT) are listed in the CLSI M100 guideline as the standard for carbapenemase detection. Both tests are laborious and present workflow issues for the clinical laboratory. A modified novel rapid carbapenemase detection kit based on the CarbaNP test (Neo-Rapid Carb Kit 98024, ROSCO Diagnostica) was compared to MHT in its performance by testing a collection of routine clinical isolates determined to be carbapenem resistant by the Vitek II (Biomerieux Diagnostics, France). **Methods:** We analyzed over 75 carbapenem resistant clinical isolates from the Mount Sinai Hospital Clinical Microbiology Laboratory in New York City. The isolates include 49 *Klebsiella* pneumonia, 15 *Pseudomonas aeruginosa*, 6 *Escherichia coli*, and 1 of each of *Serratia marcescens, Acinetobacter baumanii, Enterobacter aerogenes,* and *Enterobacter cloacae*. *Enterobacteriaciae* were selected based on resistance to both ertapenem and imipenem (VITEK II), and *P. aeruginosa* was selected based on resistance to ceftazidime, cefipime, meropenem, and imipenem(VITEK II). Strains were sub-cultured in the presence of a 10ug imipenem disk and the Neo-Rapid Carb Kit (NRC) was administered with a modified version of the manufacturer's protocol using 0.9% normal saline. The tabs were read at 30 minutes and 60 minutes. The MHT was set up concurrently and interpreted according to 2016 CLSI guidelines. **Results:** NRC successfully identified 100% of the carbapenemase producing organisms: 93% of isolates [70/75] were positive within the first 30 minutes while the remaining isolates [5/75] were positive by 60 minutes. Isolates tested 61% positive [46/75], 36% negative [27/75], and 3% [2/75] indeterminate by MHT. **Conclusions:** Further characterization of the isolates via PCR and comparison to results of the full-length CarbaNP protocol is needed. However, NRC is an accurate and reliable method of phenotypically identifying carbapenemase producing organisms (CPO). The kit can be administered and read in under 60 minutes providing a rapid alternative to the difficult to interpret, and labor- intensive MHT.

Publishing Title:

Ability of the Bd Phoenix Emerge Nmic-140 Panel to Accurately Identify Extended Spectrum Beta-Lactamase (Esbl) Isolates

Author Block:

L. L. Steed, L. L. Gauld, G. E. Palmer-Long; Med. Univ of South Carolina, Charleston, SC

Abstract Body:

Routine ESBL testing is required at the Medical University of South Carolina (MUSC) Hospital as part of our Infection Prevention and Control's program to control multi-drug resistant organisms. An internal rule was used to supplement the expert system ESBL algorithm of our previous automated instrument to avoid overcalling resistance. We sought to determine if an internal rule was still necessary for use with the BD Phoenix Emerge NMIC-140 panels. This rule required that an isolate flagged by the Phoenix as being an ESBL must have the pattern cefazolin = R/cefoxitin = S/aztreonam, cefotaxime, ceftazidime, OR ceftriaxone = R. Isolates that fulfilled the internal rule were accepted as being ESBLs; isolates that did not were confirmed by double disk diffusion per the current CLSI M100. Between October, 2014, and July, 2015, 156 isolates were called ESBL by the Phoenix. Most isolates (85%) were from urine sources. Not unexpectedly, *Escherichia coli* predominated (80%), followed by *Klebsiella pneumoniae* (17%) and *Klebsiella oxytoca* (3%). A total of 88 isolates (56%) met the internal rule and were reported as ESBL without further testing. 58% of *E. coli* and *K. pneumoniae* isolates fulfilled the internal rule. Another 31 isolates (20%) were confirmed while 37 isolates (24%) did not confirm. While 27% of *K. pneumoniae* isolates that did not meet the internal rule confirmed as ESBL by double disk diffusion, 26% of *E coli* isolates that did not meet the internal rule failed to confirm as ESBL. Our use of an internal rule complementing the expert system ESBL algorithm used by the BD Phoenix prevented false reporting of 24% of isolates as ESBLs during the study period. Providing additional β-lactam antibiotic choices to clinicians when possible and reducing unnecessary use of contact isolation in our patients is worth the additional 18-24 hours needed for confirmatory double disk diffusion testing.

Tilmicosin Cannot be Used as the Veterinary Macrolide Class Representative to Predict Tulathromycin Activity

Author Block:

M. T. Sweeney[1], H. Moyaert[2], J. Watts[1]; [1]Zoetis, Kalamazoo, MI, [2]Zoetis, Zaventem, Belgium

Abstract Body:

Background: A number of diagnostic laboratories have begun to use tilmicosin as the class representative to predict the susceptibility for tulathromycin to the bovine respiratory disease pathogen *Mannheimia haemolytica* and other BRD and SRD bacterial species. However, no *in vitro* data are available that supports the use of tilmicosin as the class representative for tulathromycin or other veterinary macrolides. We report scattergram plots of tilmicosin-tulathromycin MIC values and calculated error-bound rates when using tilmicosin versus tulathromycin clinical breakpoints.**Methods:** Veterinary laboratories from the US and Canada provided *M. haemolytica* isolates recovered from diseased or dead beef or dairy cattle over an 11-year period (2004-2014). Each participating laboratory was requested to submit no more than 32 isolates per year in order to prevent over-representation from any one geographic area. *In vitro* MIC susceptibility values for the isolates against these drugs were generated at two laboratories following Clinical and Laboratory Standards Institute (CLSI) standardized methods.**Results:** Of 3819 *M. haemolytica* isolates tested, 302 isolates were determined to be tilmicosin resistant but tulathromycin susceptible based on established clinical breakpoints for tilmicosin and tulathromycin, resulting in a major error-bound rate of 7.9% which is above the 3% CLSI-recommended limit. Susceptibility values for another 448 isolates produced an 11.7% minor error-bound rate in which 359 isolates were tilmicosin-I/tulathromycin-S, 61 strains were tilmicosin-R/tulathromycin-I, 21 strains were tilmicosin-I/tulathromycin-R, and 7 strains were tilmicosin-S/tulathromycin-I.**Conclusions:** Since all veterinary macrolides have different substituted ring structures, as well as different *in vitro* and *in vivo* properties with regards to MIC activity, dosage regimen, and pharmacokinetics, any susceptibility results for tilmicosin to predict the activity and potential treatment outcome for tulathromycin is strongly discouraged.

A Universal Screening Medium Fo Polymyxin-Resistant Gram-Negative Bacteria

Author Block:

P. Nordmann, A. Jayol, L. Poirel; Univ. of Fribourg, Fribourg, Switzerland

Abstract Body:

Background: Multidrug resistant (MDR) Gram negatives usually remain susceptible to polymyxins (colistin and polymyxin B) however emergence of polymyxin resistance is increasingly reported. Polymyxin-based selective culture media have been developed for screening intrinsic polymyxin-resistant bacterial species but they are not adapted for screening Gram negatives with acquired resistance to polymyxins that display low- to high-level resistance to polymyxins. We developed here a selective culture medium to detect any type of polymyxin-resistant gram negative bacteria. **Materials/methods:** The SuperPolymyxin medium was prepared using an Eosine Methylene Blue agar (EMB)-based culture medium in which colistin or polymyxin B, daptomycin and amphotericin B were added. Performance of the medium was evaluated with a total of 82 Gram-negative strains from various enterobacterial and non-fermenters species. Some of those strains had well-characterized mechanisms of resistance, such as mutations in the *pmrA* or *pmrB* genes (*K. pneumoniae*, *A. baumannii*), alterations in the *mgrB* gene or its promoter sequences (*Klebsiella* spp.), or produced the plasmid-mediated MCR-1 colistin resistance determinant (*E. coli*). MICs of polymyxins were determined using the broth microdilution method according to the CLSI guidelines and results were interpreted according to the EUCAST breakpoints.**Results:** Polymyxin-resistant strains grew on the SuperPolymyxin medium in 24 h, except *P. aeruginosa* and *S. maltophilia* and the intrinsically polymyxin-resistant *Burkolderia* genus that grew in 24 to 48 h. The lowest limit of detection was below the cut-off value of 1×10^3 CFU/ml for all polymyxin-resistant strains, whereas the limit of detection of the polymyxin-susceptible strains was above 1×10^3 CFU/ml, being $\geq 1 \times 10^6$ CFU/ml. The sensitivity and specificity of the SuperPolymyxin medium for selecting polymyxin-resistant gram negatives were 100%.**Conclusion:** The SuperPolymyxin medium is the first screening medium that is aimed to detect intrinsic and acquired polymyxin resistant Gram negative rods. Its usefulness applies for both human and veterinary medicine. In human medicine, it will contribute to an early identification of carriers of polymyxin-resistant strains, therefore preventing and containing outbreaks due to polymyxin-resistant isolates.

Activity of Tedizolid Tested Against Co_2-Dependent Small-Colony Variants of *Staphylococcus aureus*

Author Block:

E. Cercenado[1], A. Vindel[2], M. Marín[1], F. Román[2], E. Bouza[1]; [1]Hosp. Gen. Univ.rio Gregorio Marañón, Madrid, Spain, [2]Inst. de Salud Carlos III, Majadahonda, Spain

Abstract Body:

Background: Small-colony variants (SCVs) of *S. aureus* constitute a slow-growing subpopulation with a distinctive phenotype, usually recovered from chronic and relapsing infections. Most SCVs are auxotrophs for menadione, hemin, or thymidine, and rarely for CO_2. Tedizolid (TZD) is a novel oxazolidinone with broad-spectrum activity against Gram-positive organisms. We evaluate the in vitro activity of TZD tested against CO_2-dependent SCVs isolates of *S. aureus*. **Methods:** SCVs were identified phenotypically. Auxothrophy for hemin, menadione, and thymidine was tested with impregnated disks, and CO_2-dependency by incubation in 5% CO_2. The presence of the *mecA* gene was determined by PCR. Molecular characterization was achieved by PFGE, SCC*mec* and *spa* typing. TZD susceptibility testing was performed by the epsilon-test (Liofilchem, Italy) in Mueller-Hinton agar plates (Biomérieux, France). Readings were performed after incubation for 24 h at 37ºC in 5% CO_2. CLSI/EUCAST breakpoints were applied for TZD (susceptible ≤0.5 mg/L). *S. aureus* ATCC 29213 and *E. faecalis* ATCC 29212 were used as controls.**Results:** From January 2013 to August 2015, we recovered 54 SCVs isolates of *S. aureus*, all CO_2-dependent, from 54 patients. Among these, 35 were methicillin-resistant (MR) and 19 methicillin-susceptible (MS). The source of the isolates was respiratory tract (n=25), wounds/abscesses (n=21), blood (n=6), others (n=2). Among MRSA, all isolates carried SCC*mec* type IVc, PFGE showed 7 different profiles, and 29 isolates (82.8%) corresponded to the *spa* type t686. All MSSA showed different PFGE profiles and 8 isolates (42%) corresponded to the *spa* type t686. TZD inhibited 100% of isolates at an MIC of ≤0.75 mg/L. The TZD MIC50, MIC90, and range (mg/L) for all isolates tested were 0.38, 0.5, and 0.25-0.75 mg/L, respectively. The activity of TZD (MIC, mg/L) against MRSA and MSSA is shown in the table.**Conclusion:** This study shows potent in vitro activity of TZD against recent CO_2-dependent SCVs isolates of MRSA and MSSA.

***S. aureus* (No. isolates)**	**TZD MIC50**	**TZD MIC90**	**Range**
MRSA (n=35)	0.5	0.5	0.25-0.75
MSSA (n=19)	0.38	0.5	0.25-0.75

Publishing Title:

Clinical Isolates of *Helicobacter pylori* Demonstrate a High Rate of Combined Resistance to Clarithromycin and Elevated Metronidazole Mics

Author Block:

D. Chen, N. Cole, P. Kohner, R. Patel; Mayo Clinic, Rochester, MN

Abstract Body:

Background: Recommended treatment regimens for *H. pylori* are commonly based on clarithromycin or metronidazole. Treatment failures are often a result of antimicrobial resistance. Our clinical laboratory performs *H. pylori* antimicrobial susceptibility testing. The purpose of this study was to define current patterns of *H. pylori* antimicrobial resistance.**Methods:** Antimicrobial susceptibility testing was performed using agar dilution, as recommended by the Clinical and Laboratory Standards Institute (CLSI), on *H. pylori* isolated from routine clinical specimens and submitted for susceptibility testing from November 2011 to October 2015 at Mayo Clinic, Rochester, MN. Minimal inhibitory concentrations (MICs) were determined for clarithromycin, amoxicillin, metronidazole, tetracycline, and/or ciprofloxacin (ordered as a panel or individually). Clarithromycin results were interpreted based on CLSI breakpoints; the other four drugs do not have established interpretive criteria.**Results:** A total of 1,970 MICs were reported over the 4-year study period (clarithromycin n=412, amoxicillin n=410, metronidazole n=330, tetracycline n=409, and ciprofloxacin n=409). Clarithromycin was interpreted as resistant in 70% of isolates (n=290), intermediate in 2% (n=8), and susceptible in 28% (n=114). Metronidazole had a wide distribution of MICs (in μg/ml): ≤8 (n=58), 16 (n=24), 32 (n=66), 64 (n=116), 128 (n=63), 256 (n=2), >256 (n=1). There were 330 instances where both clarithromycin and metronidazole were tested on the same isolate. Of these, 61% (n=200) were both resistant to clarithromycin and had metronidazole MICs >8 μg/ml. The most frequent MICs for the other antibiotics were: amoxicillin ≤2 μg/ml (99%, n=405), tetracycline 1 μg/ml (60%, n=246), and ciprofloxacin >2 μg/ml (52%, n=211).**Conclusions:** A majority of clinical isolates submitted for *H. pylori* susceptibility testing showed elevated clarithromycin and metronidazole MICs; both agents are frequently used in *H. pylori* therapy. Furthermore, a substantial number of isolates showed high ciprofloxacin MICs.

Publishing Title:

Antimicrobial Susceptibility Profile of *Granulicatella* and *Abiotrophia* Species

Author Block:

A. Mushtaq, N. Cole, K. Greenwood-Quaintance, P. Kohner, S. Ihde, G. Strand, A. Virk, R. Patel; Mayo Clinic, Rochester, MN

Abstract Body:

Background: American Heart Association guidelines for treatment of *Abiotrophia* and *Granulicatella* endocarditis are based on penicillin susceptibility. For penicillin-susceptible strains, monotherapy with either penicillin or ceftriaxone is recommended. Ceftriaxone has the advantage of once-daily dosing and hence, is often selected. We have recently observed penicillin-susceptible, but ceftriaxone-non-susceptible isolates. The objective of our study was to 1) determine MICs of a collection of *Abiotrophia* and *Granulicatella* species against a panel of antibiotics and, 2) describe the proportion of ceftriaxone non-susceptible strains in the penicillin susceptible sub-group. **Methods:** Fifteen isolates of *Abiotrophia defectiva* and 72 isolates of *Granulicatella adiacens* from the clinical microbiology laboratory of Mayo Clinic, Rochester, MN, recovered from January 1980 to November 2015 were studied. Isolates were identified to the species level using MALDI-TOF MS or 16S rRNA gene sequencing. MIC values were determined by broth microdilution using the Sensititre® commercial system (Trek Diagnostics Systems®, Oakwood Village, OH) per the manufacturer's guidelines. When available, CLSI breakpoints were used to interpret results.**Results:** The percentages of isolates susceptible to penicillin and ceftriaxone were 38% (33/87) and 31% (27/87), respectively. For *A. defectiva*, all 4 penicillin-susceptible isolates were also ceftriaxone susceptible. For *G. adiacens* penicillin-susceptible isolates, only eight were ceftriaxone susceptible, while 21 were ceftriaxone non-susceptible. High susceptibility rates were found for vancomycin (100%, 83/83), levofloxacin (99%, 76/77), and meropenem (85%, 61/72). Low susceptibility rates were found for erythromycin (49%, 36/73), cefotaxime (22%, 10/46) and cefepime (12%, 9/74). A subgroup of 46 isolates was also tested against linezolid (MIC_{50} and MIC_{90}, 2 μg/mL), daptomycin (MIC_{50} and MIC_{90}, >2 μg/mL), and tigecycline (MIC_{50} and MIC_{90}, $\leq$0.015 μg/mL).**Conclusions:** *Abiotrophia* and *Granulicatella* species have low susceptibility rates to penicillin and ceftriaxone, and 72% (21/29) of penicillin-susceptible *G. adiacens* isolates test ceftriaxone non-susceptible.

Antimicrobial Susceptibility of Clinical *Ureaplasma* Isolates

Author Block:

J. Fernandez-Dominguez, X. Wang, M. Karau, K. Greenwood-Quaintance, S. Cunningham, R. Patel; Mayo Clinic, Rochester, MN

Abstract Body:

Background: *Ureaplasma urealyticum* and *Ureaplasma parvum* are involved in urogenital tract infection and associated with adverse pregnancy outcomes and bacteremia alongside complications such as bronchopulmonary dysplasia and meningitis in newborns. Recently, *Ureaplasma* species have been associated with fatal hyperammonemia among lung transplant patients. There are limited reports on the antimicrobial susceptibility of *Ureaplasma* species, especially separated by species. The aim of this study was to determine the susceptibility of contemporary isolates of this genus recovered at Mayo Clinic (including from Mayo Medical Laboratories patients). **Methods:** Over a three month period (October-December 2015), all patient specimens of any origin positive by PCR at Mayo Clinic for *U. parvum* or *U. urealyticum* were cultured in SP4 media with urea. A total of 131 recovered isolates (113 *U. parvum* and 18 *U. urealyticum*) were studied. MICs to doxycycline, azithromycin, ciprofloxacin, tetracycline, erythromycin and levofloxacin were determined by broth microdilution and the last three interpreted according to CLSI guidelines. The *tetM* gene for tetracycline resistance was assessed by PCR. **Results:** All isolates were susceptible to tetracycline and had equal or lower doxycycline MICs; *tetM* was not detected in any isolate. All isolates had azithromycin MICs ≤8µg/mL; however, two *U. parvum* isolates (1.7%) were resistant to erythromycin (MIC >16µg/mL). Resistance to levofloxacin was observed in 3 *U. parvum* isolates (2.6%) and 1 *U. urealyticum* isolate (5.5%). Furthermore, 6 (5.3%) and 3 (16.6%) isolates of *U. parvum* and *U. urealyticum*, respectively, had ciprofloxacin MICs ≥8µg/mL. All isolates had MICs at least one dilution lower for levofloxacin compared to ciprofloxacin. **Conclusion:** We report the antimicrobial susceptibility of contemporary *U. parvum* and *U. urealyticum* isolates from the United States. The resistance rate was low in comparison with previous studies from elsewhere in the world and simultaneous resistance to more than one antimicrobial class was not observed in the same isolate.

***Aerococcus urinae* Antimicrobial Susceptibility Testing Methods Comparative Analysis**

Author Block:

S. Grandjean Lapierre[1], F. Brisebois[1], D. Creely[2], D. Pincus[2], S. Dufresne[3], J-M. Leduc[1]; [1]Hosp. Sacré-Coeur de Montréal, Montreal, QC, Canada, [2]BioMérieux, Hazelwood, MO, [3]Hosp. Maisonneuve Rosemont, Montreal, QC, Canada

Abstract Body:

Background: *Aerococcus urinae* is an increasingly recognized urinary pathogen. The objective of this study was to compare Kirby-Bauer (KB) disk diffusion, broth microdilution (BMD) and E-Test™ methods for *A. urinae* antimicrobial susceptibility testing (AST). **Methods:** This study included 47 *A. urinae* isolates from urinary tract clinical samples. Identification was confirmed by ribosomal 16S RNA gene sequencing. Thirteen antibiotics including those recommended by newly introduced Clinical Laboratory Standard Institute (CLSI) M-45 guidelines were tested. KB disk diffusion, BMD and E-Test™ were respectively performed according to CLSI M02-A12, CLSI M-45 and manufacturer's instructions. BMD and E-Test™ interpretation was based on CLSI M-45 susceptibility breakpoints.**Results:** Applying CLSI breakpoints to E-Test™ results, all isolates were susceptible to cefotaxime, meropenem, vancomycin and linezolid. Thirty-six isolates were resistant to trimethoprim-Sulfamethoxazole (TMP-SMX), 2 to ciprofloxacin, 2 to tetracycline and 2 to levofloxacin. KB disk diffusion and E-Test™ MICs correlation was analyzed as E-Test™ MICs and susceptibility categories were stratified for every KB inhibition zones. Isolates with non-susceptible MICs by E-Test™ presented the following KB inhibition zone intervals; penicillin 30-36 mm, ceftriaxone 30 mm, tetracycline 0-12 mm, ciprofloxacin 0-28 mm, levofloxacin 0-15 mm and TMP-SMX 0-20 mm.Concordance between E-Test™ and BMD could only be assessed for a subgroup of 8 isolates. All isolates were uniformly susceptible to penicillin, cefotaxime, ceftriaxone, meropenem and vancomycin. Both methods reported the same unique isolate as resistant to tetracycline. For levofloxacin, TMP-SMX and linezolid respectively 2, 1 and 1 isolates were reported as susceptible by E-Test™ and resistant by BMD. Also, for TMP-SMX, 4 isolates were reported as resistant by E-Test™ and susceptible by BMD.**Conclusions:** It is possible to perform E-test™ for *A. urinae* using a blood-containing medium. However, when considering CLSI M-45 guidelines' BMD as a gold standard, applying the same breakpoints to E-Test™ AST on MHB can lead to major and very major errors regarding TMP-SMX, levofloxacin and linezolid.

Instantaneous Antimicrobial Susceptibility Testing (AST) Using Piezoelectric Plate Sensors

Author Block:

X. Xu[1], C. L. Emery[2], B. Sen[1], K. Krevolin[2], S. G. Joshi[1], W-H. Shih[1], W. Y. Shih[1]; [1]Drexel Univ., Philadelphia, PA, [2]Drexel Univ. - Hahnemann Univ. Hosp., Philadelphia, PA

Abstract Body:

Background: MALDI-TOF mass spectrometry has revolutionized the clinical microbiology laboratory by generating definitive bacterial and yeast culture isolate identifications within minutes, however FDA-approved automated phenotypic AST methods still require at least 8 additional hours to generate AST results. We developed a novel patent-pending rapid phenotypic AST method using low cost piezoelectric plate sensors (PEPS) that generates virtually instantaneous AST results.**Methods:** Clinical Laboratory Standards Institute (CLSI)-recommended quality control (QC) strains used for AST (*S. aureus* ATCC 29213, *E. coli* 25922, *E. coli* 35218) and *S. aureus* ATCC BAA-1026 (MRSA) were tested against various antibiotics using PEPS rapid AST. Strain suspensions were standardized to a 0.5 McFarland prior to testing. Minimum inhibitory concentration (MIC) results obtained for each strain/antibiotic combination tested using PEPS rapid AST were compared to the modal MIC result (or breakpoint MIC value range) obtained using the VITEK$^{@}$2 (each strain tested in quintuplicate) and the modal MIC result obtained using the E-test method (each strain tested in triplicate). Broth microdilution testing was used to confirm discrepant results.**Results:** For all three CLSI-recommended QC strains, PEPS rapid AST MIC results correlated well (100% essential agreement) with VITEK modal MICs (or breakpoint MIC ranges), and with E-test MICs (83% essential agreement); 100% interpretive categorical agreement was achieved among PEPS rapid AST results and VITEK and E-test results, and all PEPS rapid AST results fell within published CLSI QC strain MIC ranges. For *S. aureus* ATCC BAA-1026 (MRSA), PEPS rapid AST MIC results correlated well (100% essential agreement) with VITEK modal MICs (or breakpoint MIC ranges), and with E-test MICs (100% essential agreement); 100% interpretive categorical agreement was achieved among all three methods.**Conclusions:** PEPS rapid AST is a novel method that yields virtually instantaneous antibiotic MIC results, and its results correlated well with commonly-used AST methods based on our limited preliminary study. Additional testing of different microbes and antimicrobial combinations is warranted to further assess PEPS rapid AST performance characteristics.

Comparison of *Clostridium difficile* Antimicrobial Susceptibility Testing by Agar Dilution, Broth Microdilution, and Etest Methods

Author Block:

G. Igawa[1], M. Casey[1], E. Sawabe[2], Y. Nukui[2], S. Okugawa[3], K. Moriya[3], S. Tohda[2], R. Saito[1]; [1]Tokyo Med. and Dental Univ., Tokyo, Japan, [2]Med. Hosp., Tokyo Med. and Dental Univ., Tokyo, Japan, [3]The Univ. of Tokyo Hosp., Tokyo, Japan

Abstract Body:

Background: The Clinical Laboratory Standard Institute (CLSI) recommends agar dilution method (AD) for antimicrobial susceptibility testing of *Clostridium difficile*. However, because automation is difficult for the AD and most *C. difficile* clinical isolates are generally susceptible to metronidazole and vancomycin, antimicrobial susceptibility testing is routinely omitted. This study evaluates the performance of broth microdilution method (BMD) and Etest methods in testing the antimicrobial susceptibility of *C. difficile* to metronidazole and vancomycin, by comparing it with the performance of the CLSI recommended AD. **Methods:** Sixty-four non-duplicate *C. difficile* clinical isolates from the Medical Hospital of Tokyo Medical and Dental University were used in this study. The AD was performed according to the CLSI document M100-S24. The BMD was performed with Brucella broth supplemented with vitamin K_1 (1 μg/mL), haemin (5 μg/mL), and 5% laked sheep blood. Etest was conducted according to the manufacturer's instructions with some modifications.**Results:** All three methods showed that all 64 isolates were susceptible to metronidazole and vancomycin. Based on the quality control ranges for *C. difficile* ATCC 700057 according to CLSI, the MICs of metronidazole and vancomycin showed 100% agreement between the AD and BMD. On the other hand, more than 95% agreement in MICs for metronidazole and vancomycin was noted between the AD and Etest, although 4.7% (3/64) had MICs out of the quality control range for metronidazole.**Conclusions:** Our results show that the BMD and Etest are acceptable for routine antimicrobial susceptibility testing of *C. difficile*, as their performances were comparable with that of the AD. In addition, we noted that metronidazole-or vancomycin-resistant isolates are extremely rare in Japan.

Kirby-Bauer-Based Automated Antibiotic Susceptibility Panel Testing for Antibiotic Resistance Determination

Author Block:

C. C. Otto, S. E. Kaplan, T. He, K. A. Gilhuley, E. Babady, S. K. Seo, Y-W. Tang; Mem. Sloan Kettering Cancer Ctr., New York, NY

Abstract Body:

Background: Rapid and accurate phenotypic antimicrobial susceptibility testing (AST) has been shown to improve patient care by decreasing length of stay and mortality. The i2a SIRscan 2000 Automatic is a system that performs automated Kirby-Bauer (KB)-based AST on a panel of user-chosen antibiotics. The use of this system has several benefits over broth microdilution including customizable antibiotic panels and the SIRscan allows for enhanced laboratory automation when used in combination with the i2a plate streaker. Here, we validate the performance of the SIRscan as compared to conventional Microscan AST.**Methods:** A total of 309 consecutive clinical isolates, including Gram-negative rods (GNR) and staphylococci, were collected and tested with Microscan as part of the routine clinical practice. The samples were also tested in parallel with the SIRscan. Results from the two platforms were interpreted as concordant or minor (sensitive-intermediate, intermediate-resistant), major (sensitive, reported as resistant), or very major errors (resistant, reported as sensitive) based on Clinical Laboratory Standards Institute criteria.**Results:** A total of 309 consecutive clinical isolates, including Gram-negative rods (GNR) and staphylococci, were collected and tested with Microscan as part of the routine clinical practice. The samples were also tested in parallel with the SIRscan. Results from the two platforms were interpreted as concordant or minor (sensitive-intermediate, intermediate-resistant), major (sensitive, reported as resistant), or very major errors (resistant, reported as sensitive) based on 2015 Clinical Laboratory Standards Institute (CLSI) interpretive criteria.**Conclusions:** The SIRscan is a platform for automated KB-based AST to test a panel of antibiotics in clinical laboratories. Overall, the SIRscan performed equivalently to Microscan for the majority of the drugs tested. The antibiotics tested on the KB panel are customizable, providing the potential for personalized AST.

Expression of Type 1 Fimbriae in Broad-Host-Range *Salmonella* and Host-Adapted *Salmonella* Serovars

Author Block:

H-C. Lin, C-H. Chang, **K-S. Yeh**; Natl. Taiwan Univ., Taipei, Taiwan

Abstract Body:

Fimbriae are hair-like structures present on the outer membrane of bacteria and are implicated in adherence to the host epithelial cells. Type 1 fimbriae with the binding specificity to mannose residue is the most commonly found fimbrial type in *Salmonella*, a food borne pathogen with public health concern. While previous reports indicated that 80% of *Salmonella* isolates possessed type 1 fimbriae, information regarding the correlation between the specific serovars and the capacity to produce such fimbriae remained limited. Here we would like to test the hypothesis that most of the broad-host-range *Salmonella* serovars like Typhimurium or Enteritidis would possess the capacity to produce type 1 fimbriae, which confer *Salmonella* to trigger intestinal inflammatory response, resulting in shedding *Salmonella* from feces to contaminate the environment. On the contrary, most of the host-adapted serovars such as Choleraesuis may be devoid of this fimbrial antigen and thus cause less of an inflammatory response. The non-fimbriated *Salmonella* may evade the host immune attack and easily enter bloodstream by lowering inflammatory response. In the present study, 187 *Salmonella* strains comprising 68 serovars were screened by yeast agglutination test to detect the expression of type 1 fimbriae in vitro. Our findings revealed that Choleraesuis, Pullorum, Paratyphi A and B, Cerro, Dressau, and Arizonae were the only serovars that were fimbriae-negative (Fim^-), while other serovars including Typhimurium, Enteritidis, Derby, and Albany, just to name a few, produced type 1 fimbriae (Fim^+) when incubated either in static broth, solid agar or both culture conditions. Fimbrial structures from representative strains of Fim^+ and Fim^- groups were also examined by transmission electron microscopy using negative stain. Current results are in line with our argument that a higher percentage of broad-host-range *Salmonella* produce type 1 fimbriae, whereas host-adapted serovars like Choleraesuis and Pullorum would inhibit the expression of this fimbriae. Gain or loss of gene function and/or expression in type 1 fimbriae in different *Salmonella* serovars may be a selective advantage for bacteria to sustain during their spread and growth in diverse host milieu.

Emergence of Ceftriaxone and Ciprofloxacin Non-Susceptible Isolates of Non-Typhoidal *Salmonella enterica* from Nebraska

Author Block:

C. N. Murphy[1], R. C. Fowler[1], A. Williams[2], P. C. Iwen[2], P. D. Fey[1]; [1]U of Neb Med Ctr., Omaha, NE, [2]Neb Publ. Hlth.Lab, Omaha, NE

Abstract Body:

Background: Non-typhoidal *Salmonella enterica* enteritis typically does not require antimicrobial treatment except in systemic infections where fluroquinolones (e.g. ciprofloxacin [CIP]) and expanded-spectrum cephalosporins (e.g. ceftriaxone [CRO]) are recommended as treatment options for adult and pediatric patients, respectively. The purpose of this study was to determine the prevalence and genetic mechanisms associated with CRO and CIP resistance among *Salmonella* isolates collected in Nebraska. **Methods:** Antibiotic resistance rates among human isolates of S*almonella* were monitored as part of an ongoing surveillance program. Isolates were subjected to serotyping and pulsed-field gel electrophoresis. The ARM-D® for ß-Lactamase ID (Streck, Inc.) was used to screen for β-lactamase genes. CIP resistance determinants such as *gyrA*, *gyrB, parC*, *parE*, *qnrS, qnrD, oqxA*, and *oqxB* were screened for by PCR and sequencing. **Results:** From 2010-2014 >1,500 *Salmonella* isolates were submitted for susceptibility testing. Only one of these isolates was non-susceptible to both CRO and CIP. However, in 2015, eight isolates that were non-susceptible to CRO and CIP were isolated. These isolates are members of three different serotypes, Typhimurium (3 isolates), Newport (1 isolate), and 4,[5],12:i:- (4 isolates), and have four unique PFGE patterns. Characterization of these isolates demonstrated that resistance to CRO was due to the presence of either $bla_{\text{CTX-M-15}}$ in 4,[5],12,:i:- isolates or $bla_{\text{CMY-2}}$ in the Newport and Typhimurium isolates. In all but the Newport isolate, no mutations in the quinolone resistance determining region or only a single point mutation in *gyrA* was observed. Screening for quinolone resistance genes demonstrated that the 4,[5],12,:i:- isolates contained *qnrS,* a topoisomerase protection gene, and the Typhimurium isolates contained *oqxAB,* quinolone efflux pump genes. **Conclusion:** These data add to a growing body of literature demonstrating a diversity of resistance mechanisms underlying both fluoroquinolone and expanded-spectrum cephalosporin resistance in the United States. In addition, our study demonstrates that these resistance genes are isolated from a variety *Salmonella* serotypes and backgrounds suggesting rapid horizontal gene transfer within the population.

***Campylobacter* Spp., *Brachyspira* Spp. and *Salmonella* Spp. In Western Jackdaw (*Corvus monedula*) Populations In Finland**

Author Block:

T. T. Nieminen[1], S. M. Kovanen[1], M. Pohja-Mykrä[1], M. Raunio-Saarnisto[2], S. Olkkola[1], R. Kivistö[1], M-L. Hänninen[1]; [1]Univ. of Helsinki, Helsinki, Finland, [2]Finnish Food Safety Authority Evira, Helsinki, Finland

Abstract Body:

Background: During this millennium, western jackdaws have become common in some urban and agricultural surroundings in Finland, which has increased the interest of their potential role as reservoir of certain human and production animal pathogens.**Methods:** We sampled fecal droppings of a total of 212 jackdaws and cultured the droppings for *Campylobacter* spp., *Brachyspira* spp. and *Salmonella* spp., all of which are bacterial pathogens associated with wild birds. Samples were collected in 2014-2015 within a period of five months (September-February) from two rural cities in Finland and represented a total of eight flocks.**Results:** *Salmonella enterica* serovars Typhimurium and Kentucky were isolated from a single flock from three out of seven pooled samples each consisting of fecal material of five to six birds. Altogether 43 pooled samples were collected from the eight flocs. *Brachyspira* spp. was isolated from 112/212 fecal samples (53 %) originating from all eight flocks. Ninety-seven of these isolates were identified by partial 16S rRNA gene sequencing. All of the sequences were nearly identical to that of a tentatively described species "*Brachyspira corvi*" and different from the known pathogenic *Brachyspira* species. *Campylobacter* spp. was isolated from 107/212 fecal samples (50 %) originating from all eight flocs. Multi locus sequence types (MLST) were obtained from 91 *C. jejuni* strains. These were assigned to 63 sequence types of which 46 (74%) were novel to the *Campylobacter* PubMLST database. ST-1339, ST-6442, ST-6460 and ST-6589 have been earlier isolated from human patients in Sweden or The Netherlands. Clonalframe analysis showed that most jackdaw isolates had no common microevolution with other *C. jejuni* STs suggesting that these strains have mainly evolved in jackdaws.**Conclusions:** We conclude that the studied populations of jackdaws could be a source for transmission of salmonella to domestic animals or humans. Most *C. jejuni* ST types detected from jackdaws seem to have evolved with the bird species. Similarly, "*Brachyspira corvi"* is a host-associated sp. that has not been associated with pathogenicity.

Enteropathogenic *E. coli* Multidrug Resistance (Mdr) in a Human Diarrhea and Swine Colonization Interface Model

Author Block:

C. Alpuche[1], E. Tamayo[1], E. Moreno[1], D. Arellano[1], J. Silva[1], F. Tellez[1], F. Mariscal[2], H. Lopez-Gatell[1], V. Richardson[3], F. Hernández[3], R. Medina[3], LESP Group; [1]Natl. Inst. of Publ. Hlth., Cuernavaca, Mexico, [2]SAGARPA, Cuernavaca, Mexico, [3]Human Hlth.Services, Cuernavaca, Mexico

Abstract Body:

Selection of MDR in bacteria, including *E. coli*, is a major pubic health problem and it has been associated to antimicrobial use in the human-animal interface. We determined the frequency and profile of MDR and pathotype markers in *E. coli* isolates from swines colonization and human diarrhea cases in a close surveillance model. Stool samples of every swine in a semitechnified farm in the state of Morelos Mexico, were obtained (April 2015). A focalized, clustered surveillance system of diarrheal disease was developed in paralleled from June-December 2015 in the community surrounding the farm. Conventional microbiology, API 20E and Kirby Bauer test (CLSI) were used for bacteria and antimicrobial susceptibility detection. Three colonies suggestive of *E.coli* were collected per sample for further characterization. Enteropathogenic *E. coli* was detected by multiplex PCR. Stool cultures of 280 pigs and 186 human diarrhea cases, were obtained; 821 and 510 *E. coli* were isolated from pigs and humans respectively. MDR was identified in 286/821 (34.8%) isolates in the swine group and 11.2% of these were enteropathogenic (23 EPEC, 1 EPEC/EHEC, 1 ETEC and 7 EHEC); 19/280 pigs were colonized with enteropathoghenic MDR *E. coli*. The main MDR profile detected in pigs, were resistance to AMP-SXT-NAL-CIP (75%). In the human isolates, 149/510 (29.2%) were MDR and 27.5% were enteropathogenic (13 EPEC, 13 DAEC, 7 EAEC, 5 ETEC, 2 EHEC and 1 EIEC). Two main profiles of MDR enteropathogenic *E.coli* were detected in the human isolates: AMP-SXT-NAL (78%), and AMP-SXT-NAL-CIP-CAZ (14.6%). MDR enteropathogenic *E. coli* was associated to 28% of diarrhea cases with a stool culture positive for enteric bacteria. These results support that swine are a potential reservoir for MDR enteropathogenic *E. coli*. Antimicrobial resistance such as AMP and SXT are broadly selected either in the *E. coli* colonizing swine or those causing human diarrhea; CIP resistance was higher in the swine isolates but CAZ resistance seems to be selected only in the human isolates. Further genetic characterization will allow to define the spread of same clonal strains between human and swine populations in this study.

Up-Regulation of Immuno-Regulatory Genes by Bcg Vaccine

Author Block:

N. T. Iqbal, K. Ahmed, J. Samad; Aga Khan Univ., Karachi, Pakistan

Abstract Body:

Background: Pakistan has more than 90% coverage of BCG vaccine through Extended Program on Immunization (EPI). As per schedule, BCG is administered in neonates during first month of life. BCG does not confer protection against transmissible form of tuberculosis. However, BCG provides additional benefits to young infants in the form of immune surveillance. This nonspecific immune surveillance has been evidenced in bladder and melanoma cancers where BCG vaccine is used as immunotherapeutics. The immune surveillance mechanism of BCG is thought to be mediated by cell wall components that activate TLRs present on antigen presenting cells, which activates inflammatory cascade and provide maturation signals for immune cells. Among several immunomodulatory genes, BCG up-regulates co-stimulatory genes belong to Butyrophilins (BTN) family which are structurally similar to B7 molecule. The aim of this study was to understand the mechanism of immune surveillance of BCG by activation of innate and adaptive genes in BCG vaccinated subjects. We studied Butyrophilin (BTN3A2), Granzyme and TNFa gene in BCG vaccinated healthy controls (n=9). **Methods:** We stimulated PBMCs with BCG vaccine (MOI 1) at 24 hrs for expression of BTN gene (BTN3A2), TNFα and TLR4 genes using q-RTPCR (SYBR green, Biorad labs, Hercules CA, USA) from healthy donors. Two step q-RT PCR was performed after RNA extraction through Trziole using CDNA and q-RT PCR protocol as per manufacture instructions. **Results:** We found a 3-7 fold higher induction in BTN3A2 and TNFα genes using BCG compared to un-stimulated media control. The fold changes were calculated after normalization of target genes with housekeeping gene. **Conclusions:** Our results show an increase expression of BTN3A2 (2 fold), and TNFα (2-7 fold) gene in healthy controls. The differential expression of BTN3A2 gene will be further confirmed in BCG vaccinated and non-vaccinated healthy donors. **Funding resource:** AKU Seed money project **ERC**: *2885-BBS-ERC-14*1

Lipid and Protein Profiles in Tuberculous Patients on Anti-Tuberculosis Therapy

Author Block:

C. N. N. Nwadike; Imo State Univ. Owerri, Imo State Nigeria, Owerri, Nigeria

Abstract Body:

AbstractThe present study assessed the serum lipid and protein profiles of Pulmonary Tuberculosis (TB) patients on Anti-Tuberculosis therapy in Owerri, Imo State ,Nigeria.The subjects were divided into four groups, comprising of 105 apparently healthy adults, 50 newly diagnosed TB patients, 50, three months post treatment TB patients and 50 six months post treatment TB patients, respectively. Serum fasting lipids and protein profiles of these subjects were analyzed, using standard methods.Serum levels of total cholesterol (TC), Triglyceride (TG), HDL and albumin, were significantly reduced in newly diagnosed TB patients than in other group, ($P<0.05$), but showed significant increase after treatment, in exception of TG. Globulin and LDL increased significantly in newly diagnosed patients, as compared to the control and other groups.These findings suggest that hypocholesterolaemia and hypoalbulminaemia are of diagnostic importance in pulmonary tuberculosis and could also assist in assessing the progress of treatment.

Factors Associated with Successful Screening for Latent Tuberculosis Infection with the Interferon Gamma Release Assay in an Urban Hiv Clinic

Author Block:

A. Andrews[1], J. Adams[2], S. Varghese[1], **C. Vinnard**[1]; [1]Drexel Univ. Coll. of Med., Philadelphia, PA, [2]Brown Univ., Providence, RI

Abstract Body:

Background: National guidelines recommend screening for latent tuberculosis infection (LTBI) in all HIV-infected patients, with either tuberculin skin testing (TST) or interferon gamma release assays (IGRAs) as acceptable testing methods. We sought to determine the rates of successful LTBI screening in an urban HIV clinic following the adoption of IGRA-based testing as the preferred screening method in 2012.**Methods:** We conducted a retrospective study of 178 new patients enrolled in the Partnership Comprehensive Care Practice, the largest HIV clinic in the Philadelphia region, between January 1, 2013 and December 31, 2013. We collected data regarding demographics, CD4+ T cell counts, viral load, and receipt of antiretroviral therapy (ART). We hypothesized that patients with lower CD4 T cell counts would be less likely to receive LTBI screening within one year, given the competing needs of the provider to address barriers to ART and then initiate therapy. We performed multivariate logistic regression to examine the association of CD4+ T cell counts with LTBI screening, adjusting for potential confounders.**Results:** Among 178 patients new to the clinic, 93 (53%) had no discussion of LTBI within the first year of follow-up. In an additional 17 (10%) patients, LTBI screening was discussed by the provider but not performed. Among the remaining 68 patients, 12 (7%) had documentation from another clinic demonstrating a negative test for LTBI, and 56 (31%) had an IGRA test performed during the first year in the clinic (all were negative). In an adjusted analysis, we found that patients with high CD4+ T cell counts (>1000 cells/uL) were least likely to have successful LTBI screening performed (aOR 0.12, 95% CI 0.02, 0.54), compared with patients with CD4+ T cell counts under 350 cells/uL.**Conclusion:** Less than half of patients new to our HIV clinic received LTBI screening within the first year of follow-up. Contrary to our hypothesis, patients in the highest tier of CD4+ T cell counts were least likely to have LTBI screening performed during the first year of follow-up. There were no positive IGRA tests out of 56 performed. Future work will compare LTBI screening rates before and after the conversion from TST to IGRA based testing.

Urine Colorimetry to Detect Low Rifampin Exposure During Tuberculosis Therapy: A Proof-of-concept Study

Author Block:

I. Zentner[1], H. P. Schlecht[1], L. Khensouvann[2], N. Tamuhla[3], M. Kutzler[1], V. Ivaturi[4], J. Pasipanodya[5], T. Gumbo[5], C. A. Peloquin[6], G. P. Bisson[7], **C. Vinnard**[1]; [1]Drexel Univ. Coll. of Med., Philadelphia, PA, [2]Genomind, Inc, King of Prussia, PA, [3]Botswana-Upenn Partnership, Gaborone, Botswana, [4]Univ. of Maryland, Baltimore, Baltimore, MD, [5]Baylor Inst. for Immunology Res., Dallas, TX, [6]Univ. of Florida, Gainesville, FL, [7]Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Background: We sought to determine whether urine colorimetry could have a novel application as a form of therapeutic drug monitoring during anti-TB therapy.**Methods:** Among healthy volunteers, we evaluated 3 dose sizes of rifampin (150 mg, 300 mg, and 600 mg), performed intensive pharmacokinetic sampling, and collected a timed urine void at 4 hours post-dosing. The absorbance peak at 475 nm was measured after rifamycin extraction. The optimal cutoff for the colorimetric urine assay was evaluated in a study of 39 HIV/TB patients undergoing TB treatment in Botswana, based on a receiver-operating-characteristic (ROC) curve.**Results:** In the derivation study, a urine colorimetric assay value of 4.0 x 10-2 Abs, using a timed void 4 hours after dosing, demonstrated a sensitivity of 92% and specificity of 60% to detect a peak rifampin concentration (Cmax) under 8 mg/L, with an area under the ROC curve of 0.92. In the validation study among HIV/TB patients in Botswana, this cutoff was specific (100%) but insensitive (28%). We observed similar test characteristics for a target Cmax target of 6.6 mg/L, and a target area under the drug concentration-versus-time curve (AUC0-8) target of 24.1 mg•hour/L (Figure).**Conclusions:** The urine colorimetric assay was specific but insensitive to detect low rifampin serum concentrations among HIV/TB patients.

Causes Of Death In Hiv-Infected Patients In The Va Loma Linda Healthcare System

Author Block:

M. McCormick[1], L. Strnad[2], W. Brown[3], J. Cho[1], H. San Agustin[4], G. Aung[4], M. Ing[4]; [1]Loma Linda Univ., Loma Linda, CA, [2]Univ. of California San Francisco, San Francisco, CA, [3]Univ. of Utah, Salt Lake City, UT, [4]Loma Linda VA Med. Ctr., Loma Linda, CA

Abstract Body:

Background: As antiretroviral therapy has improved in efficacy and accessibility, primary causes of death in the HIV population are shifting from AIDS-related complications towards chronic disease-related deaths[1]. The VA medical system treats a unique subset of patients with risk factors differing from the general population. We aimed to identify primary causes of death and note various epidemiological and clinical associations among a population of HIV-positive veterans at a single VA medical center.**Methods:** We conducted a retrospective chart review for 156 HIV-positive patients of the Loma Linda VA Medical Center who died between 2000-2014. The specific cause of death was aggressively pursued including obtaining death certificates when death summaries and inpatient notes were unavailable. Cause of death data were categorized using a standardized case report form from the Coding Causes of Death in HIV (CoDe) project[2]. Other analyzed data included demographics, lab studies, comorbidities, and substance use history.**Results:** AIDS-related deaths accounted for 21.8% of the 156 total deaths. Cardiovascular (19.9%), non-AIDS malignancy (16.0%), and accidental/violent deaths (14.7%) were notable contributors in the remaining 78.2%. AIDS-related deaths per year decreased steadily from 45.5% in 2000 to 0% in 2010-2013 with an increase to 22.2% in 2014. At the time of death, 48% of subjects were actively smoking, 32% had active drug or alcohol abuse, and 55% had documented psychiatric diagnoses. Further statistical analysis is pending.**Conclusions:** The percentage of AIDS-related deaths is within the range reported by prior HIV-mortality studies. The high percentage of accidental and violent deaths may be related to the prevalence of substance abuse and psychiatric disease among this population. Furthermore, a high smoking prevalence may contribute to the rates of malignancy and cardiovascular related deaths. An HIV-positive VA population may require increased access to psychiatric support and addiction treatment, and HIV providers may require additional training in these domains.

Serological and Molecular Surveillance for Influenza A Virus in Dogs and Their Owners in Oyo State, Nigeria

Author Block:

D. O. Oluwayelu, O. B. Daodu, A. I. Adebiyi; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: The close interaction of dogs with humans coupled with their possession of specific receptors for human and avian influenza viruses provide opportunities for cross-species virus transmission, thus posing a threat to human health. In Nigeria, there is an upsurge in the acquisition of exotic and local dogs as pets accompanied by increased bonding between the dogs and their owners. Moreover, Nigerian game hunters traditionally enjoy a close association with their dogs. Therefore, the objective of this study was to detect the presence of antibodies against influenza A virus (IAV) in dogs, as well as the presence of RNA of IAV in nasal swabs of dogs and their owners, and thereby assess the possible transmission of the virus between humans and dogs.**Methods:** Sera from 239 apparently healthy pet and hunting dogs in Oyo state, Nigeria were screened for IAV antibodies using competition ELISA while haemagglutination inhibiting (HI) antibodies were detected using canine influenza virus (CIV) H3N8 antigen. Suspensions prepared from 239 and 39 nasal swabs from dogs and their owners, respectively were tested for presence of IAV RNA by RT-PCR.**Results:** The ELISA revealed that 1.7% (4/239) and 4.6% (11/239) of the dog sera were positive and doubtful for IAV antibodies, respectively while 1.9% and 1.2% seroprevalence was obtained for hunting and pet dogs, respectively. HI test to confirm presence of CIV H3N8 antibodies in the ELISA-positive and doubtful sera showed that a sample each was positive with HI titre of 1:128 and 1:64, respectively. All the nasal swabs assayed by RT-PCR were negative for IAV nucleic acid.**Conclusions:** This study provides serologic evidence of IAV infection in pet and hunting dogs which are major companion animals of humans. Although at a low prevalence, this finding suggests that dogs may serve as source of transmission of novel influenza viruses to humans in Nigeria. Continuous surveillance for IAV among dog populations in Nigeria is recommended to facilitate early detection of emergent IAV strains that could be potentially harmful for humans and or animals.

Antibacterial Action of Copper Plus Blue Light

Author Block:

J. M. PISCIOTTA, N. Russo; West Chester Univ., West Chester, PA

Abstract Body:

Waterborne illnesses are a major cause of mortality and morbidity and novel, low cost water treatment options are needed. Copper has known antibacterial properties and is relatively low cost. However, the EPA limits the concentration of copper ion permissible in drinking water to 1.3 ppm. Our preliminary testing indicated that 1.3 ppm copper was insufficient to inhibit diverse species of waterborne bacteria and thus would not be an efficient means of low cost wastewater treatment. Accordingly, the goal of this research was to test the hypothesis that blue light, recently found to possess antimicrobial properties, can bolster the efficacy of low dose copper ions present in water at below EPA threshold levels. Visible blue light, from 400-500nm, has recently been found to exert anti-microbial effects against diverse species including *Pseudomonas aeruginosa* and *Staphylococcus aureus* (MRSA). Here, *E. coli, P. aeruginosa, S. typhimurium, S. aureus* and *B. subtilis* were grown on LB agar with or without copper and variable exposures of blue light to ascertain if the dual treatments could additively or synergistically inhibit bacteria at EPA allowable levels of copper in the treated water. All species had reductions of ~20% with copper treatment alone. Consistent with prior published studies, *P. aeruginosa* was the only species to show sensitivity to blue light alone. Synergistic reductions using copper plus blue light were evident after 10 min, 30 min, and 45 min for *P. aeruginosa, E. coli,* and *S. typhimurium* respectively. Gram positive microbes were relatively less susceptible than were the gram negatives tested. These results indicate low-dose copper plus blue light exposure can provide a safe, low cost means of targeting Gram negative pathogens during water treatment.

Epidemiology, Impact, Prevention & Control of Nipah Encephalitis in Bangladesh: A Systematic Review

Author Block:

M. Asaduzzaman, S. Mahmood; Inst. of Epidemiology,Disease Control and Res.(IEDCR), Dhaka, Bangladesh

Abstract Body:

Background: Nipah virus poses an eminent threat in Bangladesh as it encounters almost yearly outbreak since 2001.So,comprehensive understanding of the disease is of paramount importance for public health professionals due to high case fatality as well as person to person transmission. The objective of this systematic review is to summarize the coherent understanding of the disease.**Method:** We searched three different databases- PubMed, Web of Science & Google Scholar using different search term as appropriate for those databases mixing the Boolean operators that yielded 144, 113 & 1530 articles respectively. We screened the titles first for relevance & later abstracts. 47 articles met our criteria & were finally reviewed. A literature matrix was formed in Excel for compilation & analysis.**Results:** Nipah outbreaks in Bangladesh were different compared to initial outbreak in Malaysia in 1999. Unlike Malaysian outbreak, person to person transmission occurred in Bangladesh. Infections were reported in domesticated pigs, dogs, cats in South Asia & serological study in Bangladesh showed 6.5%, 4.3% & 44.2% seroprevalence in cattle, goat & pig respectively. *Pteropus* bat plays key role in Nipah transmission & risk factors include drinking raw date palm sap contaminated with bat urine or faeces, eating half-eaten bat saliva laden fruit & close contact or involvement in burial of cases. As date palm sap is harvested during winter, Nipah outbreaks occurred during this season. Nipah occurred mostly within the “Nipah belt” & had a high case fatality of more than 70%. Avoiding raw date palm sap & drinking sap from trees protected with bamboo skirt or “bana” remain the principle preventive measures along with strict infection control in hospitals for prevention of secondary cases.**Conclusion:** Nipah encephalitis is an emerging zoonosis and extensive knowledge of the disease is the key for prevention and saving lives. Community sensitization and multidisciplinary action through One Health approach can prevent this deadly disease especially in outbreak areas where date palm sap consumption is a delicacy.

2-Aminoimidazole Based Small Molecule Compound Potentiates Bactericidal Activity of ß-Lactam Drugs against *Mycobacterium tuberculosis*

Author Block:

A. B. Jeon[1], D. Ackart[1], A. Obregon-Henao[1], B. Podell[1], J. Belardinelli[1], M. Jackson[1], R. Melander[2], C. Melander[2], R. Basaraba[1]; [1]Colorado State Univ., Fort Collins, CO, [2]North Carolina State Univ., Raleigh, NC

Abstract Body:

Controlling the global spread of tuberculosis (TB) continues to be a challenge due in part to the lack of new anti-TB drugs and the emergence of drug-resistant *Mycobacterium tuberculosis* (*Mtb*). Despite the proven efficacy of ß-lactam drugs against bacterial pathogens, these drugs have no practical clinical use in the treatment of TB owing to the expression of inherent resistance by *Mtb*. Previously, our group have shown the ability of 2-aminoimidazole (2-AI) based small molecules to reverse both phenotypic drug tolerance and genotypic drug resistance in a variety of different microorganisms. Based on the mode of action demonstrated in other bacterial species, we hypothesized that 2-AI would reverse inherent resistance of *Mtb* against ß-lactam drugs either by inhibiting ß-lactamase enzyme activity or affecting cell wall integrity. For determination of bactericidal capacity of ß-lactam drugs against *Mtb*, *Mtb* H37Rv was treated with sub-minimum inhibitory concentrations of carbenicillin (4 and 64 µg/µL), amoxicillin (4 and 64 µg/µL), cefotaxime (2 and 32 µg/µL) and meropenem (0.0625 and 1 µg/µL) in the presence or absence of 2-AI compounds (62.5 and 125 µM). All four drugs tested showed improved bactericidal capacity when used in combination with 2-AI compounds as determined by colony forming units (CFUs) of cultures. For assessment of ß-lactamase activity, *Mtb* cultures in mid-log phase growth were treated with 2-AI compounds (62.5 and 125 µM) for 3 and 24 hrs and ß-lactamase activities were measured by colormetric assay using nitrocefin. *Mtb* cultures treated with 2-AI compounds had reduced ß-lactamase activity in both time points (3 and 24 hrs) tested. Finally, we evaluated cell wall integrity by measuring sensitivity to membrane disrupting agent SDS. *Mtb* cultures treated with 2-AI compounds (62.5 and 125 µM) for 24 hrs were exposed to 0, 0.1, and 0.05% SDS for 0, 1, and 4 hr. Percent survivals after exposure were determined by CFUs. Decreased survival rates over the course of the experiment were observed in 2-AI treated cultures compared to non-treated cultures. These data suggest that 2-AI based small molecules may be effective at reversing inherent drug resistance of *Mtb* to ß-lactam drugs.

Effect of Drug Resistance and Lineage of *Mycobacterium tuberculosis* on the Outcome of HIV-Positive and HIV-Negative Patients of Tuberculous Meningitis

Author Block:

M. Sharma, K. Sharma, M. Modi, A. Sharma, S. Varma; PGIMER, Chandigarh, India

Abstract Body:

Background: Most common and most fatal presentation of neurotuberculosis in Indian subcontinent is tuberculous meningitis (TBM). Little is known about the effect of HIV, drug resistance and bacterial lineage on patient outcome in TBM patients. Therefore, the present study was undertaken to evaluate the effect of drug resistance and bacterial lineage on the outcome of HIV positive and HIV negative patients of TBM from North-India.**Methods:** Genotypic profiling using 24-loci MIRU-VNTR was conducted on 30 (8 HIV-positive patients, 22-HIV negative patients) cerebrospinal fluid culture isolates of *M. tuberculosis*. Drug susceptibility was performed by MGIT-960. All patients were followed up for minimum three months after completion of ATT.**Results:** Out of 8 HIV + culture isolates, 3/8 (37.5%) were MDR and 5/8 (62.5%) were drug sensitive. Mycobacterial lineages in drug resistant isolates were Beijing type 2/3(66.6%) and CAS type 1/3 (33.3%), respectively. All the MDR cases in HIV positive patients had poor outcome. Among 22 HIV negative culture isolates, 3/22 (13.66%) were MDR and isolated DR was observed in 5/22 (22.77%). Out of 3 MDR HIV negative isolates 2 belonged to CAS type and one was Beijing type. Out of 5 mono-resistant cases, 3 were CAS, 1 was EAI and 1 was Haarlem type. Among the 14 DS HIV negative cases, 6/14 were CAS, 5 were EAI, 2 were Haarlem and one was untypable. Unfavorable outcome was observed in more than 87.5% patients with drug-resistant and in less than 30% patients with drug-susceptible profile. Among resistant strains, outcome was poor in isolates belonging to lineages of CAS and Beijing. The worst and the best outcomes were with CAS and Haarlem lineages, respectively, irrespective of the drug susceptibility profile and HIV status.**Conclusions:** Multidrug resistance, lineage of *M. tuberculosis* and HIV status are important determinants of mortality in patients of TBM. Targeting these factors can contribute to a favorable outcome.

Publishing Title:

Sequence Analysis for Detection of Drug Resistance in *Mycobacterium tuberculosis* Complex Isolates from the Central Region of Cameroon

Author Block:

J. ASSAM; Univ. OF DOUALA, DOUALA, Cameroon

Abstract Body:

The potential of genetic testing to rapidly diagnose drug resistance has lead to the development of new diagnostic assays. However, prior to implementation in a given setting, the association of specific mutations with specific drug resistance phenotypes should be evaluated. The purpose of this study was to evaluate molecular markers in predicting drug resistance in the Central Region of Cameroon. From April 2010 and March 2011, 725 smear positive pulmonary tuberculosis patients were enrolled and all positive cultures were tested for drug susceptibility. A total of 63 drug resistant and 100 drug sensitive Mycobacterium tuberculosis complex clinical isolates were screened for genetic mutations in katG, inhA, ahpC, rpoB, rpsL, rrs, gidB and embCAB loci using DNA sequencing. Of the 44 isoniazid resistant (INHR) isolates (24 high level, 1 μg/ml and 20 low level, 0.2 μg/ml), 73% (32/44) carried the katG315 and/or the −15 inhA promoter mutations. Of the 24 high level INHR, 17 (70.8%) harbored katG315 mutation, 1 a point mutation (−15C→T) in the inhA promoter and 6 were (25.0%) wild types. Thus, for INHR high level detection, katG315 mutation had a specificity and a sensitivity of 100% and 70.8% respectively. Of the 20 low level INHR, 10 (50.0%) had a −15C→T mutation in the inhA promoter region, and 1 (2.2%) a −32G→A mutation in the ahpC promoter region. All of the 7 rifampicin resistant (RIFR) isolates carried mutations in the rpoB gene (at codons Ser531Leu (71.4%), His526Asp (14.3%), and Asp516Val (14.3%)). Of the 27 streptomycin resistant (SMR) isolates, 7 carried mutations at the rpsL and the gidB genes. 1 of the 2 ethambutol resistant (EMBR) isolates displayed a mutation in embB gene. This study provided the first molecular investigation assessing the correlation of phenotypic to genotypic characteristics on MTB isolates from the Central Region of Cameroon using DNA sequencing. Mutations on rpoB, katG315 and −15 point mutations in inhA promoter loci could be used as markers for RIF and INH -resistance detection respectively.

Adverse Events of Anti-Tuberculosis Drugs in Hiv Co-Infected Tb Patients; Earlier and Higher Occurrence Than in Hiv-Uninfected Patients

Author Block:

T. Matono, T. Nishijima, K. Teruya, E. Morino, J. Takasaki, H. Gatanaga, Y. Kikuchi, S. Oka; Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan

Abstract Body:

Background: Tuberculosis (TB) drug-related adverse events (AEs) are common in HIV-infected TB patients (HIV/TB). However, the details and timing of AE occurrence are unknown. This study was aimed at evaluating first-line anti-TB drug-associated AEs in HIV/TB patients. **Methods:** This nested case-control study was conducted in Tokyo, Japan, between 2003 and 2015. The cases included HIV-infected culture-proven TB patients who were administered standard first-line anti-TB drugs. Controls were age- and sex-matched HIV-uninfected TB patients (non-HIV/TB) randomly selected from the same years as the patients with one-to-four ratio. Moderate-to-severe AEs of anti-TB drugs were defined as those with grade 2 or more which required drug discontinuation or regimen change. The groups were compared using Chi-square (χ^2) or Fisher test for nominal variables and Mann-Whitney test for continuous variables.**Results:** HIV/TB cases (94) and non-HIV/TB controls (376) were analyzed. For HIV/TB, the median age was 39 (interquartile range [IQR] 32–47) years, 95% were men, and 16% received antiretroviral therapy (ART), with a median CD4 count of 117 (IQR 51–226)/μl; isoniazid (INH) + rifampin (RIF)/rifabutin (RFB) + pyrazinamide (PZA) + ethambutol (EMB) was initiated in 91% cases. Intergroup differences in treatment regimen were insignificant. HIV/TB cases had a higher frequency of extrapulmonary TB (67% vs 28%; $p < 0.001$) and multidrug-resistant (MDR)-TB (4% vs 1%; $p = 0.016$), and a longer total treatment duration (median 12 [IQR 9-12] vs 6 [IQR 6-9] months; $p < 0.001$). AEs of anti-TB drugs were more frequent in HIV/TB (51% vs 11%; $p < 0.001$), mainly, fever (19% vs 1%; $p < 0.001$), rash (11% vs 3%; $p = 0.024$), and neutropenia (12% vs 1%; $p < 0.001$). Moreover, the time to AE from anti-TB drug initiation was shorter in the HIV/TB (median 17 [IQR 12-28] vs 26 [15-58] days; $p = 0.017$). Intergroup differences in all-cause mortality were insignificant (3% vs 2%; $p = 0.442$).**Conclusions:** Moderate-to-severe anti-TB drug AEs, mainly fever, rash, and neutropenia, occurred more commonly and earlier in HIV/TB than in non-HIV/TB patients. This frequent and early AEs of anti-TB drugs in HIV/TB may delay ART initiation.

Rapid Detection of Rpob Mutations Associated with *Mycobacterium tuberculosis* in Lagos, Nigeria

Author Block:

L. O. Efere; Nigeria Inst. of Med. Res., Lagos, Nigeria

Abstract Body:

Background: Rifampicin (RIF) is a major drug used in the treatment of tuberculosis (TB) disease and is considered a surrogate marker for multi drug resistant Tuberculosis (MDR-TB). The nature and frequency of mutations in the *rpoB* gene which accounts for majority of Rifampicin (RIF) resistance in *Mycobacterium tuberculosis* complex (MTBC) varies considerably between different geographical regions.This study determined the predominant *rpoB* gene mutations associated with RIF resistance in MTBC. **Method:** Mutation on the *rpoB* gene region conferring resistance to RIF was assessed in 164 smear positive sputum specimens using the line probe assay (Genotype MTBDRplus®) technique. The test involved deoxyribonucleic acid(DNA) extraction from the decontaminated sputum specimens, multiplex polymerase chain reaction amplification and reverse hybridization step. Resistance was interpreted based on the absence of at least one of the wild type probes and or the presence of one of the mutant genes of the *rpoB* gene. **Result:** 161(98.2%) Of the 164 specimens were identified as MTB complex while 3(1.8%) were non MTB complex. 119(73.9%) were resistant to rifampicin, which includes multidrug resistance tuberculosus (MDR-TB) while 40(24.8%) were sensitive. Mutant 3 gene (Mut 3) accounted for 90(75.6%) resistant strain, Mutant 1 gene(Mut1) 8(6.7%), Mutant 2A gene(Mut2A) 8 (6.7%), while 13(11.0%) showed no mutations. **Conclusion:** A high percentage of RIF resistance was associated with mutant 3 gene (MUT3). This characterizes the RIF resistance *Mycobacterium tuberculosis* associated with this environment, and can serve as a basis for developing or improving rapid molecular diagnostics for detection of RIF resistance in this setting.

Genotypes and Drug Susceptibility Pattern of *Mycobacterium tuberculosis* Isolates in Hiv Seropositive Patients

Author Block:

J. SINGH[1], N. Singh[2], U. Aggarwal[2], S. Singh[1]; [1]All India Inst. of Med. Sci., New Delhi, India, [2]Natl. Inst. of TB and RD, New Delhi, India

Abstract Body:

Objectives: The molecular data obtained from the *M. tuberculosis* so far in India have not addressed the issue of HIV-TB co-infected patients. Therefore, we aimed to investigate the spoligotyping and 24 loci MIRU-VNTR based population structure of *M. tuberculosis* clinical isolates in HIV-TB co-infected patients in a tertiary care setting. **Materials and Methods**: A total of 249 HIV positive patients, suspected of tuberculosis were recruited in this study. All the samples obtained were decontaminated using N-acetyl-L-cystine/ Sodium hydroxide (NALC-NaOH) method and were inoculated in BACTEC MGIT 960 as well as on LJ medium. Drug Sensitivity testing was done by using SIRE kit (Becton & Dickinson, USA). DNA for genotyping from positive cultures was extracted using QIAGEN kit. Spoligotyping was performed using a commercially available kit (M/s Ocimum Biosolutions) while 24 loci MIRU-VNTR was performed by PCR amplification of individual loci using specific primers as described previously (**Supply et al 2006)**. **Results:** From 249 samples, 120(49.3%) strains were isolated. All of them were subjected to genotype and drug susceptibility. On genotyping of HIV co-infected MTB isolates revealed that 120 strains were grouped in 23 numbers of Shared types (ST) representing 9 major clades and 10 sub-clades. CAS (46.7%) clade was most prevalent, followed by Beijing (22.5%), EAI(10.8%), LAM (5.0%), T-clade (5.8%),U (5.8%), X(1.6%), Manu(0.8%) and 0.8% strains were from Cameroon lineage. Among the CAS family, 45(80.3%) isolates of CAS1_DEL sub-family (ST26) was the most predominant. Highly discriminant HGDI was observed in miru10, miru16, miru26, miru31, miru40, Mtub04, Mtub21, Mtub30, QUB26, QUIB4156, ETR-A, ETR-C. Seventy Seven isolates (64.2%) were susceptible to all four drugs; 9(7.5%) were resistant to at least one drug; 30(25%) were Multi drug resistant TB (MDR-TB) strains and 4(3.3%) were dual drug resistant cases. Among the 30 MDR-TB isolates, 15 (50%) isolates were Beijing family strains and remaining 15(50%) were from CAS, EAI, LAM, T and U families which is statistically significant. **Conclusion:** CAS was the most prevalent strain among HIV-TB co-infected patients . Drug resistance rate was high in Beijing family strains.

Phenotypic and Genotypic Determination of Drug Susceptibility and Molecular Characterization of *Mycobacterium tuberculosis* Isolates at Debre Berhan Referral Hospital, Ethiopia: A Cross Sectional Study

Author Block:

D. G. Weldehana[1], S. K. Biru[2], S. Habtemariam[3]; [1]Wollo Univ., Coll. of medicine and Hlth. Sci.s, Dessie, Ethiopia, [2]Addis Ababa Univ., Coll. of medicine and Hlth. Sci.s, Addis Ababa, Ethiopia, [3]Addis Ababa Univ., Aklilu Lemma Inst. of pathobiology, Addis Ababa, Ethiopia

Abstract Body:

Background: Globally, *Mycobacterium tuberculosis* is the leading cause of death from a single infectious disease and it is a major public health problem in Ethiopia. Multidrug-resistant tuberculosis poses a formidable challenge to control tuberculosis due to its complex diagnostic and treatment challenges. The main aim of the study is to investigate the molecular epidemiology of mycobacterial isolates and to characterize drug susceptibility pattern phenotypically and genotypically**Methods:** Sputum samples were collected from smear positive PTB patients from January 2013 to July 2013. The bacteria were isolated on MGIT and DST was determined phenotypically and genotypically. Molecular characterization was performed by deletion and spoligotyping.**Results:** A total of 57 smear positive PTB patients were included, 46 were new cases. Out of 57 *Mycobacterium tuberculosis* isolates drug susceptibility was performed only for 45; of which, 14 were resistant to at least one of the four first line drug. There were 3 MDR. Only *katG* and *rpoB* gene are responsible for isoniazid and rifampicin resistance, respectively. There were 40 shared spoligotype and 17 orphan strains; SIT 53 and 149 were dominant strains. The predominant family was T1.**Conclusion:** the reported rate of first line drug resistance and the existence of various strain type of *MTB* isolate is an indicator for the need of large scale study in the study area.**Key words:** Debre Berhan, drug susceptibility pattern, TB, MGIT, MTBDRplus

Multi-drug Resistant *Mycobacterium tuberculosis* and Associated Risk Factors in the Oromia Region of Ethiopia

Author Block:

G. Mulisa, T. Abebe; Adama Hosp. Med. Coll., .Adama, Ethiopia

Abstract Body:

Background: Multi drug resistant tuberculosis (MDR-TB) is prevalent in Ethiopia. The study aim was to determine the risk factors for tuberculosis caused by multi drug resistant MDR-TB in Oromia region, Ethiopia. **Methods:** In a 6 months case control study in 2013-14, sputum samples and standardized questionnaire data (demographics, treatment, TB contact history, underlying disease, history of imprisonment) were collected from suspected MDR-TB cases≥18 years of age. Sputum was processed locally in the Oromia public health laboratory using standard techniques. Data from MDR-TB cases and TB positive controls were compared using logistic regression analysis. For each factors, their association with outcomes variable was estimated by calculating the odd ratio (OR) together with 95% confidence intervals (95% CI).**Results:** Of 439 suspected MDR-TB cases, 265 had confirmed *Mycobacterium tuberculosis* infection, of whom 33% (88) had laboratory confirmed MDR-TB. Over two thirds (65%) were between18 to 39 years of age. On multivariable analysis occupation (farming), known TB contact history, alcohol use, HIV infection, previous known TB history and previous TB treatment outcome were predictors of MDR-TB.**Conclusion:** The rate of MDR- TB was high among suspected cases in the Oromia region of Ethiopia. If TB is suspected, the presence of any of the above factors should alert Oromia region clinicians and public health to be screen for the MDR-TB.

The Epidemiology of Mdr-Tb at Times of Mass-migration at a Western European Tb Clinical Reference Center

Author Block:

I. D. Olaru, B. Kalsdorf, J. Heyckendorf, E. Terhalle, N. Smitsman, S. Großmann, C. Lange; Res. Ctr. Borstel, Borstel, Germany

Abstract Body:

The objective of this study is to evaluate the change in the epidemiology and characteristics of patients with multidrug-resistant tuberculosis (MDR-TB).**Methods:** Retrospective analysis of patients with microbiologically confirmed MDR-TB with available drug susceptibility test results who were hospitalized at the Research Center Borstel between January 2002 and January 2016. To evaluate the change in the characteristics of patients with MDR-TB we compared the period before and after January 2014, when an increase in population migration and the number of asylum seekers was recorded.**Results:** Of the 82 patients with MDR-TB admitted during the study period, 76 had drug susceptibility results available and were further analyzed. Median patient age was 38.5 years and male to female ratio was 2.2:1. Of the total number of patients 38 (50%) were admitted between January 2002 and December 2013 (Group 1) and 38 (50%) between January 2014 and January 2016 (Group 2). 64 (84.2%) patients were from countries of the WHO European Region, with 52 (68.4%) from countries of the former Soviet Union and 7 (9.2%) from Germany; 5 (6.6%) patients were from the WHO Western Pacific Region and Africa each, and 1 from the South-East Asia and Eastern Mediterranean Regions. There was no difference in the origin of patients according to WHO region with 27 (71%) of patients in Group 1 from former Soviet Union countries vs. 25 (66%) in Group 2. 18 (47.4%) patients in Group 1 and 19 (51.4%) had been previously treated for TB. Of the 14 patients with extensively drug-resistant (XDR)-TB, 7 (50%) were admitted since 2014. There was no difference in the proportion of patients with culture conversion after 6 months of therapy, 82.8% in Group 1 vs. 85.7% in Group 2, respectively. **Conclusions:** Although there was a dramatic increase in the number of patients with M/XDR-TB admitted for treatment since the beginning of 2014, their characteristics were not different. This was probably because the majority of patients were not from countries from where a large number of refugees originated and they were mainly from Eastern European countries.

High Rates of Antimicrobial Resistance in *Mycobacterium abscessus* from Patients with Interferon-Gamma Autoantibodies

Author Block:

A. Jitmuang[1], H. Boshoff[1], C. Henderson[1], S. Shallom[1], L. Rosen[1], S. Browne[1], P. Chetchotisakd[2], K. Olivier[1], C. Barry, III[1], S. Holland[1], A. Zelazny[1]; [1]Natl. Inst. of Hlth., Bethesda, MD, [2]Khon Kaen Univ., Muang, Thailand

Abstract Body:

Host control of mycobacterial infections relies on the interleukin-12 and interferon-gamma (IFN-γ) pathway. Patients with IFN-γ autoantibodies are exquisitely susceptible to mycobacteria, particularly *Mycobacterium abscessus* (MAB). Infections are often disseminated, refractory to treatment and tend to relapse. Microbiological data including susceptibility testing of MAB isolates from these patients is warranted for establishing optimal treatment and predicting outcomes. *M. abscessus* isolates (n=37) from US and Thai patients with IFN-γ autoantibodies were characterized phenotypically and identified to subspecies level by genotypic methods. Antimicrobial susceptibility testing was performed to 18 drugs including bedaquiline, clofazimine and newer oxazolidinones. Isolate sources were lymph node (62%), skin (11%), blood (8%), abscess (8%), and other (11%). Isolates displayed rough (52%), smooth (32%), and mixed (16%) colony morphology and were genotypically identified as MAB subsp. *abscessus* (84%), MAB subsp. *massiliense* (13%), and MAB subsp. *bolletii* (3%). All strains were amikacin susceptible and showed low MICs to tigecycline (≤0.015-2 μg/mL). Only 4% of MAB subsp. *abscessus* and 86% of MAB subsp. *massiliense* were susceptible to clarithromycin. A high percentage (25%) of isolates showed high MICs (≥16) to linezolid but increased susceptibility to newer oxazolidinones. Most isolates were intermediate or resistant to quinolones, imipenem, and cefoxitin (97%, 91%, and 81%, respectively), including 4 strains (11%) showing multidrug resistance. Interestingly, all isolates were susceptible to bedaquiline, a new agent for MDR TB. *M. abscessus* isolates (mostly *subsp. abscessus)* from patients with IFN-γ autoantibodies present a therapeutic conundrum. Their intrinsic and presumptively acquired drug resistance makes these strains challenging for testing newer drugs. Tigecycline, newer oxazolidinones, and bedaquiline showed promising results *in vitro*.

Geographic Distribution of Nontuberculous Mycobacteria in the United States

Author Block:

N. K. Helstrom, J. L. Marola, K. S. Messina, **M. Salfinger**; Natl. Jewish Hlth., Denver, CO

Abstract Body:

Background: While *Mycobacterium tuberculosis* is a reportable entity in the United States, nontuberculous mycobacteria (NTM) are only a reportable entity in a few states, not nationwide. Although the overall prevalence of pulmonary NTM is increasing, there is no recent nationwide data about the various NTM isolated. National Jewish Health (NJH) receives isolates from all 50 states. The purpose of this analysis is to gain a better understanding of the distribution of NTM isolates across the United States.**Method:** An analysis was conducted of all NTM isolates submitted for identification to NJH within a two year period and screened for duplicate entries; submissions from reference laboratories were excluded. Of a total of 3,096 unique isolates, 79 different species were identified using *rpoB* gene sequencing between July 2013 and July 2015. These isolates were grouped by state and by region, and frequencies were calculated per 100,000 population (pop.) in that state/region.**Results:** Only data for the most commonly identified NTM are reported here. The Southern states (pop. 183,843,053) had 2,186 NTM isolates for a frequency of 1.19/100,000; the Northern states (pop. 132,844,549) had 854 NTM isolates for a frequency of 0.76/100,000. The following differences in frequencies per 100,000 among a selection of taxa were noted between Southern and Northern states: *M. abscessus* group (N=820) 0.33, 0.16; *M. avium* complex (N=843) 0.34, 0.19; *M. gordonae* (N=204) 0.08, 0.05; *M. kansasii* (N=58) 0.03, 0.01; *M. simiae* (N=22) 0.01, 0.01; *M. xenopi* (N=61) 0.005, 0.05, respectively. Among the *M. abscessus* group the frequencies per 100,000 were *M. abscessus* (N=490) 0.18, 0.11; *M. massiliense* (N=274) 0.12, 0.04; and *M. bolleti* (N=56) 0.03, 0.004, respectively. Also, *M. avium* (N=391) 0.14, 0.12; *M. intracellulare* (N=276) 0.13, 0.04, respectively.**Conclusions:** *M. abscessus* group and *M. avium* complex are the most identified taxa. The Southern states sent 2.6 times more isolates for identification than Northern states. There are major differences in frequencies per 100,000 between Southern and Northern states, especially for *M. xenopi, M. massiliense, M. bolletii*, and *M. intracellulare*. For the following species similar frequencies were noted: *M. abscessus, M. avium, M. gordonae, M. kansasii*, and *M. simiae.* These preliminary results warrant a population based investigation.

Next-Generation Sequencing of Drug Resistance Mutations in Mycobacterium Tuberculosis

Author Block:

A. J. Caulfield, S. P. Buckwalter, N. L. Wengenack; Mayo Clinic, Rochester, MN

Abstract Body:

Mycobacterium tuberculosis is a highly transmissible bacterial pathogen and is the causative agent of tuberculosis, a disease causing significant worldwide morbidity and mortality, especially among HIV-infected patients. Multi-drug resistant strains have emerged which reduce viable treatment options and elicit great economic and quality of life burdens due to costly and time-consuming therapeutic interventions. As a slow-growing organism, current methods for the detection of *M. tuberculosis* drug resistance require weeks to months, while delayed administration of appropriate therapy may be detrimental to patient outcome. In this study, the MiSeq (Illumina) next-generation sequencing (NGS) platform was used to detect mutations within the genome of *M. tuberculosis* that are commonly associated with drug resistance. The entire coding regions of nine genes were retrospectively examined from clinical isolates with demonstrated resistance to first- and second-line drugs as determined by standard phenotypic methods. Of all isolates tested phenotypically in 2014, 23.2% were resistant to at least one first-line drug and 43.2% were resistant to a second-line aminoglycoside or fluoroquinolone. Sequencing of these isolates provided presumptive drug resistance data based on the detection of known resistance mutations. This study supports the use of NGS technology as a more rapid alternative to current drug susceptibility testing methods and addresses a largely unmet diagnostic need that will contribute to improve patient management.

Design and Validation of a Three Color Single Tube Assay for Pyrazinamide (Pza) Resistant *M. tuberculosis*

Author Block:

J. Rice[1], L. Wangh[1], S. Marras[2], B. Kreiswirth[2], M. Whitfield[3], P. D. van Heldan[3], R. M. Warren[3]; [1]Brandeis Univ., Waltham, MA, [2]Publ. Hlth.Res. Inst. Ctr., Newark, NJ, [3]Stellenbosch Univ., Tygerberg, South Africa

Abstract Body:

Background: Pyrazinamide (PZA) is a key first-line antibiotic to treat tuberculosis and it has become a critical drug in new drug regimens. A recent meta-analysis from Whitfield et al. revealed 608 distinct mutations at 397 locations in the *pncA*, the vast majority of which are non-synonymous and correlate with PZA resistance. Importantly, sequencing data also revealed that a wild-type *pncA* gene correlates with PZA susceptibility. We have developed a LATE-PCR assay using Lights-On/Lights-Off probes to distinguish the wild type drug susceptible *pncA* gene sequence from all strains that have non-synonymous genetic alterations. **Methods:** LATE-PCR is used to amplify a 685 base long amplicon encompassing the entire coding region of the *pncA* gene, including the upstream flanking sequence. The reaction mix also contained a reagent that suppressed mis-priming throughout the amplification process. Following amplification, the reaction temperature is lowered to 25^{o}C resulting in the coating of the single-stranded DNA templates with 35 Lights-On/Lights-Off fluorescent probes labeled in three colors. The probes are then melted off of the target and the resulting fluorescent signature reveals the presence or absence of mutations, which are distinguishable from a highly reproducible wild-type profile. Total time per assay 3.5 hrs.**Results:** The assay testing has been carried out at three different locations using > 500 samples of TB DNA purified from cultured cells. The results show 100% sensitivity and >97% specificity. Additional optimization is underway and will be reported at the meeting.**Conclusions:** We have successfully designed and tested a single closed-tube assay that is able to identify and distinguish the wild type *pncA* gene from strains with almost every known genetic alteration. Additional refinements will improve identification of the rare synonymous mutations in *pncA* and the few non-synonymous that were not correctly scored as PZA resistance. Supported by NIH Grant #R21AI106551.

Molecular Analysis of *pncA* Gene Target of *M. Tuberculosis* Clinical Isolates

Author Block:

V. R. Wabale, 38 years; Grant Government Med. Coll., MUMBAI, India

Abstract Body:

Pyrazinamide (PZA) is an important first line drug for tuberculosis (TB) treatment whose drug susceptibility testing (DST) in vitro is pH dependent. Gold standard for PZA DST is *pncA* Whole Gene Sequencing (WGS). Hence study was conducted to perform PZA DST by WGS and analyse sequence data using CLC Protein Workbench Software. Strain variation among drug resistant population studied by doing phylogenetic analysis. A 300 proven *M. tuberculosis* strains were tested by Wayne's Assay and WGS using Sanger's method. BLASTn and BLASTx performed for nucleotide sequence analysis and identification of amino acid changes in the drug target in comparison with wild-type *M. tuberculosis* H37RV done using CLC protein workbench. A 36.66% (110/300) showed missense & nonsense mutations causing amino acid substitutions in most cases or frame shifts leading to nonsense polypeptide. Overall 226 mutations in 110 PZA resistant strains found dispersed along *pncA* gene indicative of main mechanism for PZA resistance. Most alterations occurred in 561 bp region of open reading frame and in 82 bp region of its putative promoter. WGS analysis of *pncA* using CLC protein workbench is reliable alternative to phenotypic PZA DST technique that usually gives irreproducible results and discordance among findings from different laboratories. High degree of diversity in *pncA* gene mutations among PZA resistance strains is epidemiologically useful in predicting linked cases of TB in our high incidence setting.**Key words:** *pncA* gene mutations, *Mycobacterium tuberculosis*, Pyrazinamide resistance.

Identification of Novel Point-of-Care Biomarkers: Validation and Evaluation for the Rapid Detection of Tb and Mdr-Tb

Author Block:

A. Singh[1], A. Gupta[1], K. Gopinath[2], S. Singh[1]; [1]All India Inst. of Med. Sci., New Delhi, India, [2]Max Plank Inst. for Infection Biology, Berlin, Germany

Abstract Body:

Background: Accurate and rapid diagnosis of TB is paramount importance in the management of tuberculosis infection. The recommended culture based methods for the diagnosis of tuberculosis are cumbersome and time consuming while molecular methods are costly. The serological methods are easy and cost effective, but after finding currently available serological methods very inferior, these tests were banned in 2011 by WHO and Government of India. In this study, we report five novel protein biomarkers by comparative proteomic analysis (1) **Methods:** The selected genes were cloned, expressed, purified and named these as SS1, SS2, SS3, SS4 and SS5 (***patent filed***). The diagnostic potential of these antigens were validated using well characterized tuberculosis patients using dot-blot, ELISA and Flow through (FT) assay. The sera from PTB (n=111), EPTB (n=29) diseased controls (n=60) and healthy subjects (n=50) were included. **Result:** Our experimental results of dot-blot & FT shows 100% (SS1, SS3, SS4), 96% (SS2) and 86.3%) sensitivity and 100% (SS1), 92% (SS2), 88% (SS3, SS4) and 96% (SS5) specificity. In ELISA the AUC value of selected antigens were ranging 0.98 to 0.88 for antigens. The sensitivity of ELISA was ranging from 97.4% to 73.4% and specificity of 98.2% to 86.4%. However, for MDR-TB prediction shows the sensitivity of 100% (SS1, SS4 and SS5) and 79.2% (SS2, SS3) **(Figure 1)**. The ROC curve shows significant differences of healthy *vs* TB and MDR-TB (p=0.001). SS1, SS4 and SS5 antigens were able to discriminate drug susceptible-TB and MDR-TB (p_{ss1}=0.008, $p_{ss4,\ ss5}$=<0.001). **Conclusion:** Our results indicate that these antigens could be used as novel biomarker for detection of TB and MDR-TB directly from patient sera.

Evaluation of a Molecular Detection Assay for Diagnosis and Antimicrobial Susceptibility Testing of *Mycobacterium tuberculosis* in Pulmonary and Extrapulmonary Clinical Specimens

Author Block:

C. Jaramillo Jaramillo, D. Caceres Contreras, J. Carmona Valencia, **L. Gonzalez Nino**; DINAMICA IPS, Medellin, Colombia

Abstract Body:

Background: In 2014, 9.6 million people fell ill with Tuberculosis (TB) and 1.5 million died. Worldwide an estimated of 480,000 people developed multidrug-resistant TB. In Colombia, around 500,000 new cases of TB were diagnosed, with a mortality rate of 1.5/100,000 population. It is important to continue improving diagnostic methods for TB more accuracy, faster and cheaper. The present study aimed to evaluate the Anyplex II MTB/MDR/XDR Detection assay comparing it against conventional diagnostic tests. **Methods:** A total of 59 samples (19 pulmonary and 40 extrapulmonary) from 32 patients with clinical suspicion of TB were collected prospectively (Dinamica IPS, Medellín, Colombia). Samples were tested using the multiplex real-time PCR Anyplex II MTB/MDR/XDR Detection assay for simultaneous detection of *Mycobacterium tuberculosis* and its resistance to anti-tuberculosis drugs and compared against conventional diagnostic tests (Kinyoun stain, mycobacterial cultures BD MGIT, BD Löwenstein-Jenssen and 7H11 Thin layer agar and drugs phenotypic susceptibility testing: Bactec MGIT 960 and the indirect proportion method). **Results:** Diagnosis of TB was proven according to microbiological criteria in 4 of 32 patients (13%). When Anyplex II MTB was used in the 59 samples, diagnostic accuracy was: sensitivity 85%, specificity 96%. Kappa index was 0.45 compared with Kinyoun stain, 0.79 with mycobacterial cultures and 1.0 with drugs phenotypic susceptibility testing. The mean time to deliver a result in positive samples was 1 day for Kinyoun stain (1 to 2 days), for Anyplex II MTB was 4 days (1 to 11) and 35 days for culture (16 to 59). Regarding negative samples, the mean time to deliver a result was 1 day for Kinyoun stain (1 to 3), 4 days for Anyplex II MTB (1 to 8) and 59 days for culture (52 to 66). The cost of microbiological analysis per sample was 237 USD, compared with 230 USD of the molecular test. **Conclusions:** The Anyplex II MTB/MDR/XDR Detection assay provides results 8 times faster than culture and 55% more accurate than kinyoun stain. This multiplex assay is a rapid, cost effective and highly sensitive and specific method and therefore a viable option for the rapid and safe diagnosis of TB and antimicrobial susceptibility testing in health centers.

Application of Fluorophages for TB Detection and Screening of Antitubercular Drugs

Author Block:

E. Urdániz[1], L. Rondón[1], M. Martí[1], G. Hatfull[2], M. Piuri[1]; [1]Univ. of Buenos Aires, Buenos Aires, Argentina, [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Tuberculosis (TB) is a major cause of human mortality. The emergence of resistant *Mycobacterium tuberculosis (M.tb)* strains has become a serious public health problem worldwide complicating treatment and control of the disease. Nowadays, there is a need for new and efficient anti-TB drugs. The bottleneck on the TB drug discovery pipeline still remains in the time-consuming activity testing of compounds. Our aim is to develop a novel, rapid and sensitive assay to be used for *in vitro* and *in vivo* drug susceptibility testing (DST) of compounds as part of the solution to the serious TB health problem.The development of fluorophages, mycobacteriophages carrying fluorescent genes, was described as a simple means of revealing the metabolic state of *M. tb* cells, and therefore their response to antibiotics. Recently, we have constructed an improved version of fluorophages with higher sensitivity and shorter time to detection of signal. Red bright *M.tb* cells were observed by fluorescent microscopy after only 5 hours of infection with the new $mCherry_{bomb}\Phi$. We optimized the conditions for automated fluorimetric detection in a multiwell format as a good alternative for *in vitro* DST. Briefly, pure cultures of *M.tb* were infected at a MOI of 100 with $mCherry_{bomb}\Phi$ in the presence of the most common anti-TB drugs. A decrease in the fluorescent signal was observed over time for increasing concentrations of compounds with different targets in the bacteria and MICs were succesfully determined.To test whether our methodology would also be useful for *in vivo* DST, we developed an infection assay in eukaryotic cells. We were able to detect intracellular *M.tb* by confocal microscopy after infection with $mCherry_{bomb}\Phi$ in THP-1 derived macrophages and pulmonary epithelial cell line A549. Basically, cells were incubated with bacteria and after extensive washing, $mCherry_{bomb}\Phi$ was added overnight to reveal the presence of intracellular *M.tb*. Cells were stained with nuclear DAPI and inmunofluorescence was performed using a cytoplasmic antibody anti- LC3 autophagy marker. An automated infection assay in presence of different concentrations of drugs still must be evaluated. However, these promising results show that our phage-technology could be used for both *in vitro* and *in vivo* activity testing of compounds in a full-scale, fast and sensitive assay.

Relational Sequencing Tb Data Platform (Reseqtb): Development of a Standardized Grading System for Validating Drug-resistance Associated Mutations

Author Block:

P. Miotto[1], E. Tagliani[1], B. Tessema[2], N. Hillery[3], L. Chindelevitch[4], T. Rodwell[2], D. Dolinger[2], M. Schito[5], ReSeqTB Consortium; [1]San Raffaele Hosp., Milano, Italy, [2]Fndn. for Innovative New Diagnostics (FIND), Geneva, Switzerland, [3]Univ. of California San Diego, La Jolla, CA, [4]Simon Fraser Univ., Burnaby, BC, Canada, [5]Critical Path Inst., Tucson, AZ

Abstract Body:

A global public-private partnership has been established to develop a Relational Sequencing TB Data Platform (ReSeqTB) to simplify and standardize whole genome sequencing data analysis for interpretation of antimicrobial drug susceptibility. Here we describe the development of a standardized analytical approach for validating and interpreting *M. tuberculosis* (MTB) drug resistance (DR) associated mutations. To this aim, we merged data from two recently published data sets: the PhyResSE web tool (www.phyresse.org) and the Knowledge Synthesis TBDR DB (TBDR.org). An expert, consensus-driven approach was used to independently define a starting list of "high-confidence" DR-associated mutations in MTB and to develop a standardized approach for validating and scoring DR-associated mutations. The total number of MTB isolates (DR+ drug susceptible (DS)) used for evaluating the relationships between phenotypic and genotypic resistance to each drug ranged from 571 to 9537. Mutation frequencies across DR and DS cases were calculated, together with statistical measures of their performance, as predictors of phenotypic DR. Using statistical thresholds based on likelihood ratios (LR)—a method derived from evidence-based medicine—mutations were categorized as having "high-" (LR ≥10), "moderate-" (5≤ LR <10) or "minimal-" (1≤ LR <5) confidence associations with DR phenotypes, while mutations with LR <1 were categorized as "not-associated" with drug resistance. A list of 44 mutations to 10 drugs with moderate to high confidence associations with DR phenotypes was identified. Extensive systematic literature review for improving this first list is currently ongoing. ReSeqTB provides the first standardized and validated list of DR-associated mutations organized by level of confidence using objective analytical criteria. These methods can be applied not only to data from ReSeqTB, but also other TB DR databases and genotypic/phenotypic resistance data derived from systematic reviews and meta-analyses.

In Vitro* Activity of Clofazimine and Dapsone against Multidrug Resistant Strains of *Mycobacterium abscessus, M. Chelonae* and *M. Avium

Author Block:

M. Schwartz, K. Carroll, N. Parrish; The Johns Hopkins Med. Inst.s, Baltimore, MD

Abstract Body:

Background: Treatment of immunocompromised and chronically ill patients infected with multidrug resistant (MDR) strains of non-tuberculous mycobacteria (NTM) is a challenge for physicians. Resistance is emerging to all classes of traditional drugs used to combat these organisms. In the absence of better options, patients are now being treated with alternative drugs which often have higher toxicity. New drugs or alternatives are needed. Clofazimine is a 3rd line antibiotic used to treat tuberculosis; dapsone is used to treat leprosy. We investigated the *in vitro* susceptibility of MDR clinical isolates of *M. abcessus* (ABC), *M. chelonae* (CHE) and the *M. avium* complex (MAC) to clofazimine and dapsone using microbroth dilution.**Methods:** A total of 35 isolates (ABC, n = 17; CHE, n = 4; MAC, n = 14) were selected based on resistance to 3 or more drug classes. Resistance was defined as an MIC above currently established breakpoints for which interpretations exist or those demonstrating confluent growth at the highest concentration tested. Microbroth dilution was used to test clofazimine and dapsone against all isolates with incubation times adjusted by species (3 to 7 days for ABC and CHE; 14 days for MAC). Panels were read using a mirror-box and ambient light.**Results:** All species and strains tested had MICs to clofazimine ≤ 3 μg/ml. Of these, however, 80% (29/35) had MIC's of ≤ 1.5 μg/ml. However, there were differences between species. MAC isolates were consistently more susceptible to clofazimine with 92% (13/14) demonstrating an MIC ≤ 1.5, versus 72% (15/21) for ABC and CHE. In comparison, most of the MAC isolates tested had MICs to dapsone ≥ 50 μg/ml, or the highest concentration tested. Only one MAC strain demonstrated an MIC of 3 μg/ml versus 15/21 (71%) for ABC and CHE. Of the latter, 7/15 (33%) had MICs ≤ 1.5 μg/ml.**Conclusions:** Given the increasing threat of MDR-NTM few options remain for treatment. Clofazimine and dapsone show promising results against these organisms. Further research is needed to determine if synergy can be achieved between these and other drugs to which the organisms are still susceptible.

Mutations in *Pepq* Confer Cross-Resistance to Bedaquiline & Clofazimine in *Mycobacterium tuberculosis*

Author Block:

D. V. Almeida[1], T. Ioerger[2], S. Tyagi1, S Li1, K Mdluli3, J Grosset1, J Sacchettini4 & E Nuermberger1; [1]Johns Hopkins Univ., Baltimore, MD, [2]Texas A&M, College station, TX

Abstract Body:

Background: Bedaquiline (BDQ), a new ATP synthase inhibitor was recently approved for treatment of MDR tuberculosis. A new non-target-based mechanism of cross-resistance to BDQ & clofazimine (CFZ) mediated by mutation of Rv0678 was recently described. For new TB drugs, it is essential to define & catalog resistance-conferring mutations in order to conduct proper follow-up of patients who fail & relapse after treatment, to design diagnostic tests (including rapid molecular tests) & to conduct population level surveillance for changes in susceptibility. Here we present our findings on the selection & characterization of a novel mutations conferring cross-resistance to BDQ and CFZ. **Methods:** Resistant colonies were isolated on BDQ- & CFZ-containing plates from mice receiving BDQ with or without CFZ. MICs were determined on 7H11 agar. Mutation analysis was done by whole genome sequencing & confirmed by PCR. To confirm cross-resistance, BALB/c mice were infected with either the H37Rv parent strain or one resistant mutant (J5) & treated with either isoniazid (10 mg/kg) alone, BDQ (12.5, 25, or 50 mg/kg) alone, CFZ (20 mg/kg) alone, or BDQ 25 mg/kg plus CFZ for 4 wks before determining lung CFU counts. Complementation with the wild type gene was performed & the complemented strain was tested for BDQ & CFZ susceptibility in vitro & in vivo with the parent & mutant strains. The BDQ MIC of parent strain & the mutant was tested in presence of verapamil 40 µg/ml & reserpine 3 µg/ml. **Results:** Mice receiving BDQ alone or BDQ-CFZ harboured mutants. Their MIC for BDQ & CFZ were 0.12-0.25 & 0.5-1 µg/ml, in contrast to the wild type MICs of 0.03 & 0.25 µg/ml respectively. Whole genome sequencing revealed that 4 out of 5 isolates had mutations in *pepQ* (Rv2535c). Efficacy studies in mice with one mutant (J5) showed reduced killing by BDQ & CFZ as compared with wild type H37Rv. Complementation with wild type pepQ restored the susceptibility to BDQ & CFZ in vitro & in vivo. Use of verapamil & reserpine reduced the MIC for the H_{37}Rv parent strains from 0.03 to 0.007 µg/ml & 0.015- 0.03 µg/ml respectively, in addition for the J5 mutant, both the efflux inhibitors reduced the MIC comparable to that of the H37Rv parent strains, indicating a possible role of efflux pumps **Conclusions:** Mutations in *pepQ* gene reduce susceptibility to BDQ & CFZ.

Publishing Title:

Multi Drug Resistant *Mycobacterium tuberculosis* in Pakistan

Author Block:

R. Khan, S. Khan, U. Mazahir; Dow Univ. of Hlth.Sci., Karachi, Pakistan

Abstract Body:

Introduction: Tuberculosis is the most life threatening air born bacterial infection. According to the WHO about 2 billion people worldwide have been infected by Mycobacterium tuberculosis complex. PCR is recognized as rapid, specific and sensitive diagnostic technique as compared to the conventional methods. TB can be controlled through early diagnosis followed by effective treatment. Drugs Rifampicin and Isoniazid are commonly used for treatment, but their excessive use has led to the emergence of mutations in the genome of MTB. **Objective:** To investigate the Prevalence of mycobacterium tuberculosis and its drug resistance pattern in different areas of Sindh, Pakistan. **Methods:** Total 380 pulmonary and extra pulmonary specimens were collected from different regions of Sindh, Pakistan. Samples were decontaminated using NALC-NaOH protocol followed by DNA extraction. Amplification of extracted MTB DNA was done by real time PCR using primers and fluorescent probes specific for the MTB complex. To check the drug resistant strains, Hybridization of amplified products of positive samples were carried out by MTBDRplus assay. **Results:** The overall prevalence of MTB infection in this study population was 11%. Prevalence of MTB infection among females and males was 10.14% and 12.13% respectively. Highest positive ratio among different clinical specimens was determined in pus (52%) whereas age group 1-20 years was found most susceptible (13.5%). Among positive samples 33.3% were resistant to Rifampicin and 23.3% were resistant to Isoniazid and 6.6% samples were resistant to both the drugs. **Conclusions:** Real-time assay is rapid diagnostic tool, it can be applied to a wide range of clinical specimens including pus which might show negative AFB smear specially in developing countries like Pakistan where the false negative reporting playing crucial role in the spread of TB. In Pakistan prevalence and drug resistance of TB is on rise due to many socio economical and other issues, determination of drug resistance is important for effective treatment particularly in our region where MDR and XDR TB are not very uncommon.

Drug Resistance Patterns of Mycobacterium Tuberculosis Complex(Mtbc) Among Retreatment Cases Around Jimma Southwest, Ethiopia

Author Block:

K. G. K. W. Abdulsemed; Ji,mma Univ., Jimma, Ethiopia

Abstract Body:

Background: Information on the pattern of drug resistant tuberculosis (TB) among re-treatment cases is crucial to develop appropriate control strategies. Therefore, we conducted this study to assess the drug resistance pattern of M. tuberculosis complex (MTBC) isolates and associated factors among re-treatment cases in Jimma area, Southwest Ethiopia.**Methods:** Health facility-based cross-sectional study was conducted between March 2012 and April 2013 in Jimma area, Southwest Ethiopia. We included 79 re-treatment cases selected conveniently. Socio demographic and clinical data were collected using structured questionnaire. Sputum sample processing, mycobacterial culture, isolation and drug susceptibility testing (DST) were done at Mycobacteriology Research Centre (MRC) of Jimma University. All data were registered and entered in to SPSS version 20. Crude odds ratio (COR) and adjusted odds ratios (AOR) were calculated. P-values less than 0.05 were considered statistically significant.**Results:** Seventy-nine re-treatment cases included in the study; 48 (60.8 %) were males. Forty- seven (59.5 %) study participants were from rural area with the mean age of 31.67 ± 10.02 SD. DST results were available for 70 MTBC isolates. Majority (58.6 % (41/70)) isolates were resistant to at least one of the four first line drugs. The prevalence of multidrug-resistant TB (MDR-TB) was 31.4 % (22/70). Place of residence (AOR = 3.44 (95 % CI: 1.12, 10.60), duration of illness (AOR = 3.00 (95 % CI: 1.17, 10.69) and frequency of prior TB therapy (AOR = 2.99, (95 % CI: 1.01, 8.86) were significant factors for any drug resistance. Moreover, history of treatment failure was found to be associated with MDR-TB (AOR = 3.43 (95 % CI: 1.14, 10.28).**Conclusions:** The overall prevalence of MDR-TB among re-treatment cases around Jimma was high. The rate of MDR-TB was higher in patients with the history of anti-TB treatment failure. Timely identification and referral of patients with the history of treatment failure for culture and DST need to be strengthened.

A Comparison of Two Multiplex Molecular Methods for Direct Organism Identification from Positive Blood Culture Bottles

Author Block:

J. McCallum, S. Bollinger; Tufts Med. Ctr., Boston, MA

Abstract Body:

Direct molecular testing of positive blood cultures can significantly decrease the time to identification of both the causative organisms of bacteremia and select antimicrobial resistance markers. The rapid availability of this information can lead to more targeted initial antimicrobial treatment and/or more rapid de-escalation of empiric treatment. For the purpose of this study, two nucleic acid-detection based tests were compared: the multiplex PCR Biofire FilmArray BCID assay and the Nanosphere Verigene GP-ID and GN-ID non-amplified assays. 35 gram positive and 30 gram negative clinical samples were tested; results were juried with culture and susceptibility testing utilizing biochemical testing, KB, and the Vitek 2 system. The overall agreement fluctuated by target, but exceeded 96% for all shared targets. Of the samples with comparable results, the Biofire BCID demonstrated increased sensitivity to true positives on 2 occasions. Instances of false positives also occurred on the Biofire, but for targets that were not present on the Nanosphere assay and thus cannot be compared. The Biofire FilmArray BCID provides a shorter run time, requires less hands on time, and is a more comprehensive single panel than the Nanosphere Verigene GP and GN tests, though the Nanosphere Verigene tests are less costly to run, and tests for a significantly greater number of gram-negative resistance mechanisms, and gram-positive species. Overall, both platforms performed similarly in the detection of comparable organisms; differences in panel comprehensiveness and methodologies each have advantages dependent on the lab performing the test.

Can a Tablet Computer App Ease the Workflow for Advanced Molecular Testing?

Author Block:

L. L. Samson[1], **H. C. Schønheyder**[2], L. B. Pape-Haugaard[1], O. Hejlesen[1]; [1]Aalborg Univ., Aalborg, Denmark, [2]Aalborg Univ. Hosp., Aalborg, Denmark

Abstract Body:

Background: Molecular tests are becoming increasingly important for rapid identification of microbes causing bloodstream infections. MuxBCT is a multiplex FISH test under development aiming to identify multiple microbes at the species or genus level within one hour. The test is performed with a slide comprising 10 separate reaction wells each with up to three significant observations by fluorescence microscopy. We developed a tablet computer app to ease the test workflow, and we evaluated the performance of the prototype and the usability of the app in a clinical laboratory setting.**Methods:** This non-interventional study was performed independently but parallel to the routine work-up of blood culture flasks flagged positive (BACTEC, BD) during the dayshift. Four biotechnicians received 'hands on' training including use of the tablet with the app and fluorescence microscopy. They alternated thereafter for 25 weekdays. A sample was drawn from the first flask flagged positive in each set. The MuxBCT was performed in a manner similar to the commercial *Quick*FISH tests (AdvanDx Inc.). The app guided each step of the reading procedure at the same time recording readings and verifying controls. Results were communicated securely via Wi-Fi from the tablet computer to the laboratory information system (LIS). MuxBCT identification was compared with culture-based identification mainly by use of MALDI-TOF (Bruker).**Results:** 124 positive BCs were included in the study, 109 with one pathogen, 11 with two to four, and 4 with a false positive signal. Median time to read and record the test was 2.8 min; (median turn-around time was 74.2 min). For comparison, the median time for Gram stain results was 54.4 min, which provided less specific isolate information. Concordance of MuxBCT results with culture-based identification was 92.7% (115/124) with a PPV of 98.9% (89/90) and a NPV of 76.5% (26/34).**Conclusions:** The app supported biotechnicians in the performance of the MuxBCT prototype to obtain accurate microbe identification results that were communicated directly from the tablet app to the LIS.

Evaluation of the Portrait Staph ID-R Blood Culture Panel in Pediatric and Adult Patient Populations

Author Block:

A. Hopper[1], M. V. Powers-Fletcher[2], S. Holt[1], A. Phillips[1], R. Grand-Pre[1], M. Dickie[1], A. Blaschke[3], M. R. Couturier[2], J. A. Daly[1]; [1]Primary Children's Med. Ctr., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT, [3]U of U / Primary Children's Hosp., Salt Lake City, UT

Abstract Body:

Bloodstream infections (BSI) are associated with significant morbidity and mortality. The most common BSI pathogens are *Staphylococcus* species such as *S. aureus* and *S. epidermidis*, both which can harbor the gene (*mecA*) encoding methicillin resistance. The ability to rapidly identify these organisms is critical for patient care, particularly the choice of antibiotic therapy. The purpose of this study is to determine performance of a novel molecular diagnostic assay in identifying *Staphylococcus* spp., with or without *mecA*, from blood cultures compared to traditional methods.Blood samples collected from adult and pediatric patients were cultured and processed according to standard practice. Blood culture bottles positive for gram positive cocci were then stored up to 72 hours at 2-8°C, after which an aliquot of broth was tested using the Portrait Staph ID/R Blood Culture Panel (Great Basin Diagnostics, Utah). Results were compared to those obtained using either the BD Phoenix™ PID panel or MALDI-TOF MS for identification and cefoxitin disk diffusion for prediction of methicillin resistance.During the study period, 150 blood cultures were tested using the Portrait Staph ID/R panel; 115 of those were positive for staphylococci. Out of that total, 37 were *S. aureus* and 78 were a Coagulase negative *Staphylococcus*. The Staph ID/R panel performed with high sensitivity (99.1%) and specificity (96.3%) compared to BD Phoenix™ or MALDI-TOF MS for identification of *Staphylococcus* spp., with 100% accuracy for the identification of *S. aureus.* The Staph ID/R panel was able to predict methicillin resistance with 95.2% sensitivity and 94.3% specificity compared to cefoxitin disk diffusion for all *Staphylococcus* spp. combined, and 100% sensitivity and specificity for the detection of methicillin-resistant *S. aureus*.The Portrait Staph ID/R panel performs with high sensitivity and specificity for the identification of *Staphylococcus* spp. and detection of *mecA* compared to current laboratory methods. Implementation of this methodology in clinical laboratories could allow for accurate and more rapid identification of BSI caused by methicillin-resistant staphylococci and improve patient care.

Diagnostic Procedures Associated with Making a Diagnosis of *Propionibacterium acnes* Infective Endocarditis

Author Block:

J. M. Banzon, S. J. Rehm, S. M. Gordon, S. B. Hussain, G. B. Pettersson, N. K. Shrestha; Cleveland Clinic, Cleveland, OH

Abstract Body:

Background: *Propionibacterium acnes* is a slow-growing bacterium that is a rare cause of infective endocarditis (IE), and it may be underdiagnosed. It seems likely that diagnostic procedures employed might influence the ability to make a diagnosis of *P. acnes* IE. The aim of this study was to identify diagnostic procedures that are associated with making a diagnosis of *P. acnes* IE. **Methods:** Episodes of definite IE by Duke Criteria from 2007 to 2015 were identified from the Cleveland Clinic Infective Endocarditis Registry. 1084 episodes with an identified causative microorganism other than *P. acnes* were excluded. The remaining episodes were classified as *P. acnes* IE or IE with no identified pathogen. Diagnostic procedures examined were number of blood cultures done, extended incubation of blood cultures (beyond the standard 5 days), valve culture done, and valve microbial sequencing done. A multivariable logistic regression model was constructed, including the four diagnostic procedures, and all other factors associated with *P. acnes* IE at a significance level of 0.2. The model was reduced using stepwise backward elimination until only factors that were significant at a level of 0.05 remained in the model. **Results:** We identified 23 episodes of *P. acnes* IE and 49 episodes of IE with no identified pathogen, each in a unique patient. Almost all patients with *P. acnes* IE were male and almost all had prosthetic valve endocarditis (PVE). Factors associated with *P. acnes* IE were male sex (96% vs. 67%, p=0.008), PVE (96% vs. 71%, p=0.03), invasive disease (78% vs. 49%, p=0.02), extended incubation of blood cultures (30% vs. 10%, p=0.04), and valve sequencing (87% vs. 37%, p<0.001). Number of blood cultures (4 vs. 4 sets, p=0.88), and valve culture (91% vs. 76%, p=0.2) were not associated with a diagnosis of *P. acnes* IE. In the reduced multivariable model, the diagnostic procedures of extended incubation of blood cultures (OR 16.1, 95% CI 2.40-191.01, p=0.01) and valve sequencing (OR 15.8, 95% CI 3.5- 126.5, p=0.002) were independently associated with *P. acnes* IE. **Conclusion:** In patients with possible *P. acnes* IE (i.e. those with IE without another identified pathogen), extended incubation of blood cultures and microbial sequencing of excised heart valves are strongly associated with identifying *P. acnes* as the cause of IE.

Publishing Title:

Multicenter Evaluation Of The Miacom Hemofish For Bacterial Identification From Positive Blood Cultures

Author Block:

M. L. Faron[1], C. Coon[1], B. W. Buchan[1], M. Guralnik[2], V. J. LaBombardi[2], N. A. Ledeboer[1]; [1]Med. Coll. of Wisconsin, Milwaukee, WI, [2]New York-Presbyterian Queens, New York, NY

Abstract Body:

Background: Bloodstream infections are a life-threatening condition that can lead to mortality in 25-80% of infected patients. Early identification and administration of appropriate antibiotics can greatly reduce mortality rate as studies have shown that improper treatment is associated with significantly longer hospital stays and a 33% increase in mortality. In this study we evaluated the HemoFISH assay (Miacom Diagnostics, Dusseldorf, Germany), to identify organism from positive blood culture bottles.**Methods:** Positive VersaTREK™ blood culture bottles were collected and enrolled at two different sites. Enrolled positive bloods were Gram stained and analyzed in the HemoFISH assay according to the package insert. The laboratory standard of care (SOC), which included Verigene BC-GN and BC-GP (Nanosphere, Northbrook, IL), MALDI Tof MS, BD Phoenix (Becton Dickinson, NJ) or Vitek2 (bioMerieux, Marcy l'Etoile, France) was collected and used as a comparator assay. Isolates identified by the SOC were compared to the HemoFISH result and concordance for each target was determined.**Results:** In total, 543 monomicrobial blood specimens were enrolled within the study. The most commonly identified organisms were Coagulase Negative Staphylococcus (CoNS) 138 (25%), E. coli, 80 (15%) and S. aureus, 62 (11%). Total agreement for each target was high ranging from 99.3-100%. Positive and negative agreement for each target ranged from 96.8-100% and 99.6-100% respectively. 6 specimens were incorrectly identified by the HemoFISH, 1 correctly identified to the genus level. The remaining 5 discordant results consisted of *M. luteus* called *Staph*, *E.faecalis* called *Streptococcus*, *B. distasonis* called *E. coli*, *Acinetobacter* spp called *Enterobacteriaceae* and an *E. coli* called *Streptococcus* by the HemoFISH assay.**Conclusions:** The HemoFISH assay is an accurate test for identification of bacteria from positive blood culture bottles giving results in 30 minutes. The use of 8 wells containing two unique probes per well allows the assay to detect 14 of the most commonly identified organisms from the blood stream. Early Identification can greatly impact patient outcomes as organism ID coupled with hospitals antibiogram can guide therapy.

Multi-Center Evaluation of the Portrait Staph Id/R Blood Culture Panel

Author Block:

G. A. Denys[1], S. Young[2], J. Daly[3], M. Couturier[4], B. Buchan[5], N. Ledeboer[5]; [1]Indiana Univ. Sch. of Med., Indianapolis, IN, [2]Univ. of New Mexico/Tricore Labs, Albuquerque, NM, [3]Univ. Of Utah/Primary Children's Med. Ctr., Salt Lake City, UT, [4]Univ. of Utah/ARUP Labs, Salt Lake City, UT, [5]Med. Coll. of Wisconsin, Milwaukee, WI

Abstract Body:

Background: Blood stream infections (BSI) are a leading cause of morbidity and mortality in the United States. For hospitalized patients, MRSA BSI are associated with increased healthcare cost. The Portrait Staph ID/R Blood Culture Panel from Great Basin Scientific (Salt Lake City, UT) is a rapid, automated, DNA multiplex PCR assay performed on the Portrait Dx Analyzer for simultaneous identification (ID) of *Staphylococcus aureus, S epidermidis, S. lugdunensis* and *Staphylococcus* spp. and the detection of *mec*A gene directly from positive blood culture bottle. We evaluated the performance of the Portrait Staph ID/R compared to standard reference methods. **Methods:** A total of 723 positive blood culture bottles (BD BACTEC^{TM}) yielding Gram positive cocci (GPCC) in clusters were analyzed at 3 clinical sites using the Portrait Dx System. Aliquots of positive blood cultures were sent to a reference site for analysis. Reference ID methods included catalase and coagulase tests, BD Phoenix instrument, and MALDI-TOF MS. Detection of methicillin resistance was tested by cefoxitin disk diffusion according to CLSI. Discordant resolution of *Staphylococcus* ID and *mec*A detection was performed on colonies by *rpoB* gene sequencing and *mec*A gene sequencing, respectively. **Results:** Of the 723 positive blood culture bottles with GPCC, 647 had *Staphylococcus* spp. (*S. aureus* 209, *S. epidermidis* 236, *S. lugdunensis* 3, and *Staphylococcus* spp.155) Overall *Staphylococcus* ID agreement was 99.69% PPA and 94.74% NPA. Of the 6 false positive results by Portrait Staph ID/R, 3 were no growth and 3 were positive for *Staphylococcus* by sequencing. One false negative *Staphylococcus* by Portrait Staph ID/R was non-*Staphylococcus* by sequencing. The overall agreement for detection of *mec*A was 94.75% PPA and 94.70% NPA. **Conclusion:** The performance characteristics of the Portrait Staph ID/R Blood Culture panel compared favorably to reference methods. This multiplex amplification assay provides valuable information beyond the initial Gram stain in less than 2 hrs. of testing. Accurate and rapid organism ID and resistance mechanism could have a positive impact on patient management.

Publishing Title:

Evaluation Of Bactalert Fa Blood Culture Bottles And T2candida Assay For Detection Of *candida* in The Presence Of Antifungals

Author Block:

N. D. Beyda[1], J. Amadio[1], J. R. Rodriguez[2], K. Malinowski[2], K. W. Garey[1], A. Wanger[2], L. Ostrosky-Zeichner[2]; [1]Univ. of Houston Coll. of Pharmacy, Houston, TX, [2]UTHlth., Houston, TX

Abstract Body:

Objectives: Blood culture is the gold standard for diagnosing candidemia. Antifungal therapy has been shown to negatively impact the performance of some blood culture systems and other serodiagnostics. The objective of this study was to determine the effect of fluconazole (FLU) and caspofungin (CAS) on the performance of the T2Candida assay (T2CA) when compared to BacT/Alert FA blood culture bottles (BCX).**Methods:** Simulated candidemia samples were prepared by inoculating human whole blood with clinical bloodstream isolates of *C. albicans, C. glabrata, C. tropicalis, C. parapsilosis,* and *C. krusei* at 50 CFU/mL and 5 CFU/mL. CAS (8 ug/mL), FLU (20 ug/mL), or 0.85% NS (antifungal negative control) where then added at concentrations achieved after therapeutic doses. Samples were inoculated into either BCX bottles and incubated for up to 5 days or into K2 EDTA tubes for testing by T2CA. The proportion of samples detected by BCX and T2CA was compared. The impact of antifungals on the time to positivity (TTP) of BCX was also assessed.**Results:** A total of 240 simulated candidemia samples were tested by each method (n=8 for each species, CFU/mL, and antifungal). In the absence of antifungals, overall detection rate for all species combined was 100% for both methods at 50 CFU/mL. At 5 CFU/mL it was 97.5% and 95% for BCX and T2CA respectively (*C. parapsilosis* not detected in 1 sample for BCX; *C. glabrata* and *C. krusei* not detected in 1 sample each for T2CA). For BCX, presence of FLU reduced overall detection rates to 92.5% and 85% at 50 and 5 CFU/mL respectively, while CAS had no impact. CAS or FLU had no impact on T2CA results at either CFU/mL concentration. Compared to no-antifungal controls, presence of CAS and FLU led to a significant increase in TTP of BCX for most species, particularly for *C. albicans* at 5 CFU/mL (increase of 3.1 ± 1.3 and 66.8 ± 13.4 hrs respectively; $p<0.01$).**Conclusions:** CAS and FLU did not impact the performance of the T2CA. FLU reduced the detection rate of Candida in BCX, and both FLU and CAS prolonged TTP. These results suggest T2CA is reliable and can be used for the detection and management of candidemia in patients already receiving antifungals.

Development of a Rapid Diagnostic Method for *Staphylococcus aureus* and Antimicrobial Resistance in Positive Blood Culture Bottles Using a Pcr-Dna-Chromatography Method

Author Block:

T. Ohshiro[1], C. Miyagi[1], Y. Tamaki[1], T. Ezaki[2]; [1]Naha City Hosp., Naha, Japan, [2]Graduate school of Med. Gifu univ., Gifu, Japan

Abstract Body:

Background: When gram-positive coccoid cells are observed in blood culture bottles, it is important to determine whether the strain is *Staphylococcus aureus* and whether it has resistance genes for antibiotic selection. We developed a rapid and simple PCR-DNA-Chromatography method (PDC) based on the single tag hybridization chromatographic printed array strip method for identifying *S. aureus* and for concurrently detecting the *mecA* and *blaZ* genes in positive blood culture bottles.**Methods:** The principle of PDC is to detect the tagged PCR amplicons bound to the anti-tag printed on the strip. It is possible to detect multiple PCR amplicons simultaneously. We evaluated PDC using 42 clinical materials. Sample preparation method from positive BACTEC FX (BD) blood culture was processed using the centrifugal washing method. Cell wall synthesis gene, *ftsY*, of *S. aureus* and *mecA*, *blaZ* was selected for PCR. After completion of the PCR, treptavidin-coated blue latex was added to the PCR tube and a DNA-strip (Tohoku Bio-Array, Sendai, Japan) was placed in the tube. The results can be read 10 min. These series of operations was completed within 1 h. The results by PDC were compared with those by the conventional methods.**Results:** Of the 33 strains identified as *S. aureus* by the culture method, 32 (97.0%) were identified as *S. aureus* by the PDC. One *S. aureus* strain was misidentified as being negative for *ftsY*, but it was identified as *S. aureus* by the re-examination from the strain. Of the 33 cases identified as *S. aureus* by the culture method, 12 cases were both oxacillin resistant and *mecA* positive. Only one case among 21 MSSA cases was *mecA* positive. It was speculated that no protein was expressed from it. Of the 21 cases identified as MSSA by the culture method, 12 cases were positive for both β-lactamase and the *blaZ* gene. Only one case among the 9 β-lactamase-negative cases was positive for the *blaZ* gene by the PDC. Sensitivity and specificity of PDC for identifying *S. aureus*, *mecA*, *blaZ* were 97.0% and 100%; 100% and 95.2%; 100% and 88.9% respectively.**Conclusions:** The PDC is very rapid and simple, results can be obtained within 1 h from positive blood culture bottles, it may be useful for making rapid diagnoses even in places with a limited testing environment such as community hospitals.

Publishing Title:

Evaluation of Rapid Diagnostic Technology and Pharmacist Notification in Gram-negative Bloodstream Infections Using Time Dependent Variables

Author Block:

A. Gibble[1], S. L. Revolinski[1], **A. M. Huang**[1], N. A. Ledeboer[2], M. Graham[2], J. N. Wainaina[2], L. S. Munoz-Price[1]; [1]Froedtert & the Med. Coll. of Wisconsin, Milwaukee, WI, [2]Med. Coll. of Wisconsin, Milwaukee, WI

Abstract Body:

Background: Previous analyses showed associations between Nanosphere Verigene® Gram-Negative Blood-Culture (BC-GN) coupled with pharmacist (RPh) notification and both effective (EFTx) and optimal antimicrobial therapy (OPTx). We now aim to evaluate the impact of time on these associations by using time dependent variables and Cox proportional hazards.**Methods:** This interventional study evaluated patients with Gram-negative bloodstream infections (GN BSI). During the baseline phase (12/01/2012 - 06/30/2013) positive blood cultures were identified using traditional methods and reported directly to physicians. During the intervention phase (12/01/2014 - 06/30/2015) positive cultures were identified by BC-GN and reported to the RPh. OPTx was targeted antimicrobial therapy after de-escalation and discontinuation of unnecessary agents. EFTx was therapy deemed sensitive per culture and susceptibility report. Cox proportional hazards were used in order to evaluate the effect of exposures on time-to-OPTx or time-to-EFtx. Time zero was time of first positive blood culture draw. Patients never receiving OPTx or EFTx were censored. Exposure variables evaluated were: time dependent covariate, phase (coded as binary), age, gender, Charlson Comorbidity Index, comorbidities, and ID consult. The time dependent covariate changed through the time of observation based on both time-to-notification, and either time-to-OPTx or time-to-EFTx.**Results:** 244 GN BSIs were analyzed: 127 (52.3%) in the baseline phase and 116 (47.7%) in the intervention phase. Time-to-OPTx was associated with the time dependent covariate (adjusted hazards ratio [aHR]: 2.334; 95% CI: 1.347-4.044; p=0.003), the intervention phase (aHR: 1.599; 95% CI: 1.174-2.177; p=0.003), age greater than 60 years (aHR: 0.740; 95% CI: 0.551-0.994; p=0.046) and an ID consult (aHR: 1.430; 95% CI: 1.078-1.897; p=0.013). Time-to-EFTx was associated with the intervention phase (aHR: 1.478; 95% CI: 1.116-1.958; p=0.006) and Charlson Comorbidity Index (aHR: 0.931 [per single digit increment]; 95% CI: 0.882-0.983; p=0.010).**Conclusions:** BC-GN technology and RPh notification was found to be associated with time-to-OPTx and time-to-EFtx.

Identification of Beta Haemolytic *Streptococci*, Alpha-Hemolytic *Streptococci* and *Enterococci* Directly From Positive Blood Culture Bottles

Author Block:

M. Kedfors Holm, P. Lüthje, M. Ullberg, **V. Ozenci**; Karolinska, Stockholm, Sweden

Abstract Body:

Background: Bloodstream infections (BSI) caused by streptococci and enterococci are related to high morbidity and mortality. Identification of these microorganisms directly from blood culture (BC) bottles can facilitate early effective treatment of the patients. The aim of this study was to evaluate the performance of agglutination tests in identification of streptococci and enterococci directly from positive BC bottles. Methods: BacT/ALERT-FA and -FN Plus BC bottles were used for blood cultures in the BacT/ALERT 3D (bioMérieux, Durham, NC, USA) system. The agglutination tests for A, B, C, D and G (Phadebact® Streptococcus Tests, Sollentuna, Sweden) were performed on each 1 drop of BC broth from the positive bottle. The results were read after 1 min and analyzed by two laboratory technicians independently. Conventional methods were used as reference. Results: A total of 100 BC bottles that flagged positive with gram-positive bacteria in chains or pairs were studied. The agglutination assays could correctly identify 16/16 group A streptococci (GAS), 17/17 group B streptococci (GBS), 6/6 group C streptococci (GCS), 9/9 group G streptococci (GGS). The agglutination tests were positive for D in 25/32 enterococci. In 2/32 BC bottles with Enterococcus spp. the tests reacted positive for C and negative in the remaining 5 isolates. The agglutination tests were negative for A, C, G, B, and D in 16/18 alpha-hemolytic streptococci and enabled the preliminary identification of these isolates. In 2/18 alpha-hemolytic streptococci the tests were positive for C. In BC bottles with Aerococcus and Lactococcus spp. (one each) the agglutination tests were negative. The test results were available 15 min after blood culture positivity. Conclusions: The present study shows that the agglutinations tests are reliable in preliminary identification of streptococci and enterococci directly from positive BC bottles. The present approach does not require costly instrumentation and can easily be implemented in the clinical routine in large as well as small laboratories. A faster response to clinicians might support earlier administration of appropriate antimicrobial treatment for patients with BSI.

Publishing Title:

A Retrospective Comparison of Blood Culture Positivity Rates Between Blood Culture Systems

Author Block:

B. Williams, A. Sweeney, A. Kerr, P. Gilligan; Univ. of North Carolina Hosp., Chapel Hill, NC

Abstract Body:

Background: In July 2014, the CMIL at UNC Hospitals switched from BacT/ALERT (bioMerieux, Inc., Durham, NC) to the BACTEC FX (BD Diagnostics, Sparks, MD) for its primary blood culture system. The bottles used on BacT/ALERT system were FAN Aerobic, Standard Anaerobic and Pediatric FAN. For the BACTEC FX system, Plus Aerobic/F and Lytic/10 Anaerobic/F bottles were used. After implementing the BACTEC FX system, a higher rate of positive blood cultures was observed. This study is a retrospective data analysis of these positivity rates comparing the BacT/ALERT system with those of the current BACTEC FX system.**Methods:** Blood cultures from February 2013 - June 2014 (BacT/ALERT) and August 2014 - December 2015 (BACTEC FX) were used to determine the positivity rate. This rate was calculated by dividing the number of positive blood cultures by the total number of blood cultures. Both true positive and contamination rates were compared.**Results:** Using the BacT/Alert, 2,935 (6.8%) of 43,321 blood cultures were positive. Using the BACTEC FX, 4,001 (9.1%) of 43,762 blood cultures were positive. These data indicate a significant increase of 33.8% ($P < 0.001$) positive cultures using the BACTEC FX system. Staphylococcus aureus was isolated in 431 (BacT/Alert) and 1049 (BACTEC FX) cultures, an increase of 141% ($p < 0.01$). *Enterobacteriaceae* were isolated in 627 (BacT/Alert) and 814 (BACTEC FX) cultures, an increase of 35.7% ($p < 0.01$). *Enterococcus sp*. were isolated in 212 (BacT/Alert) and 289 (BACTEC FX) cultures, an increase of 40% ($p < 0.01$). Anaerobic organisms were isolated in 109 (BacT/Alert) and 132 (BACTEC FX) cultures ($p=0.08$). Isolation of *Candida sp*. was relatively unchanged, 213 (BacT/Alert) and 218 (BACTEC FX) cultures (p 0.45). *Streptococcus pneumoniae* isolation was also relatively unchanged, with 39 isolates by each system (p 0.48). Organisms indicating contamination were detected in 610 (BacT/ALERT) and 845 (BACTEC FX) cultures, an increase of 37% ($p < 0.01$).**Conclusions:** Conversion to the BACTEC FX system has resulted in increased blood culture positivity rates especially for *S. aureus*, *Enterococcus sp.* and *Enterobacteriaceae*. An increase in contamination rate was also observed with the BACTEC FX system which is likely due to the overall increase in isolation of coagulase negative staphylococci.

***Klebsiella pneumoniae* Volatile Metabolites Produced During Growth in Human Blood**

Author Block:

C. A. Rees[1], A. Smolinska[2], J. E. Hill[1]; [1]Dartmouth Coll., Hanover, NH, [2]Maastricht Univ., Maastricht, Netherlands

Abstract Body:

Background: *Klebsiella pneumoniae* bacteremia is an important cause of morbidity and mortality. Present diagnostic modalities require culturing the agent from blood samples, a time-consuming process that lacks sensitivity. A more rapid and sensitive diagnostic could improve patient outcomes by expediting time-to-diagnosis. Here, we show that *K. pneumoniae* produces a suite of volatile metabolites not normally present in sterile blood that may represent putative diagnostic biomarkers that can be sampled directly from blood or, via partitioning, patient breath. **Methods:** *K. pneumoniae* ATCC 13883 was incubated in human blood for 7 and 12 hours, corresponding approximately to mid-exponential and early stationary growth phases. Cultures were transferred to air-tight vials, and volatile metabolites were analyzed using GCxGC-TOFMS. The Mann-Whitney U test with Benjamini-Hochberg correction was used to identify volatiles that differed in relative abundance ($p < 0.05$) between cultures and sterile blood.**Results:** 34 volatile metabolites were identified that differed significantly in abundance between cultures and sterile blood controls. Of these, 22 were not detected in sterile blood, and likely represent the consequence of bacterial metabolism. For example, 3-hydroxy-2-butanone and 2,3-butanedione were detected only in cultures. These are known bacterial metabolites of pyruvate that have not previously been measured in the headspace of healthy blood samples [1]. 11 compounds were identified that have never previously been associated with *K. pneumoniae* metabolism. 3 significant volatiles remained detectable in cultures diluted in saline to a cell density of approximately 1×10^3 CFU/mL.**Conclusion:** Volatile metabolites can reliably differentiate *K. pneumoniae*-inoculated human blood samples from sterile blood. A subset of these metabolites remain detectable after dilution of cultures in saline to a cell density of approximately 1×10^3 CFU/mL. We hypothesize that further method optimization could reduce the limit of detection to bacterial concentrations seen in clinical bacteremia. Volatile biomarkers produced by *K. pneumoniae* in the setting of bacteremia could inform the development of a rapid, minimally-invasive breath- or blood-based diagnostic, potentially reducing time-to-diagnosis, thereby improving outcomes.

Clinical Evaluation of a Dna-based Microarray Platform in Identification of Microorganisms from Positive Blood Culture Bottles

Author Block:

M. Ullberg, e. beste, P. Luthje, M. Melaku, A. Ohlsson, **V. Ozenci**; Karolinska, Stockholm, Sweden

Abstract Body:

Background: The Prove-it sepsis assay (Mobidiag, Helsinki, Finland) is a broad-range PCR followed by specific identification on a microarray. The new, improved CE-IVD version of Prove-it assay covers 60 bacteria, 13 fungi and the *mecA* methicillin resistance marker. We evaluated the performance of the Prove-it sepsis assay in identification of bacteria and yeasts from positive BC bottles prospectively. **Methods:** The microorganisms were identified by Prove-it using 0.5 ml broth from positive blood culture bottles. BacT/ALERT-FA and -FN BC bottles and the BacT/ALERT 3D BC system were used in the study. Standard culture-based methods served as reference. **Results:** A total of 213 positive BC samples were tested. Only one blood culture specimen per patient was included. The Prove-it sepsis assay repertoire covered all present microorganisms in 195/213 (91.6%) BC bottles. Among these 195 samples, Prove-it could identify 180/195 (92.3%) microorganisms correctly. In 2/195 (1%) BC bottles microorganisms were misidentified, one *K. pneumonia* as *E. coli* and one *S. aureus* as *S. epidermidis*. In one sample positive for *S. aureus* and 14 samples with coagulase-negative staphylococci, the assay detected the *mecA* gene.[PL1] Among 4 polymicrobial samples, Prove-it could identify all microorganisms in 3/4 BC bottles. In the remaining sample that contained *C. glabrata* and *C. albicans*, the assay could identify only *C. glabrata*. Overall sensitivity of the Prove-it sepsis assay was 93.26% (95% CI: 88.76%-96.37%). [PL2] Overall specificity was not analyzed. When method accuracy was evaluated for subgroups of gram-negative and gram-positive bacteria, sensitivity and specificity values were 92.37% (95% CI: 86,01%-96,45%) and 98.7% (95% CI: 92.98%-99.97%) respectively for gram-positives, and 95.65% (95% CI: 87.82%-99.09%) and 99.21% (95%CI: 95.66%-99.98%) respectively for gram-negatives. **Conclusions:** The total procedure for the Prove-it assay took 4 hours. In contrast, results by standard methods were obtained after 24-48 hours. The present prospective study shows that the Prove-it sepsis assay has high performance in identification of microorganisms directly from BC bottles. [PL1]Was this confrimed by standard techniques? *mecA* gene which was confirmed by standard methods [PL2]Overall specificity? Negative bottles were not tested.

Publishing Title:

A Cost-Effective Dual Platform Algorithm For Rapid Molecular Detection Of Organisms In Positive Blood Culture Bottles

Author Block:

S. Collier, P. C. Schreckenberger, R. Golash, V. Rekasius; Loyola Univ. Med. Ctr., Maywood, IL

Abstract Body:

Background: In an effort to reduce the financial burden of rapid pathogen identification in blood culture samples, our laboratory adopted a testing algorithm based on the Gram stain of positive blood culture bottles by utilizing either the Xpert® BC MRSA/SA Panel (Xpert BC)[Cepheid, Sunnyvale, CA] or the FilmArray® Blood Culture Identification Panel (BCID) [Biofire Diagnostics, Salt Lake City, UT].**Methods:** A retrospective study was conducted using 505 positive blood culture samples collected between May 2015 and October 2015 (154 days). Upon signal from blood culture instrument (BACTEC™ FX), positive blood culture bottles were removed and Gram stain performed. Specimens with Gram stains showing gram-positive cocci in clusters were tested using the Xpert BC (n= 229). Specimens with Gram stains indicating yeast, multiple morphologies, or bacteria other than GPC-CL were tested using BCID (n= 276). Results were compared to traditional culture-based ID methods. Results were evaluated for Gram stain and/or instrument errors.**Results:** Of 505 blood cultures evaluated by Gram stain, 276 were reflexed to BCID (54.6%) and 229 were reflexed to Xpert BC (45.3%) for ID. There were 21 MRSA, 31 MSSA, and 177 reports of no targets detected (NTD) with Xpert BC. Of the 177 NTD instances, 173 grew Coag. Neg. *Staph* (*CoNS)* or micrococci only and 4 (1.7%) grew other organisms indicating that the Xpert BC was set up inappropriately (see Table). In 7 instances BCID was set up when only *S. aureus* (1) or CoNS (6) grew in culture (see Table). In 2 instances the Xpert BC was down for repair necessitating the use of BCID, leaving 5 (1.8%) instances where BCID was set up inappropriately. The difference in panel cost for the two systems is $68.33/panel. By reflexing 229 positive blood cultures to Xpert BC (at lower cost) instead of BCID we saved $15,647.57 in reagent cost over 154 days, extrapolated to an annual savings of $37,086.77.**Conclusion:** Based on the low Gram stain reading error rate (< 2%), the dual platform approach provides savings to the laboratory without compromising patient care.

Blood Culture Results		
Gram Stain	No. Cultures with Growth of *S. aureus/Micrococcus*/CoNS only	No. Cultures with Growth of Other Organisms or NTD
GPC-CL Run on Xpert BC (n=229)	225	4

Non GPC-CL Run on BCID (n=276)	7	269

D. Cianciminio-Bordelon, A. Quianio, K. Gilhuley, A. Paskovaty, N. Cohen, Y. Tang, S. Seo, N. Babady; Mem. Sloan Kettering Cancer Ctr., New York, NY

Abstract Body:

Background: Bacteremia caused by Gram negative rods (GNR) can be life threatening for immunocompromised, neutropenic cancer patients. Early administration of targeted antibiotic therapy is ideal. Rapid identification is therefore critical to improving patients' outcomes. The Gram-Negative *Quick*FISH™ peptide nucleic acid fluorescence in-situ hybridization (qPNA FISH) allows for identification of *E. coli*, *K. pneumoniae* and *P. aeruginosa* directly from blood culture within 30 minutes after Gram stain. We evaluated the diagnostic performance of qPNA FISH and determined the laboratory and clinical utility of the assay for patients with GNR bacteremia.**Methods:** Prior to implementation, the qPNA FISH performance characteristics were determined using both seeded blood culture bottles (for analytical sensitivity and specificity studies) and 250 consecutive blood cultures positive for GNR collected from 113 patients (for accuracy studies). Post-implementation, the sensitivity, specificity, turn-around time (TAT) to identification from receipt of culture in the laboratory, and the intervention by the antibiotic stewardship team (AST) was monitored for three months. **Results:** The overall sensitivity and specificity was 100% for all seeded bottles. For the 250 patient samples, the overall sensitivity and specificity was 100% and 93%, respectively. Post-implementation, 112 positive GNR blood cultures were tested, the sensitivity was 91% and specificity was 97%. Time to identification decreased by ~28 hours following implementation of qPNA FISH. Post-implementation, 70 patients qPNA FISH result were reported to the ordering physician and the AST simultaneously. Earlier intervention, including de-escalation and escalation of therapy, occurred in 15% and 7.5% of analyzed cases, respectively. **Conclusions:**qPNA FISH offers increased sensitivity, specificity, and faster TAT for the three most common Gram negative pathogens. This, in turn, leads to more rapid evaluation and intervention when necessary by the AST. Further monitoring and additional studies (e.g. cost analysis) will provide additional data on the potential of qPNA FISH to improve clinical outcomes.

Publishing Title:

Does Blood Culture Bottle Transport Time Before Instrument Entry Impact Instrument Detection Time of Positives?

Author Block:

R. B. Thomson, Jr., B. Link, I. Dusich, Y. Zhou, S. Das; NorthShore Univ. Hlth. Systm., Evanston, IL

Abstract Body:

Background: Positive blood culture results provide critical information for the sickest patients. Data have shown that delayed detection or reporting of results can negatively impact patient care. No data are available to judge the impact of transport times less than 24 hr. This study examines the impact of bottle transport times ranging from 2-12 hr on instrument detection times of positive cultures. **Methods:** NorthShore is a 4 hospital healthcare system with a single microbiology laboratory located at one of the hospitals. Blood for culture is collected at all 4 hospitals and transported by car in a room temp insulated carrier (3 hospitals at 4, 11 and 13 miles distance) or tube system (core hospital) to the laboratory. 451 blood cultures positive for *E. coli* collected between May, 2014 and May, 2015 were included. Blood collection time was recorded by a bar code reader used by the phlebotomist. BACTEC FX entry and positive detection times were recorded by the instrument. Transport time was calculated by subtracting BACTEC entry time from blood collection times. Instrument detection time was calculated by subtracting BACTEC positive from BACTEC entry times. Total time to positive blood culture detection was transport plus instrument detection times.**Results: T**ransport times up to 12 hr did not impact instrument detection times for *E. coli*. In fact, 89% of cultures were detected within 24 h and for this group of 400 specimens there was a statistically significant negative correlation, i.e., as transport times increased from 2-12 hr, instrument detection times decreased. Median transport times among hospitals varied between 2-6 hr with ranges from 30 min-12 hr. Total time to positive blood culture detection was approx 14 hr and was not statistically different regardless of transport time. There were no significant differences in total time to detection among hospitals.**Conclusions:** BACTEC blood culture bottle transport times up to 12 hr did not prolong instrument detection times for *E. coli*. Transport times up to 12 hr did not shorten total time to positive blood culture detection. In spite of transport time differences, total time to detection for all hospitals was similar.

Genotypic Differences of the *Mycobacterium tuberculosis* Beijing Family Originated in Adjacent Countries Based on Whole Genome Sequencing

Author Block:

S. Ryoo[1], H. Lee[1], J. Lee[2], S. Lee[3]; [1]Korean Inst. of Tuberculosis, Cheongju-si, Korea, Republic of, [2]Natl. Instrumentation Ctr. for Environmental Management, Seouol, Korea, Republic of, [3]Korea Univ. Ansan Hosp., Ansan, Korea, Republic of

Abstract Body:

Background: Tuberculosis (TB) of immigrants or foreigners is increasing in Korea. Determining the molecular epidemiology of *Mycobacterium tuberculosis(M.TB)* isolates with identifying the transmission dynamics between adjacent countries is essential for upgrading the strategy for immigration TB screening. Especially Korea and China's cultural economical interchange is rapidly increasing now. Genotypic differences of the *M.TB* Beijing family originated in adjacent countries based on whole genome sequencing is needed. We've been initiated a project on the molecular and bio-informatics for discriminating TB strain's originality, it includes multi- and extensively drug-resistant tuberculosis (MDR-/XDR-TB) clinical isolates from China and Korea in the period from 2014 to 2015. **Methods:** 1) Preliminary Bio-informatics study: We used *M. TB* genome sequences, annotation refinement and orthology assignment. The complete whole genomes of five *M. TB* strains were downloaded from NCBI, and the plasmid sequences were eliminated. The annotation refinement was carried out through coding sequence (CDS) mapping by BLAST (v2.2.26); thus, the CDSs collected from the thirteen strains were used to map each genome. Clusters of Orthologous Groups (COGs) were used as references to assign orthology, and orthoMCL was employed to generate customized orthology clusters. 2) PacBio: We construct and adopted Genome Topology Network (GTNs).**Results:** We got Mauve alignment for China and Korean *M. TB* strains. **Conclusions:** The comparative genomic analysis of these genome sequences will facilitate the identification of significant distinguishing markers associated with their local origins. Also give us more insights into the genetic and epidemiology variations occurring in MDR/XDR-TB strains circulating in Korea and China. Bio-informatics tool can be allows us comparing closely related TB genomes exist adjacent regions of Korea. We believe that our study methodology will be suitable for the exploration of genomic connections of TB strains, and phylogenetic analysis will provide additional insights into whole genome-based phylogenetic analysis.

Comparison of Gene Xpert MTB/RIF Assay with Multiplex PCR for Diagnosis of Tuberculous Meningitis (TBM): Experience from High-Endemic Low-Resource Country

Author Block:

M. Sharma, K. Sharma, M. Modi, A. Sharma, S. Varma; PGIMER, Chandigarh, India

Abstract Body:

Background: Rapid and specific diagnosis of tuberculous meningitis is of paramount importance to decrease morbidity and mortality. Therefore, present study was undertaken to do the comparison of Gene Xpert MTB/RIF (GX) assay and multiplex PCR (MPCR) using three targets (IS6110, MPB64 and protein b) for diagnosing tuberculous meningitis.**Methods:** GX and MPCR were performed on cerebrospinal fluid samples of 60 patients with culture positive TBM, 10 patients with non-TB infectious meningitis and 10 patients with non-infectious neurological disorder. rpoB gene sequencing was done for diagnosing rifampicin resistance in all positive cases.**Results:** GX and MPCR were positive in 50 (83.33%) and 56 (93.33%) patients respectively. Both the tests were negative in all controls. Rif resistance was detected in 8 of 50 (16%) by GX, and in 7 of 56 (12.5%) by MPCR along with rpoB gene sequencing. There was a case of false Rif resistance detected by GX which was Rif sensitive on rpoB gene sequencing. Cost of doing MPCR was less than $1 whereas GX required $10 per isolate.**Conclusions:** MPCR has a higher sensitivity than GX for diagnosing TBM. MPCR is a robust and cost effective method for diagnosis of TBM in low-resource and high-endemic countries.

Multi Targeted Loop-Mediated Isothermal Amplification (LAMP) for Rapid Diagnosis of Extra-Pulmonary Tuberculosis in 60 Minutes: Experience from North India

Author Block:

K. Sharma, M. Modi, A. Sharma, S. Varma; PGIMER, Chandigarh, India

Abstract Body:

Background: Rapid and accurate diagnosis of extra-pulmonary tuberculosis (EPTB) is imperative for early treatment and better patient outcome. Loop-mediated Isothermal Amplification (LAMP) is a promising nucleic-acid amplification assay. LAMP assay could be carried out in simple water bath under isothermal conditions in 60 minutes, and can be performed in any laboratory even in rural setting in resource poor endemic countries. We evaluated LAMP assay using two different target regions specific for *Mycobacterium tuberculosis* complex for the diagnosis of EPTB.**Methods:** LAMP assay using 6 primers was performed on patients suspected of EPTB on various EPTB samples (CSF, Synovial fluid, Lymph node and tissue biopsies and various other samples). Results of 150 patients clinically suspected of EPTB (50 culture positive, 100 culture negative) and 100 non-TB control subjects were compared with *IS*6110 PCR, culture and ZN smear examination.**Results:** Overall LAMP test (using any of the two targets) had a sensitivity and specificity of 96% and 100%, respectively, for confirmed (50 culture positive) cases and 84% and 100%, respectively for clinically suspected cases. Sensitivity of *IS*6110 LAMP, MPB64 LAMP and *IS*6110 PCR for clinically suspected cases was 78 (78%), 82 (82%) and 70 (70%), respectively. In total 150 EPTB patients, the overall sensitivity of microscopy, culture, *IS*6110 PCR, *IS*6110 LAMP, MPB64 LAMP and the multi-targeted LAMP assay (if any of the two targets were used) were 4%, 33.3%, 74.6%, 82.66%, 86.66% and 92%, respectively. Specificity of all the tests was 100%. There were 6 cases which were missed by *IS*6110 LAMP and 2 cases by MPB64 LAMP.**Conclusions:** LAMP assay using two targets is a promising technique for rapid diagnosis of EPTB in 60 minutes especially in a resource poor setting who are still battling with this deadly disease.

Comparison of MTBDR Plus Assay, Gene Xpert MTB/RIF Assay and Multiplex PCR for the Diagnosis of Ocular Tuberculosis

Author Block:

K. Sharma, R. Bansal, A. Sharma, V. Gupta, A. Gupta; PGIMER, Chandigarh, India

Abstract Body:

Background: Ocular tuberculosis (OTB) is an important cause of vision loss in Indian subcontinent. Rapid and timely diagnosis of ocular tuberculosis is of paramount importance to decrease the morbidity and to save these eyes from blindness. Therefore, the present study was undertaken to carry out a comparative evaluation of MTBDR plus (LPA), Gene Xpert MTB/RIF (GX) and Multiplex PCR (MPCR) for the diagnosis of intraocular tuberculosis (IOTB).**Methods:** LPA, GX and MPCR were performed on vitreous fluid (VF) of 75 patients with presumed IOTB, 20 disease controls and 20 non-uveitic controls. rpoB gene sequencing was done for diagnosing Rifampicin resistance in positive cases.**Results:** LPA, GX and MPCR were positive in 27 (36%), 19(25.33%) and 55(73.33. %) patients, respectively. All tests were negative in all controls. Rif resistance was detected in 3 by GX and 6 by LPA. MPCR followed by rpoB gene sequencing detected Rif resistance in 5 cases. False Rif resistance was detected in one patient each by LPA and GX as they were Rif sensitive on sequencing.**Conclusions:** Comparing with other two techniques, MPCR is a cost effective , robust and reliable technique for the diagnosis of paucibacilliary condition like ocular tuberculosis.

Challenges Establishing TB Culture Laboratory in Remote Environments

Author Block:

W. G. Jones[1], T. Commans[2], R. Arpornsilp[1], D. Miriti[1], M. H. Abdi[3], j. Okari[4]; [1]Intl. Organization for Migration, Nairobi, Kenya, [2]Ctr. for Disease Control and Prevention, Atlanta, GA, [3]Intl. Organization for Migration, Dadaab, Kenya, [4]Ministry of Hlth.Kenya, Nairobi, Kenya

Abstract Body:

Problem: To provide tuberculosis diagnostic services for 600,000 Somali Refugees in Dadaab area Northern Kenya. The International Organization for Migration, Centers for Disease Control and Prevention US, Ministry of Health Kenya, United Nations High Commission for Refugee, CARE partnered to provide diagnostics by smear, culture and DST testing to support MDR ward at Ifo Hospital Dadaab, a hostile, remote environment with challenges. Somali refugees travel to access treatment for MDR TB at the clinic. CDC arranges through the Kenyan Ministry of Health, National TB Program for the supply of XpertMTB/rif cassettes and media for culture testing, UNHCR supplies diesel for 24/7 electricity. **Method:** Security: 24/7 guards required at the TB laboratory, police escorts to the laboratory each day. Electricity: 24/7 staff to ensure running of the generators. Water: Water supplied from CARE in Dadaab Issues included; Contamination rates, reduced working hours, dust, sterilization of reagents, operation of equipment Increase decontamination agent in processing step remaining within 2% per volume, adding Penicillin solution to the residue make-up. Transport of specimen from camps to laboratory with security vehicles. Improving the sterilization by replacing autoclaves. Efficiency required, the workday in the laboratory was 3-4 hours due to security. Improved cleaning the laboratory, replacing filters in BSC, air conditioners regularly. Autoclaves repaired, replaced. Logistics for flights, accommodation, escorts for service technicians. Contamination rates were reduced 30% to 9% in MGIT and 27% to 4% in Lowenstein Jensen Media. **Results:** From April 2013 to 2015 diagnosis of 233 cases of MDR TB, 86 are on treatment and 126 cured. The laboratory tested sputa with GenXpert then, if positive (95%), on to smear and culture testing to identification of MTB. The isolates of MTB were shipped to Nairobi for Drug Susceptibility Testing. It was found 99% were MDR TB cases. MDR TB Cases Detected per year. The provision of TB smear and culture testing facilities in refugee camps provide excellent results for the detection of MDR TB, but many challenges must be overcome.

Long Term Evaluation of Xpert Mtb/Rif Pcr Test for Detecting *Mycobacterium tuberculosis* in Respiratory Specimens

Author Block:

J. Aslanzadeh, L. Coppola, P. Hamilton, Y. Maldonado; Hartford Hosp., Hartford, CT

Abstract Body:

Background: *Mycobacterium tuberculosis* (MTB) remains a major global public health problem. Early detection of infectious patients is essential to reduce the death rate and interrupt transmission. Most clinical laboratories rely on acid fast bacilli (AFB) smear for preliminary diagnosis of MTB. The reliability of AFB smear depends on the experience of the medical technologist and on the number of AFB present in the specimen. In addition, AFB smear does not differentiate MTB from mycobacteria other than TB (MOTT). Xpert MTB/RIF PCR (Cepheid, Sunnyvale, CA) is reported to detect MTB and it's multidrug-resistant form with high degree of sensitivity and specificity. **Methods:** In a prospective study, from November, 2011 to October 2015, AFB stain, AFB culture and Xpert MTB/RIF PCR test were performed on 864 specimens collected from 541 patients.**Results:** Severn hundred thirty three samples tested negative for MTB by AFB smear, AFB culture and Xpert MTB/RIF PCR. Forty eight samples grew MTB and 83 samples grew MOTT. Among the 48 MTB culture positive samples, AFB smear and PCR were positive on 38 and 43 samples respectively. Among the 83 samples that were culture positive for MOTT, 2 samples from 2 different patients tested PCR positive for MTB and were considered false positive. In addition, 35 of the 83 samples (42%) were AFB smear positive. Except for one sample that grew *M. avium* and was false positive for MTB by PCR the remaining 863 samples tested PCR negative for the rifampin resistant gene. The overall sensitivity, specificity, positive and negative predictive value of Xpert MTB/RIF PCR was 89.5%, 99.8%, 95.6% and 99.4% respectively.**Conclusions:** We conclude Xpert MTB/RIF PCR test is highly sensitive and specific for detecting MTB in respiratory specimens.

Diagnosis of Tuberculosis Meningitis by Real Time Pcr: Comparison of Extraction Protocols and Molecular Targets

Author Block:

F. S. Palomo, M. G. C. Rivero, M. G. Quiles, F. P. Pinto, A. M. O. Machado, A. C. C. Pignatari; Federal Univ. of São Paulo, São Paulo, Brazil

Abstract Body:

Tuberculosis meningitis is a severe form of extrapulmonary tuberculosis, because of its high morbidity and mortality. This study aimed to compare and to validate molecular protocols (PCR) for the diagnosis of tuberculosis meningitis directly from cerebral spinal fluid system (CSF) samples including the mycobacterium DNA extraction techniques and targets for PCR amplification. One hundred CSF samples from 68 patients suspected of tuberculous meningitis attended at Hospital São Paulo, Brazil from June 2011 to June 2014 were studied. Four DNA extraction techniques (Phenol-Chloroform-Thiocyanate guanidine, Silica Thiocyanate guanidine, Resin and Resin with ethanol) were compared and CSF samples were used to determine the best target (*IS6110, MPB64* and *hsp65KDa*) by qPCR for diagnosis of tuberculosis meningitis. For statistical analyzes the CSF samples were classified as true positive and negative after a survey in the site BrazilianTBweb, laboratory CSF data and evaluation of medical records of patients. The extraction protocol using the phenol chloroform-thiocyanate guanidine showed the best results in terms of quantification and sensitivity of PCR amplification, presenting up to 10 times more DNA than the second best (silica guanidine thiocyanate). The targets that showed the best amplification results was the the *IS6110* qPCR with a sensitivity and specificity, respectively, of 100 % and 79 % when compared to culture. The sample analysis for *IS6110* qPCR amplification showed 91% sensitivity, 97% specificity with the clinical diagnosis. When this analysis was grouped by patient, we showed a 100% sensitivity, specificity of 98 % and a very good agreement with the clinical diagnosis. A protocol using extraction with phenol chloroform and guanidine thiocyanate, followed by amplification of the *IS6110* target for real time PCR in house showed to be suitable for molecular diagnosis of tuberculosis meningitis in our clinical setting.

Evaluation ofMycotube, a Modified Version of Lowenstein-jensen Medium, for EfficientRecovery of *Mycobacterium tuberculosis*

Author Block:

R. NAMBIAR[1], S. Chatellier[2], N. Bereksi[3], A. van Belkum[2], A. Shetty[4], C. Rodrigues[4]; [1]PD Hinduja Hosp. & Med. Res. Ctr., Mumbai, India, [2]bioMérieux, La Balme-les-Grottes, France, [3]bioMérieux, Craponne, France, [4]PD Hinduja Hosp. & Med. Res. Ctr., Mumbai, Maharashtra, India

Abstract Body:

This study aimed to evaluate the performance of LJ Mycotube, a new variant of Lowenstein-Jensen (LJ) medium, by comparing it with MGIT (gold standard), local LJ medium, and the widely used bioMérieux LJ-T medium for *Mycobacterium tuberculosis* (MTB) cultivation, in terms of recovery rate and time.Pulmonary and extrapulmonary specimens from “anti-TB treatment-naïve clinical suspects” (n = 207) visiting our tertiary care center were included in this study, after obtaining informed consent. NALC-NaOH method was used for decontamination; the decontaminated specimens were used to inoculate MGIT, local LJ, LJ-T, and LJ Mycotube. The results were evaluated using objective (total number of positive tubes and time to growth detection) and subjective (time to tube removal and contamination) parameters.LJ Mycotube yielded 140 positive results, compared to 162, 69, and 141 from MGIT, local LJ, LJ-T, respectively. The mean time to growth detection was 17.43 days for LJ Mycotube, versus 14.53, 28.11, and 16.52 days for MGIT, local LJ, LJ-T, respectively. The mean time to growth detection for local LJ significantly differed from that of MGIT, but this parameter did not show a significant difference in case of LJ-T and LJ Mycotube ($p < 0.05$). The time to tube removal was higher in case of LJ Mycotube because the negative tubes were incubated for a longer period to confirm culture negativity. The contamination rate was 0% for all media. LJ Mycotube had a sensitivity of 85.80% and a specificity of 97.78%, with respect to MGIT.LJ Mycotube is a good solid medium, comparable with MGIT and LJ-T. Although liquid culture tends to be more rapid with higher sensitivity, the newly developed LJ Mycotube, a modification of the traditional solid LJ medium, offers good results at cheaper cost and with basic infrastructure. Moreover, contamination rate generally tends to be lower in case of solid media, giving this new medium an edge over routine liquid culture. This new reliable medium helps with definitive diagnosis of TB, as well as with the isolates required for conventional drug susceptibility testing in underdeveloped and developing countries.

An Encapsulating Microfluidics Platform for Rapid Mycobacterial Growth on Alginate-Based Particles

Author Block:

L. López-Cerero[1], M. Ramos-Guelfo[1], L. Delgado-Ramos[2], F. March[3], S. Chávez[2], P. Coll[3]; [1]Univ. Hosp. Virgen Macarena, Seville, Spain, [2]Inst. de Biomedicina de Sevilla, Seville, Spain, [3]Univ. Hosp. Santa Creu i Sant Pau, Barcelona, Spain

Abstract Body:

Background: *Mycobacterium tuberculosis* (MTB) growth is quite heterogeneous and usually involves different phenotypes with an impact in phenotypic resistance. Attempts have been made to quantify mycobacterial growth by encapsulating individual cells using agarose microdrops emulsioned in oil. This method provides limited control over particle diameter, and produces an immiscible co-flowing liquid. The aim of the study is develop a simple and rapid method of MTB culture, based on microencapsulating single bacteria cell by using a microfluidic technology (Cellena®) capable of monodisperse particles of predictable and controllable size.**Methods**: Reference *M. tuberculosis* H37Ra ATCC 25177 was used. A 0,5 McFarland suspension in 7H9 broth of the strain was filtered to remove any clump or aggregation. Single cell suspension was confirmed by using phase contrast microscopy. The different volumes of cell suspension and different concentration of alginate in medium were tried, in order to obtain occupied particles by single cells. The Cellena® system was used to generate alginate particles of a mean diameter of 100 mm. The control of inoculum was carried out by platting 100 ml of cell suspension on 7H10 agar and incubated for 3 weeks and the CFU was determined. After incubation in 7H9 broth for 24, 48 and 72 hours, the samples with encapsulated cells were fixed with 1% formaldehyde. Microcolonies detection was performed by microscopic examination using phase contrast as well as by acid fast staining.**Results**: After incubating 24 h, microcolonies were detected in 8-10% of particles in all experiments, both in unstained and Ziehl-Neelsen and Rhodamine/Auramine stained samples. The size of microcolonies increased during incubation and burst occupied particles were seen after incubating 48 and 72 h. Alginate concentrations below 3,5% were not able to retain mycobacterial growth. The limit on the number of encapsulated cells for a 99% 1-cell occupancy was determined in 1,5 x 10^5CFU/ml.**Conclusion**: The Cellena® system technology can be used to study the growth of individual cells from a mycobacterial population. The microenvironment permits a more rapid detection, measuring microcolony growth in 24h.

Publishing Title:

application Of Protein Microarrays For The Identification Of Sero-Reactive Antigens In *mycobacterium Avium* Subsp. *paratuberculosis*

Author Block:

L. Li[1], J. P. Bannantine[2], C. A. Praul[1], J. Raygoza Garay[1], M. E. Hines II[3], R. Katani[1], V. Kapur[1]; [1]The Peensylvania State Univ., University Park, PA, [2]Natl. Animal Disease Ctr., USDA-ARS, Ames, IA, [3]The Univ. of Georgia, Tifton, GA

Abstract Body:

Mycobacterium avium subspecies *paratuberculosis* (MAP) is the causative agent of Johne's disease (JD), a chronic intestinal disease of domestic animals that is controversially associated with human Crohn's disease. JD has a high prevalence rate and results in considerable adverse impact on animal health, but methods for detection of animals, particularly early in infection are currently lacking. To address this need, we have developed a MAP protein microarray as a tool for sero-diagnostic antigen discovery by studying the dynamics of the humoral immune response in a baby goat model of infection. A protein microarray consisting of ~600 recombinant MAP proteins was constructed and used to identify reactive antigens in serum samples from experimentally MAP-infected (n=10) and negative control (n=10) goats at months 0, 2, 4, 6, 8, 10, and 12 post MAP infection. The analysis resulted in the identification of a total of 53 MAP recombinant proteins that were sero-reactive in infected animals, but not in the control group. In contrast, there was no sero-reactivity noted with 3 *M. tuberculosis*-specific control antigens. Of the 53 candidate MAP antigens, a total of 15 were detected between 2 and 4 months post-infection, which is considerably sooner than the detection of fecal MAP shedding (month 6 or later) by using fecal culture and/or PCR in these same animals. Further, our preliminary analyses suggest that individual MAP recombinant proteins were reactive even in MAP-infected goats that remained serologically negative on commercially available MAP ELISA testing, suggesting that the protein microarray approach may enable the identification of antigens that are sero-reactive even during the early (pre-shedding) stages of infection. Future studies with larger numbers of recombinant proteins and serum samples are planned.

Molecular Detection And Identification Of Acid-Fast Bacteria From Formalin-Fixed Paraffin-Embedded Tissues

Author Block:

J. R. Bao, R. B. Clark, R. N. Master, K. L. Shier, L. L. Eklund; Nichols Inst., Quest Diagnostics, Chantilly, VA

Abstract Body:

Background: Identifying AFB in formalin-fixed paraffin-embedded (FFPE) tissues is challenging, and PCR methods may detect only the *Mycobacterium tuberculosis* complex. We developed a method coupling a polymerase chain reaction with pyrosequencing (PCR-Seq) to detect and identify various AFB organisms from FFPE tissues; and here, evaluate its performances.**Methods:**FFPE tissues from various tissue types were received from laboratories around the country sequentially. Most specimens were ≤6 months old from biopsy. Each block of tissue was sectioned at 6 µm thickness for a total of 6 sections. Tissue was recovered by depleting paraffin using xylene. DNA was extracted, and the 16S rRNA gene fragment was amplified by PCR. Signature sequences produced in the PyroMark® ID system (Qiagen) from the amplified fragment were aligned to an in-house database and the database of Ribosomal Database Project for AFB identification. Additional tissue sections were stained using a Ziehl-Neelsen procedure and examined for AFB cells.**Results:** The PCR-Seq method was first evaluated using paraffin-embedded tissues spiked with 1 of 14 different AFB species (11 *Mycobacterium*, 2 *Nocardia,* and 1 *Rhodococcus equi*). The method was 100% accurate with no cross-reactivity with non-AFB organisms. The detection limit was 100 spiked cells (*M. chelonae*) per reaction. The method was further evaluated using 188 patient FFPE tissues. Of these, 73 (39%) were AFB positive and 54 (74%) were identified, including 12 TB complex, 11 *M. avium*, 9 *M. intracellulare*, 1 *M. leprae*, 1 *M. genevense*, and 3 in the *M. marinum/ulcerans* group, and 27 other AFB organisms. Nineteen positive FFPE tissues were indeterminate due to either inhibited PCR reactions or failed amplifications. The rest were AFB negative and had no identification. Eight of 12 TB positive specimens were later confirmed by AFB staining and/or culturing or other detection methods. One arm tissue specimen from a southern US patient was *M. leprae* and later confirmed by The National Hansen Disease Program in Louisiana. The PCR-Seq method failed to detect a TB-positive brain biopsy specimen. The specimen was negative by TB transcription-mediated amplification and AFB stain, but was TB positive from culture.**Conclusions:** The PCR-Seq method evaluated here can directly detect various AFB species in FFPE tissues.

Publishing Title:

Evaluation of Five Targeted Multiplex Pcr for Rapid Diagnosis of Tuberculous Meningitis in Hiv Positive Patients

Author Block:

A. Sharma, K. Sharma, M. Modi, S. Varma; PGIMER, Chandigarh, India

Abstract Body:

Background: Rapid and specific diagnosis of tubercular meningitis (TBM) is of paramount importance to decrease morbidity and mortality, as the case fatality rate for untreated TBM is almost 100% and the delay in institution of appropriate treatment can lead to permanent neurological sequelae. The aim of the study was to evaluate five targeted multiplex PCR (MPCR) using protein b, MPB 64, IS6110, Dev R and Sda primers directed against M. tuberculosis complex for the diagnosis of tuberculous meningitis (TBM). **Objectives**: To evaluate the five targeted MPCR test using *IS*6110 , MPB64, Protein B, Dev R and Sda targets for *Mycobacterium tuberculosis* complex for rapid diagnosis of TBM. Comparison of results of *Five targeted MPCR* with *IS*6110 PCR, culture and ZN smear examination. **Methods:** MPCR assay using primers (each for *IS*6110, MPB64 , Protein b, Dev R and Sda) specific for *Mycobacterium tuberculosis* complex were performed on cerebrospinal fluid (CSF) of 100 patients (10 confirmed, 90 suspected) of TBM and 100 non-TBM control subjects. **Results:** Overall five targeted MPCR test (using any of the five targets) had sensitivity and specificity of 94% and 100% for confirmed (10 culture positive) TBM cases. In 90 clinically suspected but unconfirmed TBM cases, Five targeted MPCR was positive in 79 out of 90 cases (87.77%). In total 100 TBM patients, the overall sensitivity of microscopy, culture, *IS*6110 PCR, and the MPCR test (if any of the five targets were used) were 4%, 33.3%, 74.6% and 89%, respectively. Specificity of all the tests was 100%. **Conclusion:** MPCR using five targets is a promising, cost effective technique for rapid diagnosis of TBM especially in a resource poor setting where tuberculosis is an important cause of mortality and morbidity.

Pre-Analytical Protocol for the Enrichment and Lysis of Mycobacteria in Blood and Tissue Samples for the Direct Analysis with Genexpert® Mtb/Rif

Author Block:

C. Baussmerth[1], J. Becker[2], S. Saremba[2], **M. Linow**[1], C. Disqué[1]; [1]Molzym GmbH & Co.KG, Bremen, Germany, [2]Cepheid GmbH, Frankfurt a. M., Germany

Abstract Body:

Background: The diagnosis of disseminated and extrapulmonary tuberculosis is elusive and time-consuming. Rapid molecular methods may support the diagnosis of MTB infection. However, the WHO procedure recommended for GeneXpert® MTB/RIF involves tissue grinding which bears the risk of sample cross contamination and increased MTB exposure to the staff. A new method is described involving enzymatic tissue digestion and MTB lysis in a tube before loading to the GeneXpert® MTB/RIF cassette for analysis. **Material/methods:** Negative EDTA blood (10ml) was spiked with *M. bovis* BCG culture and extracted until MTB lysis using the MTB-DNA Blood kit (Molzym). Tissue biopsies were dissected and subjected to proteinase K digestion, degradation of human DNA and MTB lysis. Extracts from blood and tissue were mixed with GeneXpert® MTB/RIF sample reagent and loaded to the cartridge for further processing and analysis. For reference, the MTB-DNA Blood protocol was followed until DNA elution and then analysed by supplier X MTB test. **Results:** Blood spiked with *M. bovis* BCG was pre-treated with MTB-DNA Blood kit and then analysed by GeneXpert®. For reference, DNA eluates were analysed by another system (supplier X). BCG was detected 100% at 2.5 cfu/ml by both analytical systems, while at 1cfu/ml GeneXpert® still was 80% positive compared to only 20% using supplier X. Tissue samples from two subjects with clinically confirmed tuberculosis and one non-TB control were analysed by MTB-DNA Blood-GeneXpert®. The test confirmed the presence of MTB in the tissues of patient A and patient B and the absence in the control patient C. The reference test (MTB-DNA Blood-supplier X) was false-negative for patient A which, like with blood, may indicate a higher limit of detection compared to MTB-DNA Blood-GeneXpert®. The tests were completed within 3 hours.**Conclusions:** The MTB-DNA Blood-GeneXpert® test system proved to be rapid (3 h) and at the same time highly sensitive for the detection of MTB in EDTA blood (1cfu/ml) and tissues. The new protocol provides a procedure with a decreased risk of cross contamination.

A Rapid One Step Extraction Method for Identification of Mycobacteria and Nocardiae by Maldi-Tof Ms

Author Block:

J. K. Lemon, A. M. Zelazny; NIH, Bethesda, MD

Abstract Body:

Matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) is a quick and accurate method to identify Mycobacteria and Nocardiae in the clinical laboratory. However, extraction protocols for these genera are laborious and require a large amount of organisms (10μL). Current identification of Mycobacteria involves heat killing, ethanol washing, and a two-step extraction method. This study compared the current extraction method with a faster one-step extraction protocol, requiring only 1μL of bacteria, by prospectively analyzing clinical isolates and also frozen strains. For this rapid approach, bacteria were inoculated directly into solutions with varying ratios of formic acid, acetonitrile, and water. Proteins were extracted using a high-powered bead beating homogenizer (PowerLyzer) and the lysates directly spotted onto a target plate for MALDI-TOF MS analysis. Viability studies were conducted before and after the bead-beating step. Preliminary testing included 20 Mycobacteria isolates (*M. tuberculosis* complex, *M. avium* complex, rapid growers) and 9 *Nocardia* species, with testing ongoing to reach 100 isolates. Overall, 64 - 71% of Nocardiae and 75 - 95% of Mycobacteria isolates were identified to the species/complex level by all conditions tested (score cut off ≥1.8). Average scores for Mycobacteria using the current protocol were 2.14 ± 0.22 versus 1.94 ± 0.19 or 1.89 ± 0.21 with the faster one-step extraction, depending on the solution used. Average scores for Nocardiae with the current protocol were 1.99 ± 0.32 versus 1.96 ± 0.28 and 1.99 ± 0.29 with the one-step method (difference was not statistically significant). Notably, scores for the isolates were similar between both procedures, even though the rapid extraction protocol requires 10-fold less bacteria. Viability studies confirmed killing of the organisms prior to the bead-beating step, suggesting that the one-step protocol can be performed outside the BSL-3. Importantly, this rapid method successfully reduced extraction procedure time from over 1 hour to 5 minutes. Our data show that this one-step method substantially reduces both extraction time and quantity of organism required for testing without sacrificing the quality and accuracy of identification of clinical isolates.

Detection of Latent Tb Among Health Care Workers Vulnerable to Tb Exposure in Karachi Pakistan

Author Block:

A. Anum, s. Khan; Dow Univ. of Hlth.Sci., Karachi, Pakistan

Abstract Body:

Background: Latent tuberculosis infection is asymptomatic and in-transmissible diseases. According to the World Health Organization (WHO), in 2014 estimated incidence of Tuberculosis (TB) is 181 per 100 000, with 40% of the population infected with TB in Pakistan and approximately one-third of the population is infected worldwide. Laboratory workers dealing with positive Mycobacterium Tuberculosis (MTB) samples are always at risk of infected with TB. In this study we have investigated prevalence of latent TB in health care providers who are at risk of TB using QuantiFERON assay. **Objective:** To screen the health care workers at risk to occupational exposure for latent TB using QuantiFERON Assay **Methodology:** 3ml of whole blood were collected into three specific QFT tubes.(NIL,TB, Mitogen) from 120 health care workers including phlebotomists, Medical technologist, nurses, doctors and faculty members working closely with TB samples or patients. Samples were tested for detection interferon specifically released against TB according to the manufacturer QuantiFERON TB Gold protocol. **Result:** Out of 137 samples 27 samples were found positive, 5 samples showed indeterminate result and 105 were found negative. Out of 27 positive samples 20 were from medical technologists working closely since long time with TB samples or TB patients and 4 were from phlebotomists collecting samples from patients. **Conclusion:** Health care providers usually work with TB infected samples with minimal infection control measures. This study shows the need for effective latent TB infection control measures and emphasizes on the importance to improve over all biosafety precautions during dealing with the TB patients or samples. The study also provides recommendations for routine and regular screening and checkup of the health care workers working with TB to ensure their safety rather safety of all as no one is safe until everyone is safe.

The Long-Term Mortality of Tuberculosis Meningitis Patients in New York City

Author Block:

C. Vinnard[1], L. King[2], D. Proops[2], A. Crossa[2], K. Iwata[3], J. Pasipanodya[4], L. Trieu[2], S. Munsiff[5], S. Ahuja[2]; [1]Drexel Univ. Coll. of Med., Philadelphia, PA, [2]New York City Dept. of Hlth.and Mental Hygiene, Long Island City, NY, [3]Kobe Univ., Kobe, Japan, [4]Baylor Inst. for Immunology Res., Dallas, TX, [5]Univ. of Rochester, Rochester, NY

Abstract Body:

Background: Tuberculosis meningitis (TBM) is the most devastating clinical presentation of infection with *M. tuberculosis.* We sought to determine the relationship between the initial drug resistance and long-term mortality among TBM patients in New York City (NYC).**Methods:** We performed a retrospective cohort study of TBM patients reported to the NYC TB registry between January 1, 1992 and December 31, 2001. Date of death was ascertained by matching the registry with death certificate data for 1992 through 2012 from the NYC Office of Vital Statistics (OVS), which maintains data collected from death certificates issued in NYC. HIV status was ascertained by medical record review, matching with the NYC HIV Surveillance registry, and review of cause of death. We used multivariate survival analysis to determine the independent association of initial drug resistance with mortality.**Results:** The study population included 324 patients with culture-confirmed TBM, susceptibility results reported for isoniazid (INH) and rifampin (RIF), and initiation of at least two anti-TB drugs. HIV-infection was identified in 63 of 67 TBM patients (94%) with RIF-resistant isolates, including 57 of 61 patients (93%) with multidrug- resistant isolates. Death occurred before the completion of anti-TB therapy in 63 of 67 TBM patients (94%) with RIF-resistant disease. Among the 257 TBM patients without RIF-resistant disease, INH resistance was associated with mortality after the first 60 days of treatment (adjusted HR 2.77, 95% CI 1.28 to 6.01) when controlling for age and HIV co-infection.**Conclusion**: We observed an independent association between INH-resistant TB and death after the first 60 days of therapy for culture-confirmed TBM. While RIF-resistant TB was strongly associated with death, we were unable to estimate this association independent of HIV infection given that all patients with RIF-resistant, INH-sensitive, disease were co-infected with HIV. These findings support the continued evaluation of rapid diagnostic techniques and the empiric addition of second-line drugs for patients with clinically suspected drug-resistant TBM.

Impact of Whole Genome Sequencing of *Mycobacterium tuberculosis* Isolates in a Public Health Laboratory

Author Block:

J. Shea, T. Halse, P. Lapierre, M. Shudt, P. Van Roey, V. Escuyer, K. A. Musser; Wadsworth Ctr., Albany, NY

Abstract Body:

Background: *Mycobacterium tuberculosis* (Mtb) is a pathogen of global importance, estimated to be infecting a third of the world's population and emerging drug resistance is a growing threat. Growth-based drug susceptibility testing (DST), the gold standard, can take weeks to months to identify resistance due to the growth rate of Mtb. While molecular assays have improved the early detection of resistance, these are limited in scope detecting only a few mutations associated with resistance. Whole genome sequencing (WGS) is an alternative for Mtb diagnostics, capable of providing comprehensive drug resistance profiles more rapidly than current methodologies. **Methods:** A novel DNA extraction method was developed combining lysis using a tissue homogenizer and purification using chelex resins. Sequencing of 230 isolates from both solid and liquid media was performed on the Illumina MiSeq platform, utilizing the Nextera XT protocol for library preparation modified to incorporate a 15-cycle index PCR step. Data were analyzed using an in-house developed bioinformatics pipeline for species identification, resistance profiling, and genotyping. **Results:** WGS outperformed our current molecular assays used for species identification and genotyping and provided far more comprehensive resistance profiles an average of 18 days sooner than conventional DST. Species identification using WGS was 98% accurate, a 5% improvement over the current real-time PCR assay. Concordance between the drug resistance profile generated by WGS and current molecular and conventional methods was greater than 94% for eight drugs, with a resistance-predictive value of 93% and susceptible-predictive value of 95%. **Conclusions:** This single cost-effective WGS assay can replace several molecular assays currently used for species identification, genotyping, and drug resistance. This WGS approach to screen isolates of Mtb generates species identification, genotyping, and comprehensive drug resistance profiling results accurately and reproducibly, making it possible to identify resistance and inform patient treatment decisions sooner than before. It allows the physicians to design and implement an optimized treatment for their patients in a dramatically shortened time frame.

Mycobacterial Inactivation/Extraction/Identification from Positive Mgit Tubes Using Afa-Ultrasonication and MALDI-ToF Ms

Author Block:

S. Fisher, L. Adams, K. Dionne, N. Parrish; The Johns Hopkins Med. Inst.s, Baltimore, MD

Abstract Body:

Background: MALDI-ToF MS (MALDI) has been used for identification of *Mycobacteria*, primarily from growth on solid media. MALDI-based identification from positive MGIT tubes has been problematic. In the current study, we used adaptive focused acoustics (AFA) and ultrasonication (US) to standardize an extraction method for MALDI-based identification from positive MGIT tubes.**Methods:** A total of 99 mycobacterial isolates were used representing 12 species. For all assays, MGIT tubes were spiked with a standard volume of clinical specimen (e.g. sputum, tissue, various sterile fluid, stool, etc.) and supplement containing PANTA. Tubes were spiked with known quantities of each mycobacterial isolate to be tested and placed on the instrument. Once positive, tubes were removed and tested using the optimized AFA protocol with subsequent identification attempted using MALDI. Aliquots (1 ml) were collected from the bottom of MGIT tubes after settling for 1 hr at various timepoints past positive (48-72 hrs) and washed twice with sterile water. AFA-US was done using microTUBES™ containing glass beads and acetonitrile:70% formic acid (1:1) and instrument settings of 40 watts Peak Incident Power and 50% duty factor for 2 min. Completed extracts were spotted on polished steel plates and identification done by MALDI and an existing database. Standard identification was done from solid media using a validated MALDI assay.**Results:** Timepoints at or 24 hrs post positive on the MGIT yielded unreliable results for all species/specimen types tested. However, at 48 hrs post positive, overall agreement for all species/strains considered together was 93% (92/99) using a log confidence score of ≥ 1.7. However, differences were noted between rapid-growing (RG) and slow-growing species (SG) where agreement was 91% and 95%, respectively. Of the specimen types tested stool was the most problematic regardless of species resulting in a failure to identify any peaks in 4/4 spots. Tissues occasionally resulted in log confidence scores of < 1.7 or failure to identify any peaks. Sampling at 72 hrs resulted in 100% (14/14) agreement for the RG species, but only 73% (35/48) for the SG**Conclusions:** This study demonstrates that AFA-US-MALDI-based identification is possible from positive MGIT tubes and can be standardized for most species/strains at 48 hrs.

Performance of the Xpert Mtb/Rif Assay on Formalin Fixed Paraffin-Embedded Tissues in an Oncology Patient Population

Author Block:

T. McMillen[1], J. Chen, A. Gomez, J. Kaplan, Y.W. Tang, M. Kamboj, MSKCC, I. Budvytiene, N. Banaei, Stanford Medical Center, N. Babady[2]; [1]Mem. Sloan-Kettering Cancer Ctr., New York, NY, [2]Mem. Sloan Kettering Cancer Ctr., New York, NY

Abstract Body:

Oncology patients often undergo invasive tissue biopsies as part of their cancer evaluation. Incidental findings of positive acid-fast bacilli (AFB) stain on formalin fixed paraffin-embedded (FFPE) tissue biopsies prompts additional investigation particularly requests for detection of *Mycobacterium* tuberculosis complex (MTBC). A common challenge is non availability of fresh tissue for conventional testing and inability to perform AFB cultures on FFPE samples. The Xpert MTB/RIF is a real-time PCR assay, IVD cleared for the detection of MTBC in expectorated sputum samples. Data on the performance of the assay in FFPE samples is limited. The goal of this study is to evaluate the performance of the Xpert MTB/RIF on FFPE tissue in a tertiary care cancer center with low rates of TB and high prevalence of non-tuberculosis mycobacteria (NTM). A total of 84 FFPE tissue samples were tested by the Xpert MTB/RIF, including 36 samples positive (4 TB positive by culture/PCR) by FITE stain for AFB and 48 samples negative by FITE for AFB. The 84 samples represented 61% pulmonary FFPE tissues and 39 % extrapulmonary FFPE tissues. Additionally, one PCR confirmed MTBC positive FFPE sample was included as a positive control. Each sample was de-paraffinized, digested and pre-treated prior to inoculation into the Xpert cartridge. The Xpert MTB/RIF test was then performed according to manufacturer's recommendations. The agreement between culture result and Xpert MTB PCR was very good at 98.0% (κ=0.87). Sensitivity, specificity, positive and negative predictive value were 100% (5/5, 95% CI: 39.7-100%), 98.8% (80/81, 95% CI: 93.3-99.9%), 80% (95% CI: 28.3-99.5%), and 100% (95.5-100%) respectively. One sample was Xpert positive, FITE stain and culture negative and repeat tissue cultures three months later were positive for MTBC. For an oncology patient population, with low incidence of TB, the specificity and negative predictive value of the assay on FFPE was excellent. With its rapid turn-around time, the Xpert MTB/RIF assay offers a valid option for ruling out TB and minimizing resource utilization

Use of Pleural Fluid Interferon-Gamma Enzyme-Linked Immunospot Assay in the Diagnosis of Pleural Tuberculosis

Author Block:

T. Adilistya, D. Astrawinata; Cipto Mangunkusumo Gen. Hosp., Jakarta Pusat, Indonesia

Abstract Body:

Background: Early and accurate diagnosis of pleural tuberculosis (TB) is difficult as current diagnostic methods are lack of specificity (pleural fluid cell counts and biochemical levels), lack of sensitivity (acid fast bacilli smears), and time-consuming (TB culture). It is suggestive that whilst only a small number of antigen-specific T cells are found in peripheral circulation, highly activated, antigen-specific effector T cells accumulate at disease site and rapidly produce Th-1-type cytokines. We evaluated the diagnostic value of an interferon-gamma release assay (IGRA) with enzyme-linked immunospot (ELISPOT) method, T-SPOT.TB, in the diagnosis of pleural TB using pleural fluid mononuclear cells (PFMC). **Methods:** Forty-eight subjects, presumed to have pleural TB with exudative pleural effusion by Light's criteria, dominated by mononuclear cells, had their pleural fluid specimen tested with T-SPOT.TB, Mycobacterial Growth Indicator Tube (MGIT) culture, and adenosine deaminase (ADA) activity. MGIT culture and ADA activity with the cut-off value of 40 U/L were used as the gold standard for pleural TB. Other causes of pleural effusion such as heart failure, chronic kidney disease, hepatic cirrhosis, and malignancy were excluded.**Results:** Thirty-nine (81.25%) out of 48 patients were considered having pleural TB based on positive MGIT culture and/or ADA activity. All of them (100%) were positive for T-SPOT.TB. Among 9 patients with no pleural TB, there was 1 patient with positive T-SPOT.TB. The sensitivity, specificity, positive predictive value, and negative predictive value of the IGRA ELISPOT assay using PFMC for the diagnosis of pleural TB were 100%, 88.89%, 97.5%, and 100%, respectively.**Conclusions:** These results demonstrate that the IGRA with ELISPOT method performed on PFMC is useful for a rapid and reliable diagnosis of pleural TB in clinical practice, especially in area with high TB burden.

Diagnosis of *Mycobacterium tuberculosis* and Non-tuberculous *Mycobacterium* Infections Using a Novel Plasma-Based Next-Generation Sequencing Assay

Author Block:

D. K. Hong[1], C. Truong[2], N. Banaei[2]; [1]Karius, Inc., Menlo Park, CA, [2]Stanford Univ. Sch. of Med., Palo Alto, CA

Abstract Body:

Background: Mycobacterial infections can be difficult to diagnose by conventional culturing methods. Both *Mycobacterium tuberculosis* and non-tuberculous *Mycobacterium* species often require invasive sampling and long culturing times to make a laboratory diagnosis. Molecular diagnostic techniques have been particularly useful in increasing diagnostic sensitivity and shortening turnaround time. **Methods:** We are developing a minimally invasive next-generation sequencing (NGS)-based infectious diseases assay that takes advantage of circulating cell-free plasma DNA originating from invasive pathogens. After filtering human sequences, remaining sequences are aligned to a pathogen reference sequence database and relative abundance is assigned. **Results:** We report two patients with *Mycobacterium tuberculosis* and one patient with disseminated *Mycobacterium haemophilum* in whom the diagnosis was confirmed by our novel assay. These patients had culture-confirmed *Mycobacterium* infections from invasive biopsies. Plasma samples obtained at the time of diagnostic biopsy had high levels of *Mycobacterium* sequences that could be resolved to *M. tuberculosis* complex and *M. haemophilum*. **Conclusions:** This is the first demonstration of the use of a new NGS-based plasma assay to diagnose invasive *Mycobacterium* disease. Given the high sensitivity and open-ended nature of this NGS assay, it can aid in the diagnosis of deep infections with other fastidious organisms.

Abstract Body:

Background: *Mycobacterium chelonae* (MC), *M. abscessus* Group (MAG) and *M. fortuitum* Complex (MFC) are the most common rapid growing mycobacteria isolated from respiratory infections. The aim of this study was to validate a new laboratory developed multiplex Real-Time PCR (qPCR) test to detect MC, MAG and MFC directly from clinical samples using the open mode system of the BD MAX™ platform.**Methods:** A total of 134 clinical respiratory samples previously submitted for mycobacterial culture, were tested using the new multiplex qPCR test. Before testing, samples were treated with Proteinase K at 60°C for 30 minutes and heated at 95°C for 5 minutes. After this pretreatment step, each sample was inoculated into the BD MAX Sample Preparation Reagent Tube. Extraction and multiplex PCR were performed by the BD MAX™ system, using the BD MAX™ ExK™ TNA-3 extraction kit and BD MAX™ TNA MMK master mix, along with specific in-house designed primers and probes for MC, MAG, MFC and Beta Globin (internal control) detection. One set of common forward and reverse primers and distinct probes for MC and MAG detection were designed using the ITS region. For MFC, 2 forward and 1 reverse primers, as well as 1 probe were designed using the *rpoB* gene. Cycling conditions were: 80°C for 10min and 40 cycles of 95°C for 15s, 60°C for 60s. The Limit of Detection (LoD) of each target was evaluated by testing a serial of seven 10-fold dilutions of 4 different species of mycobacteria (1 MC, 1 MAG and 2 MFC). Specificity was carried out by testing different species of mycobacteria (n=17), aerobic bacteria (n=19) and candida (n=7) commonly found in respiratory infections.**Results:** Out of 134 clinical respiratory samples included, 73 were positive and 61 were negative for mycobacteria by culture. Four samples were identified as MC, 15 for MAG and three for MFC by culture and by the new multiplex PCR test. All 61 samples identified as negative by culture were also identified as negative by the new multiplex PCR test. The LoD was 10^2 for MC, 10^2 for MAG and 10^3 for MFC. The new multiplex was specific and correctly identified the species correspondent to each PCR target.**Conclusions:** The new multiplex qPCR test performed on the BD MAX System proved to be a sensitive and specific test to detect MC, MAG and MFC on an automated sample-in results-out platform.

Performance Evaluation of the Cobas Taqman Mtb Assay According to Its Clinical Application

Author Block:

J. Park, D. Song, H. Huh, C-S. Ki, N. Lee; Samsung Med. Ctr., Seoul, Korea, Republic of

Abstract Body:

Background: The COBAS TaqMan MTB test (COBAS MTB ; Roche Diagnostics, Basel, Switzerland) is used for rapid diagnosis of tuberculosis from clinical specimens. The purpose of this study was to evaluate the performance of the COBAS MTB assay according to its clinical application in a country with intermediate prevalence of tuberculosis.**Methods:** We retrospectively analyzed data from 514 consecutive patients from whom mycobacterial cultures and COBAS MTB assay were requested at the same day. Based on patients' medical records, two different categories of clinical applications of the COBAS MTB assay were identified: (1) clinically high probability of pulmonary tuberculosis according to their clinical and radiological features (n=66); (2) clinically low probability for pulmonary tuberculosis (n=448). Using the mycobacterial culture as the gold standard, the sensitivity, specificity, positive predictive value (PPV), and negative predictive values (NPV) of the COBAS MTB assay in each clinical application were calculated.**Results:** The sensitivity for MTB detection in category 1 was 91.7% (95% confidence interval [CI], 59.8-99.6%) while that in category 2 was 33.3% (1.8-87.5%). The specificities in category 1 and 2 were 94.4% (83.7-98.6%) and 99.3% (97.9-99.8%), respectively. The PPV and NPV were 78.6% (48.8-94.3%) and 98.1% (88.4-99.9%) in categories 1, respectively, and 25.0% (1.3-78.1%) and 99.5% (98.2-99.9%) in category 2, respectively.**Conclusion:** The COBAS MTB assay showed different performance according to its clinical application. Through this study, careful interpretation for the results of COBAS MTB assay would be needed according to its clinical application. We believe that this study would be of helpful for physicians to interpret the COBAS MTB assay.

Genus-Specific Screening for Mycobacteria from Hundreds of Samples in 4 Hours

Author Block:

Z. Cheng[1], H. Jiang[2], H. Wang[2], Z. Zheng[1]; [1]Inst. of Basic Med. Sci., Chinese Academy of Med. Sci., beijing, China, [2]Inst. of Dermatology, Chinese Academy of Med. Sci., Nanjing, China

Abstract Body:

Background: The mycobacteria bring about miscellaneous disorders in humans, especially in the lungs. Treating patients early and rendering them non-infectious is essential for control and elimination of these diseases. New diagnostics with improved sensitivity and simplified procedure are still needed. Capture and ligation probe-PCR (CLIP-PCR) is ahigh throughput RNA quantification technology that requires no RNA purification and reverse transcription, which has been used for large scale screening of*Plasmodium* 18S rRNA. In this study, we adopted CLIP-PCR for rapid, large-scale identification of genus *Mycobacterium*. **Methods:** 16S rRNA sequence of seven reference strain *Mycobacterium leprae* (GenBank: X53999.1),*Mycobacterium tuberculosis*(GenBank: X52917.1),*Mycobacterium marinum* (GenBank: X52920.1), *Mycobacterium fortuitum* (GenBank: X65528.1), *Mycobacterium abscessus* (GenBank: AJ536038.1), *Mycobacterium avium*(GenBank: X52918.1)and *Mycobacterium intracellulare*(GenBank: X52927.1)were aligned and the consensus part was selected as target. In CLIP-PCR, targeted RNA is released from blood by lyse, captured onto 96-well plates with probes, where continuously hybridized probes would be ligated, and quantified with qPCR by amplifying the ligated probes. To accelerate the hybridization process, and avoid false-negative caused by genetic variation between clinical isolates, we adopted a multi section strategy, in which more than one set of probes were added to the reaction. These probe sets would either individually or collectively capture, and quantify the target. The assay was tested using clinically collected isolates of the seven strains. **Results:** All samples of the seven strains resulted in a distinct peak in melting curve analysis. With multi section strategy, the turn around time of CLIP-PCR was reduced from about 18 hours down to 4 hours, with little compromise of sensitivity. **Conclusions:** In conclusion, CLIP-PCR is of great potential for fast and large scale screening for genus mycobacteria.

Comparison of Quantiferon-TB Gold-Plus to Quantiferon-TB Gold Assay in Health Care Workers at a Low-Incidence Setting

Author Block:

H. Moon[1], R. L. Gaur[1], M. Pai[2], N. Banaei[1]; [1]Stanford Univ. Sch. of Med., Palo Alto, CA, [2]McGill Univ., Montreal, QC, Canada

Abstract Body:

Interferon-gamma release assays (IGRAs) are used by many health programs to diagnose latent *M. tuberulosis* infection (LTBI). We prospectively compared the performance of QuantiFERON-TB Gold-Plus (QFT-plus) to QuantiFERON-TB Gold in-tube (QFT) in low risk health care wokers (HCW) at a U.S. institution. In total, 988 HCWs presenting to Stanford Health Care Occupational Clinic for TB screening were tested with the QFT and the QFT-Plus assays. Tube order for blood draw included: purge, nil, TB antigen 1 (TB1), TB 2, TB antigen, and mitogen. Risk factors for LTBI were obtained. The QFT-Plus assay was interpreted as positive when either TB1 or TB2 result was above the assay cut-off. TB1 and TB2 results were also analyzed separately. The positivity rate of QFT, QFT-plus, QFT-plus TB1, and QFT-plus TB2 were 4.3%, 6.4%, 4.1% and 5.2%, respectively. Agreement of QFT with QFT-plus, QFT-plus TB1, QFT-plus TB2 and between QFT-plus TB1 and QFT-plus TB2 was good at 95.6%, 96.7%, 96.5% and 96.5%, respectively (Kappa, 0.57, 0.59, 0.61 and 0.61, respectively). Most of the discrepant results (44/51, 86.3%) were within the borderline range of 0.2-0.7 IU/mL. Quantitative results obtained with QFT showed high degree of correlation with QFT-plus TB1 and QFT-plus TB2 (Pearson's correlation coefficient (r) = 0.743 and 0.748, respectively). QFT-plus TB1 and QFT-plus TB2 also showed very high correlation with each other (r = 0.902). The specificities of QFT, QFT-plus, QFT-plus TB1 and TB2 in 608 HCWs with no identifiable risk factors were 98.0%, 96.9%, 98.4% and 97.5%, respectively. The specificities were not significantly different between assays (P>0.05). The QFT-plus assay showed fairly good agreement with the standard QFT assay in HCW at a low-incidence setting.

Effect of Incubation at Collection Site on the Rate of Indeterminate Results of Quantiferon®-Tb Gold Samples

Author Block:

H. Kapoor[1], A. S. Edelman[2], H. J. Batterman[3]; [1]Quest Diagnostics, Chalfont, PA, [2]Quest Diagnostics, Horsham, PA, [3]Focus Diagnostics, San Juan Capistrano, CA

Abstract Body:

QuantiFERON®-TB Gold (QFT®) is an in vitro diagnostic test for *Mycobacterium tuberculosis* infection; it uses specific peptide antigens ESAT-6, CFP-10, and TB7.7 proteins to stimulate cells in heparinized whole blood. The QFT system uses specialized blood collection tubes containing these antigens, mitogen (positive control), and NIL control and should be incubated at 37°C ± 1°C within 16 hours of collection. Indeterminate results (lack of significant response in the mitogen tube) can be seen in immunocompromised patients or be secondary to pre analytic variables, including the time from collection to incubation. To reduce the time from collection to incubation and ensure that it was less than 16 hours, Quest Diagnostics started a program of incubation at the collection site in our Patient Service Centers.Phlebotomy staffs that collected the samples were trained on a standard operating procedure for the incubation at collection site. Locations enrolled for this program were provided an incubator to strictly hold temperature at 37°C ± 1°C. The specimens were placed in the incubator within a few hours of collection and the incubation time was standardized. These pre-incubated samples were sent to the Philadelphia laboratory of Quest Diagnostics for the interferon gamma ELISA. Rate of indeterminate results were monitored for non-incubated and pre-incubated samples.The incubation at collection site initiative for QFT samples was started in May 2014. Prior to this initiative the average rate of indeterminate results for the year 2013 and the first 4 months of 2014 was 10.8% of the non-incubated samples (n=2100). During the period from May 2014 through August 2015 approximately 34% of the QFT samples (n=640) were incubated at collection site and 1240 QFT sample were non-incubated. Rate of indeterminate results of non-incubated samples averaged 8.4% and of pre-incubated samples averaged 4.3% (49% reduction, $P<0.0001$).A significant decrease in the rate of indeterminate results was observed when QTF samples were incubated at the collection site.

Development of a Point of Care Diagnostic for Early Tb Diagnosis

Author Block:

P. Sule, Yunfeng Cheng , Ying Kong, Ronak Tilvawalaa, HexinXie , Hany Hassounaha, Aneesa Noormohameda,; TAMHSC, Brayn, TX

Abstract Body:

Mycobacterium tuberculosis (Mtb) caused 9.6 million new tuberculosis (TB) cases in 2014 (WHO). In the absence of prompt and effective treatment TB mortality is as high as 50% (TBDI 4th) creating a very grim scenario in resource-limited countries. Detecting TB can be a challenge and sometimes take up to months, posing a huge risk of transmission, dissemination and emergence of new cases. The current diagnostics available are either very time consuming or require training and considerable infrastructure. In this project, we detail the development of a unique point of care (POC) diagnostic assay for early TB detection, in an attempt to overcome what is perceived as a major roadblock in TB prevention. The reported test is affordable, delivers results in less than 10 minutes and is easy to perform requiring minimal setup. The diagnostic assay utilizes BlaC, a unique *Mtb* specific biomarker in a reporter enzyme fluorescence system. 160 clinical specimens (sputum) were tested using our diagnostic assay. The results obtained were compared to previously documented culture and smear results for the specimens. In this study our assay diagnosed clinical samples as being *Mtb* positive with a sensitivity of 89% for smear +/culture + samples, 88% for smear -/ culture + samples and a combined specificity of 82%. We propose the use of our diagnostic assay as the much needed triage test performed as a first line diagnostic assay with a potential to greatly benefit tuberculosis containment strategies across the globe.

The Role of Tb Lamp and Xpert Mtb Rif Assay for the Diagnosis of Smear Negative Pulmonary Tb

Author Block:

M. G. Worku, Z. Dagne, Z. Yaregal, A. H/Mariam, S. Moga, A. Meaza, A. Kebede, Y. Feseha; Ethiopian Publ. Hlth.Inst., Addis Ababa, Ethiopia

Abstract Body:

Background: Smear negative TB remains a diagnostic challenge. In the absence of sensitive diagnostic method clinician often make the diagnosis of smear-negative pulmonary TB with information obtained through the clinical history, physical examination and chest X-ray. This information is not specific which leads to over or under treatment. Thus, sensitive diagnostic methods have a considerable contribution to decide the appropriate treatment. **Methods:** The study was conducted from December, 2014 to June, 2015. All TB presumptive referred to St. Peter TB specialized hospital were enrolled according to the national recruitment criteria. Socio-demographics data, TB symptoms, chest X-ray findings and final decision for anti-TB treatment was collected for each TB presumptive. Spot-Moring-spot sputum was collected for direct ZN examination. The morning sputum was used for culture (LJ and MGIT), TB-LAMP, Xpert MTB/RIF assay and fluorescent microscopy examination. **Results:** This study enrolls 459 smear negative presumptive TB patients. Of which 57% (252/442) were Females and median age 40 IQR (28-55) years. The prevalence of HIV among the study participants were 30%. The overall culture positivity rate was 6.8% (30/439), of which 6.6% (26/391) was by MGIT and 5.3% (23/436) was by LJ method. Direct and concentrated fluorescent microscopy adds in 0.9% and 1.3% for smear negative suspects compared to direct ZN. The overall sensitivity and specificity of TB-LAMP was 61.5% (16/26) and 96.6% respectively. The overall sensitivity and specificity Xpert MTB/RIF was 70.8% (17/24) and 97.2% respectively. **Conclusions:** TB-LAMP and Xpert MTB/RIF assay can provide confirmatory result for at least two third of TB cases.

Verification and Clinical Application of a Laboratory Developed Sequencing Assay for the Identification of Mycobacteria in Pediatric Patients

Author Block:

H. Wang, J. Madison, S. Sims, C. Tomatis, A. Leber, S. Antonara; Nationwide Children's Hosp., Columbus, OH

Abstract Body:

In the United States, rates of tuberculosis in young children are low, leaving the nontuberculous mycobacteria (NTM) as the most common cause of mycobacterial infections in pediatric and cystic fibrosis patients. A conclusive diagnosis of mycobacterial infections relies upon the isolation and identification of the causative agent, which historically was a slow and labor intensive process. Currently, a number of molecular and proteomic methods are available that are both quick and precise for mycobacterial identification.Our laboratory has adopted a partial *sec*A1 sequencing technique as the primary method of identification of mycobacteria. This test targets a 700-bp fragment of the *sec*A1 gene coding for 233 amino acid residues located on the N-terminal region of the protein (Zelazny A. *et. al*., 2005). For assay verification, 84 isolates (7 *M. tuberculosis* complex, 19 *M. abscessus* group, 23 *M. avium* complex and others, a total of 24 species) comprising ATCC strains and patient isolates obtained at our hospital were included. Results were compared with two reference laboratories utilizing either a proteomic or a sequencing method. We achieved 100% agreement in identification at species level with the reference methods used. A curated sequence database representing 70 mycobacterial species (including isolates that were specifically identified in our patient population) was built and a phylogenetic tree with partial *sec*A1 sequences from this database was generated.Limitations of use of partial *sec*A1 sequencing in pediatric patients include; a) a lack of subspeciation of *M. abscessus* group isolates, and b) the lack of differentiation of some members of the *M. fortuitum* group (*M. senegalense* and *M. conceptionense*), leaving the clinical significance of these two species in this patient group unclear.The performance of this assay suggests that this is a rapid and reliable tool that reduces the turnaround time of identification of mycobacterial isolates and improves patient care. The continuous expansion of the partial *sec*A1 database ensures an accurate identification of clinical isolates as well as a source of tracking of commonly seen species in our patient population.

Clinical Risk Score for Prediction of Extended-Spectrum β-Lactamase-Producing *Enterobacteriaceae* in Bloodstream Isolates

Author Block:

M. Augustine[1], T. L. Testerman[1], J. Justo[2], P. Bookstaver[2], J. Kohn[3], H. Albrecht[1], **M. Al-Hasan**[1]; [1]Univ. of South Carolina Sch. of Med., Columbia, SC, [2]South Carolina Coll. of Pharmacy, Columbia, SC, [3]Palmetto Hlth.Richland, Columbia, SC

Abstract Body:

Background: Appropriate empiric antimicrobial therapy is associated with improved survival in patients with bloodstream infections (BSI). However, fear of extended-spectrum ß-lactamase-producing *Enterobacteriaceae* (ESBLE) may lead to inappropriate use of carbapenems, further contributing to increased antimicrobial resistance. This study aims to develop a clinical score to predict probability of BSI due to ESBLE. **Methods:** Adult patients with BSI due to *Enterobacteriaceae* hospitalized at the Palmetto Health System in Columbia, South Carolina, from January 2010 to June 2015 were identified. Multivariate logistic regression was used to identify independent risk factors for ESBLE BSI. Point allocation in ESBL prediction score was based on regression coefficients. Model discrimination was assessed by area under receiver operating characteristic curve (AUC).**Results:** Among 910 patients with *Enterobacteriaceae* BSI, 42 (4.6%) had BSI due to ESBLE. Overall, median age was 66 years and 509 (56%) were women. Independent risk factors for ESBLE and point allocation in the ESBL prediction score included outpatient procedures within 30 days of BSI (odds ratio [OR] 8.7, 95% confidence interval [CI]: 3.1-22.9; 1 point), prior colonization with ESBLE (OR 26.8, 95% CI: 7.0-108.2; 4 points), and number of courses of ß-lactams and/or fluoroquinolones used within 90 days prior to BSI: 1 course (OR 6.3, 95% CI: 2.7-14.7; 1 point), ≥ 2 courses (OR 22.0, 95% CI: 8.6-57.1; 3 points). AUC for both final logistic regression and ESBL prediction score models was 0.86. Patients with an ESBL prediction score of 0, 1, 3, and 4 had an estimated probability of ESBLE of 0.7%, 5%, 24% and 44%, respectively.**Conclusions:** ESBL prediction score estimates patient-specific risk of BSI due to ESBLE with high discrimination, which may improve empiric antimicrobial therapy and carbapenem utilization.

Current Antibiotic Susceptibility Profile of *Streptococcus pneumoniae* from North America: Data from the Test Program 2010-2015

Author Block:

D. Hoban[1], **D. Biedenbach**[1], D. Sahm[1], H. Leister-Tebbe[2]; [1]IHMA, Inc., Schaumburg, IL, [2]Pfizer, Inc, Collegeville, PA

Abstract Body:

Background: *Streptococcus pneumoniae* (SP) is commonly associated with community-acquired pneumonia (CAP), acute exacerbations of chronic bronchitis (AECB), acute bacterial sinusitis (AS), meningitis, bacteremia and acute otitis media (OM) that can progress to debilitating pneumococcal disease, causing significant morbidity and mortality worldwide. The increase in the rates of resistance of SP to frequently used antibiotics and the rapid global spread of multidrug-resistant strains even in countries with extensive SP immunization programs such as North America requires comprehensive surveillance and monitoring. The Tigecycline Evaluation Surveillance Trial (TEST) is an ongoing global surveillance program. In this study, we evaluate the susceptibility of SP from North America from 2010-2015.**Methods:** 2644 SP isolates from various sources were collected from investigative sites in North America. Minimum inhibitory concentrations (MICs) were determined by broth microdilution panels locally and interpreted according to CLSI guidelines.**Results:** Overall (2010-2015), *in vitro* penicillin susceptibility of SP from North America was 62.5%, and erythromycin susceptibility was 59.9%. Additional overall summary data are shown in the following table:

Drug	**MIC_{50}**	**MIC_{90}**	**%S**	**%I**	**%R**
Levofloxacin	1	1	99.3	0.1	0.6
Tigecycline	0.015	0.03	97.6	0	2.4
Ceftriaxone	≤0.03	1	95.3	4.2	0.5
Meropenem	≤0.12	1	80.9	5.2	13.9
Clindamycin	0.06	> 64	82.5	0.5	16.9
Penicillin	≤0.06	2	62.5	22.4	15.2
Erythromycin	0.06	64	59.9	0.6	39.5

Conclusions: Levofloxacin, ceftriaxone and tigecycline all showed potent *in vitro* activity against SP from North America with %S of >95%. Based on percent susceptibility the *in vitro* activities of erythromycin and penicillin were the lowest among the drugs evaluated. Continued

surveillance of resistance in SP to established antimicrobials is warranted and is essential in countries with extensive adult and pediatric SP immunization programs.

Publishing Title:

Identification of Genotypic and Phenotypic Antimicrobial Resistance among *Salmonella* isolated from Humans in the United States, 2014

Author Block:

J. P. Folster[1], D. Campbell[1], J. Chen[2], J. Reynolds[1], H. Carleton[1], J. Whichard[1]; [1]CDC, Atlanta, GA, [2]IHRC, Inc, Atlanta, GA

Abstract Body:

The National Antimicrobial Resistance Monitoring System (NARMS) examines antimicrobial resistance among foodborne pathogens, including *Salmonella*, in the United States. In this study, we performed whole genome sequencing (WGS) on 255 *Salmonella* isolated from humans in 2014 that were resistant to ≥1 of 14 drugs tested for antimicrobial susceptibility testing (AST) by NARMS. Sixty different resistance patterns were observed. We used BioNumerics 7.5 to analyze WGS data and identify acquired resistance genes (ResFinder [cge.cbs.dtu.dk]) and mutational resistance determinants (*in silico* PCR). Genetic predictions correlated with traditional phenotypic AST for all 14 drugs (>96% sensitivity, specificity, positive predictive value, negative predictive value and a kappa coefficient =0.97). Resistance to most drugs was mediated by common enteric resistance determinants, e.g.: ampicillin resistance by *bla*$_{\text{TEM-1b}}$, tetracycline by *tetA/B*, sulfisoxazole by *sul1/2*, chloramphenicol by *floR*. Resistance to 3rd generation cephalosporins, including ceftriaxone, was mostly mediated by *bla*$_{\text{CMY-2}}$, an AmpC-type beta-lactamase, however, we did find several extended spectrum beta-lactamases, including *bla*$_{\text{SHV-12, SHV-30, CTX-M-1, CTX-M-55}}$ and two *bla*$_{\text{CTX-M-65}}$. One isolate had decreased susceptibility to the macrolide azithromycin, and contained *mphA*, a macrolide resistance determinant. Resistance to the quinolone nalidixic acid was mainly mediated by mutations in the quinolone resistance determining region (QRDR). Most ciprofloxacin-resistant isolates had both QRDR mutations and plasmid-mediated quinolone resistance (PMQR) genes. We observed some discordant genotypic/phenotypic results, suggesting that some resistance determinants may not be functional. Notably, only three isolates had phenotypic resistance without genotypic determinants, suggesting there may be novel resistance determinants and highlights the need for continued phenotypic testing. This study shows the continued effectiveness of WGS analysis for resistance prediction in *Salmonella*.

One Health Laboratory Surveillance for Multi-Drug Resistant *Escherichia coli* in the Upper USA Midwest: Preliminary Report

Author Block:

T. R. Fritsche[1], B. J. Olson[2], M. C. Hall[1], S. K. Shukla[2], T. J. Novicki[1], F. M. Moore[1], D. A. Ortiz[2]; [1]Marshfield Clinic, Marshfield, WI, [2]Marshfield Clinic Res. Fndn., Marshfield, WI

Abstract Body:

Background: The 2015 "*National Action Plan for Combating Antibiotic Resistant Bacteria*" calls for strengthening of One Health surveillance efforts. Here we compared fecal colonizing and infection isolates of *Escherichia coli* (EC) recovered from humans, companion and food-producing animals for β-lactamases responsible for resistance to extended-spectrum (ES) agents. Our goal is to characterize and track emergence of multi-drug resistant (MDR) EC in urban and rural areas served by our health care system. **Methods**: Residual human, canine and bovine stool specimens (n=2900) submitted during 2014 were screened on chromogenic agars for EC expressing ES β-lactamases (ESBLs), cephalosporinases (AmpCs), and carbapenemases. Human (n=112) and canine (n=104) infection isolates resistant to ES cephems were included for comparison. Isolates were identified using mass spectrometry and had susceptibility profiles generated using dry-form broth microdilution panels. *bla* gene families were characterized using a commercial micro-array targeting 38 gene families. **Results**: Among fecal specimens screened, EC resistant to ES cephems were present in 5.2% (111/2143), 15.3% (96/627) and 49.2% (64/130) of human, canine and bovine samples, respectively. Of those human colonizing and infection isolates positive by microarray, 36.3% and 52.2%, respectively, were positive for ESBL genes, while 19.3% and 17.7% were positive for AmpC genes. Corresponding figures for canine colonizing and infection isolates, respectively, were 19.7% and 15.9% for ESBLs, and 48.3% and 64.5% for AmpCs. Bovine isolates included 26.2% ESBLs and 33.0% AmpCs. Of 491 MDR isolates tested by microarray, 34 (6.9%) were negative for any gene target. Among 10 gene families detected, CTX-M-15-like and CTX-M9 groups (ESBLs), and CMY-2 (AmpC) genotypes were predominant regardless of host origin. Carbapenem resistant isolates were not detected. **Conclusion**: Characterization and tracking of MDR EC emergence in our 'One Health' service area will allow us to better understand risk factors for exposure of urban dwellers, farm families and farm workers to particular pathogens and resistance profiles.

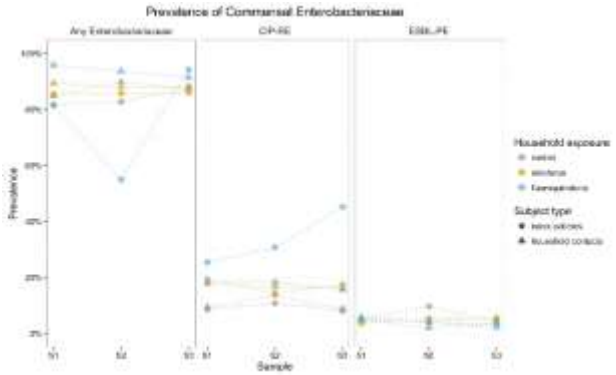
Impact of Outpatient Antibiotics for Urinary Tract Infections (Utis) on Susceptible and Resistant Commensal Enterobacteriaceae

Author Block:

A. J. Stewardson[1], N. Adriaenssens[2], S. Coenen[2], M. Godycki-Cwirko[3], B. Huttner[1], A. Kowalczyk[3], C. Lammens[2], J. Vervoort[2], S. Malhotra-Kumar[2], H. Goossens[2], S. Harbarth[1]; [1]Univ. of Geneva Hosp., Geneva, Switzerland, [2]Univ. Antwerp, Antwerp, Belgium, [3]Med. Univ. of Lodz, Lodz, Poland

Abstract Body:

Aim: To quantify the impact of antibiotics prescribed for UTIs on intestinal Enterobacteriaceae, while accounting for household microbiota clustering. **Methods:** We performed a prospective cohort study from Jan 2011 to Aug 2013 at sites in Belgium, Poland and Switzerland. We recruited outpatients requiring (exposed) and not requiring (non-exposed) antibiotics for suspected UTI, and 1-3 household contacts for each index patient. Subjects provided 3 fecal samples: baseline (S1); end of antibiotics (S2); and 28 days later (S3). We used multivariable, mixed-effects Poisson regression to model the impact of antibiotic class on intestinal colonisation by i) total Enterobacteriaceae, ii) ciprofloxacin-resistant-Enterobacteriaceae (CIP-RE), and iii) extended-spectrum beta-lactamase-producing Enterobacteriaceae (ESBL-PE).**Results:** 303 households (95 non-exposed, 208 exposed) with 722 subjects were included. UTI patients received nitrofurans (88, 42%), quinolones (77, 37%) and other antibiotics. As shown in the figure, exposure to quinolones resulted in transient suppression of Enterobacteriaceae and subsequent 1.9-fold increase in CIP-RE prevalence (adjusted prevalence ratio [aPR], 1.9; 95%CI, 1.1−3.3). Nitrofurans had no impact on CIP-RE (aPR 1.1; 0.7-2.0). Antibiotic exposure was not associated with ESBL-PE colonisation, which was detected infrequently (71 [8%] subjects).



Conclusions: These findings support recommendations to avoid quinolones as first-line UTI therapy given their collateral impact on commensal microbiota.

Publishing Title:

Molecular Characterization Of Colistin-Resistant *acinetobacter Baumannii* Isolated From A University Hospital In Thailand

Author Block:

I. Thaipisuttikul[1], P. Naksena[1], P. Thumnu[1], P. Eiamratchanee[2], S. Prombhul[1], R. K. Ernst[3], C. Tribuddharat[1]; [1]Faculty of Med. Siriraj Hosp., Mahidol Univ., Bangkok, Thailand, [2]Mahidol Univ. Intl. Coll., Nakhon Pathom, Thailand, [3]Univ. of Maryland Sch. of Dentistry, Baltimore, MD

Abstract Body:

Acinetobacter baumannii is currently one of the most concerned bacterial pathogens due to its extensive resistance to almost all antibiotics. In our institution, over 80% of *A. baumannii* isolates already resist to carbapenems and consequently colistin is considered the last line drug against this XDR organism. Although colistin resistance has been found <1%, the emergence of resistance posted a serious concern on the future of antibacterial therapy. We investigated nine colistin resistant isolates collected during the first emergence in 2010-2011, with colistin MIC ranging from 8 to >128 μg/ml, for molecular epidemiology and mechanism of resistance to gain insight into its emergence. All isolates were typed by MLST and examined for resistance mechanism in regard to binding target alteration from constitutive lipid A modification by sequencing and qPCR of *pmrCAB*, MALDI-TOF analysis of lipid A and *in vitro* fitness assays. The results suggested the presence of two separate clonal groups, with 5 and 4 isolates belong to pandemic ST2 clonal complex and ST215, respectively. Both groups exhibited different *pmrCAB* mutational and expression profiles suggesting that they might arise independently. However, only 2 from ST2 and 3 isolates from ST215 were found to have lipid A modification with phosphoethanolamine. Interestingly, ST2 clonal complex harbored fewer *pmrCAB* mutations but having higher MIC and *pmrCAB* overexpression while ST215, with higher number of mutations, was associated with lower MIC and no significant *pmrCAB* overexpression. In contrast to the previous reports that colistin resistance was associated with lower fitness, all isolates demonstrated comparable fitness with reference strain in growth assay, *in vitro* competition assay and membrane permeability assay. In conclusion, colistin resistance emerged independently within two known STs, possibly under strong selection by extensive drug use. Extensive *pmrCAB* mutations and expression modulation coupled with fitness compensation suggested that it might be on the verge of adaption to stabilize the resistance that foreshadows the spread of resistance in the future.

Antimicrobial Susceptibility of *Pseudomonas aeruginosa* from Bloodstream and Other Specimens of Same Patients in Japan for 10 Years (2005-2014)

Author Block:

K. Matsuzaki[1], H. Koyama[1], S. Matsumoto[1], A. Kanayama[2], I. Kanesaka[2], I. Kobayashi[2]; [1]LSI Medience Corp., Tokyo, Japan, [2]Faculty of Nursing, Toho Univ., Tokyo, Japan

Abstract Body:

Background: Infection with the multi-drug resistance (MDR) *Pseudomonas aeruginosa* is serious concern in a hospital setting. In this study, we summarized the frequency of *P. aeruginosa* as an etiological agent for bloodstream infection in Japan for 10 years and antimicrobial susceptibility patterns of the isolates from bloodstream were compared with those of the isolates from other specimens in same patients.**Methods:** *P. aeruginosa* isolates were recovered from 303,368 blood specimens collected from hospitals in Japan as well as other specimens of the same patients. Antimicrobial susceptibility testing was carried out according to the CLSI standard. Metallo-β-lactamase genes were detected by the PCR method.**Results:** A total of 0.25% (n=772) of blood culture bottles were positive for *P. aeruginosa*, among them, 65% were males with 91% of these patients being 60 years of age or older. In 36% of the patients (n=278) with positive blood cultures, *P. aeruginosa* were also detected in other specimens, sputum (15%), urine (16%) and central venous catheter (5.1%). The resistance rates to imipenem (IPM), ciprofloxacin (CPFX) and amikacin (AMK) were 30%, 23% and 5.9% in blood culture isolates, and 38%, 24% and 6.5% in other specimen isolates, respectively. Particularly, the antimicrobial susceptibility patterns of 10% of isolates from other specimens were different from those of isolates from bloodstream in same patients. MDR *P. aeruginosa*, resistant to IPM, CPFX and AMK, were also detected in 5.4% (1.5-13% in each year) in blood culture isolates and 5.6% (0-12%) in other specimen isolates, respectively. The metallo-β-lactamase gene, bla_{IMP}, were identified in 87% (53/61) of these MDR *P. aeruginosa*.**Conclusions:** We observed that different antimicrobial susceptibility patterns of *P. aeruginosa* between the isolates from other specimens and bloodstream were observed in the same patient. Antimicrobial therapy for *P. aeruginosa* infection should take into account the differences in antimicrobial susceptibility of isolates from blood cultures and the other specimens in the same patients.

***In Vitro* Activity of Tedizolid and 10 Other Antimicrobial Agents in Gram-Positive Anaerobe Cocci Derived from Clinical Specimens in Austria**

Author Block:

E. Leitner, J. Tribus, E. Ullrich, G. Feierl, A. J. Grisold; Inst. of Hygiene, Microbiolgoy and Environmental Med., Med. Univ. of Graz, Graz, Austria

Abstract Body:

Background: For empiric therapy strategies resistance-surveillance is needed due to an increase of resistance in anaerobic bacteria. Recently, tedizolid was introduced for soft tissue infections. Consequently, the aim of this study was to investigate the in vitro activity of tedizolid and 10 other antimicrobial agents of Gram-positive anaerobe cocci (GPAC) in Austria.**Methods:** In total 83 non-duplicate GPAC isolates including 31 Fingoldia magna, 8 Peptrostreptococcus anaerobius, 23 Peptoniphilus assacharolyticus, 13 Peptoniphilus spp. and 8 Parvimonas micra were analyzed, collected at the Institute of Hygiene from June to December 2014. Etest (bioMérieux) or MIC test strip (Liofilchem) were used to determine the MICs of the following drugs: penicillin, ampicillin/sulbactam, piperacillin/tazobactam, imipenem, meropenem, moxifloxacin, vancomycin, clindamycin, linezolid, tedizolid and metronidazole. Interpretation was performed according to EUCAST or CLSI guidelines. For the antimicrobial agents linezolid and tedizolid with no interpretation criteria available, MIC50 and MIC90 were determined.**Results:** Within the 83 GPAC isolates highest resistance levels were found for clindamycin with 24.1% (20; 12 F. magna, 6 P. assacharolyticus, 2 P. micra) followed by moxifloxacin with 22.9% (19; 12 F. magna, 5 P. anaerobius and 2 Peptoniphilus spp.). Resistance was detected for penicillin; ampicillin/sulbactam and piperacillin/tazobactam in one P. anaerobius isolate and for metronidazole in one F. magna isolate, respectively. No resistance was detected for imipenem, meropenem and vancomycin. The MIC (50/90) were determined for linezolid with 1/2 µg/ml (range; 0.25 to >256) and tedizolid with 0.125/0.5 µg/ml (range; 0.064 to 1).**Conclusions:** The findings of this surveillance study present constantly low resistance levels for GPAC in Austria. Remarkable resistance was only observed for clindamycin and moxifloxacin which underlines the need of periodic resistance surveillance of GPAC. Based on our findings ß-lactam antibiotics and metronidazole remain useful drugs for treatment of anaerobic Gram-positive infections.

Antimicrobial Susceptibility of 39,811 Pathogens Isolated from Patients in Canadian Hospitals: Canward Study 2007-2015

Author Block:

G. G. ZHANEL[1], H. Adam[2], M. Baxter[1], B. Weshnoweski[2], R. Vashisht[1], S. Biju[1], N. Laing[1], K. Nichol[2], A. Denisuik[1], A. Golden[1], P. Lagace-Wiens[2], J. Fuller[3], J. A. Karlowsky[2], A. Walkty[2], M. Gilmour[4], D. Bay[1], F. Schweizer[1], M. R. Mulvey[4], G. R. Golding[4], CARA, D. J. Hoban[2]; [1]Univ. of Manitoba, Winnipeg, MB, Canada, [2]Diagnostic Services Manitoba, Winnipeg, MB, Canada, [3]Alberta Hlth.Services, Edmonton, AB, Canada, [4]Natl. Microbiol. Lab., Winnipeg, MB, Canada

Abstract Body:

Background: CANWARD is a national, annual, Public Health Agency of Canada (PHAC) endorsed surveillance study assessing pathogens causing infections in Canadian hospitals and their antimicrobial resistance patterns.**Methods:** From 2007 to 2015, 39,811 pathogens were collected from tertiary-care hospitals across Canada. Antimicrobial susceptibility testing was performed using CLSI broth microdilution methods with >45 marketed and investigational agents.**Results:** Specimen source composition of the 39,811 isolates was 43.8% blood, 32.7% respiratory, 13.4% urine and 10.2% wound specimens. Patient demographic characteristics were: 54.5/45.5% male/female; 13.1/44.4/42.5% patients aged ≤17/18-64/≥65 years; and 38.1/24.9/18.9/18.1% patients located in medical and surgical wards/emergency rooms/ICUs/clinics. The most common pathogens were: *E. coli* (EC 19.6%), MSSA (16.6%), *P. aeruginosa* (PA 8.9%), *S. pneumoniae* (SPN 6.3%), *K. pneumoniae* (KP 6.1%), *Enterococcus* spp. (5.5%), MRSA (4.7%), and *H. influenzae* (4.1%). Susceptibility rates (SR) for EC were: 99.9% for meropenem (MER) and tigecycline (TGC), 99.7% ertapenem (ERT), 97.6% piperacillin-tazobactam (PTZ), 92.3% ceftriaxone (CTR), 90.4% gentamicin (GEN), 77.1% ciprofloxacin (CIP) and 73.0% TMP-SMX (SXT). SR for PA were: 94.4% colistin, 84.2% PTZ, 82.7% ceftazidime (CAZ), 80.5% MER, 78.0% GEN and 74.3% CIP. SR for MRSA were: 100% for linezolid (LZD) and telavancin (TLV), 99.9% daptomycin (DAP) and vancomycin, 99.1% TGC, and 93.5% SXT. Rates of resistant organisms between 2007-2015 increased significantly for ESBL-producing EC (3.4%-9.2%) as well as VRE (1.8%-4.4%), whereas MRSA rates (26.1%-19.4%) significantly declined.**Conclusions:** EC, MSSA, PA, SPN, KP, and MRSA are the most common pathogens in Canadian hospitals. SR for EC were highest for MER, TGC, ERT and PTZ. SR for PA were highest for colistin, PTZ, CAZ and MER. 99-100% of MRSA were susceptible DAP, LZD, TLV, and vancomycin.

Resistance to Antimicrobial Agents Among *Enterococcus faecalis* and *Enterococcus faecium* Isolates Recovered from Human, Environmental and Food Sources in Brazil

Author Block:

R. Ribeiro[1], C. Melo[2], A. Faria[3], J. Castro[1], A. Gomes[1], T. Pinto[1], A. Regua-Mangia[2], V. Merquior[3], L. Teixeira[1]; [1]Univ.e Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [3]Univ.e do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract Body:

Enterococci are opportunistic pathogens with a remarkable ability to acquire and exchange mobile genetic elements associated with antimicrobial resistance. Their presence in environmental and food sources may be indicative of human or animal contamination representing a risk to human health. Moreover, the dispersion of resistance-associated genes through a variety of routes has been the subject of increasing attention. We evaluate the susceptibility to antimicrobials among isolates of two major enterococcal species recovered from recreational waters (RW; 139 isolates), chicken carcasses ready to be marketed (CC; 105) and human sources [H; 204: including both colonization (83) and infection (121)], from 2010 to 2014. MALDI-TOF-MS was used for species identification. Antimicrobial susceptibility was evaluated by the disk diffusion method. The presence of genes associated with high-level resistance to aminoglycosides (HLR-A) was evaluated by multiplex PCR. Among 448 isolates, 60.1% were identified as *E. faecium* and 39.9% as *E. faecalis*. The highest rates of non-susceptibility were found to ciprofloxacin (61.1%), norfloxacin (48.4%), nitrofurantoin (42.6%) and levofloxacin (41.7%). Resistance to beta-lactams ranged from 27.3% to 33.7%. Resistance to streptomycin (HLR-S) was observed in 25.4% (15.4% H, 7.8% CC and 2.2% RW) of the isolates, while to gentamicin (HLR-G) was found in 21.2% (18.5% H, 1.6% CC and 1.1% RW). Occurrence of VRE was detected among isolates from H (25.6%), RW (1.3%) and CC (0.3%). Multidrug resistance (MDR) was observed in 310 (69.2%) isolates. The most common genes associated with HLR-A were *ant(6')Ia* (31.8% H, 16.6% CC, 5.3% RW), *aph(3')IIIa* (35.6% H, 3.0% CC and RW each), and *aac(6')-le-aph(2")-la* (34.8% H, 4.5% CC, 1,5% RW). Enterococcal isolates presenting MDR were recovered from the different sources investigated. Considering that these strains may represent a public health risk, these findings indicate the importance for continuous monitoring and improvements on antimicrobial usage and on the quality of environmental and food sources.

Antibiotic Resistance in Sputum Isolates of *Pseudomonas aeruginosa* from Children Receiving Mechanical Ventilation: Impact of Antibiotic Exposure and Mic Heterogeneity

Author Block:

K. B. Flett[1], H. Chung[2], M. Schaefers[1], G. P. Priebe[1]; [1]Boston Children's Hosp., Boston, MA, [2]Harvard Med. Sch., Boston, MA

Abstract Body:

Background: *P. aeruginosa* causes significant morbidity in ventilated patients and frequently develops antibiotic resistance. Few pediatric studies have evaluated the timing of this resistance and impact of antibiotic exposure.**Methods:** We conducted a prospective cohort study of 32 pediatric patients receiving mechanical ventilation and with $\geq$ 2 respiratory cultures growing *P. aeruginosa*. We evaluated change in MIC ratio compared to previous culture, with MICs performed using VITEK. Antibiotic days of therapy during the 30 days prior to culture collection was collected and impact of antibiotic exposure on MIC ratio was assessed by Wilcoxon rank sum test. Multilocus sequence typing (MLST) was performed on samples with MIC change $\geq$ 2-fold to confirm the presence of the same strain within a patient. Additional MIC testing using a high-throughput method was performed on 24 colonies for two paired samples.**Results:** 130 respiratory cultures were evaluated, with 9 subjects having $\geq$ 5 cultures. MIC changes $\geq$ 2-fold often occurred within 1-4 days of the previous culture, sometimes with no exposure to the antibiotic tested. For cefepime and ceftazidime, MIC changes were not significantly associated with cephalosporin or beta-lactam days. For meropenem, the number of carbapenem days approached significance (p=0.06), but the number of beta-lactam days was not significant (p=0.43). For ciprofloxacin, fluoroquinolone days also approached significance (p=0.08). Eleven pairs of samples had MLST analysis performed, with each pair having congruent sequence type. MIC testing of multiple colonies for two paired samples revealed both MIC heterogeneity within each sample and changes in MIC diversity over time.**Conclusions:** MIC changes can occur rapidly and are not robustly associated with exposure to the corresponding antibiotic, suggesting more complex mechanisms. Given the heterogeneity of MIC results for individual colonies in a single sample, insufficient representation of resistance likely contributes to observed changes in MIC.

Publishing Title:

Resistance to Ciprofloxacin and Ceftriaxone in Human Non-Typhoidal <*salmonella*> Isolates from Cambodia

Author Block:

W. Lurchachaiwong; Armed Forces Res. Inst. of Med. Sci., Bangkok, Thailand

Abstract Body:

Non-typhoidal *Salmonella* (NTS) causes around 94 million cases of acute gastroenteritis each year. NTS resistance to fluoroquinolones, first line treatment for diarrhea, and decreased susceptibility to third generation cephalosporins, is an emerging problem. This study reports antimicrobial resistance of NTS in Cambodia. A total of 566 stool samples collected from 283 diarrhea cases and 283 non-diarrhea controls during July 2014 - October 2015 were investigated. NTS was identified and serotyped by standard microbiology techniques and antimicrobial susceptibility testing to ampicillin (AMP), azithromycin (AZM), ceftriaxone (CRO), ciprofloxacin (CIP) and co-trimoxazole (SXT) was performed by the disc diffusion assay. NTS infections accounted for 22% (63/283) of cases and 26% (74/283) of controls. Resistance to AMP, SXT, CIP, CRO and AZM was detected in 57%, 86%, 3%, 5%, and 0% of NTS isolates from cases and 51%, 38%, 22%, 5% and 2% of isolates from controls, respectively. Serotyping was performed on isolates that was resistant to CIP and CRO. Among 16 CIP-resistant isolates, *Salmonella* Kentucky (group C) was predominant (52.4%; 9/16), followed by *Salmonella* Give (group E) (37.5%; 6/16). Four of six (67%) of the CRO-resistant NTS were *Salmonella* enterica subsp. enterica serotype 4, 5, 12: i: - (group B) which also showed intermediated susceptibility to CIP. One *Salmonella* Rissen (group C) and one *Salmonella* Corvallis (group C) showed resistant to CRO and the latter was also resistant to CIP. In conclusion, this study demonstrates resistance to CIP and CRO among NTS isolates from the indigenous population in Cambodia. Resistance to CIP was mainly found in *Salmonella* group C while the resistance to CRO was found in *Salmonella* group B. Surveillance for NTS antibiotic resistance is needed particularly in areas where resistance is prevalent and likely underestimated such as Southeast Asia.

Multidrug Resistance Gram-Negative (Mdr-Gn) Organisms in the Inpatient and Outpatient Settings in the US: 2008-2015

Author Block:

H. Hoffman-Roberts[1], P. Scoble[1], X. Sun[2], J. Mohr[1], Y. Tabak[2], R. Johannes[2], V. Gupta[2];
[1]Tetraphase Pharmaceuticals, Watertown, MA, [2]Becton Dickinson & Co, Franklin Lakes, NJ

Abstract Body:

Background: MDR-GN organisms are increasing and may vary by clinical setting, source, and pathogen. We evaluated trends in MDR-GN organisms over 8 years. **Methods:** The Becton Dickinson electronic research database from 154 US hospitals (2008 - 15) was evaluated. Non-duplicate isolates (first isolate of a species per 30 day period) from respiratory, blood, urine, skin, intraabdominal, and other sources were identified as MDR per NHSN definitions. Isolates were categorized into 3 settings by the specimen collection time: 1) Admission: < 3 days of an inpatient admission and no previous admission ≤ 14 days; 2) Hospital-onset: 3 days post-admission or ≤ 14 days of discharge; 3) Ambulatory. Pearson correlation was used to evaluate trend, and t-tests to compare between sources. **Results:** Overall, 3,077,168 isolates were tested; 5.3% (163,688) were MDR. MDR rates differed by settings: 3.4% (69,599/2,020,015, ambulatory), 6.6% (34,202/522,010, admission), and 11.2% (59,887/535,143, hospital onset) (all p<0.01). Top 5 pathogens accounted for 92.1% of MDR isolates: *E. coli* (38.7%), *P. aeruginosa* (29.5%), *K. pneumoniae* (13.2%), *A. baumannii* (5.5%), and *Enterobacter spp.* (5.3%). Sources with the highest MDR rates were: respiratory (15.9%), blood (7.5%), and skin (7.3%). The overall MDR rate remained stable (p=0.09) with rates decreasing in hospital-onset (p<0.01) setting but increasing in ambulatory and admission settings (both p<0.01). **Conclusion:** MDR-GN rates remained the highest in the hospital onset setting, and in the respiratory source. MDR trends were downward in the inpatient, but upward in ambulatory and admission settings.

Antibiotic Susceptibility Profiles of Clinical *Clostridium difficile* Isolates in a Pediatric Population

Author Block:

L. K. Kociolek[1], D. N. Gerding[2], J. R. Osmolski[3], S. J. Patel[1], R. Patel[1], D. W. Hecht[3]; [1]Ann & Robert H. Lurie Children's Hosp. of Chicago, Chicago, IL, [2]Edward Hines, Jr. VA Hosp., Hines, IL, [3]Loyola Univ. Med. Ctr., Maywood, IL

Abstract Body:

Background: The rising incidence of *C. difficile* infections (CDIs) in adults is partly related to the global spread of fluoroquinolone-resistant strains, namely BI/NAP1/027. Although CDIs are also increasingly diagnosed in children, BI/NAP1/027 is relatively uncommon in children. Little is known about antibiotic susceptibility of pediatric CDI isolates.**Methods:** *C. difficile* was cultured from *tcdB*-positive stools collected from children diagnosed with CDI between Mar. 2011 and Dec. 2013 at an academic children's hospital. CDI isolates were grouped by restriction endonuclease analysis (REA). Mean inhibitory concentrations (MICs) were measured by agar dilution method for the 7 antibiotics listed in the Table. Subsequent isolates from the same patient that were identified as the same REA group as the previous CDI (i.e., CDI relapses) were excluded. Susceptibility breakpoints were based on CLSI and/or EUCAST guidelines.**Results:** Antibiotic susceptibilities of the 115 isolates meeting inclusion criteria are summarized in the Table. Only one BI isolate was identified. The 3 moxifloxacin-resistant isolates were REA groups BI, CF, and non-specific. The 2 rifaximin-resistant isolates were REA groups DH and Y. The 21 clindamycin-resistant isolates were distributed among 9 different REA groups (A, CF, DH, G, L, M, Y and 2 unique non-specific REA groups). Resistance to metronidazole or vancomycin, or elevated MICs for fidaxomicin or surotomycin, was not identified among these isolates.**Conclusions:** Antibiotic resistance is uncommon in the diverse group of *C. difficile* isolates collected from children in this single-center cohort.**Table: Summary of antibiotic susceptibility testing of 115 *C. difficile* isolates**

Publishing Title:

Implementation of Antibiotic Susceptibility Testing (AST) for Resistance Tracking Using Clinical and Laboratory Standards Institute (CLSI) M100 and M02 in Cambodian Microbiology Laboratories

Author Block:

S. Oeng, J. Letchford; Diagnostic Microbiol. Dev. Program, Phnom Penh, Cambodia

Abstract Body:

Background: DMDP collaborates with the Cambodian Ministry of Health (CMoH) to build microbiology diagnostic capacity as part of the National Strategic Plan for Medical Laboratory Services. We introduced CLSI M100 and M02 disc diffusion methods to 6 Cambodian laboratories to achieve quality AST results to report to hospital clinicians and create surveillance data for the Ministry of Health.**Methods:** DMDP used a multi-strategy approach in 2014-15 which included 9 manager meetings, the CLSI annual AST update webinar and used M100 (S23, S24, S25) and M02 (A11, A12) documents to prepare an AST guideline adapted to fit Cambodian practices. 3 International (16 months) and 3 Cambodian mentors (24 months) provided regular bench microbiology diagnostic training at all 6 sites. In 2015, DMDP and CMoH organized a 2-day AST workshop of 21 participants and 8 facilitators with a practical exercise book (cases and questions) and pre/post tests to improve and evaluate participant capacity. We created an electronic tool for weekly monitoring AST Internal Quality Control (IQC) performance and provided corrective action advice when problems arose. Monthly activity reports and clinician reports were monitored for adherence to the guideline. Also, practical AST exercises were regular activities in DMDP supported microbiology manager meetings during 2014 and 2015.**Results:** 5 of 6 DMDP supported laboratories have implemented AST according to CLSI M100 and M02. In 2015, 5 of 6 laboratories performed weekly AST IQC. Problems diminished from weekly to none over 12 months. Laboratory assessments in 2015 showed the 'AST' component to be in the top 2 of 9 components assessed at 5 sites. All 6 laboratories achieved good scores in the Pacific Paramedical Training External Quality Assessment (EQA) program. Average scores in 2015 ranged from 85% to 95%. Workshop participant test scores showed 14% improvement.**Conclusions:** The multi-strategy approach strengthened Cambodian laboratory capacity for AST. Regular on site mentoring and support were essential. Repetitive practice, encouragement and cultural awareness were key components. Implementation and standardization of AST have provided opportunity for Cambodia CDC to collect important AMR surveillance data.

Big Data Vs. Bad Bugs: Fighting Eskape Pathogens Electronically

Author Block:

U. Chukwuma[1], T. Coster[2], M. LaCour[2], K. McAuliffe[1], R. Thelus[1], C. Neumann[1], M. Hinkle[3], R. Clifford[3], M. Julius[3], P. Waterman[4], **E. Lesho**[3]; [1]NMCPHC, Portsmouth, VA, [2]PVDAS, Falls Church, VA, [3]WRAIR, Silver Spring, MD, [4]AFHSC, Silver Spring, MD

Abstract Body:

Background: Size and complexity are two components of 'big data' (BD). Organizations increasingly exploit BD to identify opportunity, associations, and patterns, or predict threats or outcomes. We sought to demonstrate how BD can be leveraged to support patient safety and public health. **Methods:** BD is created and analyzed by: 1) leveraging public health and infection control surveillance mandates; 2) using a high-throughput organism identification, susceptibility testing, and whole genome sequencing pipeline; 3) establishing specialized datamarts. The two datamarts are the Military Health System (MHS) Health Level 7 (HL7) repository of the U.S. Navy and the Pharmacovigilance Defense Application System (PVDAS) of the US Army. MHS HL7 receives laboratory, radiology and pharmacy data. The PVDAS receives data for medical claims, eligibility and enrollment, death files, and pharmacy transactions. MHS HL7 uses SQL algorithms to identify ESKAPE pathogens and to generate specific surveillance products. Java, SAS and SQL queries against PVDAS perform pharmacovigilance by monitoring prescribing and adverse drug reactions and safety alerts. 36,000 multidrug resistant ESKAPE pathogens have been centrally characterized, all of which will be fully sequenced by 2017 using the pipeline. **Results:** Analysis of 14.5 million cultures revealed carbapenem resistance (CR) 73 fold higher in non-fermenters compared to Enterobacteriaceae. Bloodstream infections were associated with higher relative risks of CR ($p < 0.001$). The incidence of *S. aureus* with clinically problematic vancomycin minimum inhibitory concentrations decreased or remained constant, and is predicted to be stable from 2016-2018. 311 patients received potentially problematic prescriptions or formulations of an antimicrobial. There were >13 million visits for acute respiratory infections. In 2006, 2011, and 2014, 49%, 54% and 48% respectively, of these visits had an antibiotic prescribed. Antibiotics were more likely to be prescribed to females, retirees and dependents of retirees, and persons 45 years and older. **Conclusion:** The above are just a few highlights of the results, outcomes, and usefulness of our approach, which informed stewardship and quality improvement efforts.

A Hierarchical Classification, Naming, and Annotation System for Acquired Antimicrobial Resistance Protein Sequences

Author Block:

D. H. Haft, V. V. Brover, M. Feldgarden, A. B. Prasad, W. Klimke; Natl. Library of Med., Bethesda, MD

Abstract Body:

Antimicrobial resistance (AMR) proteins have been named variably according to their biochemical activity, the resistance they confer or contribute to, the homology family to which they belong, and even the relative order of their discovery. For beta-lactamases in particular, function may differ if a single amino acid differs and names may be assigned to individual alleles. NCBI has taken over responsibility for providing new allele designations upon submission for beta-lactamases in families whose nomenclature previously was handled by researchers at the Lahey Clinic (www.lahey.org/studies). We have compiled and curated a broadly comprehensive database of bacterial AMR proteins from multiple sources, including Lahey Clinic, Resfinder, the Comprehensive Antibiotic Resistance Database, curated data contributed by outside experts, and our own surveys of primary and review articles. In our hierarchical treatment, AMR proteins are grouped first by type (e. g. beta-lactamases, whose members are not all related by homology), then by broad homology family (e.g. all class D beta-lactamases), then specific family (e. g. OXA-60 family carbapenem-hydrolyzing class D beta-lactamases), then allele. For every node in the hierarchy, we assign a descriptive protein product name that is suitable for use in submissions of sequence data to GenBank. We have developed a collection of over 450 profile hidden Markov models (HMMs) as AMR classifiers, and assigned 3688 distinct complete sequences to a hierarchy with 3419 families, including 2289 alleles. Our classification improves functional predictions for many AMR proteins, especially class D (OXA) beta-lactamases. Our toolkit includes a hierarchical representation of AMR protein families, a matching library of corresponding HMMs with cutoff scores, and a comprehensive curated set of AMR proteins with consistent and informative protein names, for distribution but also replicated as RefSeq records. These resources assist in annotating pathogen genomes, comparing sets of AMR proteins across strains, and predicting resistance phenotypes from whole genome shotgun sequencing data.

Multidrug-resistance *Acinetobacter baumannii* (Mdr Ab) Trends from All Sources in the Inpatient and Outpatient Setting in US Hospitals: 2008-2015

Author Block:

H. Hoffman-Roberts[1], H. Patel[1], X. Sun[2], Y. Tabak[2], J. Mohr[1], R. Johannes[2], V. Gupta[2];
[1]Tetraphase Pharmaceuticals, Watertown, MA, [2]Becton Dickinson & Co, Franklin Lakes, NJ

Abstract Body:

Background: MDR AB is traditionally a nosocomial pathogen, but started emerging more in the outpatient setting. We evaluated trends in susceptibility of MDR AB over 8 years. **Methods:** The Becton Dickinson electronic data research database from 154 hospitals (2008 - 15) was analyzed. Non-duplicate isolates (first of a species per 30 day period) from respiratory, blood, urine, skin, intra-abdominal, and other sources were identified as MDR per NHSN definitions. Isolates were categorized into three settings by the specimen collection time: 1) Admission: within 3 days of an inpatient admission and no previous admission within 14 days; 2) Hospital-onset: 3 days post-admission or within 14 days of discharge; 3) Ambulatory. Pearson correlation was used to evaluate the trend of MDR rates over time, and t-tests to compare between sources. **Results:** Overall 20,559 isolates were tested; 43.4% (8,927) were MDR AB. MDR rates differed by setting: 25.2% (1,868/7,417, ambulatory), 43.6% (1,992/4,568, admission), and 59.1% (5,067/8,574, hospital onset) (all $p<0.01$). There were downward trends in MDR AB rates for three settings (all $p < 0.05$) and for all sources (all $p < 0.01$). MDR rates remained highest in respiratory isolates across three settings (49.4% to 63.3%). The overall MDR rate for respiratory isolates (60.5%) was higher than each of other sources (ranged from 24.5% to 43.4%; all $p < 0.01$). **Conclusion:** In this collection of isolates, rates of MDR in ACB decreased over time. MDR AB was highest in the inpatient setting. Respiratory isolates showed the highest MDR AB rates in all settings.

Characterization of Increased Macrolide Resistance in *Campylobacter coli*

Author Block:

C. T. Bennett[1], D. Campbell[2], C. Fitzgerald[2], J. Reynolds[2], J. Chen[1], J. Folster[2]; [1]IHRC, Inc., Atlanta, GA, [2]CDC, Atlanta, GA

Abstract Body:

Campylobacter causes an estimated 1.3 million infections, 13,000 hospitalizations, and 120 deaths in the United States each year. The Centers for Disease Control and Prevention (CDC) estimates that 310,000 *Campylobacter* infections are antimicrobial-resistant annually in the U.S. Primary treatment options for campylobacteriosis are fluoroquinolone or macrolide drugs; however, macrolides such as erythromycin and azithromycin are frequently the sole treatment option due to prevalent resistance to fluoroquinolones. CDC's National Antimicrobial Resistance Monitoring System (NARMS) has screened *Campylobacter* isolates from FoodNet sites since 1997, and has observed an increase in resistance to macrolides among *C. coli* in recent years. NARMS performs antimicrobial susceptibility testing (AST) using the broth microdilution method with nine drugs, and confirms *Campylobacter* genus and species using conventional PCR methods. In 2013, NARMS performed AST on 142 surveillance *C. coli* isolates from humans who sought clinical care for illness, and found that 17% (n = 24) were macrolide-resistant (azithromycin MIC greater than 0.5 and erythromycin MIC greater than 8). In 2012, 9% of 134 *C. coli* isolates tested in NARMS were macrolide-resistant. We performed whole genome sequencing (WGS) on twelve macrolide-resistant isolates from 2013 using the Illumina platform. We identified several acquired resistance determinants conferring resistance to aminoglycosides, β-lactams, and tetracycline; however, we did not find any acquired macrolide-resistance determinants. With WGS analysis we identified common mutations in the 23S ribosomal gene (including A2074G, which is predicted to confer macrolide resistance). Comparative genome analysis indicated that the 12 *C. coli* were not closely related, suggesting that macrolide resistance is not emerging because of clonal expansion of resistant strains.

Fluoroquinolone-Nonsusceptible *Streptococcus pneumoniae* Isolates from a Medical Center in Pneumococcal Conjugate Vaccine Era

Author Block:

H-H. Chen, H-C. Li, L-H. Su, C-H. Chiu; Chang Gung Mem. Hosp., Taoyuan City, Taiwan

Abstract Body:

Background: *Streptococcus pneumoniae* is one of the most common pathogens to cause mucosal and invasive infection in humans. Resistance to fluoroquinolones (FQ) was associated with clinical treatment failure when treating pneumococcal diseases.[1] The induction of pneumococcal conjugate vaccine (PCV) was reported to be associated with the reduction of ciprofloxacin resistance in previous observational study.[2] **Methods:** We collected clinical isolates of *Streptococcus pneumoniae* from Jan. 2011 to Jul. 2015 at Chang Gung Memorial Hospital. The levofloxacin or moxifloxacin-nonsusceptible (FQ-R) pneumococcal isolates were analyzed by serotyping, multilocus sequence typing (MLST), and sequencing of the quinolone resistance-determining regions (QRDR) of the *gyrA, gyrB, parC,* and *parE*. **Results:** During the study period, 42 FQ-nonsusceptible pneumococcal isolates were identified. The rate increased from 1.6% of total pneumococcal isolates (2 of 127) in 2011 to 4.6% (13 of 283) in 2014, then decreased to 1.5% (3 of 202) in the first half-year of 2015. These isolates belonged to13 serotypes, and serotype 14 (12 of 42, 33.3%) was the most prevalent. Most of the isolates belonged to international clones or their variants. After QRDR analysis, there were 19 isolates in five clusters that shared both the same sequence type and QRDR mutation. **Conclusions:**FQ resistance emerged in either vaccine or non-vaccine serotypes. Majority of the isolates were international clones or related variants, suggesting the resistance was disseminated through clonal spread. The wide use of PCV since 2013 appears to reduce the spread of FQ-R pneumococci.

Resistance Profiles of *K. pneumoniae* Urinary Tract Isolates from European and North American Intensive Care Units (2012 - 2014)

Author Block:

S. Lob, K. Kazmierczak, D. Sahm, D. Biedenbach, **R. Badal**; IHMA, Inc., Schaumburg, IL

Abstract Body:

Background: Intensive care units (ICUs) are often described as hotbeds of antimicrobial resistance, with high rates of extended-spectrum β-lactamase (ESBL)-producing and multidrug-resistant (MDR) *Enterobacteriaceae*, especially among *Klebsiella pneumoniae*. This report from the Study for Monitoring Antimicrobial Resistance Trends (SMART) describes susceptibility patterns of *K. pneumoniae* from urinary tract infections (UTI) in 2012-2014 in Europe (EU) and North America (NA), comparing ICU and non-ICU wards.**Methods**: 82 sites in 20 countries in EU and NA collected up to 50 consecutive gram-negative pathogens from UTI per year. Susceptibility was determined by broth microdilution per CLSI guidelines for 1,377 *K. pneumoniae* isolates. MDR was defined as resistance to ≥3 drug classes (aminoglycosides, β-lactam/β-lactamase inhibitors, cephems, carbapenems, quinolones).**Results**: Susceptibility to selected agents and MDR rates are shown below.

Region/ward type (n)	% Susceptible[A,B]								% MDR[C]
	ETP	IPM	FEP	CRO	CAZ	TZP	CIP	AMK	
Europe									
ICU (170)	67.1	77.7	37.7	37.7	40.6	51.2	39.4	80.6	55.3
Non-ICU (725)	88.3	**94.2**	61.8	59.2	62.9	73.5	60.7	**92.4**	31.3
North America									
ICU (69)	**95.7**	**94.2**	87.0	84.1	84.1	92.8	89.9	**95.7**	8.7
Non-ICU (413)	**97.1**	**96.9**	**92.3**	**91.5**	**92.5**	**93.0**	89.6	**97.1**	6.3

[A] Susceptibility values ≥90% are bolded.
[B] Significant differences between ward types are shaded (Fisher's exact test, p<0.05).
ETP=ertapenem, IPM=imipenem, FEP=cefepime, CRO=ceftriaxone, CAZ=ceftazidime, CIP=ciprofloxacin, TZP=piperacillin-tazobactam, AMK=amikacin

Among both ICU and non-ICU isolates, susceptibility was significantly lower and MDR rates higher in EU than NA (p<0.05). The most common ESBL in both regions was CTX-M-15. Carbapenemases detected in EU included KPC, OXA, NDM, and VIM, whereas in NA only KPC were found.**Conclusions:**•Resistance in *K. pneumoniae* from UTI was very high in EU ICUs with significantly lower susceptibility and higher MDR rates than in non-ICU wards.•In contrast, differences between ward types were small in NA. Susceptibility was significantly higher in NA than in EU, especially in ICUs.•Investigation of the reasons for the differences in resistance between EU and NA ICUs may be useful for the development of effective strategies to reduce antimicrobial resistance in ICUs.

High Prevalence of *qnrb* and Other Plasmid-mediated Quinolone Resistance Determinants Among *Enterobacteriaceae* Isolated from Urine Samples in Sierra Leone

Author Block:

T. A. Leski[1], M. G. Stockelman[2], U. Bangura[3], D. Chae[4], R. Ansumana[3], D. A. Stenger[1], G. J. Vora[1], C. R. Taitt[1]; [1]Naval Res. Lab., Washington, DC, [2]Naval Med. Res. Ctr., Silver Spring, MD, [3]Mercy Hosp. Res. Lab., Bo, Sierra Leone, [4]Thomas Jefferson High Sch., Alexandria, VA

Abstract Body:

Background: Fluoroquinolones are a family of broad-spectrum bactericidal antibiotics used for the treatment of infections caused by both Gram-positive and Gram-negative bacteria. Their widespread and sometimes indiscriminate use has exacerbated the spread of genes that can confer fluoroquinolone resistance. In this study, we analyzed a set of urine *Enterobacteriaceae* isolates from Sierra Leone for the presence and prevalence of plasmid-mediated quinolone resistance genes (PMQR) and found that 86% harbored PMQRs and 47% were highly resistant to ciprofloxacin.**Methods and Results:** We analyzed a total of 70 *Enterobacteriaceae* isolates that were obtained from the urine of subjects with symptoms of urinary tract infection. These isolates belonged to six species (*Citrobacter freundii*, *Enterobacter cloacae*, *Klebsiella pneumoniae*, *Leclercia* sp./*Enterobacter* sp., *Escherichia hermannii* and *Escherichia coli*) and included both ciprofloxacin-resistant and -sensitive strains. Each isolate was screened for the presence of 10 PMQR genes (*qnrA*, *qnrB*, *qnrC*, *qnrD*, *qnrS*, *qnrVC*, *aac(6')-Ib-cr*, *qepA*, *oqxA* and *oqxB*) by polymerase chain reaction. The identity of the detected genes was confirmed by DNA sequencing. The results demonstrated a high carriage rate of three *qnr* family genes: *qnrA*, *qnrB*, *qnrS* (66%) and *aac(6')-Ib-cr* (60%). They were found in all of the tested species except *E. coli*. The most frequently encountered PMQR gene was *qnrB*, especially among *C. freundii* isolates which harbored at least four alleles of *qnrB* as well as truncated *qnrB* pseudogenes. The *oqxA* and *oqxB* genes were found in 23% and the *qepA* gene in 4% of the isolates.**Conclusions:** Ciprofloxacin is recommended for travelers visiting Sierra Leone and is widely used in this part of West Africa. The results of this study indicate that continued efficacy of this antimicrobial in the region might be threatened by uncontrolled spread of transferrable fluoroquinolone resistance determinants. The ubiquitous presence of multiple *qnrB* alleles and pseudogenes in *C. freundii* support previous evidence suggesting that this species might be the original source of this gene.

Emerging Global Colistin Resistance

Author Block:

L. S. Gucer, S. Hızal, O. Yilmaz, H. Nuhoglu, F. Can, **o. ergonul**; Koc Univ., Sch. of Med., Istanbul, Turkey

Abstract Body:

Colistin resistance among K.pneumoniae has been increasing in recent years. There are several reports regarding colistin resistance rates and mechanisms of the resistance in veterinary and clinical isolates of K.pneumoniae. This meta-analyses was performed to identify the incidence of colistin resistance in K.pneumonia and to identify the mechanisms of colistin resistance and to assess the risk of spread of the resistance.A systematic search of PubMed database from 1 January 2000 until 10 January 2016 identified 10 original studies. Articles that were included in the systematic review were from 10 different countries. Density of resistance to colistin among human clinical Klebsiella isolates (Figure 1a) and mcr1 plasmid detected countries were presented (Figure 1b).Figure 1. a) Colistin resistance rates of human clinical Klebsiella isolates. b) Global mcr1 positivity.Conclusion: Emergence and spread of colistin resistance and related genotypes should be screened and followed up. Our study group will update emerging data on monthly basis.

Dissemination of *cfr* by Clonal Spread of St475 and St16 *Enterococcus faecalis* Strains Harboring a Pcppf5-like Plasmid

Author Block:

x-p. liao, j. sun, y-h. liu; South China Agricultural Univ., guangzhou, China

Abstract Body:

Objectives: The *cfr* multiresistance gene of *Enterococcus faecalis* has been associated with transfer of linezolid resistance but little is known about its prevalence and mode of transmission due to only sporadic reports. In this study, the prevalence of the *cfr* gene among *E. faecalis* origin from swine was investigated. **Methods:** A total of 91 *E. faecalis* isolates, obtained from swine faecal swabs from 30 farms in Guangdong Province of China during 2012, was conducted to screen the *cfr* gene. Southern blotting, conjugation and transformation analyses were conducted to confirm the plasmid location and transferability of *cfr* gene. The genetic environment of *cfr* was determined by sequence analysis.**Results:** A total of 11 isolates were *cfr*-positive. All the *cfr*-positive *E. faecalis* strains presented a multi-resistance phenotype but all were still susceptible to vancomycin and linezolid. Molecular typing of the 11 *cfr*-positive isolates indicated clonal spread of ST475 and ST16 *E. faecalis* from different swine farms. S1-PFGE and Southern blotting showed that all the *cfr* genes were located on plasmids. A12 kb *cfr*-positive plasmid (pE30) was identified in most (9/11) isolates. Sequence analysis and comparison showed that pE30 was a pCPPF5-like plasmid and the region surrounding the *cfr* gene was the same with the *cfr*-carrying IS*Enfa5*-composite element of *Streptococcus* plasmid pStrcfr with 4 bp direct repeat (GTAT) on both sides. This suggests that the *cfr* gene on plasmid pE30 may have originated from the *Streptococcus* plasmid pStrcfr.**Conclusions:** In conclusion, the clonal spread of ST475 and ST16 *E. faecalis* strains and the horizontal transfer of the pCPPF5-like plasmid have contributed to the dissemination of the *cfr* gene in *E. faecalis*.

Publishing Title:

Clinical Sensitivity of a Real-Time PCR Assay Targeting *gyrA* Gene for Prediction of Ciprofloxacin Resistance in *Neisseria gonorrhoeae*

Author Block:

P. Hemarajata, S. Yang, J. D. Klausner, R. M. Humphries; UCLA, Los Angeles, CA

Abstract Body:

Background: *Neisseria gonorrhoeae* (NG) has become an urgent threat to public health due to high prevalence of antimicrobial resistance. Prevalence of fluoroquinolone-resistant gonococci has is currently at 19.2%, suggesting that ciprofloxacin (CIP) may still be a viable option for treatment in the majority of isolates. We previously evaluated accuracy of a *gyrA* RT-PCR with melt genotyping to predict CIP susceptibility based on the presence of Ser91 mutation on *gyrA* gene, for urine specimens positive for NG. This study evaluates clinical sensitivity of *gyrA* RT-PCR on other specimen types.**Methods:** Specimens were processed on COBAS® 4800 CT/NG assay (Roche Diagnostics). Residual DNA from deep-well plates was collected from specimens positive for NG and used for *gyrA* RT-PCR. PCR results were used to evaluate overall and specimen-specific clinical sensitivity of PCR.**Results:** *gyrA* RT-PCR was performed on 46 clinical specimens positive for NG (Table 1). Among these, 31 (67.4%) could be genotyped by RT-PCR, as wild-type (23, 74.2%) or mutant (8, 25.8%), but 15 (32.6%) failed to produce *gyrA* signal. Among specimens tested, 15/16 urines (93.8%) but only 4/18 throat swabs (22.2%) produced a gyrA signal that could be genotyped as either wild type or mutant. The low clinical sensitivity in throat specimens seems to be independent of crossing point (Cp) on COBAS® assay, since all specimens except throat with Cp above the previously established limit of detection of 28 were genotyped successfully, while none of throat specimens with similar Cp was. For 3 patients, both throat and rectal specimens were positive for NG. Among these, 0/3 throat specimens yielded a *gyrA* RT-PCR signal as compared to 3/3 rectal swabs.**Conclusions:** The overall clinical sensitivity of the *gyrA* PCR was 67.4%. Excluding throat specimens, the sensitivity increased to 96.4%. We hypothesize poor performance on throat specimens may be related to the presence of PCR inhibitors unique to this specimen. Further investigation and optimization of PCR to improve sensitivity on throat swabs is underway.

Table 1: PCR results for clinical specimens tested

Specimen type	*gyrA* genotype		
	Wild-type	Mutant	Indeterminate
Genital swabs (3)	2	1	0
Rectal swabs (8)	5	3	0
Throat swabs (18)	3	1	14

ThinPrep® (1)	0	1	0
Urines (16)	13	2	1
Total	23	8	15

Publishing Title:

High Prevalence of Plasmid-mediated Colistin-resistance Gene *Mcr-1* in Fecal Metagenomes of Dutch Travelers

Author Block:

C. J. H. von Wintersdorff, **P. F. G. Wolffs**, P. H. M. Savelkoul, J. Penders; Maastricht Univ. Med. Ctr.+, Maastricht, Netherlands

Abstract Body:

Background: Colistin is increasingly used as a last resort antibiotic for the treatment of infections with carbapenem resistant bacteria. Recently, the first plasmid-mediated colistin resistance gene (*mcr-1*) was reported in China. Studies thus far have focused on detecting *mcr-1* in existing collections of cultured isolates, or by mining metagenomic sequencing data. As these existing collections were mostly restricted to specific bacteria or resistance profiles (e. g. ESBLs), and sensitivity of sequence-based metagenomics is relatively low, we hypothesize that the prevalence of *mcr-1* reported in these studies might be an underestimation of the carriage rates. Here, we applied a PCR-based targeted metagenomic approach to detect *mcr-1* in the fecal metagenomes of Dutch travelers between 2010 and 2012. **Methods:** Pre- and post-travel stool samples of 122 healthy Dutch travelers were collected and submitted to metagenomic DNA extraction. Detection of *mcr-1* and CTX-M genes was performed by qPCR. All *mcr-1* positive samples were confirmed by sequencing.**Results:** Screening of the fecal metagenomes of 122 travelers before and after travel, yielded 7 samples positive for *mcr-1*, reflecting a post-travel prevalence of 4.9% (95% CI 0.021-0.105) and acquisition rate of 4.1% (95% CI 0.015-0.096). Travelers with *mcr-1* acquisition visited destinations in South(east) Asia or southern Africa. In 4 out of 6 *mcr-1*-positive post-travel metagenomes, CTX-M genes were detected. Moreover, CTX-M harboring *E. coli* were previously cultured from fecal samples of 5 out of 6 *mcr-1*-positive individuals. However, none of these ESBL-producing *E. coli* were positive for *mcr-1*, indicating that the detected *mcr-1* genes originate from other bacteria.**Conclusion:** We report here the highest *mcr-1* prevalence in human microbiomes thus far, highlighting the potential of PCR-based targeted metagenomics as an unbiased and sensitive method to screen for the carriage of *mcr-1*. The high acquisition rates show that travel contributes to the dissemination of *mcr-1*. Furthermore, that one participant was positive for *mcr-1* before travel indicates that *mcr-1* may already be present in the microbiomes of Dutch residents, warranting further investigation of its prevalence in the general population and possible sources.

Rapid, Accurate, and Actionable Next Generation Sequencing Based Identification of Pathogenic Agents in Heart Valve Tissue and Cerebrospinal Fluid

Author Block:

N. A. Hasan[1], M. Vondracek[2], B. Yen-Lieberman[3], D. A. Wilson[3], R. P. Isom[4], P. Subramanian[4], S. Choi[4], H. Li[4], T. Allander[2], G. W. Procop[5], R. R. Colwell[1]; [1]Univ. of Maryland, Coll. Park, College Park, MD, [2]Karolinska Inst., Stockholm, Sweden, [3]Lerner Coll. of Med., Cleveland, OH, [4]CosmosID, Inc., Rockville, MD, [5]Lerner Coll. of Med., Cleveland, MD

Abstract Body:

Reduced cost, rapid turnaround time, and deep sequencing capability of next generation sequencing (NGS) make it an important component of medical diagnostics and clinical applications. However, bioinformatics analysis remains an impediment to universal adoption. MetaGenID has been developed for rapid (within minutes), accurate (>98%), and actionable microbial identification and was used to identify microbial agents in heart valve tissue and cerebrospinal fluid (CSF). Two sets of tricuspid, aortic, and mitral valve tissues from patients undergoing heart surgery were analyzed by extraction of total nucleic acid, whole genome sequencing (Illumina HiSeq), and sequence analysis employing the MetaGenID system. Results were obtained within minutes and compared with results from culture, PCR, and 16S sequencing. Four heart valve tissue and four CSF samples from Karolinska Institute and 12 heart valve tissue samples from Cleveland Clinic were included, showing pathogens identified by culture and confirmed by PCR were also identified by MetaGenID. In addition, MetaGenID provided antibiotic resistance, pathogenicity factors, and proportional content within samples. *Staphylococcus aureus, Neisseria meningitides*, *Listeria monocytogenes*, and *Enterobacter* were identified in the samples. MetaGenID identified *Candida* species in one sample negative by culture and PCR. In one case, MetaGenID identified *Enterococcus faecium and Enterobacter cloacae* whereas 16S could identify only *Enterobacter* sp. Only two cases in each of the dual sample sets yielded discrepancies whereby either an agent was identified by NGS/ MetaGenID but not by culture and PCR or vice versa. Both sets of tissue samples had been stored for extended periods (in the case of the Cleveland Clinic samples, since 2011 at -80C), thus demonstrating sensitivity and accuracy of NGS/ MetaGenID. The system is operated using a laptop and server.

Validation of easyMAG DNA Extractor for Bacterial Isolates for Use in a Clinical Laboratory

Author Block:

E. Powell, **J. Mortensen**; Cincinnati Children's Hosp., Cincinnati, OH

Abstract Body:

Background: Since molecular testing plays an increasingly large role in clinical microbiology laboratories, traditional research methods are being incorporated and thus need to be validated under more stringent guidelines. One such technology is DNA extraction from bacterial isolates, a necessary first step before test methods such as16S rRNA sequencing and whole genome sequencing. The purpose of this study was to evaluate the BioMerieux NucliSENS easyMAG total nucleic acid extractor for extracting DNA from bacterial isolates in the clinical microbiology laboratory. **Methods:** Forty-eight reference isolates from the American Type Culture Collection were selected to represent the variety of isolates typically encountered in the clinical laboratory: Gram-positive cocci (9 isolates), Gram-positive bacilli (10 isolates), *Enterobacteriaceae* (14 isolates), and non- *Enterobacteriaceae* Gram-negative organisms (15 isolates), DNA was extracted from 100 µL of 1.0 McFarland solution of each isolate using the Biomerieux NucliSENS easyMAG. Extracted DNA was quantified using an Eppendorf Biophotometer and confirmed with a NanoDrop spectrophotometer. The two samples with the lowest DNA concentration from each group were submitted for 16S rRNA sequencing.**Results:** For DNA concentrations and qualities, see table below. DNA concentration as measured by the Eppendorf Biophotometer corresponded to concentration as measured by the NanoDrop (r^2=0.9781). For the eight isolates tested by 16s sequencing, there was sufficient DNA for testing and all identifications were in agreement: *Enterobacter cloacae, Klebsiella oxytoca, Staphylococcus aureus* group, *Enterococcus faecalis, Exiguobacterium mexicanum/ aurantiacum, Clostridium septicum, Campylobacter jejuni/coli*, and *Prevotella melaninogenica*.**Conclusion:** The Biomerieux NucliSENS easyMAG total nucleic acid extractor is appropriate for DNA extraction from clinical bacterial isolates and will be incorporated in the clinical microbiology laboratory.

	DNA Concentration (ng/ µL)		A_{260}/A_{280}	
	Median	Range	Median	Range
Gram-positive cocci	8.5	7.4-14.5	1.35	1.05-1.70
Gram-positive bacilli	9.1	8.0-37.8	1.47	1.09-1.80
Enterobacteriaceae	15.9	12.1-20.4	1.63	1.27-1.94

non- *Enterobacteriaceae*	17.4	7.8-22.0	1.67	1.02-1.82

Clinical and Epidemiological Correlation of *E. coli* Bacteraemia Isolates by Whole Genome Sequencing (WGS): A Single UK Centre Experience 25 Years Apart

Author Block:

M. Albur[1], B. Pascoe[2], G. Meric[2], S. K. Sheppard[2], A. P. MacGowan[1]; [1]North Bristol NHS Trust, Bristol, United Kingdom, [2]Swansea Univ., Swansea, United Kingdom

Abstract Body:

Background: *E. coli* is the most common cause of bacteraemia in the UK. ST131 has emerged as a successful pathogenic *E. coli* lineage amongst the extra-intestinal *E. coli* isolates worldwide in the last decade. Whole genome sequencing of consecutive *E. coli* bacteraemia isolates from a UK tertiary centre collected 23 years apart, to study the local epidemiology and correlate different sequence types with clinical outcomes.**Methods:** In total 89 *E. coli* bacteraemia isolates from 1988 (42) and 2011 (47) were sequenced by Illumina MiSeq. Genetic phylogenies of both collections were compared to each other and the published ECOR collection. Isolate lineages were evaluated in context with 28-day and in-hospital mortality. Resistance and virulence genes were also identified and *in silico* antimicrobial susceptibility prediction compared to laboratory assay.**Results:** Phylogenetic tree of all isolates is shown in **Figure 1**. **A)** Annotated Neighbour-joining tree comparing 1988 isolates with 2011 isolates plus the published ECOR collection **B)** Neighbour-joining tree of 2011 isolates including patient outcome. Significant proportion of 2011 isolates belonged to the phylogenetic group B2 lineage as compared to 1988 isolates (p=0.001). ST131 isolates from 2011 were associated with a poor clinical outcome as compared to other sequence types (p=0.002).**Conclusions:** Our findings are in concordance with the global epidemiologic trend of emergence of a successful ST131 clone. Whole genome sequencing in routine clinical microbiology laboratories will improve understanding of this emerging, clinically-relevant epidemiological trend.

Characterization of Isolates of *Eisenbergiella tayi* Derived from Blood Cultures Using Whole Genome Sequencing Analysis

Author Block:

K. A. Bernard[1], T. Burdz[1], D. Wiebe[1], C. Huynh[1], A. M. Bernier[2]; [1]Natl. Microbiol. Lab., Winnipeg, MB, Canada, [2]Univ. of Saint Boniface, Winnipeg, MB, Canada

Abstract Body:

Background: *Eisenbergiella tayi* was first described for a strictly anaerobic, curved bacillus derived from a human blood culture [2014 Amir et al, IJSEM 64:907-914, Israeli/French collaboration]. That paper remains to date the sole publication associated with this pathogen. That genus best fit, but was not at the time assigned to, the family *Lachnospiraceae*, part of the Clostridiales 'Clostridium cluster XIVa' group. We describe here a study of 8 Canadian isolates of this agent. **Methods:** Eight blood culture isolates recovered from 2005-2015 and consistent with this genus and species from 7 patients located in 2 Canadian provinces were characterized by whole genome sequencing (WGS), by 16S, biochemically, by MALDI-TOF (Bruker) and cellular fatty acids (CFAs). Some underwent AST. WGS was performed on an Illumina MiSeq and genomes were assembled using Spades (version 3.5.1). Average nucleotide identity values (ANIb and ANIm) were calculated by JSpeciesWS. **Results:** Canadian isolates consistent with *E. tayi* by 16S were found to be similar to each other by WGS, CFAs and biochemically. Whole-genome sequence comparisons found ANIb and ANIm values between all strains was above 96%. Average genome size was large, at 7.5MB with a G+C content of 47%. Isolates were unidentifiable by MALDI-TOF when tested against the Bruker Biotyper library but gave rise to 2.2-2.7 scores if tested against a locally-created entry. These bacteria were curved or 'wavy', staining Gram variable (consistent with the description by Amir as Gram-stain negative but Gram positive structurally). Bacteria were fastidious growing and saccharolytic; some strains when plated on BBE had raised darkened colonies like those of *Bilophila.* AST indicated that strains were susceptible to nearly all drug classes tested. **Conclusions:** Clinicians should be aware of the potential for this strictly anaerobic bacterium to cause disease in humans; as this agent is not included in commercial ID systems, definitive identification must be done using a molecular approach.

Superior Detection of *Legionella pneumophila* by Multiplex Real-Time PCR During the 2015 New York City Outbreak

Author Block:

A. Chandrasekran, S. Juretschko, Ph.D.; Northwell Hlth.Lab., Lake Success, NY

Abstract Body:

Background: Legionellosis is a form of pneumonia caused by the bacterium Legionella. *L. pneumophila* is the predominant species accountable for approximately 90% of the reported human cases. The recent 2015 New York City Legionella outbreak resulted in 133 infected individuals and 16 deaths. Conventional culture is still considered the gold standard for identification of Legionella, although showing poor sensitivity and requiring long incubation. We have developed and validated a multiplex real time PCR (MRT-PCR) assay for *L. pneumophila* (*mip* gene) and *L. pneumophila* serogroup-1 (LSg1, *wzm* gene) and compared its performance with culture. **Methods:** Northwell Health Laboratories, serving as reference laboratory during the NYC Legionella outbreak, used 109 outbreak related sputum samples collected from July to August 2015 to validate the Legionella MRT-PCR assay using previously published primers and probes. LOD of the assay was determined using serial dilutions of an ATCC^{T} *L. pneumophila* culture isolate. Culture results were compared with both, MRT-PCR results and the Luminex Respiratory Pathogen Panel (RPP) assay using Luminex MAGPIX system.**Results:** Of the 109 samples tested, only 6 (5.5%) were positive for *L. pneumophila* by culture, whereas 22 (20%) resulted positive by MRT-PCR, 3 of these 22 with the LSg1 target only. A subset of 40 sputum samples (20 positives and 20 negatives by MRT-PCR) was also tested with the Luminex RPP assay. 17 of the 20 samples were positive by RPP, but the same 3 LSg1 positive only samples were missed. The overall correlation between MRT-PCR and RPP was 92.5%. LOD of the MRT-PCR was determined as 10 CFU/mL with a combined detection of 100% using both targets and 80% with individual targets. The overall sensitivity of LSg1 PCR was higher than the *L. pneumophila* species PCR and Luminex RPP. **Conclusions:** The MRT-PCR assay developed and validated for the detection of *Legionella pneumophila* and *Legionella* serogroup-1 in sputum samples is simple, rapid and more sensitive than culture and Luminex RPP. This assay can be used as a fast screening tool to identify Legionella infections for future outbreak situations. Positive PCR samples could subsequently be cultured for epidemiology purposes.

Molecular Epidemiologic Analysis of *Streptococcus pyogenes* Using the *emm* Cluster System in Korean Children

Author Block:

H. Lee[1], J. Park[2], J. Lee[2], K. Lee[2], K. Yun[2], E. Choi[2], H. Lee[2]; [1]Seoul Natl. Univ. Bundang Hosp., Seongnam, Korea, Republic of, [2]Seoul Natl. Univ. Children's Hosp., Seoul, Korea, Republic of

Abstract Body:

Streptococcus pyogenes (Group A streptococcus, GAS) is responsible for a various spectrum of diseases, including acute pharyngitis, skin and soft tissue infections (SSTI), invasive diseases and also postinfectious complications, which makes this bacteria a major cause of mortality and morbidity in children throughout the world. The *emm* typing method is a molecular typing method widely used in classification of GAS and more than 233 types have been reported. Recently a new classification has been developed based on functional and structional properties of M proteins. In this study, isolates collected from 1992 to 2012 among children under 19 years of age in Korea were analyzed by the *emm* cluster typing system. Among 134 isolates, invasive disease (19, 14.2%), SSTI (34, 25.4%), scarlet fever (37, 27.6%) and acute pharyngitis (44, 32.8%) were included. *emm*-clusters found among these isolates included A-C3, A-C4, A-C5, E1, E3, E4, E6 and clade Y. A-C4 (20.9%), E1 (20.9%), E4 (20.1%) and A-C3 (19.4%) were the most prevalent and accounted for 81.3% of all isolates. *emm*-cluster A-C3 and A-C5 were associated with invasive diseases, whereas E1 and A-C4 were associated with non-invasive infections. A-C3 was the most common cluster in invasive diseases by 47.4% and E1 accounted for 48.6% of all scarlet fever cases. There was no predominance for SSTI and pharyngitis, however A-C4 and E4 were the most common clusters in both cases. This study reports epidemiological information of GAS by the new functional classification system among children in Korea.

A Retrospective Analysis of Bacterial Dna Identified from Clinical Isolates Using 16s Rrna Gene Pcr and Sequence Analysis: 2009-2015

Author Block:

M. Dickinson, T. Passaretti, L. Thompson, D. Wroblewski, T. Quinlan, L. Mingle, K. Mitchell, A. Kidney, T. Halse, E. Nazarian, K. Musser; Wadsworth Ctr., New York State Dept. of Hlth., Albany, NY

Abstract Body:

The 16S rRNA gene is essential for the survival of all bacteria and is highly conserved. The characterization of the 16S rRNA gene is accepted as a standard method for the identification of families, genera, and species of bacteria. As a reference laboratory for New York State, we routinely perform 16S rDNA sequence analysis to identify bacterial isolates that are difficult to classify by phenotypic methods alone. Our laboratory has been approved by the Clinical Laboratory Evaluation Program to report 16S rDNA PCR and sequencing results for isolates since 2009. To assess the ability of this method to provide a definitive identification, a retrospective analysis was performed on 3438 isolates that were tested and analyzed from 2009-2015. The range of isolates tested per year was 333-670, with an average of 491. As per our protocol, 16S rDNA sequences are analyzed using the two separate databases. Based on the percent similarity of sequences from clinical isolates compared to these databases, identifications are placed into one of five categories: species level identification (>99% similarity), most closely resembles a species (98-99% similarity), most closely resembles a genus (95-98% similarity), genus level (>99% to multiple species-unable to differentiate), or unable to be identified (<95%). Of the 3438 isolates tested from 2009-2015, 1886 (55%) were identified to the species level, 929 (27%) genus level-unable to differentiate, 272 (8%) most closely resembled a genus, 192 (6%) most closely resembled a species, and 150 (4%) were unable to be identified. Nine samples are pending. The majority of sequences provided identification to one species, followed by a genus level identification. The most frequently identified species were *Staphylococcus epidermidis* and *Streptococcus intermedius* (35 each), followed by *Moraxella osloensis, Neisseria elongata,* and *Nocardia farcinica farcincia* (32 each). Of the 929 sequences that are were >99% similar to multiple organisms, the majority aligned to multiple species within the *Achromobacter* genus (91), followed by *Streptococcus* (60), and *Bacillus* (48). Overall, 16S rDNA sequence analysis is an invaluable tool that our laboratory has used for many years to identify bacterial isolates.

Mixed Batch Testing on the Cobas® 4800 System For *Staphylococcus aureus*, MRSA, C*lostridium difficile*, and Herpes Simplex Virus 1 And 2

Author Block:

M. Espy[1], M. Binnicker[1], M. England[2], W. Greene[2], K. Marcy[3], R. Kuhne[3], E. Holdman[3], J. Thompson[3], M. Lewinski[4], O. Liesenfeld[4], **J. C. Osiecki**[4]; [1]Mayo Clinic, Rochester, MN, [2]The Pennsylvania State Univ. Coll. of Med., Hershey, PA, [3]Sanford Hlth., Fargo, ND, [4]Roche Molecuar Systems, Pleasanton, CA

Abstract Body:

Background: Mixed batch testing allows users to mix sample types and tests being included in a single run on the same instrument. We evaluated the performance of the **cobas®** 4800 system using contrived samples for *Clostridium difficile* (Cdiff), Methicillin-resistant *Staphylococcus aureus* (MRSA), *Staphylococcus aureus* (SA), and Herpes simplex virus (HSV) 1 and 2 tested at three US centers. Methods: Contrived samples were diluted at predetermined concentrations with MRSA, SA, HSV-1 and HSV-2 in MSwab media (Copan Diagnostics, Murrieta, CA) or with Cdiff in cobas PCR Media (Roche, Pleasanton, CA). Contrived positive samples were interspersed with negative samples, creating blinded panels for testing. Each participating site performed mixed batch testing with the **cobas®** MRSA/SA Test, **cobas** Cdiff Test, and **cobas** HSV 1 and 2 Test on two batches of specimens per day. Each batch was comprised of 40 reactions, and following three days of testing, provided 240 results per site. Results: All positive samples containing Cdiff, MRSA, SA, HSV-1 or HSV-2 were detected on the **cobas** 4800 system by each of the three testing sites regardless of concentration, and all negatives were "Not detected". The Ct values showed consistent results across testing sites, targets, and dilutions. Conclusions: The cobas 4800 system demonstrated high accuracy and precision among three US testing sites. Further evaluation using a large number of clinical samples is warranted.

			Results Across Test Sites		Ct Values		
Target	Expected Concentration	Number of Replicates (N)	Percent Agreement (n/N)	95% Exact CI	Mean	SD	Range

Performance Analysis of the Bd Max Enteric Bacterial Pathogens Panel in a Regional Clinical Laboratory

Author Block:

S. M. Melanson[1], K. D. Culbreath[2]; [1]TriCore Reference Lab., Albuquerque, NM, [2]Univ. of New Mexico, Albuquerque, NM

Abstract Body:

Background: We evaluated the BD MAX Enteric Bacterial Pathogens Panel (EBPP) (BD, Sparks, MD) to replace routine stool culture as it detects 4 of the most commonly cultured microorganisms *Campylobacter* spp., *Shigella* spp., *Salmonella* spp., and Shiga-toxin 1/2. **Methods:** Fresh and preserved (Cary-Blair) stool samples were run on the EBPP and the results compared to standard lab procedures of culture (*Salmonella, Shigella, Campylobacter)* and immunoassay (Shiga-toxin 1/2). One hundred and twenty five previously run samples were examined.**Results:** Agreement was found for 117 out of 125 samples (93.6%). The 89 positive samples were comprised of *Salmonella* (27), *Campylobacter* (23), *Shigella* (13) and Shiga-toxin (24). There were 2 specimens culture positive for *Salmonella* that were negative on EBPP. Both were detected upon repeat of the EBPP. The remaining 6 discrepant samples were all detected by EBPP and missed by culture or immunoassay (2 C*ampylobacter*, 1 *Salmonella*, 3 Shiga-toxin). Discrepant analysis with an alternative molecular assay demonstrated that the 6 samples were all true positive results. One culture was positive for *Pleisiomonas* which can be a cause of gastroenteritis, but is not detected in this assay. Internal confirmation of the limit of detection, using spiked stool samples in stool were in the range in accordance with the manufacturer claims. Assay results are available within 2.5-3 hours, compared to 48-72 hours for routine methods. The average laboratory hands-on-time is 2.7 minutes for EBPP compared to 22.3 min for culture. **Conclusions:** We have found that the BD MAX EBPP, in our hands, meets the stated performance claims and outperforms our current methods for pathogen detection. The assay has an improved turn-around-time for detection of stool pathogens and decreased hands-on time in the laboratory.

Publishing Title:

Direct Identification of Bacteria in Positive Blood Cultures by Matrix Assisted Laser Desorption Ionization Time-of-Flight Mass Spectrometry (MALDI-TOF MS) Using a Novel Freeze-thaw Method

Author Block:

D. Nikolic[1], D. Donnell[2], G. L. Woods[3]; [1]Univ. of Arkansas for Med. Sci. (UAMS), Arkansas Children's Hosp. (ACH), Little Rock, AR, [2]ACH, Little Rock, AR, [3]UAMS and ACH, Little Rock, AR

Abstract Body:

Background: Rapid identification of the etiologic agents of bloodstream infections is critical to the timely initiation of the most appropriate antimicrobial therapy. Here we report an optimized in-house method that is cheap, simple, fast and highly reproducible for identification of bacteria in positive blood cultures by MALDI-TOF MS (Bruker Daltonics).**Methods:** When a bottle (Pediatric, Aerobic, Anaerobic, MycoF Lytic) flagged positive (BACTEC 9240, BD), Gram stain and subcultures were done. Then 1 ml of broth was transferred to a 15 ml polystyrene tube, which was placed at -20C for 30 min, rapidly thawed under running hot water for 45 sec, and centrifuged at 150 x *g* for 5 min. The supernatant containing organisms was transferred to a 1.5 ml tube and centrifuged at 13,000 rpm for 2 min. The pellet was washed twice with 1 ml of deionized water and tested by MALDI according to the manufacturer's instructions for bacterial/yeast colonies. Results obtained by testing pellets and colonies were compared.**Results:** Fifty-one broth samples were tested by our freeze-thaw method of lysing red blood cells. Using a score of >1.7 as an acceptable identification with the lysis method, agreement between testing pellets and colonies was 84% (21 of 25) for gram-positive bacteria and 77% (9 of 13) for gram-negative bacteria. There were no incorrect identifications with the lysis method; the result either was correct or no identification was provided. Agreement in identification between testing pellets and colonies by bottle type was: Pediatric, 81% (25 of 31); Aerobic, 50% (2 of 4); and Anaerobic, 100% (3 of 3). The lysis method did not identify yeasts (n=10) in any bottle type, polymicrobial infections (n=3), or any organism in a MycoF Lytic bottle (n= 8).**Conclusions:** Our results indicate that with the freeze-thaw method described here, MALDI can accurately identify the causative agent of bacteremia with the hands-on time < 1 hour. Testing to confirm using a score of >1.7 is ongoing. Further research is needed to validate this method with other blood culture systems and MALDI-TOF MS instruments.

Whole Sequences of Three Plasmids Carrying the *bla*$_{\text{ndm-5}}$ of *Klebsiella pneumoniae* Isolates Transmitted by Cross-Border Transfer from Uae to South Korea and Their Stability

Author Block:

J. Shin, K. S. Ko; Sungkyunkwan Univ., Su-won, Gyeonggi-do, Korea, Republic of

Abstract Body:

Objectives: Three NDM-5-producing *Klebsiella pneumoniae* isolates were identified in Korea. The first isolate was collected from a patient who was transferred from UAE to Korea, and the second and third isolates were collected from Korean patients after four months. We sequenced the three whole plasmids carrying *bla*$_{\text{NDM-5}}$ and characterized them. **Methods:** Three plasmids pCC1409-1, pCC1410-1 and pCC1410-2 were extracted and analyzed from *K. pneumoniae*. The *K. pneumoniae* ST147 isolates have been determined to produce NDM-5 enzymes to be resistant to most antimicrobial agents. The whole sequences of plasmids pCC1409-1, pCC1410-1 and pCC1401-2, which showed IncFII-type, were determined and analyzed using a MiSeq sequencer system and aligned against existing GenBank data. We also determined their stabilities in *Escharichia coli* J53 transconjugants.**Results:** The pCC1409-1, pCC1410-1 and pCC1410-2 plasmids encode various resistance genes to diverse antibiotics including macrolides, aminoglycosides, sulfonamides, trimethoprim, quaternary ammonium compounds and carbapenems. Two addiction systems (*mok*/*hok* and *pemKI*) are identified in three plasmids, ensuring stabilization of the plasmids in host strains. The plasmids share high similarity in backbone and resistance region with those of pGUE-NDM from Indian *E.coli* isolate and pMC-NDM from Polish *E. coli* isolate. *E. coli* J53 transconjugants lost the third plasmid, pCC1410-2, relatively fast.**Conclusion:** The plasmids pCC1409-1, pCC1410-1 and pCC1410-2 may originate from IncFII plasmids carrying the highly conserved NDM structure adding recombination events of other resistance genes. However, their stabilities in host were different each other.

Role of Specific PCR in the Diagnosis of Blood Culture-Negative Endocarditis

Author Block:

P-E. Fournier, F. Gouriet, J-P. Casalta, H. Lepidi, G. Habib, D. Raoult; Aix-Marseille Univ., Marseille, France

Abstract Body:

Background: Blood culture-negative endocarditis (BCNE) may account for up to 70% of all cases of endocarditis depending on countries.**Methods:** In a prospective study from January 2010 to December 2015, we used systematized sampling and testing of blood and/or valvular biopsy specimens to investigate the aetiologies of 235 patients suspected as having BCNE in Marseille, France.**Results:** We identified an aetiology in 65 patients (28 % of cases). Of these, two (one allergy to pork and marantic endocarditis) were noninfective (0.8%). In the other 63 patients, PCR from valvular biopsies identified a causative agent in 26 patients (11.5%), serology in 19 (8%) and PCR from blood in 17 (7.2%). Streptococci were identified in 35% of BCNE cases, followed by zoonotic agents (29%) and staphylococci (14%). Proportionally, staphylococci, but not streptococci, were less frequent among BCNE agents than in BCPE patients ($p < 10^{-2}$ and 0.06, respectively).**Conclusions:** By using a syndrome-based serological and PCR testing from blood and/or valves, we identified streptococci, zoonotic agents and staphylococci as the main agents of BCNE in Marseille. Specific PCR assays reduced the ratio of IE without identified diagnosis by 28%, including 8% of patients in whom a specific antibiotic therapy was required.

Comparison of Molecular Identification of Gram-Positive and Gram-Negative Bacteria with Phenotypic Identification During Routine Use in a Large Clinical Laboratory

Author Block:

M. Almaayteh[1], R. Chaudhry[2], E. Abdulfatah[2], B. Alosh[2], R. Mitchell[3], M. Fairfax[4], H. Salimnia[4], P. Lephart[3]; [1]Royal Jordanian Med. Services/Detroit Med. Ctr. Univ. Lab., Amman, Jordan, [2]Wayne State Univ., Detroit, MI, [3]Detroit Med. Ctr. Univ. Lab., Detroit, MI, [4]Wayne State Univ. Sch. of Med. & DMC Univ. Lab., Detroit, MI

Abstract Body:

Background: Rapid identification and treatment of etiologic agents of blood stream infections significantly reduces mortality and morbidity. DMC University Laboratories serves eight hospitals (2000 beds) and many clinics. During the four months after implementation of the Verigene System Gram-negative (GN; 9 organism targets) and Gram- positive (GP; 13 target organisms) blood culture tests (Nanosphere, Northbrook, IL), we compared the results of the molecular organism identification (available in about 2.5 hr) to those of our laboratory's phenotypic assays (1-3 days).**Methods**: When a blood culture bottle was flagged as positive by the Bactec FX instrument (BD, Sparks, MD), fluid from the bottle was Gram stained. Based on Gram-stain results, additional aliquots were subjected to Verigene. Other aliquots were streaked on standard laboratory medium; bacterial growth and antibiotic sensitivities was obtained from isolated colonies using the BD Phoenix. Results of organism identification by both systems were compared.**Results**: Of the 1,748 Verigene tests, 1312 were GP and 436 GN. Relative to culture, one Verigene false positive was detected (*Acinetobacter baumannii*; 29 detected by culture). Six Verigene false negatives included: 4/65 *Klebsiella pneumoniae*, 1/156 *Escherichia coli*, 1/44 *Enterobacter*, and 1/68 *Enterococcus fecalis*. Organisms not included in the panel were present in almost 5% of the cultures**Conclusions**: The Verigene GN and GP blood culture identification tests were sensitive, specific, rapid and reliable, providing results in about 2.5 hours after the blood cultures flagged as positive. Verigene gave one FP result. Sensitivities for all organisms were 100% except as noted above.

Development of TaqMan Real-Time PCR Assays for Typing of *Mycoplasma Pneumoniae* Based on Type-Specific Indels Identified Through Whole Genome Sequencing

Author Block:

B. Wolff, A. Benitez, D. Heta, S. Morrison, M. Diaz, J. Winchell; CDC, Atlanta, GA

Abstract Body:

Background: *Mycoplasma pneumoniae* is a common cause of community-acquired pneumonia. Historically, *M. pneumoniae* has been classified into two subtypes based upon sequence variation within the gene encoding the major adhesion molecule P1. Variation in the global circulation of these type strains is thought to contribute to a cyclic pattern of *M. pneumoniae* epidemics caused by alternating predominance of the two main types. Although a variety of molecular methods have been developed for P1 typing, no one-step real-time PCR assay currently exists.**Methods**: We performed whole genome sequencing on 67 *M. pneumoniae* isolates from various geographical origins, dates, and patient outcomes. Using whole genome comparisons with PacBio and Illumina data, we identified three type-specific indels (13-15 bp in length); two regions were present only in type 1 isolates and one region was found only in type 2 isolates. Based on bioinformatics analysis, we designed two TaqMan real-time PCR assays to rapidly type *M. pneumoniae* based upon the presence or absence of amplification of two of these sequences. We screened 64 *M. pneumoniae* isolates (n=34 type 1 and n=30 type 2), including the type strain M129 and FH, using the newly-developed assays.**Results**: 100% of *M. pneumoniae* isolates were correctly identified as type 1 or 2 based upon comparison to the type identified using a validated real-time PCR assay with high-resolution melt. Additionally, we confirmed the presence of the type-specific sequences in 40 *M. pneumoniae* genomes available in GenBank. Using this approach we confirmed the P1 type of *M. pneumoniae* in nucleic acid extracts and corresponding recovered isolates from 20 clinical specimens.**Conclusion**: Recent whole genome sequence analyses support the separation of *M. pneumoniae* strains into two distinct lineages based on P1. The real-time PCR assays described here for identifying strain type are more robust, rapid, and simpler to interpret compared to traditional P1 typing methods. Monitoring the circulation of *M. pneumoniae* strain types may be useful for epidemiological investigations and for predicting temporal and geographic variation in disease burden.

Frequency of Aminoglycoside Resistance Genes in Carbapenem-Resistant *E. coli* Isolates

Author Block:

B. Shrestha[1], T. Tada[2], H. Ohara[2], T. Kirikae[2], B. P. Rijal[1], J. B. Sherchand[1], B. M. Pokhrel[1]; [1]Inst. of Med., Kathmandu, Nepal, [2]Res. Inst., Tokyo, Japan

Abstract Body:

Background: Multidrug-resistant (MDR) *Escherichia coli(E.coli*), has increased and spread worldwide. In MDR *E. coli*, resistance to carbapenems and aminoglycosides has become a major concern[1]. The evaluation of cross-resistance and identification of resistance mechanism of MDR *E. coli* is needed.**Methods:** A total of 174 MDR *E. coli* isolates were obtained from single hospitalized patients during December 2013 to December 2014 in two tertiary care centers of Kathmandu, Nepal. Cross-resistance to carbapenems and aminoglycosides was examined in 135 carbapenem-susceptible MDR *E. coli* and 39 carbapenem-resistant MDR *E. coli*. Disk diffusion method was used for screening of MDR *E. coli*. MICs were determined by using the microdilution method. PCR was performed to identify the aminoglycoside resistance genes i.e. 16S rRNA methylase genes and carbapenem-resistant genes in carbapenem-resistant *E. coli* isolates.**Results:** Gentamicin and Amikacin resistance were more common in carbapenem-resistant isolates (35/39 strains; 89.7%) than in carbapenem-susceptible isolates (56/135 strains; 41.5%). The main aminoglycoside resistance gene was *armA* (18/39; 46.1%) followed by *rmtB* (13/39; 33.3%). *rmtC* was detected in 4 isolates. The commonest carbapenemase gene detected was bla_{NDM-1}(16/39; 41.0%). Most of the carbapenem-resistant *E. coli* carried any one of the 16S rRNA methylase genes.**Conclusions:** Our findings strongly suggested that carbapenem-resistant *E. coli* isolates with genes encoding both NDM-type Metallo-β-lactamases and 16S rRNA methylases disseminated in medical settings of Nepal. Thus, the emergence of such carbapenem-resistant *E. coli* strains should be undertaken as a serious public health threat.

Focus Diagnostics Simplexa™ Bordetella Direct Assay Verification Study

Author Block:

J. Chen, H. Mai, Y. Xie, M. Tabb; Focus Diagnostics, Cypress, CA

Abstract Body:

Background: Whooping cough is an infection of the respiratory system caused mainly by *Bordetella pertussis* and, less frequently, by *Bordetella parapertussis* and *Bordetella holmesii*. Differentiating Bordetella species can provide epidemiologic value as both *B. parapertussis* and *B. holmesii* can cause *B. pertussis*-like symptoms but vaccines against these 2 species are not available. In addition, patients can receive optimized antimicrobial treatment when the infected Bordetella species is identified. The Simplexa™ Bordetella Direct assay is in development to detect and differentiate *B. pertussis*, *B. parapertussis*, and *B. holmesii* from nasopharyngeal swab specimens. To run the Simplexa Bordetella Direct assay (Simplexa assay), nasopharyngeal swab specimens collected in universal transport media are loaded directly onto a Direct Amplification Disc without up-front nucleic acid extraction or other specimen preparation; real time PCR and detection follow. The goal of this study was to evaluate the clinical performance of the Simplexa assay versus DNA sequencing assays using nasopharyngeal swab specimens. **Methods:** A panel of 284 (249 de-identified nasopharyngeal swab and 35 contrived) specimens were tested with the Simplexa assay and IS481 (*B. pertussis)*, IS1001 (*B. parapertussis*), and hIS1001 (*B. holmesii*) bi-directional DNA sequencing assays. Cross reactivity was evaluated using a panel of bacteria and viruses. **Results:** Positive and negative agreement of the Simplexa assay with DNA sequencing were 97.1% (99/102) and 95.6% (174/182) for *B. pertussis*, 100% (37/37) and 98.8% (244/247) for *B. parapertussis* and 100% (37/37) and 99.6% (246/247) for *B. holmesii*, respectively. No cross reactivity with tested bacteria and viruses was observed. **Conclusions:** The Simplexa Bordetella Direct assay was capable of rapidly (~80 minutes) and directly detecting *B. pertussis*, *B. parapertussis*, and *B. holmesii* from nasopharyngeal swab specimens. The Simplexa assay can identify positive and negative specimens at rates comparable to bi-directional DNA sequencing assays. The Simplexa Bordetella Direct assay is in development; it is not currently available for sale and is not FDA cleared.

Rapid, Reagent-Free Identification of MRSA and VRE by Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy

Author Block:

P. Lebel[1], H. Kim[2], L. Lam[2], A. Choudhuri[2], M. Langella[2], J. Sedman[2], S. Levesque[3], A. Ismail[2]; [1]McGill Univ. Hlth.Ctr., Montreal, QC, Canada, [2]McGill Univ., Ste-Anne-de-Bellevue, QC, Canada, [3]Laboratoire de santé publique du Québec, Ste-Anne-de-Bellevue, QC, Canada

Abstract Body:

The effectiveness of active screening and isolation programs in controlling the spread of MRSA and VRE in acute-care settings relies on the availability of rapid, accurate, and cost-effective diagnostic tests for these pathogens. FTIR spectroscopy is a reagent-free technique for bacteria identification and classification with subspecies-level discriminatory capabilities. Advantages of recently developed compact, portable ATR-FTIR spectrometers include the simplicity and enhanced reliability of FTIR bacteria identification in the ATR mode by comparison with the conventional transmission mode. In this study we evaluated the discriminatory power of ATR-FTIR spectroscopy as a potential technique for the rapid identification of MRSA and VRE.ATR-FTIR spectra of 800 Gram-positive clinical isolates were acquired by transferring isolated colonies from blood agar plates onto the sampling surface of a portable ATR-FTIR spectrometer. The spectral acquisition time was ~1 min. Four spectra were collected for each isolate from different colonies on the same culture plate. For a randomly selected subset of 200 clinical isolates, spectra were also acquired on a second portable ATR-FTIR spectrometer. Spectral data analysis was performed by hierarchical cluster analysis (HCA) and principal component analysis (PCA) in conjunction with the use of a feature selection algorithm.HCA of the ATR-FTIR spectra showed clustering of all replicate spectra and demonstrated excellent instrument-to-instrument spectral reproducibility as required for transferability of spectral databases. Discrimination between MRSA and MSSA was achieved by PCA of the *S. aureus* spectra and resulted in 95% concordance with PCR testing. PCA of the spectra of the enterococcal isolates resulted in successful discrimination between VRE and VSE (100% correct classification). The capability of ATR-FTIR spectroscopy to discriminate between antibiotic-resistant and susceptible strains in the absence of antibiotic provides a new rapid, inexpensive and reagent-free technique that can contribute to the control of antibiotic-resistant nosocomial pathogens.

Copan Fecalswab^{tm} for the Detection of Enteric Pathogens Using the Nimbus and Allplex^{tm} Gi-Bacterial (I) Assay

Author Block:

A. Giambra[1], S. Razeti[2], M. Renzulli[2], S. Castriciano[1]; [1]Copan Italia, Brescia, Italy, [2]ARROW DIAGNOSTICS SRL, Genova, Italy

Abstract Body:

Background: Proper diagnosis of diarrheal diseases can be complex due to the variety of pathogens that can cause gastro enteric infections. A specimen collection device that allows efficient nucleic acid extraction, Multiplex Real-Time PCR systems and culture is essential. Copan FecalSwab^{TM} (FS) is an LBM device, consisting of a flocked swab and a tube with 2ml Cary-Blair medium, compatible with manual and WASP^{TM} automated plating for culture, and antigen and toxin detection and nucleic acids (NA) amplification assays. Nimbus (Hamilton) is an instrument for nucleic acid extraction and PCR set-up. Allplex^{TM} GI-Bacteria (I) (Seegene) is a multiplex Real-Time PCR that detects 7 pathogens from stool. The objective of this study was to compare original stools to stool samples in FecalSwab, extracted with the Nimbus and tested with Allplex^{TM} GI-Bacterial (I) assay for the detection of enteric pathogens.**Material/methods:** Forty three stools, tested in duplicate, were used for this validation. Two equal aliquots of each stool were weighted: one was added to a FS and another to a microtube with 1 ml of ASL buffer (Qiagen). The FS tube was loaded on Nimbus, while the fresh stool required other preparation steps: 10m incubation at RT, 2m centrifugation prior DNA extraction and PCR reaction set up on the Nimbus and run on the CFX96 Real Time PCR (Bio-Rad). Stool preparation time for NA extraction was also calculated.**Results:** Concordant results were obtained with all the negative samples with both nucleic acids extractions (24/24), 21/21 positive were detected with the FS samples and 20/21 positive with 1 discordant with the samples in ALS buffer, which was previously positive by TOX A/B QUIK CHECK (Alere) . Among positives, 4 Salmonella spp., 2 C. diff toxin B and 3 campylobacter spp. were detected. The Cts analysis confirms that 17/21cases, positive samples in FS amplified as average 3 Cts before original stools, in 2/21 the difference than stool but not higher than 1 Ct. The samples preparation time was compared: FS preparation time 5 seconds versus 15 minutes for stools.**Conclusions:** The results obtained in this study demonstrated that the Copan FecalSwab^{TM} in combination with Nimbus extraction system and Allplex^{TM} GI-Bacterial (I) assay improved both stool positivity rate of gastroenterical pathogens, and preparation time.

Evaluation of Surveillance Cultures and Molecular Methods for Identification of Multidrug Resistance Bacteria in Chronic Renal Failure Patients

Author Block:

T. Rezende[1], **A. Dói**[2], M. Quiles[1], A. Pignatari[1], S. Manfredi[1], C. Groethe[1], M. Taminato[1], L. Fehlberg[1], D. Barbosa[1]; [1]UNIFESP, São Paulo, Brazil, [2]UNIFESP, São Bernardo, Brazil

Abstract Body:

Introduction: Multidrug resistant bacteria (MDR) colonization is a serious problem among chronic renal failure patients (CRFP),because the risk for infection is higher. Surveillance culture is recommended as a component of infection control programs (ICP). **Objective:** Compare the performance of phenotypic methods for surveillance of MDR bacteria with real time PCR (qPCR) in a population of CRFP. **Methods:** We included a total of 546 CRFP from a tertiary center in São Paulo, Brazil, specialized in chronic renal failure care. These patients were divided in 3 groups: conservative treatment (129), dialysis (217) and transplanted (200). We collected nasal swabs for MRSA detection and rectal swabs for carbapenemase and VRE detection, in two different moments; total of 1092 samples (ESwab^{TM}). For phenotypic screening we used CHROMagar for KPC, MRSA and VRE. For the molecular analysis we used the qPCR for detection of the genes: *bla*$_{KPC}$, *bla*$_{NDM}$, *bla*$_{SPM}$, *bla*$_{GES}$, *bla*$_{VIM}$, *bla*$_{OXA48}$, *van*A, *mec*A and *aur (S. aureus* identification). Conventional PCR were performed if necessary. **Results:** Among the 1,092 samples we found 13.8% of KPC positives according to chromogenic agar (CA). Only 26 were confirmed as KPC positive according conventional PCR. According to qPCR direct from swab 31 (2,8%) were positives to KPC, 39 (3,6%) for GES and 3 (0,3%) for SPM with a kappa of 0,256. For VRE the CA was positive in 16 (1,5%) of the patients and the qPCR positive in 20 (1,8%), kappa of 0,135. For MRSA we tested only 298 samples, and we observed 4 (1,3%) of positivity with CA and 15 (5%) according to qPCR. **Conclusions:** We observed for carbapenemase, VRE and MRSA detection an increased rate of false positives results using CA. For VRE we observed a low sensitivity using the qPCR. The molecular method can provide results faster than cultures allowing the early implementation of ICP to reduce the dissemination of MDR.

Impact of Environment and Attitude on Burden of Intestinal Parasites Among Primary School Children Living Around the Creeks of Calabar, Nigeria

Author Block:

A-A. Eyo, R. R. Solomon; Univ. of Calabar, Calabar, Nigeria

Abstract Body:

Background: Intestinal parasitic infections are among the most common infections worldwide. They are regarded as major health problems in tropical and subtropical countries and still remain potent causes of morbidity and mortality thereby constituting important obstacles to the development of these nations. The WHO estimates that about 576-740 million people are infected with intestinal parasites globally, majority of them children. Intestinal helminthes, especially hookworm, are implicated in anemia in children. Poor sanitation and low socio-economic status promote the survival and transmission of these parasites. This study was designed to assess the impact of environment and attitude on burden of intestinal parasites among primary school children in the Creek Area of Calabar South.**Method:** A total of 200 stool samples were collected from pupils aged 5-13 years randomly selected from four primary schools in the study area, whereas 50 samples collected from children in a primary school located within a University served as control. All stool samples were analyzed for intestinal parasites using methods of direct smear and formal-acetone concentration technique. Questionnaires were used to collect demographics, personal hygiene habits and environmental determinants from subjects/guardians.**Results:** The overall prevalence of intestinal parasite infection was 27.6%(69/250); test and control subjects had 32.5%(65/200) and 8.0%(4/50) respectively. The rate of infection was highest among children aged 5-7 years. There was a statistically significant effect of age on infection rates ($\chi^2 = 18.6$, $p = 0.01$). Hookworm and *Ascaris lumbricoides* had the highest occurrence rates of 35.4%;32.5% and 50.0%;50.0% in test and control subjects respectively. Co-infection of both parasites was also observed. Male children were more infected, 38.8%(40/103) compared to females with 19.7%(29/147) while 56.0%(112/200) and 47.5%(95/200) of test subjects did not have pipe-borne water and toilet facilities respectively in their homes.**Conclusion:** The deplorable state of environmental and personal hygiene, inadequate water supply and improper faecal disposal in the study area are to a great extent responsible for the high prevalence reported.

Pneumococcal Carriage and Antimicrobial Resistance among Children after Four Years of Routine Conjugate Vaccines Use in Brazil

Author Block:

F. P. G. Neves[1], N. T. Cardoso[2], D. R. Silva[2], L. A. Motta[2], R. E. Snyder[1], M. A. Marlow[1], C. A. Cardoso[2], L. M. Teixeira[3], L. W. Riley[1]; [1]Univ. of California, Berkeley, CA, [2]Univ.e Federal Fluminense, Niterói, Brazil, [3]Univ.e Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract Body:

Background: Pneumococcal disease is a major cause of morbidity and mortality in children. In 2010, the 10-valent pneumococcal conjugate vaccine (PCV10) was included in the Brazilian immunization program and the 13-valent vaccine (PCV13) was offered in private clinics. To assess changes in pneumococcal carriage after four years of PCV10 and PCV13 use, we investigated the carriage rate, risk factors for colonization, and antimicrobial resistance among pneumococci obtained from the nasopharynges of Brazilian children.**Methods:** We conducted a cross-sectional study recruiting 573 children aged < 6 years in a public (287) and two private (286) clinics in Niterói city, RJ, Brazil from September to December, 2014. Isolates were identified by conventional methods. Antimicrobial susceptibility was assessed by the disk diffusion method. Bivariate analyses (χ^2) was carried out to assess the relationship between overall or resistant isolates carriage and risk factors.**Results:** The overall pneumococcal carriage rate was 23% (132; 20.3% in private clinics vs. 25.8% in public clinic) and it was associated with age ≥ 2 years, day care center or school attendance, presence of fever, acute respiratory symptoms, rhinitis, asthma/bronchitis, household residents ≥ 5, and slum residence ($p<0.05$). All isolates were susceptible to levofloxacin, rifampicin and vancomycin. The highest rate of non-susceptibility was observed for trimethoprim/sulfamethoxazole (53; 40.2%). We detected 50 (37.9%) penicillin non-susceptible pneumococci (PNSP). Erythromycin (ERY) resistance was observed in 36 (27.3%) isolates, which displayed the $cMLS_B$ (25; 69.4%) or M (11; 30.6%) phenotypes, and carried the *erm*(B) (25, 69.4%) and/or *mef*(A/E) (13, 36.1%) genes. Previous antibiotic use was the only risk factor associated with both PNSP and ERY-resistant (ERY-R) isolates carriage ($p<0.05$).**Conclusions:** Since introduction of PCV10 and PCV13 for use in the area investigated, the overall colonization rate decreased by 16.5%, while PNSP and ERY-R isolates carriage frequencies increased by 13.9% and 25.7%, respectively.

Characteristics of *Staphylocccus aureus* Nasal Carriage among United States Industrial Beefpacking Workers

Author Block:

J. H. Leibler[1], J. A. Jordan[2]; [1]Boston Univ. Sch. of Publ. Hlth., Boston, MA, [2]Milken Inst. Sch. of Publ. Hlth., The George Washington Univ., Washington, DC

Abstract Body:

Background: Occupational contact with swine and poultry is associated with human exposure to livestock-associated *Staphylococcus aureus*. While *S. aureus* is known to infect cattle, characteristics of *S. aureus* carriage among industrial cattle workers in the United States are unstudied.**Methods:** We recruited a cross-sectional sample of beef slaughterhouse workers at an industrial facility in Nebraska. Workers were interviewed in English and Spanish and nasal swabs were collected. Culture methods were used to identify presumptive *S. aureus* isolates, which were screened for mecA, SCCmec and staphylococcal protein A genes. Confirmed *S. aureus* isolates were evaluated for susceptibility to 12 antimicrobials and the presence of the *scn* gene, a biomarker of human adaption in *S. aureus*. *Spa* typing and real-time PCR for Panton-Valentin leukocidin (PVL) genes *lukS*-PV and *lukF*-PV were also conducted.**Results:** In total, 137 workers were enrolled. Prevalence of *S. aureus* nasal carriage was 27%, with five workers (3.6% of all participants; 13.5% of *S. aureus* carriers) carrying *scn*-negative methicillin-sensitive *S. aureus* (MSSA) isolates indicating putative association with livestock. Among *scn*-negative isolates, four distinct *spa* types were identified, t338, t748, t1476 and t2379. These *spa* types have not been previously identified as associated with livestock. Prevalence of MRSA nasal carriage was 3.6%, and all MRSA isolates were human adapted. MRSA isolates included *spa* types t002, t008 and t024, representing community-acquired strains. Eighty percent of MRSA isolates were PVL positive.**Conclusion:** Nasal carriage of livestock-associated MSSA was recovered from beefpacking workers in the United States, with *spa* types not previously identified in livestock. *Spa* type t338 and t1476, identified in two scn-negative isolates, are associated with human epidemic clones of MSSA (ST30 and ST8 respectively), which may suggest adaptation of these *S. aureus* strains to livestock and subsequent transmission back to humans. Elevated nasal carriage of PVL-positive MRSA among these beefpacking workers may indicate heightened risk of clinical MRSA infection in this workforce.

Taking Evidence-Based Microbiology to the Community Level in Lower Nyakach, Kenya, to Eliminate Waterborne Diseases

Author Block:

R. H. Metcalf[1], D. Chienjo[2]; [1]California State Univ., Sacramento, Sacramento, CA, [2]Friends of the Old Dev. Group, Kisumu, Kenya

Abstract Body:

Motivation: WHO estimates that waterborne diseases among a billion people living in extreme poverty EVERY DAY leads to >4,600,000 people suffering from diarrhea and >2,000 deaths. Most of these people must use contaminated unimproved drinking water sources and have no expectation that they will be connected to a safe water supply in the foreseeable future. We have developed and implemented a successful and replicable strategy with the goal of eliminating waterborne diseases in the Friends of the Old (FOTO) project in Lower Nyakach, Kisumu County, Kenya, where 70,000 people have no access to safe drinking water sources and use heavily contaminated rivers, streams, ponds and shallow wells. **Methods:** The first step was for the FOTO staff to take evidence-based microbiology to communities to demystify microbiology and have people understand the relationship between contaminated drinking water and disease. Two tests for *Escherichia coli* from the water and food industries were used: the Colilert® 10 ml presence/absence test (IDEXX, Westbrook, ME) and the *E. coli*/Coliform Count Petrifilm™ (3M, St. Paul, MN), a quantitative test for 1 ml. These tests were inoculated directly, incubated overnight, and provided easily interpreted results the next day that correlated with WHO disease risk categories: low, moderate, high, or very high. The second step was to provide effective household water treatment options. All 14,000 households were given a bottle of commercially available 1.2% sodium hypochlorite every other month, and all 42 schools received chlorine during the academic year. **Results:** From February-May, 2015, two districts adjacent to Lower Nyakach, Migori and Homa Bay, had serious cholera outbreaks: 915 cases and 12 deaths in Migori, 377 cases and 5 deaths in Homa Bay. In Lower Nyakach, where education and use of chlorine was universal, there were no cases of cholera and steadily decreasing rates of diarrhea. **Conclusion:** Evidence-based microbiology was critical in educating communities that their drinking water sources were contaminated and must always be treated. Providing free chlorine to all households and schools enabled all to treat water and avoid disease. Replicating FOTO's approach could bring relief to millions who suffer daily from preventable waterborne diseases.

Cervicovaginal Microbiome of Isolated Amerindian Populations in Amazonian Brazil

Author Block:

C. P. Zolnik[1], A. J. Fonseca[2], A. E. Miranda[3], L. C. Ferreira[2], Z. Chen[4], R. D. Burk[1]; [1]Albert Einstein Coll. of Med., Bronx, NY, [2]Univ.e do Estado do Amazonas, Manaus, Amazonas, Brazil, [3]Univ.e Federal do Espírito Santo, Vitória, Brazil, [4]The Chinese Univ. of Hong Kong, Shatin, Hong Kong

Abstract Body:

Indigenous women in the Brazilian Amazon have a life-style adapted to the harsh environment and the isolated nature of their existence. They have a high prevalence of cervical HPV, HPV genotypic diversity and cervical cancer. However, comprehensive studies on reproductive health in these groups are limited. Although the composition of the cervicovaginal microbiome has been shown to affect various health outcomes including susceptibility, prevalence, and transmission of STIs, little is currently known regarding the cervicovaginal bacterial communities of these indigenous Amerindian populations.The goal of this study was to characterize the cervicovaginal microbiome of isolated populations from northern Amazonian Brazil. Cervical samples were collected in 2013 from Yanomami women (n=307), geographically and culturally isolated groups living in the forest, and from women in the Eastern Indigenous District (n=360), comprised of isolated populations adapted to living standards of western society. Extracted DNA was amplified for the V4 region of the bacterial 16S rRNA gene and PCR products were sequenced on a MiSeq Illumina platform (300 bp PE). Sequence reads were processed for quality and analyzed using in-house scripts in combination with pplacer, uparse, and QIIME.Overall, 35% of the samples were dominated with *Lactobacillus* spp., (28.7% Yanomami and 40.5% Eastern population), and 9% were dominated by *Gardnerella vaginalis* (13% Yanomami and 6% Eastern population). This contrasts recent studies of North American women where >60% of samples were dominated by bacterial species within these two genera. Our results suggest a more diverse cervical microbiome in these populations, a finding that contributes to a recent study that reported high diversity of fecal and skin microbial communities within isolated Yanomami groups in Venezuela. Variation in lifestyle (hunter-gatherer), social structure, sexual behavior, and isolation may have contributed to the cervical bacterial diversity observed in this study. Future work will examine the cervicovaginal microbiome of these groups in relation to infection with HPV, cervical dysplasia, and progression to cervical cancer.

Investigation on Household Contamination of *Vibrio cholerae* in Bangladesh

Author Block:

Z. Hossain[1], I. Farhana[1], S. Tulsiani[2], R. Sultana[1], P. Jensen[2], A. Begum[1]; [1]Univ. of Dhaka, Bangladesh, Dhaka, Bangladesh, [2]Univ. of Copenhagen, Copenhagen, Denmark

Abstract Body:

The role of in-house transmission on the incidence of *Vibrio cholerae*, the deadly waterborne pathogen, is still not developed. The aim of the current study was to investigate possible contamination routes in household domain for effective cholera control in Bangladesh.To examine the prevalence of *V. cholerae*, routine swabs from four hotspots (cutting knife, latrine door knob, drinking water pot and food plate surface) and leftover food samples were collected. The cohort of 22 low income households has been studied for every 6 weeks between November 2014 and December 2015, from an urban area of northwest Dhaka, Bangladesh. Molecular genotypic and phenotypic traits of *V. cholerae* strains were assessed.Total 660 hotspot samples were analyzed by *V. cholerae* species-specific *ompW* gene PCR. Among them most predominant was food plate swabs with 37 samples positive out of 163 (22.69%), followed by water pot (17 of 163, 10.43%), knife (6 of 167, 3.6%), latrine door knob (5 of 167, 2.9%). In total 137 food samples were analyzed, only 10 found positive in PCR. Further characterization of *ompW* positive hotspot total DNA for virulence genotype revealed the presence of *rfb O1, rfb O139, tcp, cep* genes but lacked the major cholera toxin genes *ctxA* and *ctxB*. Only one food tDNA sample was positive for *rfb O1* gene.Of the 12 hotspot and 2 food *V. cholerae* strains isolated from PCR positive samples, 8 (66.6%) were harvested during time period of May-June. One hotspot strain was confirmed as *V. cholerae* O1 and others as non-O1/ O139 through PCR based analysis. The O1 strain lacked cholera toxin genes but possessed other regulatory and virulent genes like *toxR, rtxC, hly, msh, HA/protease*. Genes for type three secretion systems were detected in two non-O1/O139 isolates. All the strains including clinical *V. cholerae* El Tor strain N16961, showed hemolysis and proteolysis activity but none of them exhibited any hemagglutinin activity on human erythrocytes.The study findings indicate that *V. cholerae* contamination is mostly originated in and around kitchen area rather than latrine area. Contaminated food and water supply may be the reason behind this relatively high presence of virulence factors in food plates and water pots. Direct exposure routes of disease transmission should be a major consideration in cholera prevention policies.

Extended-spectrum Cephalosporin Resistance and Pmqr in *Salmonella* Heidelberg Isolated from Poultry Farms in Argentina

Author Block:

J. E. Dominguez[1], P. Chacana[2], M. Herrera[3], **G. Gutkind**[4], E. Mercado[2], J. Di Conza[4]; [1]CONICET, Buenos Aires, Argentina, [2]INTA, Hurlingham, Argentina, [3]SENASA, Martinez, Argentina, [4]UBA, Buenos Aires, Argentina

Abstract Body:

Background: *Salmonella* infections are important zoonoses worldwide. Historically, *S.* Typhimurium and *S.* Enteritidis have been the most prevalent serovars in both humans and poultry but in the last years, in Argentina *S.* Heildelberg (SH) has been found to be the more common serovar isolated from broilers and thus more studies are needed in order to evaluate implications that this emerging serovar. Resistance to third generation cephalosporins (TGC) and fluoroquinolone has been described in SH isolates but very little is known on the associated mechanisms. The aim of this study was to characterize them mechanisms, especially those encoded in plasmids, in SH isolated from broiler farms, in Argentina, between years 2010 and 2012. **Methods:** Susceptibility profile was analyzed in a selected group of 42 strains of SH by disk diffusion according to CLSI recommendations. Screening for extended spectrum β-lactamases (ESBL) or plasmid AmpC β-lactamases (AmpCp) were conducted by double disk synergy tests. ESBL and PMQR determinants were characterized by PCR using specific primers followed by sequencing. **Results:**Twenty-five isolates (59.5%) were found to be resistant to TGC and 13/25 of these strains were also resistant to FEP but remained susceptible to FOX. Furthermore, ESBL confirmatory test was positive for all of them. The ESBLs were characterized as members of CTX-M-14 (n = 8) and CTX-M-2 (n= 5). The remaining strains (12/25) were resistant to FOX but susceptible to FEP. Synergy was observed between PBA and both CAZ and CTX disks, thus suggesting the presence of an AmpCp. Finally, CMY-2 was identified in these 12 isolates. The most prevalent PMQR determinant detected among ESBL producers was *qnr*B (22/42), no association between the presence PMQR and CTX-M enzyme was found. Twelve isolates (28.5%) harbored *qnrB* genes, but all were susceptible to TGC. **Conclusions:** This is the first report of the presence of both CTX-M-14, CTX-M-2 and *qnrB* isolates of *S.* Heidelberg isolates from broiler farms in Argentina. Active monitoring programs of ATM resistance in SH strains should be considered in order to minimize the impact in both poultry and Public Health

Hepatitis-C Viral Infection among Children Visiting a Tertiary Care Hospital in Lahore, Pakistan

Author Block:

T. Ijaz[1], S. Raja[2], S. Ahmad[3]; [1]Mayo Hosp.,King Edward Med. Univ., Lahore, Pakistan, [2]LMDC; Sch. of Pharmacy, Lahore, Pakistan, [3]CEMB, Lahore Pakistan, Lahore, Pakistan

Abstract Body:

Background: Hepatitis C viral (HCV) infection is basically a blood borne viral infection, ultimately causing malignant disease of liver if untreated. Risk factors play major role in transmission of HCV including blood transfusion, dental and surgical procedures, sharing of razor, blades, toothbrushes, nail clippers and manicure pliers. Hepatitis C infection is an emerging global health problem with a worldwide prevalence of about 3%. Hence a study was designed to investigate the prevalence of Hepatitis C viral infection among the children visiting a tertiary care hospital in Lahore, and also to assess the associated risk factors contributing towards the disease. **Methods:** This prospective and observational. Study was carried out at a children department of a tertiary care public hospital in Lahore Pakistan. The study was conducted during the month of March-July 2012. The children visiting Oncology ward, Emergency and ICUs were also included during the entire study period. A total of 200 Blood samples were collected with the informed consent and were processed to detect the antibodies against HCV by using third generation ELISA kits. **Results:** The percentage prevalence of HCV infection was found as 8%. The prevalence of anti-HCV among children was significantly associated ($P<0.05$) with age group (9-12 years). History of blood transfusion, surgery, visit to dentist, circumcision by barber were found to be important risk factors associated with hepatitis C infection among children. **Conclusion:** A high prevalence of HCV infection has been observed and certain risk factors also identified. A well-streamlined surveillance and reporting system is required to developed strategy at national level for the rapid identification, treatment and infection prevention measures for infected children.

The Prevalence of Lifestyle-Related Diseases in Vietnamese Adult Hiv-Infected Patients on Antiretroviral Therapy

Author Block:

D. Mizushima[1], S. Matsumoto[1], N. T. Dung[2], N. H. Dung[2], N. V. Trung[2], N. V. Kinh[2], S. Oka[1]; [1]Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan, [2]Natl. Hosp. of Tropical Diseases, Hanoi, Viet Nam

Abstract Body:

Background: Lifestyle diseases are becoming common in some developing countries with the westernization of food life. However, little is known about the diseases in Vietnamese HIV-infected patients. Thus, we evaluated the prevalence of the diseases and its risk factors in this population. **Methods:** A cross-sectional study was done in a cohort of Vietnamese HIV-infected patients on ART at the National Hospital of Tropical Diseases in Hanoi, Vietnam. Lifestyle diseases included hypertension (HT), hyperglycemia (HG) and dyslipidemia (DL). Blood pressure, fasting blood sugar and lipid profile were evaluated for every patient who visited the hospital on October and November 2015. As for statistical analysis, to determine factors associated with the diseases, logistic regression was used in uni and multivariate analysis. **Results:** Of 1371 study patients, females were 40%. Age, body mass index (BMI), CD4+ T cell count and the duration of HIV infection were averagely 38.5 years, 21.2 kg/m^2, 456 cells/μl and 6.1 years, respectively. 97.4% of the patients achieved viral suppression. As a key drug, 89.5% of the patients used non-nucleoside reverse transcriptase inhibitors (nevirapine 23.3% and efavirenz 66.2%) and 9.8% of the patients used the second line, lopinavir boosted with ritonavir (LPVr). As backbone drugs, 77% of the patients used tenofovir. The prevalence of HT, HG and DL were 18.7%, 4.2% and 53.5%, respectively. Age, female sex and BMI were significantly associated with HT in multivariate analysis (OR: 1.085, CI:1.067-1.103, OR:0.439, CI:0.313-0.614 and OR:1.161, CI:1.096-1.231, respectively). Age, sex and duration of HIV infection were associated with HG (OR: 1.078, CI:1.050-1.106, OR:0.463, CI:0.240-0.894 and OR:1.084, CI:1.018-1.154, respectively). Age, sex, BMI and use of LPV were associated with DL (OR: 1.032, CI:1.017-1.047, OR:0.417, CI:0.329-0.529, OR:1.212, CI:1.153-1.275 and OR:5.230, CI:3.173-8.620, respectively). **Conclusions:** The prevalence of dyslipidemia was disproportionally higher compared to the other lifestyle diseases and the use of LPVr was statistically associated in addition to known risk factors. A further study is required to evaluate the link between these findings and cardiovascular diseases.

Publishing Title:

Prevalence Of Bacterial Etiologies Of Gastrointestinal Disease In Children Living In The Peruvian Amazon River Basin

Author Block:

A. Huyler[1], H. Montilla-Guedez[1], L. Nguyen[1], A. Rogers[1], M. Lotfipour[1], W. Beachy[1], R. Perez[1], D. Nesterova[1], O. Munizza[1], I. Marji[1], R. Burga[2], R. Abadie[2], C. Rocha[2], H. Tilley[2], D. W. Craft[1]; [1]Milton S. Hershey Med. Ctr., Hershey, PA, [2]NAMRU-6, Lima, Peru

Abstract Body:

Background: In the Peruvian Amazon River Basin, diarrhea has been shown to affect many aspects of children's health and is responsible for 7% of deaths under the age of 5. However the prevalence of bacterial pathogens in fecal samples from children in this area has not been previously reported. This study assesses the prevalence of bacterial etiologies of infectious diarrhea in children in the impoverished Amazon River Basin community of Belen, Peru. **Methods:** 232 stool samples were collected from children under the age of five in Belen from May to October 2014. Fresh stool was cultured using conventional culture media and pathogens identified using standardized techniques. Stool was also directly analyzed for the presence verotoxin- and shiga toxin-producing *E. coli* (VTEC/STEC) using QUIK CHEK (TechLab, Blacksburg, VA). **Results:** The overall prevalence of enteric bacterial pathogens was 21.1% (49/232). 44 of 49 (97.8%) cultures yielded one bacterial pathogen and 5 (2.2%) cultures yielded 2 pathogens. The most prevalent was *Salmonella* spp. (14/232), which was twice that of *Shigella* spp. (7/232). For *Campylobacter* spp., the prevalence of *C. coli* (11/232) was twice that of *C. jejuni* (6/232), the latter being essentially equivalent in prevalence to *Aeromonas* spp. (6/232) and *Plesiomonas* spp. (5/232). There was no evidence of VTEC/STEC based on direct detection of toxin in the stool samples.

Pathogen	**Prevalence**
Salmonella spp.	6.0%
Shigella spp.	3.0%
C. coli	4.7%
C. jejuni	2.6%
Aeromonas spp.	2.6%
Plesiomonas spp.	2.2%
VTEC/STEC	0.0%

Conclusions: Of the 232 stool samples analyzed, 21.1% yielded at least one enteric pathogen, a slightly higher percentage than previously reported for worldwide incidence (vs. prevalence)(10-20%) of bacterial diarrhea in children. Water quality is considered a risk factor in this community. Ongoing longitudinal studies are assessing prevalence against the demographics of Belen households as well as investigation of other etiologies of pediatric and adult diarrhea in the Amazon River Basin of Peru.

Human Brucellosis Cases in Georgia in 2015

Author Block:

M. Makharadze, R. Burdilaze, N. Naveriani, T. Zaqaraia; Res. Inst. of Med. Parasitology and Tropical Med., Tbilisi, Georgia

Abstract Body:

Brucellosis is one of the most widespread and debilitating zoonotic diseases in the world. The causative agent (genus *Brucella*) remains endemic in Georgia, and causes substantial human morbidity and significant agriculture economic loss. In addition, *Brucella* species are considered potential biological threat agents by the United States government. To assess epidemiology, clinical course, laboratory findings, and treatment outcomes of brucellosis cases a study was conducted at the Institute of Parasitology and Tropical Medicine (IPTM) of Georgia, the reference clinic for brucellosis where patients are diagnosed and treated.For detecting *Brucella* antibodies, we used the Wright-Huddleston reaction. All suspected brucellosis cases are tested using ELISA (IgG + IgM). All positive blood samples are sent to National Center for Disease Control for further investigation. All patients were treated with a two-drug combination of antibiotics Doxycycline + Streptomycin/Gentamycin or Doxycycline + Rifampin for six week.A total of 153 brucellosis cases were diagnosed in Georgia from January 2015-October2015, a 6.7% increase in the incidence compared to the same period in 2014. The majority of cases were found in eastern Georgia (93%). In the 2015 study period, the incidence rate of brucellosis was highest in the Kakheti region (2.0 cases per 10000 population). Men (65%) were more likely to be infected compared to women (35%); the most affected age group was patients 30-59 years old. The most frequent clinical symptoms were sweats (90%), joint pain (84%), aches (85%), malaise (90%), fatigue (75%), and rigors (86%). Lymphadenopathy (92%) and hepatosplenomegaly (90%) occurred as well. Neuropsychiatric symptoms such as depression, difficulty concentrating, and sleep disturbance were observed less frequently. Most symptoms resolved after 10-14 days of treatment. In some cases, arthralgia remained for two weeks or longer.The most important risk factor was occupation. The highest incidence was among farmers and shepherds, whose reported source of infection was contact with infected animals and consumption of unpasteurized milk and dairy products. In 2015, the prevalence of brucellosis is still high. Currently there are more cases of brucellosis in eastern Georgia. Treatment of brucellosis is effective, however, preventive measures against the disease is of significant importance.

The Critical Factors for a Nationwide Major Reduction of Antimicrobial Use in Animals in the Netherlands with a Parallel Reduction in Antimicrobial Resistance

Author Block:

J. Wagenaar[1], I. Van Geijlswijk[1], J. Mouton[2], D. Mevius[3], K. Veldman[3], J. Jacobs[1], D. Heederik[1]; [1]Faculty of Vet. Med., Utrecht, Netherlands, [2]Erasmus Univ., Rotterdam, Netherlands, [3]Central Vet. Inst., Lelystad, Netherlands

Abstract Body:

Introduction: After a doubling of antimicrobial use (AMU) in Dutch livestock between 1990 and 2007, measures were initiated by the Dutch Government, livestock sectors and the Royal Dutch Veterinary Association (KNMvD) to reduce the use of antimicrobials. A major trigger for action was the emergence of multi-resistant bacteria (LA-MRSA and ESBLs) in livestock. **Methods:** The Netherlands Veterinary Medicines Authority (SDa) was formed as an independent body to i) collect the AMU data of Dutch livestock (approximately 42,000 units); ii) define benchmark targets for AMU for pigs, poultry, veal calves and dairy; iii) report annual trends in AMU; iv) identify frequent- or mis-users/prescribers. Reduction targets were set by the government at 20%, 50% and 70% reduction in 2010, 2013 and 2015, respectively, with reference to 2009. Several other actions were performed at different levels; e.g. report of the Dutch Health Council, the development of treatment guidelines. Parallel to these actions, continuous monitoring of resistance in commensal *E. coli* had already been set up in livestock from 1998 onwards, enabling measurement of trends in resistance. **Results:** The total reduction of AMU between 2009 and 2014 was 58.1%. Compared to 2007, the year with the highest veterinary usage, there was a reduction of 65%. The use of antimicrobials defined as ‘’critically important for human health’’ (fluoroquinolones and 3rd/ 4th generation cephalosporins) in livestock were reduced to almost zero. The Dutch farmers and their veterinarians achieved this through improved infection and health control measures, which resulted in overall less, and more individual treatments instead of group treatments. As a result of the enforced 1-to-1 relationship of farmers and veterinarians, it was possible to develop the Veterinary Benchmark Indicator allowing to compare prescription levels between veterinarians. All farms were benchmarked (action, signaling and target level). **Conclusions:** A major reduction in AMU could be achieved and parallel to reduction of AMU there was a reduction of AMR in livestock observed.

Health and Healthcare Determinants of Antibiotic Resistance in Oecd Countries

Author Block:

S. Karahan, P. Duzgun, E. D. Aksu, D. C. Karaaslan, B. AK, F. Can, **O. Ergonul**; Koc Univ., Sch. of Med., Istanbul, Turkey

Abstract Body:

Background: Emerging antibacterial resistance is one of the leading global public health problems; however, healthcare determinants were not explored in depth. We aimed to identify the health and health care determinants of antibacterial resistance between countries. **Methods:** We reviewed the relevant parameters that could be related with antibacterial resistance. Bacterial resistance was defined as fluoroquinolone resistance to *E. coli*. We retrieved healthcare determinants data from open sources of OECD and resistance data from WHO. By using linear regression, we tested the effect of each health and healthcare parameter on antibiotic resistance (STATA, USA, 12v, $p<0.05$). **Results:** Five parameters were found to have an effect on antibacterial resistance, and three of them were significant (Table 1). 1) In OECD countries, As the ratio of the nurses to doctors increases, antibiotic resistance decreases, 2) As the share of health expenditure in GDP increases, antibacterial resistance decreases, 3) A positive effect of vegetable consumption, but a negative effect of fruit consumption on antibiotic resistance was detected. Fluoroquinolones are stable and have long half-lives compared to other antibiotics that are used in agriculture, 4) Among educational indicators, direct public expenditure on educational institutions plus public subsidies as a percentage of GDP had a negative effect on antibiotic resistance (Table 1). **Conclusions:** In order to decrease resistance to antibiotics, not only should the health system be developed, but also making alterations in the educational expenditures and enhancements in educational systems should be targeted.Table 1: Univariate linear regression of health and healthcare indicators for the rate of fluoroquinolone resistance against E.coli.

Indicator	coefficent	95% Confidence Interval	p

Acute Dentoalveolar Infections, Microbiology and Susceptibility Patterns Over a 27 Year Period in Glasgow, UK

Author Block:

A. J. Smith[1], G. Morgan[2], L. Smith[3]; [1]Univ. of Glasgow, Glasgow, United Kingdom, [2]Bacteriology Dept, Glasgow, United Kingdom, [3]Dental Practice, Glasgow, United Kingdom

Abstract Body:

Relatively little surveillance data is undertaken on the antimicrobial susceptibility of isolates from acute dento-alveolar infections. We present data collated from routine diagnostic microbiology specimens submitted over a 27 year period in Glasgow, UK. Specimens from acute dento-alveolar infections are routinely processed for predominant facultative and anaerobic isolates. Over the study period isolates were identified using biochemical properties (API system), VITEK 2 and MALDI-TOF. Antimicrobial susceptibility tests were undertaken using combinations of Stokes method and/or E-tests. Baseline data used was that reported from Glasgow by Lewis et al., (JAC 23,69-77 1989) and compared to isolates from 1998 -2015. Data were available from 621 specimens. Predominant facultative groups isolated during the study period comprised Anginosis (n=196) and Mitis group Streptococci (n=448) . Strict anaerobes frequently isolated included anaerobic streptococci (n=116), Fusobacteria (n=121) and Prevotella (n=140) species. With regards to antimicrobial susceptibility the majority of isolates remain susceptible to Penicillin, Macrolides and Clindamycin. Relatively small numbers of annual specimens and isolates confounds data interpretation trends over time, however, no discernable increase in resistance patterns over the 27 year time period of analysis was observed. Conclusion, practitioners should be encouraged to submit samples from acute dento-alveolar infections to provide systematic surveillance data to inform empiric antimicrobial prescribing.

Recurrent Melioidosis in a Tertiary Referral Centre in Singapore

Author Block:

E. Y. Lim, J. M. F. Chien; Singapore Gen. Hosp., Singapore, Singapore

Abstract Body:

Background: *Burkholderia pseudomallei* infections are notoriously difficult to eradicate. Reported rates of recurrent infections ranged from 5.2% to 9.3% but data from Singapore has yet to be published. We report our 14-year clinical experience of recurrent melioidosis. **Methods:** All patients with a positive culture for *B. pseudomallei* from 1 Jan 2001 to 31 Dec 2014 were retrospectively identified and their case records reviewed. An episode of recurrence was defined in a patient on treatment or who had completed treatment and presented with new clinical features or microbiological results suggestive of re-infection. **Results:** Two hundred patients had culture-proven melioidosis, of which 36 (18%) had at least 1 episode of recurrence. Twenty-four were culture-positive recurrences, while twelve were clinical recurrences. 50% of recurrences occurred during maintenance phase of treatment. Recurrent cases were more likely to have skin and soft tissue infection (41.7% vs 20.7%, p=0.008) and involvement of the musculoskeletal system (25% vs 12.2%, p=0.048). Recurrent patients also tended towards a longer duration of bacteremia, 9.48 vs 7 days (p=0.094), and having >1 organ involvement (63.9% vs 51.2%, p=0.168). Susceptibility to co-trimoxazole was significantly less among isolates from the recurrent group (41.7% vs 64%, p=0.013). Mortality rate of recurrent cases was similar to non-recurrent cases. Choice of induction antibiotic across both groups was similar with ceftazidime being the commonest. Mean duration of induction was 34 days among recurrent cases vs 31.8 days in non-recurrent group (p=0.533). Co-trimoxazole and doxycycline combination was the commonest choice of maintenance therapy, with 5mg/kg as the average dose of trimethoprim component. Amongst the recurrent group, doxycycline monotherapy was more commonly used during maintenance (11.7% vs 3.4%, p=0.085). Mean duration of maintenance therapy was also shorter (16.2 weeks vs 21.2 weeks, p=0.025).**Conclusions:** Most of our recurrent cases were a result of incomplete prior therapy and it will be interesting to investigate if the low dose co-trimoxazole and doxycycline maintenance combination in addition to decreased susceptibility to co-trimoxazole had contributed to our high recurrence rates. In agreement with published studies, the duration of bacteremia and type of oral maintenance therapy is associated with risk of recurrence.

Publishing Title:

Ctx-M-15-Producing Multidrug Resistant *Klebsiella pneumoniae* High-risk Lineages Cause Urinary Tract Infection in Companion Animals

Author Block:

C. Marques[1], J. Menezes[1], G. Trigueiro[2], A. Belas[1], L. Telo da Gama[1], C. Pomba[1]; [1]CIISA, Faculty of Vet. Med.-UL, Lisbon, Portugal, [2]Laboratório Joaquim Chaves, Lisbon, Portugal

Abstract Body:

The increase of multidrug-resistant (MDR) *Klebsiella pneumoniae* is a great concern. Companion animals with urinary tract infection (UTI) caused by MDR *K. pneumoniae* may have a critical role as reservoirs to humans. This study aimed to determine clonal lineages, antimicrobial resistance and resistance mechanisms of *Klebsiella* spp. isolated from humans and CA with UTI.Susceptibility testing against 28 antimicrobials was conducted by disk diffusion in 37 *Klebsiella* spp. from CA (2002-2015) and 61 from humans (2014) with UTI. The following resistance genes were screened by PCR: ESBL (TEM, SHV, CTX-M), pAMPc (CMY, DHA, MOX), *aac*(6')-Ib, *aph*AI-IAB, *qnr (*A, B, C, D, S), *sul*1, *sul*2, t*et*A and *tet*B. *K. pneumoniae* from CA and third-generation cephalosporin (3GC) resistant human isolates were typed by MLST.CA *Klebsiella* showed high frequencies of resistance to cefotaxime (54.0%), ciprofloxacin (67.6%), trimethoprim/sulphamethoxazole (61.1%) and tetracycline (62.2%). Only *qnr*B was detected in ciprofloxacin-resistant isolates. *tet*A (55.6%, n=10/18) and *tet*B (38.9%, n=7/18) were found in CA tetracycline-resistant *Klebsiella*. Most CA and human (90.6%, n=29/31) trimethoprim/sulphamethoxazole resistant *Klebsiella* harbored *sul*1 and/or *sul*2. All CA 3GC-resistant *K. pneumoniae* (56.2%, n=18/32) were MDR. Both in CA and human *Klebsiella*, CTX-M-15 was the most frequent (66.7%, n=12/18), followed by CMY-2 (16.1%, n=5/31) and DHA-1 (9.7%, n=3/31). ST15 (n=11/15) was the main 3GC-resistant *K. pneumoniae* lineage found in CA. Yet, one ST11, one ST37, one ST147 and one ST348 were also detected. *K. pneumoniae* ST15 clonal lineage was also found among CA 3GC-susceptible isolates (n=4/10). Eleven human community-acquired 3GC-resistant *Klebsiella* STs were found including ST15 (n=2/13) and ST348 (n=1/13).ESBL CTX-M-15 is known to be worldwide distributed in companion animals and humans. This study shows a wide dissemination of the MDR zoonotic ST15 CTX-M-15-producing lineage in CA with UTI. Furthermore, the detection of other human high-risk lineages such as ST11 is worrisome. Since CA with UTI are generally treated in ambulatory by the owners, measures should be taken to minimize the spread of MDR *K. pneumoniae* to humans and the environment.

Evaluation of Copan Fecalswab^{tm} for Molecular Detection of Pathogens Using the Bd Max^{tm} Enteric Bacterial Panel

Author Block:

V. P. Prakash, L. LeBlanc, K. Chapin; Rhode Island Hosp., Providence, RI

Abstract Body:

Background: The Copan FecalSwab^{TM} (FS) is an FDA-cleared collection device consisting of a flocked swab in modified Cary-Blair (CB) medium for transporting and preserving enteric stool pathogens for culture. Collection of a rectal swab specimen at the time the patient presents addresses the unmet clinical need of consistently obtaining a specimen for analysis. No GI molecular assays are FDA-cleared for use with the FS. The objective of this study was to evaluate and validate the FS for detection of GI pathogens using the BD MAX^{TM} Enteric Bacterial Panel (EBP).**Methods:** Optimal specimen input volume, limit of detection (LoD) and clinical performance for the FS with the EBP assay were assessed. Input volume for EBP was determined by testing volumes between 50-500 ul in triplicate of pooled negative stool in the FS medium and analytical sensitivity (LoD) by spiking negative FS medium matrix with concentrations (1.5×10^6 - 1.5×10^1 CFU/mL, 4 replicates/dilution) of ATCC strains bearing the assay targets. The LoD was set as the lowest concentration that was positive for 3/4 replicates with matching corresponding bacterial concentration in CFU/ml. Clinical performance was determined by FS EBP results compared to FS culture results. Discrepant analysis included EBP and culture from CB stool and alternate PCR.**Results:** Input volume of 500 ul FS medium was the highest volume found to be non-inhibitory for EBP based on Ct value of the Sample Processing Control (SPC) compared to the control specimens. The LoD values were 571 CFU/mL Sample Buffer Tube (SBT) for *Salmonella*, 100 CFU/mL SBT for *Shigella*, 1261 CFU/mL SBT for STEC and 20 CFU/mL SBT for *Campylobacter*. Clinical performance among 55 FS samples (to date), showed five samples positive (9%) for 6 analytes: *Salmonella* (3), *Shigella* (1), *Campylobacter* (1) and STEC (1). Paired CB stool tested simultaneously for 38/55 samples were concordant with FS results by EBP and culture.**Conclusions:** Detection of enteric pathogens using the FS collection system and EBP assay was equivalent to culture and EBP results from stool collected in CB. LoD values were similar to those reported in the EBP package insert. The FecalSwab™ provides convenient collection, preservation and testing by multiple methods, including culture and the BD MAX^{TM} Enteric Bacterial Panel.

Pathogen Distribution in Infectious Diarrhea in Beijing Area Determined with a Comprehensive Detection Method

Author Block:

X. Lu, W. Feng, X. Gu, S. Zhang, M. Wang, Y. Huang, X. Li, X. Li, M. Zhang, L. Yuan, Y. Sun, J. Wu; Beijing Tongren Hosp., Capital Med. Univ., Beijing, China

Abstract Body:

Background: Infectious diarrhea (ID) is the second leading cause of death worldwide, so understanding its regional epidemiology should improve preventive practices. **Methods:** In this study, 592 stool samples were collected from outpatients diagnosed with ID between October, 2013, and September, 2014, at Beijing Tongren Hospital, Capital Medical University. A new method, xTAG® GPP multiple PCR and traditional methods (culture, rapid immunochromatography, microscopic examination, and real-time PCR) were used to identify the causative organisms.**Results:** Pathogens were detected in 340 samples (57.5%) with xTAG® GPP multiple PCR and in 254 samples (42.9%) with traditional methods. Viruses were detected in 107 (18.1%) samples. *Rotavirus A* was the most prevalent virus (8.8%),followed by *Norovirus* (8.4%) and adenovirus (0.84%). A variety of bacteria was detected in 263 (44.4%) samples. *Vibrio parahaemolyticus* was the most frequently detected bacterial pathogen (13.5%),followed by enterotoxigenic *E. coli* (8.4%), *Campylobacter* (7.7%), *Salmonella* (7.0%), *Clostridium difficile* A/B (3.5%), *Shigella* (3.3%), *E. coli* O157 (3.3%), and others(4.2%). In 10 samples, the following parasites were found: *Cryptosporidium* (5), *Entamoeba histolytica* (3), and *Giardia* (2).**Conclusions:** Our data show the specific epidemiological characteristics of the ID pathogens detected in our hospital in different populations. We also demonstrated that xTAG® GPP multiple PCR combined with traditional methods effectively increases the detection rate for ID pathogens.**Table Samples results detected from 592 samples compared between xTAG® GPP and the traditional method**

Utilizing BD MAX Enteric Bacterial Panel to Detect Stool Pathogens from Rectal Swabs

Author Block:

B. DeBurger, S. Hanna, C. Ventrola, E. Powell, J. Mortensen; Cincinnati Children's Hosp., Cincinnati, OH

Abstract Body:

Background: The BD MAX™ Enteric Bacterial Panel (EBP) is designed to detect *Salmonella, Shigella, Campylobacter,* and Shiga toxin from stool samples. However rectal swabs, which are not FDA-cleared for clinical testing with the BD MAX EBP, are common specimens received from pediatric patients for enteric pathogen testing. The purpose of this study was to evaluate the ability of the BD MAX EBP to detect stool pathogens from rectal swabs. **Methods:** Routine cultures, Shiga toxin testing, and molecular testing with BD MAX EBP were performed on 272 sequential rectal swabs collected from August 2015 to December 2015. 36 challenge samples (3 *Shigella* spp., 13 *Salmonella* spp., 10 *Campylobacter* spp., and 10 Shiga toxin positive *E. coli*) were tested using reference strains (American Type Culture Collection and previous patient isolates diluted to10^3-10^4 cfu/ml in saline then adding to Sample Buffer Tube (SBT) with negative stool matrix. Limit of detection testing was performed by serial 10 fold dilutions in saline then adding to SBT with negative stool matrix. Discrepant test results were resolved using Verigene® Enteric Pathogens Nucleic Acid Test.**Results:** See table for the patient results. All discrepant results were BD MAX EBP positive and culture negative. 8.8% of the patient samples did not initially yield a result on the BD MAX System. Upon repeat, 4.4% resolved. All organisms in the challenge samples were detected. Limits of detection for BD MAX EBP testing of rectal swabs were as follows (in CFU/mL in SBT): *Shigella*-5.10 x 10^0; Shiga Toxin-1.13 x10^3; *Salmonella*-1.44 x 10^2 ; and *Campylobacter*- 1.51 x 10^1.**Conclusion:** Rectal swabs are acceptable samples for detecting *Salmonella, Shigella, Campylobacter,* and Shiga toxin using BD MAX™ EBP.

Target	Number Positive	Positive Percent Agreement	Negative Percent Agreement
Shigella	79	100%	95.3%
Shiga Toxin	2	100%	100%
Campylobacter	4	100%	99.6%
Salmonella	4	100%	100%

Publishing Title:

Validation of Bd Max Enteric Parasite Pathogen (Epp) Panel with Alternate Transport Systems

Author Block:

B. DeBurger, S. Hanna, C. Ventrola, E. Powell, J. Mortensen; Cincinnati Children's Hosp., Cincinnati, OH

Abstract Body:

Background: The BD MAX™ EPP is FDA-cleared for the detection of *Giardia lamblia*, *Cryptosporidium* spp., and *Entamoeba histolytica* from unpreserved stool or 10% formalin-fixed stool. In an effort to eliminate the use of 10% formalin from the laboratory due to its hazardous nature and increase efficiency with a single vial for both culture and parasitic examination, four different transport systems were compared: 10% formalin, Total-Fix™, Cary-Blair medium, and the Para-Pak® SVT. **Methods:** Each transport system was inoculated with 5 ml of stool, previously determined to be negative for the three targets. Reference stocks of the target organisms were serially diluted 10 fold. Sample Buffer Tubes (SBT) were inoculated in quadruplicate with 10 µl of the appropriate organism dilution and 10 µl of the fixed negative stool matrix. The BD MAX EPP was performed on each SBT using the BD MAX™ System. The limit of detection (LOD) was defined to be the concentration of organism in SBT where all four replicates were positive.**Results:** The challenge samples show equivalent LOD for each transport type for *G. lamblia* and *E. histolytica*. The alternate transport systems may have superior analytical sensitivity for *Cryptosporidium parvum* detection as compared to 10% formalin.**Conclusion:** In these initial laboratory studies, Total-Fix, Cary-Blair, and Para-Pak SVT have equal or superior limits of detection for all pathogens tested as compared to 10% formalin. Validation of these various transport systems for use with the BD MAX™ EPP with patient specimens is ongoing.

Target	Limits of Detection (organisms/ml in SBT)			
	10% formalin	Total Fix	Cary-Blair	SVT
Giardia lamblia	$1.6x10^1$	$1.6x10^1$	$1.6x10^1$	$1.6x10^1$
Cryptosporidium parvum	$1.6x10^3$	$1.6x10^1$	$1.6x10^2$	$1.6x10^2$
Entamoeba histolytica	$5.3x10^1$	$5.3x10^1$	$5.3x10^1$	$5.3x10^1$

Publishing Title:

Molecular Detection of Gi Pathogens Offers Greater Diagnostic Yield versus Conventional Ordering Practices for Diarrheal Illness in a Large Academic Hospital System

Author Block:

B. Couturier[1], M. Powers-Fletcher[2], W. Hymas[1], K. Kalp[1], M. R. Couturier[2]; [1]ARUP Lab., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: Bacteria, parasites, and viruses cause diarrheal illness with any number of non-specific symptoms such as diarrhea, vomiting, abdominal pain, and fever. Testing for gastrointestinal (GI) pathogens causing acute diarrhea typically includes stool cultures, ova & parasite microscopic examination, and enzyme immunoassays. Our study examined the analytical yield of a laboratory-developed molecular GI panel compared to conventional testing using stool cultures +/- adjunct conventional stool testing.**Methods:** Stool samples sent for routine stool culture from the University of Utah were collected between June 2012 to February 2013 (n=583). Nucleic acid was extracted and tested in a real-time PCR panel that targets bacterial, viral, and parasitic pathogens (*Salmonella* sp [Salm], *Shigella* sp., *Campylobacter jejuni/C. coli*, *C. upsaliensis*, *C.lari/ureolyticus/hyointestinalis*, shiga-like toxin 1 and 2, *Cryptosporidium* sp [Crypto], *Giardia* sp., *Dientamoeba fragilis*, *Cyclospora cayetanensis*, *Entamoeba histolytica*, astrovirus, norovirus group 1 & 2, rotavirus, and adenovirus 40/41). An internal control was used to monitor inhibition. Charts were reviewed for all PCR or culture positive specimens to assess adjunct testing.**Results:** A total of 104/583 (17.8%) stool samples were positive by PCR. Fourteen patients were positive for 2 targets yielding a total of 118 positive results. Of the 118, 55.9% contained a bacteria, 28.0% a virus, or 16.1% a parasite; 13 results correlated with stool culture, or antigen testing. The most frequently detected targets were Salm. (n=34), Norovirus (n=26), *C. jejuni/C. coli* (n=14), and Crypto (n=12). Five *C. jejuni/C. coli* PCR positives and 30 Salm PCR positives were not detected by culture. One *C. jejuni* culture positive sample was negative by real-time PCR. Three samples PCR positive for Crypto were tested by antigen, but only 1 was detected by Crypto antigen.**Conclusions:** The use of molecular methods for stool samples from suspected GI infections has increased analytical sensitivity and specificity compared to traditional stool culture and antigen testing methods, and reveals significant deficiencies with the performance of conventional methods used in routine ordering practices.

Publishing Title:

Evaluation of the Bd Max™ System for Detection of Bacterial and Parasitological Infectious Gastroenteritis

Author Block:

M. England, C. Lowe, D. Myers, D. Craft; Penn State Hershey Med. Ctr., Hershey, PA

Abstract Body:

Introduction: Infectious gastroenteritis due to bacteria and parasites is a leading cause of morbidity and mortality worldwide. Routine identification is labor-intensive, slow, and considered insensitive compared to molecular assays. We compared sensitivity and turnaround time of the BD MAX™ Enteric Bacterial Panel (EBP) and BD MAX™ Enteric Parasite Panel (EPP) performed on the BD MAX™ System to routine culture, shiga-toxin EIA, and parasite microscopy/antigen detection (EIA). **Methods:** Over a 4 month period, 409 bacterial culture (unpreserved & Cary-Blair) and 151 parasite (10% formalin) specimens were concurrently tested via conventional stool culture or microscopy/EIA and BD MAX™ EBP and EPP. Stool culture specimens were inoculated onto routine media and GN broth. Broths were analyzed for shiga-toxin producing *E. coli* (STEC) by ImmunoCard STAT!® EHEC (EIA; Meridian). Parasite specimens were sent to a reference laboratory for ova and parasite (O&P) identification. Discrepancies were adjudicated by FilmArray™ Gastrointestinal Panel (BioFire).**Results:** The BD MAX™ EBP reported 29 organisms in 28 positive specimens (6.8%), with 1 false positive *Campylobacter* spp.; whereas, routine culture correctly identified 17 organisms (4.2%). Notably, EIA failed to identify all 4 STEC-positive specimens, all of which were identified by BD MAX™ and confirmed by FilmArray™ or PA DOH. The BD MAX™ EBP improved time for reportable results by 12-20 hours. The BD MAX™ EPP matched microscopy/EIA in sensitivity (3/151 positive) and improved report time by 5 days.**Conclusions:** The BD MAX™ EPP correlated with EIA and O&P microscopy, though the positivity rate was low (n=3). The BD MAX™ EBP increased sensitivity by 50% over routine stool culture and shiga-toxin EIA and decreased overall turnaround time by 12 hours. Decreased time to result may lead to faster appropriate management of outpatients and discharge of inpatients with suspected gastroenteritis. Importantly, we noted a significant improvement in sensitivity of BD MAX™ EBP over EIA for STEC. While further validation is needed to confirm the BD MAX™ EPP, the decreased turnaround time is significant if parasite testing is sent to reference labs. A limitation of these multiplex assays is the inability to distinguish between active and resolving infection and lack of bacterial isolates for epidemiological analysis.

Evaluation of the Great Basin Shiga Toxin Direct Molecular Assay for the Detection of Shiga-Like Toxin Producing *Escherichia coli* (Stec) in Diarrheal Stool Specimens

Author Block:

M. L. Faron[1], N. A. Ledeboer[1], J. Connolly[1], P. A. Granato[2], J. Dien Bard[3], J. A. Daly[4], S. Young[5], **B. W. Buchan**[1]; [1]Med. Coll. of Wisconsin, Milwaukee, WI, [2]Lab Alliance of Central New York, Syracuse, NY, [3]Children's Hosp. Los Angeles, Los Angeles, CA, [4]Univ. of Utah, Salt Lake City, UT, [5]Univ. of New Mexico, Albuquerque, NM

Abstract Body:

Background: *E. coli* harboring Shiga Toxin genes *stx1* or *stx2* (STEC) cause acute gastroenteritis and HUS. Serotype O157 is commonly associated with STEC, however, > 100 other *E. coli* serotypes may carry *stx1* or *2*. Detection of STEC using EIAs or culture requires a minimum of 24 h and is 29-80% sensitive compared to NAAT. The Shiga Toxin Direct Test (ST Direct) is a 2 h sample to result test that uses NAAT to identify *stx1*, *stx2*, and *E. coli* serotype O:157 in stool specimens.**Methods:** Stool specimens (n=1,087) were prospectively collected at 5 clinical centers and tested using ST Direct and culture. Each specimen was inoculated to SMAC agar and MacConkey broth and incubated 18-24 h. Colorless colonies on SMAC were tested with latex agglutination to confirm serotype O:157. Positive broths were tested with a STEC EIA. Retrospectively collected specimens including 36 STEC positive (17 O:157 positive) and 24 STEC negative stools were used to augment results from the prospective study set.**Results:** Results represent 1,082 prospective samples, 5 specimens were unresolved by ST Direct and were excluded. Twelve specimens tested positive for *stx1* or *stx2* and two tested positive for O:157 by ST Direct. No samples were EIA positive and ST Direct negative. Four of the 12 (33%) ST Direct positive samples were Shiga Toxin positive by EIA. No specimens were O:157 positive by culture. All specimens testing positive for STEC or O:157 by ST Direct were analyzed using bi-directional sequencing and an FDA-cleared NAAT capable of detecting *stx1*, *stx2*, and serotype O:157. Both comparator methods supported with the positive ST Direct results. Among retrospectively collected specimens, ST Direct identified 36/36 STEC positive and 17/17 O:157 positive stools.**Conclusions:** In this study ST Direct was 100% sensitive for detection of STEC, including serotype O:157, compared to culture and EIA. ST Direct identified an additional 8 specimens, including 2 serotype O:157, that were missed by culture. Compared to ST Direct, EIA is only 33% sensitive for detection of STEC. Culture is insensitive for the detection of O:157.

Multiplex Real-Time PCR Dection for Enteropathogenic Microsporidia

Author Block:

B. Couturier[1], M. Powers-Fletcher[2], **W. Hymas**[1], P. D. Khot[1], K. Kalp[1], M. R. Couturier[2];
[1]ARUP Lab, Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: Microsporidia are opportunistic fungal pathogens primarily causing gastroenteritis. Stool ova/parasite exams do not detect microsporidia and the modified trichrome stain is under-utilized and lacks sensitivity/specificity. The purpose of this study was to develop a molecular detection assay for microsporidia in stool specimens to improve diagnostic accuracy and patient care.**Methods:** A real-time PCR assay was developed for the detection of the enteropathogenic microsporidia Enterocytozooon bieneusi (Eb) and Encephalitozoon spp. (Es) (E. cuniculi, E. hellem, and E. intestinalis). Nucleic acid extraction was optimized for fungal spores by incorporating bead-beating prior to automated extraction. Analytical performance was determined using stool specimens spiked with spores of Es/Eb or plasmids containing the Eb target. Clinical specimens sent for routine stool culture between June 2012 and February 2013 were tested to assess the clinical utility of the assay, with correlative chart review.**Results:** The analytical sensitivity was 100% for the detection of Eb and 97% for Es. No cross-reactivity was observed for 27 tested organisms. The limit of detection for Eb and Es was 1.6×10^4 copies/ml and 4.4×10^3 copies/ml, respectively. Of the 583 clinical specimens tested, 3 tested positive for microsporidia by PCR and had documented persistent diarrhea. Two of the patients were immunocompromised, while the third had evidence of disrupted intestinal flora post-cholecystectomy. For all cases, no microsporidia testing was ordered, no infectious etiology was detected, and gastrointestinal symptoms were ultimately attributed to underlying conditions or abnormal bacterial growth in the intestine.**Conclusions:** Molecular detection of enteropathogenic microsporidia provides high analytical specificity and sensitivity. In patients with symptoms sufficient to warrant stool culture, microsporidia were detected in very few samples. This suggests lack of carriage in symptomatic patients and the potential for this assay to provide clinically relevant information when applied judiciously to an immunocompromised patient population or those with persistent/chronic diarrhea without an alternative diagnosis.

Evaluation of a Multiplex PCR Assay for the Detection of Gastrointestinal Pathogens

Author Block:

J. Karichu, D. Wilson, S. M. Harrington, G. W. Procop, **S. S. Richter**; Cleveland Clinic, Cleveland, OH

Abstract Body:

Background: Molecular assays detecting multiple gastrointestinal (GI) pathogens directly from stool are available to evaluate patients with diarrhea. We compared the performance of the FilmArray (FA) GI Panel (BioFire Diagnostics) to current methods used for the diagnosis of gastroenteritis at the Cleveland Clinic. **Methods:** Stool samples in Cary Blair medium from patients with positive results for a bacterial, viral or parasite using routine methods (culture, EIA, microcopy) were selected for testing by the multiplex PCR FA panel within 4 days of specimen collection date. Frozen archived positive stool samples were also selected for testing. For each positive sample selected for FA testing, a negative sample was also tested. Discrepant results were arbitrated by comparator PCR/sequencing testing for targets that differ from those in the FA.**Results:** The age distribution of patients with samples tested was 12% ≤5 years, 14% 6-20 years, 54% 22-64 years, and 20% ≥65 years. FA detected at least one target in 145 (72%) of the 200 samples tested. One, two, three, four and five targets were detected in 98 (68%), 37 (26%), 5 (3.4%), 4 (2.8%), and 1 (0.7%) of the 145 positive samples, respectively. Only 49 of the 96 samples negative by routine test ordered were also negative by FA. The predominant targets detected by FA were *Salmonella* (n=33), *Clostridium difficile* toxin A/B (n=30), *Campylobacter* (n=26), Norovirus (n=20), Enteroinvasive *E. coli* [EIEC] (n=13), Enteroaggregative *Escherichia coli* [EAEC] (n=12), Sapovirus (n=12), Rotavirus (n=10), Astrovirus (n=9), Enteropathogenic *E. coli* [EPEC] (n=9), and *Shigella* spp. (n=9). The FA sensitivity for the 18 different targets detected was 100%. The highest rates of co-infections (77-100%) occurred for samples with EIEC, EAEC, EPEC, Enterotoxigenic *E. coli* [ETEC], and *Plesiomonas shigelloides*. FA specificity ranged from 96.9-100% with 20 FA results that could not be confirmed by comparator molecular testing (6 Sapovirus, 4 *C. difficile* toxin, 3 Norovirus, 2 *Giardia lamblia*, 1 *Cryptosporidium*, 1 *Campylobacter*, 1 *Salmonella*, 1 EIEC, 1 ETEC, 1 Astrovirus).**Conclusion:** Use of the FA GI panel in our patient population would identify etiologic agents of infectious diarrhea that are currently unrecognized.

Publishing Title:

GI Panel Testing of Inpatients Detects Organisms Missed by Routine Stool Testing

Author Block:

C. Kwong, P. Schreckenberger; Loyola Univ. Med Ctr, Maywood, IL

Abstract Body:

Background: In a hospital setting, determining infectious causes of acute diarrhea in a timely manner is important when a pathogen warrants contact precautions (e.g. C. difficile). The detection of pathogens by either traditional culture methods or by target specific molecular methods is limited because it often results in no pathogens found. The goal of this study is to determine if stools that tested negative for C. difficile by PCR contain a pathogen that was not detected. **Methods**: Stool samples with negative C. difficile PCR results were stored at -20C. The electronic health record was examined for patient inclusion criteria (inpatient status and qualitative and/or quantitative stool descriptors) and exclusion criteria (no mention of diarrhea in the chart, therapeutics that cause diarrhea, diarrhea associated with certain disease states). Thirty stool samples were tested by Biofire FilmArray Gastrointestinal (GI) panel, a multiplex PCR array that detects 23 common bacterial, viral and protozoal GI pathogens. Cost comparison between current laboratory methods versus the GI panel was examined. **Results**: 8 samples out of 30 (26.7%) tested positive for one or more of the pathogens on the panel. The pathogens detected included: astrovirus, norovirus GI/GII, sapovirus (2 patients), giardia (2 patients), enteroaggregative and enterotoxigenic E. coli (both positive in 1 patient), and enteropathogenic E. coli. A total of 66 stool related laboratory tests were performed on these patients at a total cost of $2780.94. 30 GI panels cost $4231.80. The cost difference is $1450.86 or an additional $48.36 per patient to perform the GI panel only. **Conclusion**: The FilmArray GI panel identified 26.7% more pathogens that otherwise would have been missed by physician ordered tests at an increased cost of $48.36 per patient. With a quick turn around time at a relatively low increase in cost per patient, the use of the GI panel will lead to appropriate isolation precautions and earlier diagnosis and thus earlier initiation of appropriate therapy, shorter duration of symptoms, shorter length of stay and increased patient satisfaction.

Test	Unit price ($)	Total tests	Total cost ($)
C. difficile PCR	52.70	30	1581.00
Culture	40.67	18	732.06

Publishing Title:

Comparison Of Verigene® Enteric Pathogens Test, Biofire Filmarray™ Gastrointestinal Panel And Luminex Xtag® Gastrointestinal Pathogen Panel For Identification Of Enteric Pathogens

Author Block:

C. JOHNSON[1], R. Huang[1], R. Hepler[2], J. Dunn[2]; [1]Baylor Coll. of Med., Houston, TX, [2]Texas Children's Hosp., Houston, TX

Abstract Body:

Introduction: Stool culture has traditionally been considered the gold standard for identifying common bacterial pathogens, but the turnaround time can be 72 hours or longer. Rapid identification of stool pathogens would facilitate more timely treatment and/or infection control decisions. Several rapid, multiplex molecular assays are currently available for simultaneous detection and identification of common pathogenic enteric bacteria and viruses. This study compared the performance characteristics of three FDA-approved molecular assays.**Methods:**One hundred thirty-five stool specimens (40 prospective, 95 retrospective) in Cary-Blair media were tested according to the manufacturer's instructions with the three platforms: Verigene Enteric Pathogens Test, Biofire FilmArray Gastrointestinal Panel and Luminex xTAG® Gastrointestinal Pathogen Panel. The assays were assessed only for the targets common among all three; namely, *Campylobacter*, *Salmonella*, *Shigella*, Shiga toxin-producing *E. coli* (STEC), Norovirus and Rotavirus. Conventional methods including culture and EIA were used for comparison.**Results:**The sensitivities (%) and specificities (%) of the three assays for each target were: *Campylobacter*, Biofire (100, 100), Verigene (100, 99.2), Luminex (29, 100); *Salmonella*, Biofire (94, 100), Verigene (76, 100), Luminex (71, 100); *Shigella*, Biofire (98,100), Verigene (100, 100), Luminex (100, 100); STEC, Biofire (100, 100), Verigene (91, 100), Luminex (73, 99.2); Norovirus, Biofire (100,100), Verigene (98,100), Luminex (88,100). Two Rotavirus-positive samples were detected by Biofire and Luminex while Verigene detected only one.**Conclusions:** Overall, Biofire exhibited the best performance followed by Verigene and then by Luminex. The decrease in turnaround time afforded by the Verigene EP, Biofire GI and Luminex GPP assays compared to traditional culture provides a substantial benefit to laboratories with medium to high volume testing.

Publishing Title:

Comparison of Commercial Clinical Diagnostic Kits for Shiga Toxin-producing *Escherichia coli*

Author Block:

E. L. Brown, M. Stark, R. Boyer, R. Williams; Virginia Tech, Blacksburg, VA

Abstract Body:

Shiga toxin-producing *Escherichia coli* (STEC) are pathogens that cause bloody diarrhea, vomiting, and, in severe cases, hemolytic uremic syndrome. Immunological diagnostic kits are able to differentiate illnesses caused by STEC by detecting the presence of Shiga toxin antigens. The objective of this study was to compare the performance of four diagnostic kits: Premier® EHEC and Immuno*Card* STAT!® EHEC (Meridian Bioscience, Inc.) and *SHIGA TOXIN CHEK*™ and *SHIGA TOXIN QUIK CHEK*™ (TECHLAB®, Inc.) Fecal samples (n=189) were tested using the Premier® EHEC, *SHIGA TOXIN CHEK*™, and *SHIGA TOXIN QUIK CHEK*™ according to each kit's directions for direct fecal testing. The Immuno*Card* STAT!® EHEC is not intended for direct fecal samples. Standard curves created with purified Shiga toxin toxoids diluted in negative fecal broth culture were tested with each kit to determine the limit of detection (LOD; ng/mL) in order to compare the experimental result with the package insert. Additionally, correlation of toxin production with concentration of cells in broth culture was examined using 12 STEC strains isolated from foodborne illness. Results from direct fecal testing were compared to PCR detection of *stx1* and *stx2* (38 fecal samples positive). Sensitivity/specificity (calculated using PCR) for the Premier® EHEC = 81.6%/ 97.3%; *SHIGA TOXIN CHEK*™ = 86.8%/98.6%; *SHIGA TOXIN QUIK CHEK*™ = 94.7%/99.3%. Between the rapid tests, the *SHIGA TOXIN QUIK CHEK*™ detected lower levels of toxin compared to the Meridian Immuno*Card* STAT!® EHEC in purified toxin tests (Table 1). Between the ELISA tests, the Meridian Premier® EHEC detected lower levels of toxin than *SHIGA TOXIN CHEK*™ (Table 1).

Table 1. Limit of detection (LOD; ng/mL) of Shiga toxin toxoid in kits when diluted in broth culture

Kit	**Stx1**	**Stx2**
Premier EHEC	0.59	1.60
SHIGA TOXIN CHEK	0.89	2.37
Immuno*Card* STAT EHEC	0.78	3.13
SHIGA TOXIN QUIK CHEK	0.15	0.11

No consistent LOD (CFU/mL) was determined in broth cultures because toxin production varied between the strains; however, the LOD (CFU/mL) was 10 times more sensitive for the Meridian Premier® EHEC, *SHIGA TOXIN CHEK*™, and *SHIGA TOXIN QUIK CHEK*™ in comparison to the Immuno*Card*® STAT!. Due to toxin production discrepancy, the concentration of bacterium in broth is not accurate determination for LOD.

Publishing Title:

Development of a Real-time Pcr Assay for Simultaneous Identification of Shiga Toxin-producing *Escherichia coli* (Stec) Subtypes *stx*$_{2e}$ and *stx*$_{2f}$ from Clinical Isolates

Author Block:

P. Smith[1], D. Fasulo[2], D. Stripling[1], H. Martin[1], L. M. Gladney[1], N. Strockbine[1], R. L. Lindsey[1]; [1]CDC, Atlanta, GA, [2]Pattern Genomics, LLC, Madison, CT

Abstract Body:

Background: Shiga toxin-producing *Escherichia coli* (STEC) are common foodborne pathogens that may cause mild to severe illness in humans. STEC are characterized by the presence of Shiga toxin (*stx*$_1$ or *stx*$_2$) genes. The *stx*$_2$ virulence gene has seven subtypes (*stx*$_{2a-f}$); in this study we address *stx*$_{2e}$ and *stx*$_{2f}$. The *stx*$_{2f}$ subtypes is increasingly associated with Hemolytic Uremic Syndrome. Commercial molecular diagnostic panels and immunodiagnostic tests do not detect the presence of *stx*$_{2f}$. A conventional PCR assay exists to detect *stx*$_{2e}$ and *stx*$_{2f}$. We developed and optimized a real-time PCR assay targeting these subtypes in a single reaction for a rapid and higher throughput method than the conventional PCR method.**Materials/Methods:** The Daydreamer™ (Pattern Genomics, USA) software platform was used to analyze the whole genome sequence of a total of 342 isolates, 104 positive for Shiga toxin genes (STEC) and 238 negative for Shiga toxin genes. A region was identified as unique to *stx*$_{2e}$ and *stx*$_{2f}$, and TaqMan primers and probe were generated. The primers and probe were validated by both in silico and RT PCR. The primers and probe were tested in the laboratory on a set of 71 STEC isolates using a LightCycler® 96 (Roche, Switzerland).**Results:** When tested with *in-silico* PCR the primers and probe combination were 100% accurate in identifying *stx*$_{2e}$ and *stx*$_{2f}$ strains. Laboratory testing of the primers and probe correctly identified all isolates: *stx*$_{2e}$ positive strains (6), *stx*$_{2f}$ positive strains (33), and *stx*$_{2e/f}$ negative STEC strains (32) all tested in duplicate. To test assay robustness, the concentration of primer and probe mixes were varied and made a minimal difference in detection of target positive and negative strains.**Conclusions:** We developed a singleplex real-time PCR assay that accurately detects *stx*$_{2e}$ and *stx*$_{2f}$ isolates in a rapid, cost-effective and high-throughput manner. This assay should help reference and diagnostic laboratories more efficiently identify these two Shiga toxin subtypes.

Detection of Shiga-toxin Producing *Escherichia coli* (Stec) in the Era of Molecular Diagnostics: A Retrospective Study

Author Block:

M. J. Lee, K. H. Jerke, R. B. Mirasol, R. M. Humphries; David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract Body:

Background: Our laboratory recently replaced routine testing for Shiga-toxigenic Escherichia coli (STEC) from an enzyme immunoassay (EIA) method, to a multiplex stool pathogen PCR that detects STEC (BD Max Bacterial Enteric Panel). Since implementation, we identified a significant increase in the detection of STEC, from 5 over a 30-month period (pre-PCR) to 20 in the first 4 months of testing by the BD MAX. We sought to validate the STEC results by a second method, to confirm performance of this target among our patient population. **Methods:** Twenty remnant, frozen stool specimens that tested positive for STEC by the BD MAX were re-processed using the same method. In parallel, a second PCR was performed to detect and differentiate Stx-1 and Stx-2. Primer/probe used for the second PCR were as described elsewhere (Grys et al, JCM 2009;47(7):2008-2012), and PCR was performed on an LC 480 (Roche Diagnostics) thermocycler. An EIA was performed per manufacturer's instructions (ImmunoCard STAT EHEC, Meridian Biosciences, Inc.). UCLA institutional review board approval was obtained to conduct review of patient charts. Charts for 2 patients were not available for review.**Results:** Upon repeat testing, 16/20 STEC specimens were confirmed as STEC positive by both PCR assays (BD MAX and RT-PCR), but only one was positive by EIA (6.25% agreement). Four samples tested negative by all methods, possibly due to freeze/thaw loss of target. Among the STEC PCR-positive patients, 33% (6/18) had watery diarrhea, 39% (7/18) exhibited bloody diarrhea, 45% (8/18) traveled abroad, and 28% (5/18) had chronic gastrointestinal disorders (CGID). In contrast, among the 5 patients positive for STEC prior to implementation of the PCR, 60% (3/5) exhibited bloody diarrhea, 20% (1/5) traveled abroad, and 60% (3/5) had indications for CGID.**Conclusion:** Collectively, our data suggest the increase in STEC positivity is due to: 1) increase in sensitivity associated with PCR-based testing, and 2) routine screening for STEC among all patients with stool submitted for bacterial pathogen testing. Additional studies and clinical data are needed to further evaluate STEC colonization and the clinical value of PCR testing.

Improvements in Sample Collection, Nucleic Acid Extraction and Target Quantification to Optimize Enteropathogen Detection

Author Block:

J. Liu[1], C. Amour[2], R. Nshama[2], A. Maro[3], J. Gratz[1], J. Platts-Mills[1], E. Houpt[1]; [1]Univ. of Virginia, Charlottesville, VA, [2]Haydom Global Hlth.Inst., Haydom, Tanzania, United Republic of, [3]Kilimanjaro Clinical Res. Inst., Moshi, Tanzania, United Republic of

Abstract Body:

Background: Diarrhea remains the second leading cause of death for children under five worldwide. Detection of enteropathogens from stool may be technically challenging in several aspects, including stool sample collection and transport, nucleic acid extraction, detection of a broad panel of enteropathogens, and target quantification. **Methods:** 173 diarrheal specimens from Tanzanian children were collected with both flocked rectal swab and stool, and pathogen detection was compared. Nucleic acid extracted from a single procedure (TNA) using QIAamp Stool DNA mini kit was compared with combined extracts from separate DNA and RNA extractions (DNA+RNA) on 41 stool samples. Both comparisons were performed with qPCR on TaqMan Array Card interrogating 32 enteropathogens. Standard curves were generated with combined positive controls on TAC and utilized to derive target copy numbers from quantification cycle. Stool spiked with known number of targets were used to demonstrate the principle of quantification.**Results:** *Pathogen detection on swabs.* Comparing to qPCR results on stool, swab yielded higher Cqs (29.7±3.5 vs. 25.3±2.9 on stool, $P<0.001$). >90% of the detection with Cq<25 on stool were also positive by swab.*Total nucleic acid extraction.* 88% (318/361) of the positive results from TNA and DNA+RNA were concordant between the two. There was no significant difference in Cqs between TNA and DNA+RNA ($\Delta Cq_{(DNA+RNA-TNA)} = -0.01 \pm 1.17$, $P = 0.972$, N = 318).*Target quantification.* All the assays exhibited good linearity with 90% - 110% PCR efficiency and 0.990 to 1 Pearson coefficient. After normalization to external controls, the derived target copy numbers were within 0.5 fold of the starting materials (59.3±31.9%).**Conclusion:** Swab can be used as an alternative for specimen collection, especially where flexibility is needed; A single nucleic acid extraction procedure using QIAamp Stool DNA mini kit was sufficient to recover total nucleic acid; A comprehensive panel of enteropathogens were interrogated with TAC; A quantification scheme with normalization to external controls is established, which enables reporting adjusted target copy numbers.

Publishing Title:

Impact of Filmarray Gi Panel on *Shigella* Outbreak Management

Author Block:

N. KANWAR, J. Jackson, R. Selvarangan; Children's Mercy Hosp. and Clinics, kansas City, MO

Abstract Body:

Background: Shigellosis is the third most common enteric disease in the United States with highest incidence in children less than five years. Fecal culture for isolation and identification of *Shigella* may take days. The FilmArray Gastrointestinal (GI) Panel is a PCR based assay that detects 22 different enteric pathogens including *Shigella* in an hour. The aim of this study is to evaluate the impact of GI Panel detection of *Shigella* in an emergency department (ED) during an outbreak.**Methods:** Children with acute gastroenteritis were prospectively enrolled and stool specimens were tested by GI Panel. Test results were either withheld in pre-intervention (PRE) or reported to clinicians/families in post–intervention (POST) period during the current *Shigella* outbreak in Kansas City area. The impact of the GI Panel testing on patient management and outcomes was measured.**Results:** To date, 188 subjects (139 PRE and 49 POST) have been enrolled in the study. *Shigella* was identified by GI Panel in the PRE (N=30) and POST (N=11) phase. Diarrhea was the most common symptom in subjects (median age of 46 (6-168) and 70 (16-175) months). During PRE phase, *Shigella* was isolated in 8/10 stool cultures requested as standard of care. In the POST phase, *Shigella* was isolated in 9/11 stool cultures set up per study protocol. Azithromycin therapy was prescribed for 3 (10%) subjects in the PRE phase and 5 (45.5%) subjects in the POST phase (*P*=0.02). Decision to treat *Shigella* infection with Azithromycin therapy seem to be influenced by severity of infection as measured by number of diarrheal episodes (treated: 8(4-20) stools *vs.* not treated: 2.5(1-13) stools) and onset of illness (treated:1(1-6)days *vs.* not treated: 3(1-4)days). Following initial visit to ED, six subjects in PRE phase visited additional providers compared with none in the POST phase (*P*=0.17). More parents missed work days in PRE phase (43%) as compared with POST phase (36%) (*P*=0.7). Similarly, more subjects missed school/daycare in PRE phase (73%) compared with POST phase (55%) (*P*=0.3).**Conclusion:** Prompt diagnosis of shigellosis with the FilmArray GI Panel may provide opportunity for prompt antimicrobial therapy and avoid additional visits to providers due to early definitive diagnosis. Laboratory diagnosis of *Shigella* at ED visit has the potential to optimize patient management, and reduce spread of disease.

Compatibility of Alcorfix, for *Giardia* and *Cryptosporidium* Antigen Testing

Author Block:

B. Couturier[1], **M. R. Couturier**[2]; [1]ARUP Lab., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: Our laboratory recently converted to a single-vial stool fixative (Alcorfix) for ova & parasite testing; eliminating formalin from our laboratory and simplifying specimen processing. A limitation with this change is requiring an additional frozen stool aliquot for parasitic antigen testing. Alcorfix compatibility with antigen detection ELISAs has not been evaluated and it is unknown whether the low concentration of polyvinyl alcohol (PVA) is inhibitory. We assessed and validated Alcorfix for detection of *Giardia* and *Cryptosporidium* [Crypto] antigens and whether concentrated stool sediments were also compatible.**Methods:** Unpreserved stools previously tested by antigen detection ELISA for Crypto or *Giardia* were collected. Aliquots of the stool were preserved in Alcorfix at a 1:3 ratio and spiked with various concentrations of Crypto oocysts (n=40) or *Giardia* cysts (n=40). Spiked specimens of each organism were also concentrated using a Parasep concentrator tube. The pellet and the supernatant were tested for the presence of Crypto or *Giardia* antigen by ELISA. The pellet was tested like a fresh stool specimen (1:4 in diluent). The supernatant was directly tested without dilution. Antigen stability for the Crypto and *Giardia* in Alcorfix was also assessed.**Results:** The analytical sensitivity was 100% (40/40) for the detection of *Giardia* and 92.5% (37/40) for Crypto. The majority of *Giardia* antigen was reactive in the pellet rather than the supernatant. Crypto antigen was also concentrated in the pellet though there was still significant reactivity in the supernatant. The stability of the antigens in Alcorfix was limited to 7 days with Crypto (vs 14 days frozen unpreserved) and 14 days for Giardia (same as unpreserved).**Conclusions:** Alcorfix, despite containing PVA, is compatible with *Giardia* and Crypto antigen testing by ELISA. A pellet from concentrated stool is suboptimal for detecting Crypto, as low parasite burden specimens may not be detected. Furthermore, the supernatant from the concentrated stool specimen is not acceptable for antigen testing. Using a Parasep tube with Alcorfix is a compatible combination for Giardia and Crypto antigen detection only when the entire sample is filtered, pelleted, and then resuspended before testing. The remaining suspension can then be pelleted again for further microscopic examination as needed.

Cost and Turnaround Time Analysis Comparing Routine Stool Culture to Bd Max Enteric Bacterial Panel for Routine Identification Bacterial Stool Pathogens

Author Block:

K. A. Bryant, V. Hoover; Orlando Helath, Orlando, FL

Abstract Body:

Background: Routine stool culture is the most commonly used method in the clinical microbiology laboratory to identify bacterial pathogens causing infectious diarrhea. Laboratories must provide cost effective methods with the shortest turnaround times (TAT) to provide the best patient care. A retrospective study was performed comparing cost and TAT of the BD Max Enteric Bacterial Panel (EBP) to routine stool culture. **Methods:** Routine stool culture and the EBP detect *Salmonella* spp., *Campylobacter jejuni/coli*, *Shigella* spp. and Shiga-toxin producing *E. coli*. Costs comparison of routine stool culture to EBP was performed using July-October 2015 volumes, expense reports, and estimated technologist time for each method. TAT analysis was performed comparing the average time to final result using EBP (July-October 2015) to the same period the previous year (July-October 2014). **Results:** In the period between July and October 2015, a total of 1387 EBP's were performed with the following results: 1272 no organism detected, 27 *Shigella*, 65 *Salmonella*, 20 *Campylobacter* and 3 Shiga Toxin positive *E. coli* were detected. Cost comparison between EBP and stool culture show EBP was 21% ($9,803.64) more expensive than stool culture. The EBP had significant hands on technologist time savings 231 hours compared 836 hours for stool culture. TAT analysis comparing July-October showed a significant difference between EBP and stool culture reducing TAT by 81% (49 hours). **Conclusion:** The enteric bacterial panel allows significant reductions in TAT and technologist hands on time with a 21% increase in cost.

Implementation of Culture-independent Testing of Gastrointestinal Pathogens in the Clinical Laboratory

Author Block:

R. C. Fowler[1], C. N. Murphy[1], P. C. Iwen[2], P. D. Fey[1]; [1]Univ. of Nebraska Med. Ctr., Omaha, NE, [2]Nebraska Publ. Hlth.Lab., Omaha, NE

Abstract Body:

Background: Culture-independent testing such as the Biofire FilmArray™ GI Panel (FGIP) has improved sensitivity for the identification of infectious causes of gastroenteritis. The FGIP was implemented at our institution in January 2015 to replace traditional methods for the detection of gastrointestinal (GI) pathogens. The purpose of this study was to evaluate the detection rates of GI pathogens with the FGIP and the incidence of GI pathogens detected by the FGIP in 2015 compared to traditional methods in 2014. **Methods:** Stools submitted for FGIP testing from January to December 2015 were evaluated. Stools with *Clostridium difficile* detected were also tested by EIA. The incidence of GI pathogens detected by the FGIP in 2015 was compared to those reported by traditional methods in 2014. Sapovirus, Astrovirus, diarrheagenic *Escherichia coli* (EAEC, EPEC, ETEC), and *C. difficile* were excluded from comparative analyses. **Results:** A total of 2255 stools were tested by the FGIP with ≥ 1 pathogen detected in 910 (40.4%). Among the 910, coinfections were detected in 176 (19.3%) with 2 and ≥ 3 pathogens detected in 145 (15.9%) and 30 (3.3%) of the positive specimens, respectively. The highest rates of detection with the FGIP were observed for *C. difficile* (336 at 14.9%), EPEC/EAEC (234 at 10.4%), Norovirus (196 at 8.7%), *Campylobacter* spp (51 at 2.3%), Sapovirus (44 at 2.0%), and Rotavirus A (36 at 1.6%). Each of the remaining FGIP pathogens had a detection rate of ≤ 1.5%. Of the 336 *C. difficile* detected by the FGIP, only 87 (25.9%) were toxin positive by EIA. Most GI pathogens showed an increased incidence from 2014 to 2015, respectively: *Campylobacter* spp. (18 and 51), *Salmonella* (16 and 30), *Shigella*/EIEC (3 and 15), shiga toxin producing *E. coli* (12 and 32), *Plesiomonas shigelloides* (1 and 11), *Vibrio* spp (0 and 4), *Yersinia enterocolitica* (0 and 10), Norovirus (115 and 196), Rotavirus (8 and 36), *Giardia lamblia* (7 and 17), and *Cryptosporidium* (5 and 28). **Conclusions:** Implementation of the FGIP increased the cases of infectious gastroenteritis detected and provided increased awareness of coinfections. These data suggest that the FGIP can be used to monitor trends in disease incidence and aid in clinical decision-making. Ongoing studies are being done to assess the impact the FGIP has on public health practices and patient outcomes.

Performance of the Artus *Clostridium difficile* Qs-rgo Kit for the Detection of Toxigenic *Clostridium difficile*

Author Block:

H. Kim[1], H-W. Moon[1], M. Hur[1], H. Kim[2], Y-M. Yun[1]; [1]Konkuk Univ. Sch. of Med., Seoul, Korea, Republic of, [2]Yonsei Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: *Clostridium difficile* is the most common cause of healthcare-associated diarrhea, and nucleic acid amplification testing for the direct detection of toxigenic *C. difficile* is commonly used. We evaluated the diagnostic performance of newly launched, artus *C. difficile* QS-RGO Kit (artus *C. difficile*, QIAGEN, Hilden, Germany), in comparison with toxigenic culture and Xpert C. difficile (Cepheid, Sunnyvale, CA, USA).**Methods:** In prospectively collected, 261 diarrheal specimens, the artus *C. difficile* and the Xpert *C. difficile* assays were performed. Toxigenic culture using chromogenic agar (chromID CD agar, bioMerieux, Marcy-l'Etoile, Frace) was used a reference method.**Results:** Based on toxigenic culture, the sensitivity and specificity of the artus C. difficile were 98.2% and 93.6%, respectively, and those of the Xpert C. difficile were 94.6% and 94.6%, respectively; there was no statistical difference. Te agreement between the artus *C. difficile* and the Xpert *C. difficile* was almost perfect (weighted kappa = 0.918).**Conclusions:** The performance of the artus *C. difficile* is excellent compared with toxigenic culture and is comparable to that of the Xpert *C. difficile*. The artus *C. difficile* could be a useful diagnostic option for the direct detection of toxigenic *C. difficile* in clinical laboratories.

Potential of the Intergenic Spacer Profiling (Is-Pro) Technique for Simultaneous Assessment of the Intestinal Microbiome and *Clostridium difficile* Ribotyping in Patients with *Clostridium difficile* Infection

Author Block:

J. van Prehn, C. M. J. E. Vandenbroucke-Grauls, Y. H. van Beurden, A. E. Budding; VU Univ. Med. center, Amsterdam, Netherlands

Abstract Body:

Background: *Clostridium difficile* infection (CDI) often arises after antibiotic therapy and is thought to be caused by disruption of the intestinal microbiome, which facilitates outgrowth of toxigenic *C. difficile.* Strain ribotyping is important for hospital epidemiology, as some ribotypes appear to be more virulent than others. We aimed to assess the potential of the high-throughput intergenic spacer profiling (IS-pro) technique for *C. difficile* ribotyping and intestinal microbiome analysis in CDI patients.**Methods:**The intergenic spacer profiling (IS-pro) technique is based on length polymorphisms of the 16S-23S rDNA interspace region which is used for instant species identification by phylum-specific fluorescently labelled PCR primers. The *Firmicutes* primer was used to generate intergenic spacer (IS) profiles of 37 *C. difficile* isolates with known ribotypes: 027 (n=8), 014 (n=8), 001 (n=6), 002 (n=5), 078 (n=5), 015 (n=4) and 106 (n=1). In addition, a pilot study was performed in which the microbiota richness and diversity on the day of CDI diagnosis of was assessed in 7 patients who developed recurrent CDI and in 14 patients who did not developed a recurrence.**Results:**The IS profiles of the isolates clustered as expected by their known ribotype: all strains of each ribotype showed identical profiles, except for one 001 strain that showed a profile identical to the 027 strains, and one 015 strain that showed a unique profile. The peak profiles were concordant with profiles of a recently published international standardized protocol for capillary gel-based electrophoresis PCR-ribotyping.[1] The pilot microbiota study showed a decrease in diversity of *Firmicutes* in patients with recurrent CDI, compared to patients without.**Conclusions:**IS-pro is a useful tool for both *C. difficile* ribotyping and intestinal microbiome analysis. The predictive value of these analyses for CDI outcome should be evaluated in a prospective clinical trial.

Comparison of Diagnostic Algorithms for Detection of Toxigenic *Clostridium difficile* in Routine Practices at a Tertiary Referral Hospital in Korea

Author Block:

H. Kim[1], H-W. Moon[1], M. Hur[1], H. Kim[2], Y-M. Yun[1]; [1]Konkuk Univ. Sch. of Med., Seoul, Korea, Republic of, [2]Yonsei Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: Since every single test has some limitations for the diagnosis of *Clostridium difficile* infection (CDI), multistep algorithms are recommended. This study aimed to compare the currently representative diagnostic algorithms and assays for the detection of CDI, using VIDAS *C. difficile* toxin A&B (toxin ELFA) and VIDAS *C. difficile* GDH (GDH ELFA, bioMerieux, Marcy-l'Etoile, France), and Xpert *C. difficile* (Cepheid, Sunnyvale, California, USA).**Methods:** Using 271 consecutive, remnant diarrheal stool specimens, toxigenic culture, toxin ELFA, GDH ELFA, and Xpert *C. difficile* were performed. We simulated two algorithms including screening by GDH ELFA and confirmation by Xpert *C. difficile* (GDH + Xpert) and combined algorithm of toxin ELFA, GDH ELFA, and Xpert *C. difficile* (GDH + Toxin + Xpert). The performances of each assay and algorithms were assessed.**Results:** The agreement of toxin ELFA and GDH ELFA with toxigenic culture were weak and moderate (Kappa, 0.564 and 0.678, respectively). The agreement of Xpert *C. difficile* and two algorithms (GDH + Xpert and GDH + Toxin + Xpert) with toxigenic culture were strong (Kappa, 0.848, 0.857 and 0.868, respectively). The Xpert *C. difficile* demonstrated sensitivity, specificity, PPV and NPV of 94.6%, 94.9%, 82.5%, and 98.6%, respectively. Those of algorithms (GDH + Xpert and GDH + Toxin + Xpert) were 96.7%, 95.8%, 85.0%, 98.1%, and 94.5%, 95.8%, 82.3%, 98.5%, respectively. There were no significant differences between Xpert *C. difficile*, GDH + Xpert, and GDH + Toxin + Xpert in sensitivity, a specificity, PPV and NPV (all $P>0.05$).**Conclusions:** Both algorithms showed comparable performances to that of Xpert *C. difficile*. This data would be helpful to choose the diagnostic algorithms for detection of CDI in clinical laboratories. Each laboratory may optimize the workflow depending on costs, test volume, and clinical needs.

Validation Of The Fecalswab As A Transport Medium For Detection Of *c. Difficile* using The Xpert *c. Difficile* assay

Author Block:

M. Faron[1], E. Beck[2], B. W. Buchan[1], **N. A. Ledeboer**[1]; [1]Med. Coll. of Wisconsin, Milwaukee, WI, [2]Wisconsin Diagnostic Lab., Milwaukee, WI

Abstract Body:

Background: Liquid based microbiology (LBM) eases transport of specimens and improves specimen yield compared to cotton swabs; however, many FDA-cleared molecular assays were not cleared using LBM specimens. For this reason it is unclear how the differences in matrix and specimen loading with these devices will affect test performance. The purpose of this study was to determine the amount of FecalSwab medium required (Copan Diagnostics, Inc. Murrieta, CA) to obtain equivalent results to cotton swabs with the Cepheid Xpert *C. difficile* assay (Cepheid, Sunnyvale, CA).**Methods:** *C. difficile* strain BAA-1875 was spiked into *C. difficile* negative stool to create surrogate specimens containing 10 times the limit of detection (LOD) of the assay. FecalSwab collection devices were inoculated with at least 200mg of spiked specimen ensuring the max fill line was not exceeded and varying amounts of the FecalSwab liquid medium ranging from 200µL to 1mL were added to the Xpert sample vial, vortexed, and loaded into the cartridge. A cotton swab loaded with the spiked stool specimen was also tested in parallel following the FDA-cleared package insert protocol to compare CT values. Analytical sensitivity was determined by spiking stool specimens at 10^6, 10^5 and 10^4 CFU/mL in triplicate using the optimal volume of FecalSwab medium obtained in the previous experiment.**Results:** When FecalSwab collection devices were inoculated with stool specimens containing *C. difficile* near the limit of detection, toxin B nucleic acid could be detected in all volumes tested except a single 200µL test. Analytical sensitivity and Ct values were equivalent between cotton swabs and FecalSwabs when using 400µL of FecalSwab medium. No inhibition of the internal control was detected with any amount of FecalSwab medium. All stool specimens with both transport devices at 10^6 CFU/mL were positive for *C. difficile*. At 10^5 CFU/mL each collection device was positive in 1of 3 tests. No positive specimens were detected at 10^4 CFU/mL.**Conclusions:** These data demonstrate that 400µL of FecalSwab medium provides equivalent analytical results compared to the FDA-cleared protocol for the Xpert *C. difficile* assay. Future studies evaluating the clinical performance of FecalSwab collection devices compared to the FDA-cleared collection will also be discussed.

Prevalence of *C. diffile* Toxin in Patients Positive by Polymerase Chain Reaction (Pcr)

Author Block:

C. Bittencourt[1], J. Ciurca[2], F. Lee[1], **R. Hollaway**[1]; [1]UT Southwestern Med. Ctr., Dallas, TX, [2]William P. Clements Jr. Univ. Hosp., Dallas, TX

Abstract Body:

Clostridium difficile infection (CDI) is the major infective cause of nosocomial diarrhea in adults. *C difficile* exerts its pathologic effects through the action of toxin A (TcdA) and toxin B (TcdB). Conventional laboratory methods for diagnosis of CDI (cell culture cytoxicity, neutralization assay, toxigenic culture and toxin immunoassay) can be time consuming, labor intensive and/or insensitive. Molecular amplification tests are now often used for detection of *C. difficile* toxin B gene sequences.We compared the performance of *C DIFF* QUIK CHEK COMPLETE® (Alere North America, Orlando, Florida) to Xpert® *C. difficile* assay (Cepheid, Sunnyvale, California) to determine the presence of toxin in patients who had a positive PCR result. Xpert® *C. difficile* PCR detects the gene for *C. difficile* toxin B in stool samples. Alere is a membrane enzyme immunoassay for the detection of *C. difficile* glutamate dehydrogenase antigen (GDH) and toxin A and B.From October 2015 to January 2016, stool samples were submitted to the microbiology laboratory for *C. difficile* testing by Xpert®. Specimens were subsequently tested by Alere to determine the presence of toxin. Thirty percent (24/79) were tested within 72h of collection and 70% (55/79) were frozen samples. *C. difficile* culture with reflex to cytotoxin cell assay is underway to evaluate the 40 discrepant samples.A total of 79 diarrheal stool samples were analyzed by Xpert® and Alere. Eighty-seven percent (69/79) were PCR positive and 13% (10/79) were PCR negative. Of the PCR positive samples, 43% (30/69) were GDH and toxin positive, 54% (37/69) were only GDH positive and 3% (2) were GDH and toxin negative. Positive agreement for the presence of *C. difficile* was 97% (67/69), negative agreement was 90% (9/10) and overall agreement was 96% (76/79).Between the two assays, we found excellent overall agreement for C. *difficile* detection. However, detectable toxin in PCR positive samples was found in only 43% of the cases. Given the sensitivity limitations of current toxin assays and inability to distinguish disease from colonization using PCR, the diagnoses of CDI is still a challenge. Appropriate patient selection and an algorithmic testing approach might improve diagnostic accuracy for CDI. We are seeking IRB approval for chart review of cases to develop an appropriate testing strategy.

Fecal Calprotectin as an Surrogate Marker for Clinical Diagnosis of *Clostridium difficile* infection in Cancer Patients

Author Block:

T. He[1], S. Kaplan[1], L. Gomez[1], X. Lu[2], L. V. Ramanathan[1], M. Kamboj[1], Y-W. Tang[1]; [1]Mem. Sloan Kettering Cancer Ctr., New York, NY, [2]Futian Hosp., Guangdong Med. Coll., Shenzhen, China

Abstract Body:

Background: Fecal calprotectin (fCPT) has been used as a surrogate marker for inflammation in several gastrointestinal disorders. We explore the utility of fCPT values as a diagnostic aid to distinguish between *C. difficile* infection (CDI) and *C. difficile* colonization (CDC) in cancer patients. **Methods:** From January 2012 to December 2013, 232 stool specimens from 156 patients were randomly selected from patients with diarrhea where stool was submitted for the GeneXpert *C. difficile* PCR and additional testing at MSKCC. The 232 samples included 80 patients with single specimens (PCR-negative, n=39; PCR-positive, n=41) and 76 patients with paired specimens with one *C. difficile* PCR result - negative to positive (n=38) and from positive to negative (n=38), respectively. All specimens were tested for (i) fCPT by the Phical Test (Calpro AS, Oslo, Norway) and (ii) *C. difficile* glutamate dehydrogenase (GDH) and toxin A/B antigens (TechLab, Blacksburg VA). Clinical severity of CDI cases was determined blindly by the IDSA/SHEA severity scoring criteria. **Results:** The Phical Test quantitatively detected 343.3±548.8 (mean±S.D.) µg/g stool of fCPT in 232 stool specimens. There were no significant differences of fCPT values between CDI (n=110; 354.8±384.0) and non-CDI (n=122; 336.8±443.8) groups ($p>0.05$). However, fCPT values were significantly higher in CDI than those without CDI in patients with single (375.4±361.4 vs. 237.0±319.2, $p=0.035$) specimens. Similar results were revealed in severity score determination. Although there were no significant differences in fCPT values between patients with mild-moderate (n=190) and with severe-complicated (n=42) scores ($p>0.05$), fCPT values were significantly higher in severe-complicated than those in mild-moderate scores in patients with single (412.4±479.6 vs. 270.9±286.1, $p=0.039$) and positive to negative paired (729.3±509.0 vs. 437.0±661.2, $p=0.045$) specimens. **Conclusion:** The fCPT values were significantly higher in patients with CDI and severer clinical manifestations than non-CDI and milder clinical manifestations in patients with single specimens collected. The fCPT values provide a potential adjunctive tool to differentiate between CDI and CDC in cancer patients with diarrhea.

Comparison of a Combination Assay for *Clostridium difficile* Gdh Antigen and Toxins A and B Plus the *C. difficile* Lamp Assay with Physicians' Clinical Evaluation of the Patient's Medical Record to Determine True *C. difficile* Disease

Author Block:

E. Francis, T. Crook, M. Ali, W. Greene; Penn State Coll. of Med. M.S. Hershey Med. Ctr., Hershey, PA

Abstract Body:

Background: *C. difficile* may cause serious nosocomial infections. Toxin detection assays lack sensitivity to detect all infections, however molecular assays that detect the toxin genes lack clinical specificity to differentiate patients with disease from those that are carriers.**Methods:** We evaluated 250 unformed fecal specimens using the *C. DIFF QUIK CHEK COMPLETE*, that detects GDH antigen and toxins A/B in a single assay. All specimens were also tested using the *illumigene C. difficile* LAMP assay to detect the presence of the toxin A gene. Three infectious disease physicians performed retrospective chart reviews on 24 patients that were found to be positive by any of the assays. The reviewers were blinded to which 12 specimens were positive by all assays and which 12 were positive by the GDH and molecular assays but negative by the toxin assay. All 3 reviewers used a defined list of clinical criteria for the evaluations.**Results:** Fecal samples (N=250) submitted for *C. difficile* molecular assay were included in this study. One hundred ninety-seven specimens were negative for all 3 targets (GDH, toxin and toxin gene) and 24 were positive for all 3. Seventeen were positive for the GDH antigen only and were not considered to contain toxigenic *C. difficile*. All specimens that were positive by the molecular assay were also positive by the GDH assay. Twelve patients with specimens that were positive for all 3 targets and 12 with specimens that were positive for GDH antigen and the toxin gene but were negative for the toxins were selected for chart review. The reviewers determined that 9/12 of the specimens that were positive for all 3 targets came from patients that met the criteria for *C. difficile* disease. They determined that 8/12 that were positive for GDH and the toxin gene but negative for the antigen toxin also met the criteria for *C. difficile* disease.**Conclusions:** This study has shown that a negative GDH result can be used to identify negative specimens and a positive toxin antigen test can be used to identify positive specimens. The presence or absence of toxin antigens and toxin genes can not be used alone to differentiate patients with *C. difficile* disease from those that are carriers.

Characterizing the *Clostridium difficile* Volatilome

Author Block:

C. A. Rees[1], M. Nasir[1], T. R. Mellors[1], A. Shen[2], J. E. Hill[1]; [1]Dartmouth Coll., Hanover, NH, [2]Univ. of Vermont, Burlington, VT

Abstract Body:

Background: *Clostridium difficile* is a nosocomial pathogen capable of causing pseudomembranous colitis (PMC), a life-threatening disease of the large intestine. Current diagnostic techniques for PMC are limited by low sensitivity, long assay times, and the inability to differentiate between *C. difficile* infection and colonization. Here, we report on a suite of volatile molecules produced by *C. difficile* that could inform the development of a novel, rapid, and highly-accurate diagnostic for PMC.**Methods:** *C. difficile* strain R20291 (isolated from a PMC outbreak) was grown in brain-heart infusion supplemented (BHIS) broth for 4 and 7 hours, corresponding approximately to mid-exponential and stationary growth phases, respectively. Culture supernatants were transferred to air-tight vials, and volatile metabolites were analyzed using GCxGC-TOFMS. The Mann-Whitney U test with Benjamini-Hochberg correction was used to identify volatiles that differed in relative abundance ($p < 0.05$) between mid-exponential and stationary phase cultures. **Results:** GCxGC-TOFMS detected 1079 unique volatile molecules in the headspace of *C. difficile* samples. After eliminating volatile molecules that were also present in media controls, 331 unique volatiles remained that likely represent the consequence of bacterial metabolism. 155 of these differed significantly in relative abundance between cultures at mid-exponential and early stationary phases of growth. Amongst those volatiles that could be assigned putative identifications, the most abundant classes of compounds included sulfur-containing molecules (42.8%), carboxylic acids (8.2%), aldehydes (8.2%), ketones (7.5%), and esters (7.5%). Derivatives of heterocyclic molecules accounted for the majority of observed sulfur-containing compounds, including several that are not previously reported.**Conclusion:** *C. difficile* produces heterocyclic sulfur-containing metabolites when grown in BHIS, which have potential diagnostic value. Volatile biomarkers produced by *C. difficile* in the setting of PMC could inform the development of a rapid, minimally-invasive diagnostic, potentially reducing time-to-diagnosis and improving outcomes.

Comparison of Collection Methods for Oral and Fecal Samples in Microbiome Studies

Author Block:

E. Vogtmann[1], J. Chen[2], A. Amir[3], J. Shi[1], C. Abnet[1], H. Nelson[2], R. Knight[3], N. Chia[2], R. Sinha[1]; [1]Natl. Cancer Inst., Bethesda, MD, [2]Mayo Clinic, Rochester, MN, [3]Univ. of California San Diego, La Jolla, CA

Abstract Body:

Background: Large, prospective cohort studies are needed to evaluate the temporal relationship between the microbiome and health and it is important to be able to collect samples at home. We evaluated the technical reproducibility, stability at ambient temperature, and accuracy of five fecal collection methods (no additive, 95% ethanol, RNA*later*, fecal occult blood test (FOBT), and the fecal immunochemical test (FIT)) and two oral collection methods (OMNIgene DISCOVER and Scope mouthwash). **Methods:** Fifty-three healthy volunteers were recruited from the Mayo Clinic. Oral and fecal samples were collected. One set of each oral and fecal sample collection type was frozen immediately and a second set was left at room temperature for 96 hours and then frozen. DNA was extracted using the MO-BIO PowerSoil kit and the V4 region of the 16S rRNA gene was amplified. Intraclass correlation coefficients (ICC) were calculated for the relative abundance of three phyla, two alpha and four beta diversity metrics. **Results:** For technical reproducibility, the ICCs for all of the duplicate fecal samples frozen immediately were high. For stability, the ICCs were high for all collection types, although the methods tended to have lower ICCs for the relative abundance of the three phyla and weighted UniFrac. When compared to fecal samples frozen immediately, the FOBT cards had the highest ICCs. For the oral samples, Scope mouthwash samples were fairly stable, but accuracy was low compared to the OMNIgene kit frozen immediately. **Conclusions:** The methods for fecal sample collection appeared to be relatively reproducible, stable, and accurate. Scope mouthwash samples were relatively stable, although appeared to differ from oral samples collected using the OMNIgene kit. Future studies could utilize these collection methods to assess the impact of the oral and gut microbiome on health.

Utility of Perirectal Swabs for Analysis of Intestinal Bacterial and Fungal Biomes of Geriatric Long-term Care Facility Residents

Author Block:

M. E. Tomas[1], M. A. Retuerto[2], B. M. Wilson[1], S. Kundrapu[2], P. K. Mukherjee[2], M. A. Ghannoum[2], C. J. Donskey[1]; [1]Cleveland VA Med. Ctr., Cleveland, OH, [2]Case Western Reserve Univ., Cleveland, OH

Abstract Body:

Background: Characterization of the intestinal biome has led to better understanding of the interplay of organisms in healthy and diseased states. Fecal specimens are most often used for analysis. However, collection of fecal specimens can be challenging in real-world settings such as hospitals and long-term care facilities (LTCFs). In particular, it is often not possible to collect baseline specimens prior to antibiotic therapy or other interventions. Therefore, we evaluated the utility of perirectal swabs for analysis of the intestinal bacterial and fungal biomes of LTCF residents.**Methods:** We collected paired fecal and perirectal swab specimens from LTCF residents. Fecal specimens were cultured for *Clostridium difficile* and fluoroquinolone-resistant gram-negative bacilli. 16S RNA next generation sequencing was used to analyze the bacterial and fungal biomes and results for fecal and perirectal swab specimens were compared.**Results:** 18 paired fecal and perirectal swab specimens were collected from 12 LTCF residents (1-3 specimens per patient). The mean age of the residents was 75 (range, 65-87). Four (33%) residents had received antibiotics within the past 90 days. All 4 antibiotic-exposed LTCF residents were colonized with *C. difficile* and/or fluoroquinolone-resistant gram-negative bacilli, whereas none of the residents with no recent antibiotic exposure were colonized. For both fecal and perirectal swabs, the predominant bacterial phyla were Firmicutes and Bacteroides, while the predominant fungal phyla were Ascomycota, Basidiomycota, and unculturable fungi. All bacterial and fungal genera identified in fecal samples were also identified by perirectal swabs. There was no significant difference in bacterial or fungal diversity based on Shannon's diversity index.**Conclusions:** For analysis of intestinal bacterial and fungal biomes of LTCF residents, perirectal swab and fecal specimens correlated well. Perirectal swabs may provide a relatively non-invasive and convenient method to collect specimens for characterization of the intestinal bacterial and fungal biomes.

Theoretical Impact of a Multiplex Gastrointestinal Pcr Panel on Patient Outcomes

Author Block:

G. J. Berry, L. Suazo, G. Nair, A. C. White, M. Loeffelholz; Univ. of Texas Med. Branch, Galveston, TX

Abstract Body:

Diarrhea is among the most common infectious disease syndromes with numerous causes that are often not clinically distinguishable. Current diagnostic testing strategies have significant limitations and are not prompt, leading to inappropriate empiric treatment. Multiplexed molecular testing panels have led to an ability to test more pathogens simultaneously, increase testing sensitivity, and dramatically shortening turn-around time. We evaluated current testing trends in our lab and evaluated how implementation of the FilmArray Gastrointestinal (GI) panel could theoretically improve testing and patient outcomes. 98 stool specimens were tested from September to December 2014 from inpatients (hospitalized within 3 days) and out-patients. A combination of a convenience sample set (positive by routine methods) and a prospective sample set (routine stool cultures), were tested. Demographics, clinical presentation, additional tests, all laboratory results, empirical treatment, and number of health care provider revisits were recorded.The FilmArray GI panel detected twice the number of pathogens as compared to current testing methods. Viral causes of diarrhea were most often missed, followed by cases of Diarrheagenic *E. coli*. Multiple *C. difficile* cases were also missed by routine testing. In addition, traditional stool culture missed 2/8 and 2/2 cases of *Campylobacter* and *Plesiomonas*, respectively. Chart review demonstrated both overtreatment (e.g. viral infections given antibiotics) and undertreatment (*C. difficlie, Campylobacter, E. coli*, and *Plesiomonas* not given antibiotics). Multiple episodes had 2 or more duplicated tests ordered, with 1/3 of patients having 3 or more tests. Several outpatient revisits, Emergency Department visits and hospitalizations for the same episode of diarrhea were also recorded, emphasizing the need for accurate diagnoses during the initial patient visit.In summary, current testing paradigms for diarrhea-causing pathogens are limited by limited sensitivity and the requirement for multiple tests. This leads to costly improper therapy and additional use of inpatient and outpatient facilities. Implementation of a multiplex molecular assay for these pathogens as a diagnostic tool for diarrheal illnesses would potentially aid diagnosis and treatment, leading to better patient outcomes.

Adaptive Focused Acoustics Processing to Aid Recovery of Fungi from Cf Patient Sputum Samples

Author Block:

H. B. Miller, S. Lewis, A. Gluck, S. Fisher, S. X. Zhang; Johns Hopkins Med. Inst.s, Baltimore, MD

Abstract Body:

Background: Cystic fibrosis (CF) is a genetic disorder that afflicts over 70,000 people worldwide. It is characterized by viscous mucus that accumulates in the lungs creating challenges for microbiology labs processing sputa to isolate slower growing fungal species. Our laboratory attempted to liquefy and homogenize mucoid sputum samples by exposure to Adaptive Focused Acoustics (AFA) in order to increase recovery of fungal pathogens. **Methods:** Twenty sputum samples were processed by AFA using Covaris S220x Focused Ultrasonicator (Covaris Inc., Woburn, MA). Variables considered included power input, time of exposure, sample volume and mechanical disruption. Once optimized, four fungi commonly isolated from CF patients (*Trichosporon mycotoxinivorans*, *Scedosporium apiospermum*, *Exophiala dermatitidis*, *Aspergillus fumigatus*) were selected to determine AFA's potential effect on viability. They were first processed in sterile saline with subsequent emulsions plated in parallel with unprocessed stock. Next, non-CF patient mucoid sputum was pooled and spiked with fungal isolates above; samples were diluted 1:1 with sterile saline. CF sputum was diluted but not spiked. Prior to AFA, samples were inoculated to blood agar plates (BAP) and Sabouraud Dextrose (SAB) plates. Samples were processed by AFA until homogenized and liquefied, then plated to BAP and SAB. BAP incubated for 72 hrs at 37^0C and were read at 24 / 72 hrs; SAB plates were incubated at 25^0C and read over 14 days. **Results:** Dilution (1:1) and AFA was successful in the homogenization and liquefaction of mucoid sputa, including those from our CF clinic. Optimal conditions: 100 Peak-Incident-Power / 50 Duty Factor / 200 Cycles per Burst for 15 sec. Processing by AFA did not affect the viability of fungal organisms either in solution or spiked into sputa. No effects were observed on fungal viability pre-and-post-AFA in CF sputa. Two CF sputum samples exhibited biofilm production on direct- BAP but resulted in isolated colonies on post-AFA BAP. **Conclusion:** AFA paired with sample dilution offers an optimal process for the homogenization / liquefaction of viscous sputa while maintaining fungal pathogen viability. Additionally, it may disrupt biofilm formation, assisting in fungal recovery. Potential application of AFA to enhance fungal culture in CF patients warrants future studies.

Publishing Title:

Sensitivity Of Calcofluor White Staining For The Detection Of Fungal Organisms In Multiple Specimen Types

Author Block:

E. Washburn, C. Miller, D. Myers, D. Craft; Penn State Hershey Med. Ctr., Hershey, PA

Abstract Body:

Background: Early detection of fungal elements in specimens sent for fungal culture can inform the clinical management of a patient. Calcofluor white (CW) is a fluorescent dye that is commonly used for the rapid detection of yeast and mold fungal elements in patient specimens. We assessed the sensitivity of CW smears in specimens submitted for fungal culture that yielded a fungal isolate(s). Additionally, we compared the sensitivity of CW to Gram stain (GS) for detection of fungal elements in vaginal specimens. **Methods:** A total of 1,924 specimens submitted for fungal culture from Oct-Dec 2014 yielded 422 (21.9%) positive fungal cultures. Laboratory and hospital information systems were queried for data to determine initial smear and final culture results. Vaginal specimen GS for Nugent Score was also reviewed for fungal element comments and compared to CW smear results. **Results:** CW staining identified fungal elements in 73 of 422 (17.3%) positive fungal cultures. CW was most sensitive in vaginal (28.9%), skin/nail/wound (16.3%), respiratory (13.8%), and urine (12.5%) specimens; and least sensitive in bronchoscopy/BAL (5.2%) and sterile site (7.3%) specimens. *Candida* spp. was the most frequent isolate in all specimen types (range 44.9% to 100%). 142 of 688 (20.6%) vaginal specimens were culture positive for fungi, 41 (28.9%) were detected by CW, 53 (38.4%) were detected by GS, with 18 GS + / CW - and 6 GS - / CW + .

Specimens (n=)	**Fungal Culture Positive**	**CW Positive**	**CW Sensitivity**
Total (1924)	**422**	**73**	**17.3 %**
Vaginal (688)	142	41	28.9%
Respiratory secretions *(+ BAL = 350 total)*	109	15	13.8%
Bronchoscopy/BAL *(+ Resp = 350 total)*	57	3	5.3%
Sterile Sites (612)	41	3	7.3%
Skin/Nail/Wound (200)	49	8	16.3%
Urine (74)	24	3	12.5%

Conclusion: These data suggest CW is a relatively insensitive method to detect fungal elements, particularly for bronchoscopy/BAL and sterile site specimens. For vaginal cultures, GS is more sensitive than CW in specimens that yield positive fungal culture results and could replace CW for this specimen type. Most CW smear positive and/or culture positive results yielded *Candida* spp. The clinical and therapeutic relevance of smear results in fungal specimens obtained across mucosal membranes should be discussed with the clinical staff when considering direct smear / staining protocols and result reporting for specimens submitted for fungal culture.

Eswab™ for the Collection of Fungal Surveillance Culture from Immunocompromised Patients

Author Block:

C. Fontana, M. Favaro, M. Del Principe, M. Bossa, S. Minelli, A. Altieri, C. Favalli; Dep. of Med. ,Hematology and Microbiol. Tor Vergata Univ., Roma, Italy

Abstract Body:

Background: Fungal infections are an important cause of morbidity and mortality in immunocompromised patients especially when undergoing chemotherapy for cancer treatment or immune suppression for bone-marrow and solid organs transplantation. *Candida* and *Aspergillus* are the most common fungal pathogens responsible for invasive fungal infection (IFI) and its diagnosis is difficult and late to confirm. Throat, nasal and rectal swabs are collected for fungal surveillance cultures (SCs) for IFIs. Copan ESwab™ (ES) is a Liquid Based Microbiology device that is used for collecting all clinical specimens for the diagnosis of infectious diseases including fungal. The objective of this study was to demonstrate the performance of ES for the collection of clinical specimens for the detection of fungal and yeast in SCs. **Methods:** The study was carried out on 23148 samples received by the Microbiology laboratory of Tor Vergata university from 05, 2009 to 12 2015. All samples were collected in ES from immunocompromised patients (oncohematology, and stem cell transplantation). SCs for the detection of yeasts and filamentous fungi were performed on swabs collected in ES, (nasal 12,499 (54%), throat 8796 (38%) and rectal 1852 (8%). All ES specimens were loaded on the WASP™, plated on appropriate agar, incubated at 37°C for 24h, and 15d at 28°C and read daily. Positive isolates were identified by Vitek 2 System (bioMérieux) for yeasts and by microscopic exam as well as MALDI-TOF (Bruker) for filamentous fungi (FI). FI were sequenced, with a partial 18S rDNA gene (Applera) and aligned to NCBI data bank.**Results:** Two hundred and sixty (1.12%) positive were isolated (80.1% throat, 8.1% rectal and 11.8% nasal) including (90.7%) *Candida* spp. like *C. albicans*, (59.5%) *C. tropicalis* (15.8%), *C. glabrata* (9.7%) and *C. parapsilosis* (5.1%). *Penicillium* was isolated in 2.2% specimens (3.2% *Aspergillus* (*niger*, *fumigatus* and *nidulans)* 0.8%) other filamentous fungi). SCs detected a fatal case of *Scopulariopsis acremonium* in a bone marrow transplant recipient and 3 clinical cases of *G. clavatum*.**Conclusions:** Both *Candida* and FI were easily detected (after 24-48h for yeast and 48h-5d for fungi) from all clinical specimens submitted in Eswab™, demonstrating that is a good device for preserving yeasts and fungi viability.

Publishing Title:

Performance Evaluation of the T2*candida* Panel in the Icu Setting - Data from an Ongoing Study

Author Block:

M. C. Arendrup[1], J. Schierbeck[2], N. Reiter[3], K. B. Krarup[2], J. S. Andersen[3]; [1]Statens Serum Inst., Copenhagen, Denmark, [2]Odense Univ. Hosp., Odense, Denmark, [3]RigsHosp.et, Copenhagen, Denmark

Abstract Body:

Background: Diagnosis of invasive candidiasis (IC) is suboptimal due to low sensitivity and extended time to result of blood culture (BC). This ongoing study compares T2Candida (T2C), which detects and speciates *Candida* in 3-5 hours directly from whole blood, to BC and Mannan antigen (MAg) testing for diagnosis of IC in critical care patients from two large tertiary hospitals.**Methods:** 102 patients with 261 paired samples have been enrolled. Inclusion criteria are initiation of prophylactic, empiric or pre-emptive antifungal treatment (unless specifically on aspergillus indication), colonisation index ≥0.5 or at least 2 recognised risk factors in patients with fever despite 3-days broad spectrum antibiotics. Blood was taken for BC (BACTEC and BacT/ALERT), MAg (Platelia, Bio-Rad) and T2*Candida* test (T2Biosystems). Microbiology test results were reviewed for each patient. Cases were classified as proven IC according to the EORTC/MSG criteria, likely IC when BC negative but T2 test positive and mannan Ag >500 mg/L and/or multiple non-superficial sites colonised with the same species or no infection (remaining cases). The MAg test was evaluated using the standard (>125 pg/mL) as well as a more stringent cut off (>250 pg/mL) for positivity.**Results:** 11 cases (6 proven and 3 likely) of IC were diagnosed involving 6 *C. albicans*, 1 *C. glabrata*, 1 *C. tropicalis*, 1 *C. krusei*, 1 *C. kefyr* and 1 *C. tropicalis + C. glabrata*. Performance characteristics are shown in the table for each test individually and in combination.

Performance characteristics For T2Candida, BC and Mannan Antigen detection

	Sensitivity	Specificity	PPV	NPV
BC	54.5% (6/11)	100% (91/91)	100% (6/6)	94.8% (91/96)
T2C	81.8% (9/11	96.7% (88/91)	75% (9/12)	97.7% (88/90)
T2C for the target	90% (9/10)	96.7 (89/92)	75.2% (9/12)	98.9% (89/90)
MAg	54.5% (6/11)	95.6% (87/91)	60% (6/10)	94.6% (87/92)
MAg using stringent Cut off	54.5% (6/11)	96.7% (88/91)	100% (6/6)	94.8% (91/96)
T2C+MAg	100% (11/11)	93.4% (85/91)	64.7% (11/17)	100% (85/85)
T2C+MAg w stringent cut off	100% (11/11)	96.7% (88/91)	78.6% (11/14)	100% (88/88)

Conclusions: T2Candida was superior to mannan antigen and BC and may be a valuable tool to initiate appropriate therapy earlier in positive patients and de-escalate empiric antifungal therapy in negative patients. When combined with MAg detection using a stringent cut off the sensitivity was 100% without compromising specificity.

Publishing Title:

Verification of T2candida Panel for the Identification of *Candida* Species in Edta-preserved Whole Blood

Author Block:

A. Styer, K. Rygalski, L. Scicchitano, D. M. Wolk, D. R. Hernandez; Geisinger Hlth.System, Danville, PA

Abstract Body:

Background: Candidiasis in high risk patient populations leads to longer hospital stays, higher cost, and elevated morbidity and mortality. It is estimated that 50% of fungal infections are never identified due to their fastidious growth in blood culture. The lack of highly accurate and sensitive diagnostic tools leads to both overuse of empiric therapy and exposure to needless toxicity for high risk groups, as well as underuse of antifungal therapy when candidemia is not suspected.**Methods:** T2Candida (T2 Biosystems) is an FDA-cleared rapid diagnostic method that uses T2 Magnetic Resonance to detect 5 species of *Candida* from whole blood samples, in 3 analytical channels: *C. albicans/C. tropicalis* (A/T), *C. parapsilosis* (P), and *C. krusei* /*C. glabrata* (K/G). The verification of the T2Candida was conducted under conditions of Good Clinical Practices and according to CLIA'88 regulations.**Results:** An accuracy challenge panel consisting of 16 *Candida* and 3 bacterial species (N=119 spiked whole blood samples) was evaluated. 20 day QC was performed at 100% accuracy. The overall analytical sensitivity of T2Candida was 100%; analytical specificity was 97.7%, substratified by channel, 99.0%, 98.1%, and 97% A/T, P and K/G channel respectively. The limit of detection (LOD) was tested at 10-20X the reported LOD. The T2Candida product insert reports cross reactions with 3 bacterial strains (*E. coli*, *E. faecium* and *A. lwoffii*); however, no cross reactions were identified when we tested these strains or other *Candida* spp. at 100 CFU/ml. Therefore consider local specificity testing prior to implementation and use best molecular diagnostics practice, including strict contamination control policies during testing.**Conclusions:** T2Candida is a rapid and highly accurate test for detection of the most common *Candida* species. While spiked samples may be required for method verification, it will be important to rigorously validate and monitor clinical test performance including review of concurrent focal infections to better understand the clinical utility of this powerful method to initiate appropriate and reduce unnecessary antifungal therapy.

***In Vitro* Volatile Metabolite Signatures of Common Pathogenic Mucorales**

Author Block:

X. Yu[1], M. Al-Kateb[1], O. Aloum[1], L. R. Baden[1], F. M. Marty[1], S. Z. Manolakos[2], N. P. Wiederhold[3], A. Chowdhary[4], **S. Koo**[1]; [1]Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, [2]Draper Lab., Cambridge, MA, [3]Univ. of Texas Hlth.Sci. Ctr., San Antonio, TX, [4]Vallabhbhai Patel Chest Inst., Univ. of Delhi, Delhi, India

Abstract Body:

Background: Members of the order Mucorales cause life-threatening, rapidly progressive infections. The diagnosis of mucormycosis is challenging.**Methods**: We characterized the *in vitro* volatile metabolite profiles of *Rhizopus arrhizus* var. *arrhizus* (n=8) and var. *delemar* (n=8), *Rhizopus microsporus* (n=4), and *Mucor circinelloides* (n=4), the most common species causing mucormycosis, using thermal desorption-gas chromatography (GC)/tandem mass spectrometry and, in parallel, GC-differential mobility spectrometry (DMS), a rapid, portable method of identifying specific volatile metabolite signatures in complex gas mixtures.**Results**: Each of these 4 species consistently emitted a distinctive profile of volatile sesquiterpene secondary metabolites, all distinct from volatile sesquiterpenes released by *Aspergillus*: longipinene, maaliene, gurjunene, selinene, and himachalene in *R. arrhizus* var. *arrhizus*; caryophyllene, isocaryophyllene, and gurjunene in *R. arrhizus* var. *delemar* (**Figure**: corresponding DMS metabolite plots); caryophyllene and cubebol in *R. microsporus*; and caryophyllene, cubebol, and guaiene in *M. circinelloides.***Conclusion**: Volatile sesquiterpene secondary metabolite signatures of Mucorales are highly distinct from secondary metabolites released by *Aspergillus* spp. These distinctive metabolic features may be useful in the breath-based diagnosis of mucormycosis, particularly in helping distinguish mucormycosis from aspergillosis. DMS appears to be a useful technique for the rapid identification of these sesquiterpene metabolites.

A Rapid and Sensitive (1→3)-β-D-Glucan Microfluidic Assay for Early Detection of Invasive Aspergillosis Infections in a Murine Model

Author Block:

R. Kapoor[1], N. Wiederhold[2], L. K. Najvar[2], T. F. Patterson[2], W. P. Chang[1]; [1]Wako Life Sci., Mountain Vew, CA, [2]UT Hlth.Sci. Ctr., San Antonio, TX

Abstract Body:

Background: Incidence of invasive aspergillosis (IA) is rising in recent decades with poor morbidity and mortality in neutropenic patients. Early detection and treatment are key to improved clinical outcomes. Timely diagnosis is suboptimal using existing tools. A fungal cell wall component, (1→3)-β-D-glucan (BDG), has been used as a surrogate marker for fungal infection. We report here the results from an automated liquid phase binding assay for the early detection of serum BDG in infected mice.**Method:** Immunosuppressed ICR mice were inoculated with 10^5 inhaled *A. fumigatus* conidia (Sheppard et al *Antimicrob Agents Chemother* 2004; 48: 1908). Serum was collected daily for 7 days post infection (5 mice for each day); kidney fungal burden and BDG levels were measured. We measured BDG level by a liquid phase binding assay (Kawabata et al Electrophoresis, 2008; 29:1399) using microfluidic electrophoresis. Here, BDG is recognized by a recombinant protein (BGRP); detection is achieved through BGRP-conjugated fluorescent dye. The BDG level is correlated to peak area of the immunocomplex (BDG-BGRP).**Results:** The median BDG level (10.3, integrated peak area of immunocomplex) of 5 uninfected mice is used as a cutoff. All 5 infected animals from day 1 (median = 34.8; range = 32.0 - 43.7) were positively identified. Mice from days 2-7 were also correctly identified as being infected (median = 42.9; range = 17.6 - 204.0). However, results from a commercial kit (Fungitell®, cutoff = 80pg/mL) failed to ID 2 out of 5 mice for day 1 and 1 out of 5 for day 2. Samples from later time points (days 3 - 7) remained positive in infected mice as judged by results from both assays (microfluidics and Fungitell®).**Conclusion:** In this study, our assay detects serum BDG as early as day 1 in the course of IA in infected mice. This assay has the potential of being a useful tool for detecting IA in at risk patient population, with several advantages over existing assays, including a shorter assay time (~ 2 min), low reagent consumption, robotic liquid and sample handling, and automated runs with a single or multiple samples. Future studies will include the assessment of the performance of this assay using a larger pool of human specimens.

Evaluation of Beta-D-Glucan Assay at Different Cut-off Values for the Diagnosis of Invasive Fungal Infections in Pediatric Cancer Patients from India

Author Block:

P. Gupta, A. Ahmad, A. Kumar, M. Singh; King George's Med. Univ., Lucknow, India

Abstract Body:

Background: Limited specific data and investigations are available for invasive fungal infection (IFI) in pediatric cancer patients. Beta D glucan assay (BDG) has been approved by EORTC-MSG for the diagnosis of IFI in cancer patients. But its role in the diagnosis of IFI in pediatric cancer patient is controversial. Typical cut-off values for BDG range from 80 to 150 pg/ml. A cut-off of 80 pg/ml is currently approved by FDA. Different cut-off values needs to be evaluated for the diagnosis of IFI in pediatric cancer population.**Methods:** 64 pediatric cancer patients suspected of IFI were enrolled. 70 blood samples were collected. Blood samples were tested for serum BDG assay (Fungitell, Cape Cod, USA). BDG was evaluated at four different cut off values: 80, 100, 120 and 150.**Results:** According to EORTC-MSG guidelines 64 patients were classified as follows: 8 (12.5%) proven, 17 (26.5%) probable and 39 (76.5%) no IFIs. Receiver operating curve (ROC) analysis showed that the most reasonable cut off value in our study population is also 80 pg/ml. The sensitivity, specificity, PPV and NPV of BDG at cut-off 80 pg/ml was 71%, 29%, 51% and 50% respectively.**Conclusions:** The most reliable cut-off value for BDG assay for the diagnosis of IFI in pediatric cancer patient in our settings is 80 pg/ml. BDG assay is not a very promising test for the diagnosis of IFI in pediatric cancer patients.

Role of Broad Range Pan Fungal Real Time Pcr in the Diagnosis of Ifi in Pediatric Cancer Patieints from India

Author Block:

M. Singh, P. Gupta, A. Ahmad, A. Kumar; King George's Med. Univ., Lucknow, India

Abstract Body:

Background: Invasive fungal infection (IFI) in pediatric cancer patients is a serious threat to their life. We evaluated a broad range pan fungal real time PCR with two reactions covering almost 80 genera of fungi, which included yeast as well as filamentous fungi. This assay has been developed by Landlinger C et al in year 2010. An excellent correlation was found between PCR positivity and the presence of proven, probable or possible fungal infections. We evaluated this assay at our settings on single blood samples. **Methods:** 64 pediatric cancer patients suspected of IFI were enrolled. Patients were classified as proven, probable, possible and no IFI according to the definitions of European Organization for Research and Treatment of Cancer criteria. 64 blood samples were collected from each patient. Real time PCR was done according to the protocol of Landlinger C et al.**Results:** According to EORTC-MSG guidelines 64 patients were classified as follows: 8 (12.5%) proven, 17 (26.5%) probable and 39 (76.5%) no IFIs. Sensitivity of the assay was found to be 78%. The negative predictive value of this assay was 74%, while the specificity and the positive predictive value were 46% and 51% respectively. Diagnostic accuracy was found to be 60%. LR positive and negative values were 1.4 and 0.4 respectively.**Conclusions:** The results indicate that broad range pan fungal real time PCR during febrile neutropenic episodes could be of significant value in diagnosing IFI in pediatric cancer patients, even in single samples. This assay also has significance in ruling out the disease.

Development of a Molecular Assay for the Identification of *Histoplasma capsulatum* from Tissue

Author Block:

J. L. Cox, **E. N. Tessier**, A. G. Freifeld, P. C. Iwen; Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract Body:

Background: Many current testing protocols to identify and diagnose histoplasmosis have low sensitivity and specificity, which hinders clinicians from delivering appropriate treatment to their patients[1]. While histologic examination is relatively sensitive, morphologic mimics of *Histoplasma* are common, limiting the specificity. Conversely, fungal culture, as the gold standard in diagnosis, is not always performed and when done leads to a delayed diagnosis due to the extended time required for culture diagnosis[2]. To address these shortcomings, polymerase chain reaction (PCR) may provide a sensitive and specific rapid diagnosis of *H. capsulatum* infection. **Methods:** Surgical biopsies and autopsy specimens that had corresponding tissue culture diagnosis of *H.capsulatum* and/or had budding-yeast organisms on histologic examination were identified. Also included was a negative specimen as a negative control. Tissue blocks selected had been stored in similar conditions. DNA was extracted from the formalin fixed, paraffin embedded tissue, and was used in downstream analysis. Real-time PCRs were performed using primers and a fluorescent probe specific for a 99-bp portion of the H. capsulatum-specific 100-kDa protein gene.**Results:** Three specimens with a corresponding positive tissue culture diagnosis tested positive by our PCR assay. We also examined autopsy tissues from a patient with pre-mortem culture positive Histoplasmosis. Interestingly, 6 of 7 (86%) tissues collected from various sites at autopsy demonstrated positivity on our assay, corroborating pre-mortem tissue culture, and suggest that different input tissues do not affect the outcome of our assay. Moreover, cycle threshold values recorded corresponded with organism burden seen histologically. A negative PCR result was found in 100% of 6 specimens diagnosed on histopathologic examination as having budding-yeast organisms, supporting this technique as an appropriate tool to rule-out *H.capsulatum* infection. Overall sensitivity was 90% (n=10) and specificity was 100% (n=7).**Conclusions:** Real-time PCR has the ability to provide a sensitive and specific rapid diagnosis, and may provide a new tool for rapid assessment of budding-yeast forms seen histologically. Additional studies are being performed to evaluate more samples as a means to validate this assay for approved clinical diagnostics.

A Point-Of-Care Lateral Flow Assay For The Diagnosis Of Histoplasmosis In Hiv/Aids

Author Block:

S. Noor-Mohammadi, B. Crider, B. Neary, S. Bauman; IMMY, Norman, OK

Abstract Body:

Progressive disseminated histoplasmosis is a common and life-threatening fungal infection among patients with HIV/AIDS in the United States and Latin America. Incidence rates in HIV/AIDS can be >20%, with mortality rates >30% in resource-limited countries where the fungus, *Histoplasma capsulatum*, is endemic. Early diagnosis and treatment are essential to reducing this high mortality rate. Diagnosis currently depends on culture or histopathology, which have low sensitivity, are time consuming, expensive, and require trained personnel. IMMY has developed a point-of-care (POC) diagnostic test in the lateral flow (LFA) format for the rapid identification of disseminated histoplasmosis in the urine samples of patients. The LFA detects the polysaccharide antigen of *H. capsulatum* (HGM) that is shed into urine during infection using high-affinity monoclonal antibodies and follows the World Health Organization's ASSURED criteria by providing rapid results in under 30 min. Analysis of HGM-spiked urine samples demonstrates that the HGM LFA has a limit of antigen detection (LOD) of 0.5 ng/ml. Furthermore, comparison of archived infected patient urine specimens in the HGM LFA and IMMY's HGM EIA kit, had a positive and negative agreement of 100% [95% CI: 0.69-1.00] and 95% [95% CI: 0.59-1.00] respectively [n=21]. The HGM LFA offers a rapid, accurate, and sensitive method for qualitatively detecting *Histoplasma* antigen in immune compromised patients.

Publishing Title:

Performance Characteristics of the Mvista® Histoplasma Antigen Eia Developed as an Ivd

Author Block:

P. A. Connolly, M. C. Minderman, L. J. Wheat; MiraVista Diagnostics, Indianapolis, IN

Abstract Body:

Background: The MVista® *Histoplasma* Antigen EIA has been offered as a lab developed test (LDT) for 30 years. As an LDT, it is only available as a service at MiraVista Diagnostics (MVD) and cannot be offered at other laboratories. An *in vitro* diagnostic (IVD) test kit has been developed and is at clinical trial with planned submission to FDA. Advantages of the IVD compared to the LDT include production under good manufacturing practices (GMP), and opportunity for other laboratories to perform the MVD EIA resulting in improved clinician and patient access. This report describes the analytical performance of the IVD and compares it to the LDT.**Methods:** The IVD kit uses microplate wells coated with anti-*Histoplasma* rabbit polyclonal IgG. Urine samples or controls are incubated in the wells, after which the wells are washed and a biotinylated IgG with streptavidin HRP solution is added to the wells and incubated. The wells are again washed and TMB chromogen is added followed by an acid stop solution. The plate is read at 450 nm with 620-630 nm reference. The EIA uses a cutoff calibrator to calculate the assay cutoff which is defined as 1.0 EIA Units (EU); the reportable range is $\geq$1.0 EU with a reference value of <1.0 EU.**Results:** Evaluating multiple IVD kit lots, the LoB was 0.50 EU with a LoD of 0.59 EU. In 24 assays with samples run in triplicate by two operators, each graded positive sample had repeatability and within-lab precision results of <10% CV. The negative and high negative samples had <15% CV for both repeatability and within-lab precision. A group of clinical residual samples from the MVD LDT were banked frozen and re-tested in the LDT and tested in the IVD. Of 45 urines that were originally negative, 43 (95.6%) were negative in the LDT and 44 (97.8%) were negative in the IVD. Of 39 histoplasmosis patient urines, 38 of which were initially positive in the LDT, 38 (97.4%) were positive in the LDT retest and 35 (89.7%) were positive in the IVD. McNemar's Test for paired proportions shows no significant difference between the LDT and IVD results, P=0.1250.**Conclusions:** The MVista® *Histoplasma* Antigen IVD assay is capable of detecting low level antigen demonstrating the cutoff is appropriately set with consistent interpretation. Precision and repeatability meet design goals at all levels of detection. The IVD exhibits similar clinical performance to the LDT.

Retrospective Analysis of *Candida parapsilosis* Species Complex Comparing Molecular and Maldi-Tof-Ms Identification Methods

Author Block:

L. M. Leach, X. Li, S. Chaturvedi; Wadsworth Ctr., Albany, NY

Abstract Body:

Background: The *Candida parapsilosis* complex was the second most prevalent species isolated from patients with invasive candidiasis or superficial candidiasis in several studies. The *Candida parapsilosis* complex contains three species: *C. parapsilosis*, *C. metapsilosis*, and *C. orthopsilosis* that exhibit differences in epidemiology, virulence, biofilm formation and antifungal susceptibility. The Matrix Assisted Laser Desorption/Ionization-Time Of Flight-Mass Spectrometry (MALDI-TOF-MS) is an emerging technology for rapid and accurate identification of microorganisms. In this study, we compared the MALDI-TOF-MS method to that of conventional PCR targeting exon-primed intron of the manganese superoxide dismutase (*MnSOD*) gene for the identification of *C. parapsilosis* species complex.**Method:** Sixty clinical isolates that were previously identified as *C. parapsilosis* using conventional or biochemical methods were obtained from the NYS Mycology Culture Collection Repository. The DNA was isolated and subjected to a previously established conventional PCR targeting an exon-primed intron of the manganese superoxide dismutase (*MnSOD*) gene followed by restriction enzyme digestion. Proteins from the isolates were extracted by first treatment with 75% ethanol followed by formic acid/acetonitrile mixture. The extracted proteins were analyzed by MALDI-TOF-MS (Bruker Daltonics).**Results:** The majority of the isolates, 56 (93.3%), were identified as *C. parapsilosis*. Interestingly, one isolate each was identified as *C. metapsilosis* (1.7%) and *C. orthopsilosis* (1.7%) and two isolates were identified as *Lodderomyces elongisporus* (3.3%). The species level identifications obtained with MALDI-TOF-MS was 100% concordance with PCR method.**Conclusions:** The MALDI-TOF based method was proved to be rapid, reproducible and accurate, with low consumable costs and minimal preparation time. The MALDI-TOF-MS has the potential to positively impact patient care and laboratory efficiency.

Publishing Title:

identification of Filamentous Fungi by Maldi-Tof Mass Spectrometry

Author Block:

A. Bateman, L. Bourassa, L. Curtis, S. Butler-Wu; Univ. of Washington, Seattle, WA

Abstract Body:

Background: Traditional identification of filamentous fungi can be slow and requires extensive experience. MALDI-TOF mass spectrometry has revolutionized bacterial and yeast identification in the clinical laboratory, and could improve the turn-around-time for mycology laboratories. Building on previous work in our laboratory, we evaluated the ability of the Bruker microflex LT mass spectrometer to identify fungi, using two databases: the Bruker Filamentous Fungal Library and an augmented library developed at the University of Washington.**Methods:** The augmented library consists of the Bruker library (Bruker Daltonics, Billerica, MA) plus 95 strains (50 species) of fungi identified by 28S and ITS sequencing. Fungi grown on Inhibitory Mold Agar (Remel, Lennexa, KS) were extracted with 70% ethanol, 70% formic acid, and acetonitrile, and run on the MALDI-TOF instrument. To evaluate the libraries, we tested 124 strains that were identified by morphology. To evaluate the usefulness of MALDI-TOF in a real-world setting, a prospective study is underway to compare the time to an accurate identification by MALDI-TOF versus morphology.**Results:** Using the Bruker library, 37/124 (30%) isolates were identified to the genus level (score value ≥1.7), with 13/37 (10% of the total) identified to the species level (score value ≥2.0). The augmented library showed improved performance: 71/124 (57%) were identified to the genus level, with 56/71 (45% of the total) identified to the species level. *Aspergillus fumigatus*, *Trichophyton rubrum*, and *Pseudallascheria boydii* complex are three of the most common fungi identified in our laboratory. The augmented library identified 36/36 (100%) isolates of these fungi to the genus level and 92% to the species level, but identification of other fungi varied by species. Data acquisition and analysis are ongoing for the prospective study.**Conclusions:** The augmented library outperformed the Bruker Library with the simplified extraction protocol. The augmented library identified common fungi well, and we plan to add additional isolates to the database to improve its performance for identifying less commonly isolated fungi.

Publishing Title:

Impact of Maldi-Tof Ms on the Cost and Time to Identification of Filamentous Fungi

Author Block:

E. S. Slechta[1], **M. V. Powers-Fletcher**[2], T. Lunt[1], A. P. Barker[2], K. E. Hanson[2]; [1]ARUP Lab., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: MALDI-TOF MS is used routinely to identify bacteria and yeast isolated from clinical specimens. The purpose of this study was to determine the impact of using MALDI-TOF MS, with an in-house-developed spectral database, on the accuracy, time and cost of mould identification (ID) in a national mycology reference laboratory.**Methods**: Moulds isolated from clinical specimens as a part of routine clinical practice were identified using conventional phenotypic and/or genotypic methods based on standard operating procedures. Isolates were then sub-cultured and reanalyzed by MALDI-TOF MS. Comparisons of IDs made by different methods, the time required for results and the cost of labor and reagents was determined. rDNA sequencing was considered the diagnostic gold standard for ID.**Results**: A total of 261 isolates were identified during this study; 253 (96.9%) isolates had high quality spectra using MALDI-TOF MS and were included in this analysis. The most commonly encountered fungi were hyaline hyphomycetes (≈ 50%) followed by dematiaceous moulds (≈ 18%), with approximately 80% of isolates representing established human pathogens. **Table 1** shows the frequency of IDs using phenotypic, genotypic, or MALDI-TOF MS. There were 9 isolates for which the conventional method and MALDI-TOF MS did not agree. Resolution testing is underway. The median time to ID was 2 d (interquartile range [IQR] = 1 d), 4 d (IQR = 3 d) and 6 d (IQR = 2 d) using MALDI-TOF MS, phenotype or genotype, respectively. The cost of MALDI-TOF MS was $12.41/isolate as compared to phenotypic testing ($22.09/isolate) and sequence analysis ($67.58/isolate).**Table 1**

	Phenotypic ID (%)	Genotypic ID (%)	No ID (%)	**Total (%)**
MALDI-TOF MS Genus-Level Only (%)	7 (2.8)	2 (0.8)	0 (0)	9 (3.6)
MALDI-TOF MS Species-Level (%)	123 (48.6)	44 (17.4)	5 (2.0)	173 (68.4)
MALDI-TOF MS No ID (%)	40 (15.8)	20 (7.9)	12 (4.7)	71 (28.1)

Total (%)	170 (67.2)	66 (26.1)	17 (6.7)	**253**

Conclusion: Compared to conventional methods, MALDI-TOF MS provides rapid results with similar accuracy, even in a laboratory with a high-level of mycology expertise. Implementation of MALDI-TOF MS for mould ID has the potential to reduce costs and improve the turn-around-time (TAT) to critical results. However, a small proportion of isolates may require repeat extraction to obtain acceptable spectra for analysis.

Publishing Title:

Rapid One-step Extraction Method for the Identification of Molds Using Maldi-Tof Ms

Author Block:

P. Luethy, A. Zelazny; NIH, Bethesda, MD

Abstract Body:

Matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS) has revolutionized the identification of clinically important molds. Previously, our group developed an extraction procedure to generate a comprehensive clinically relevant mold database (Lau et al, 2013, JCM). Although easy to perform, this extraction method is time consuming, requiring bead-beating and several chemical processing steps. In this study, we optimized and validated a rapid one-step method for protein extraction from filamentous fungi. Excised mold (~5 mm) was placed into tubes containing zirconia-silica beads and 100 µL of extraction solution without prior washing or ethanol soaking. Different ratios of acetonitrile, formic acid, and water were compared. Inoculated tubes were processed by a PowerLyzer high power bead based homogenizer and supernatants spotted for MALDI-TOF MS. Viability studies were performed before (extraction solution alone) and after bead beating by culturing in liquid and solid media for 7 days at 27 °C. The rapid method was evaluated prospectively and in parallel with our current mold extraction method. Preliminary analysis of 50 clinical mold isolates (28 hyaline molds, 12 dematiaceous molds, 3 mucorales, 6 basidiomycetes, and 1 dermatophyte) resulted in a decrease of extraction time by 30 minutes (current = 35 mins, new rapid = 5 mins). Some molds were not represented in MALDI-TOF databases. All organisms were found to be non-viable after 5 mins in the extraction solutions (bead beating was not required). Acceptable identification score (≥ 2.0) was achieved for up to 64% of isolates by the rapid method compared with 54% of isolates by the current method (Table 1). One dermatophyte and three hyaline mold isolates identified by the current method but with lower scores (< 2.0) by the rapid method were still identified correctly by either method. The rapid method was more sensitive for mucorales, basidiomycetes, and dematiaceous molds. This rapid method significantly reduces processing time while maintaining excellent scores for the identification of clinical mold isolates.

Table 1

	Current	Rapid
Hyaline	19/28 (67.9%)	16/28 (57.1%)
Dematiaceous	7/12 (58.3%)	8/12 (66.7%)
Dermatophyte	1/1 (100%)	0/1 (0%)
Mucorales	0/3 (0%)	2/3 (66.7%)

Basidiomycetes	0/6 (0%)	6/6 (100%)

Evaluation of Maldi-Tof Mass Spectrometry for Identification of 342 Clinical Isolates of *Aspergillus* Species from 11 Korean Hospitals

Author Block:

S. Kim[1], J. Park[1], J. Shin[1], J. Kim[1], M. Choi[1], M. Shin[1], S. Suh[1], S. Jang[2]; [1]Chonnam Natl. Univ. Med. Sch., Gwangju, Korea, Republic of, [2]Chosun Univ. Med. Sch., Gwangju, Korea, Republic of

Abstract Body:

Background: Matrix-assisted laser desorption/ionization-time of flight mass spectrometry (MALDI-TOF MS) has become increasingly recognized as an alternative to morphological and molecular-based identification (ID) of *Aspergillus* species. The aim of our study was to evaluate the commercial mold database, entitled Filamentous Fungi Library 1.0 (Bruker Daltonics) of the Bruker MALDI Biotyper to identify 342 clinical isolates of *Aspergillus* species. **Methods:** A total of 342 clinical isolates (collected in 2012-2013) from 11 hospitals in Korea were assessed. Bruker MALDI Biotyper ID featured liquid cultivation followed by ethanol-formic acid extraction, according to the manufacturer's instructions. The results yielded by the Filamentous Fungi Library version 1.0 were compared to those obtained upon sequencing of internal transcribed spacer (which affords ID to the species complex level) and the β-tubulin region (which affords ID to the species level within the complex). **Results:** For the 342 isolates, the frequencies of correct ID to the complex level by the MALDI Biotyper were 94.2% and 98.5% at cutoff values of 2.0 and 1.7, respectively. Sixteen (4.6%) isolates (6 *A. fumigatus,* 2 *A. lentulus,* 5 *A. flavus,* 2 *A. tamarii,* and 1 *A. terreus* isolates) were not identified at a cutoff of 2.0, but only one *A. fumigatus* isolate was not identified at a cutoff value of 1.7. Only four isolates (1.2%) were misidentified at either cutoff value: these were of the *A. versicolor* complex and were misidentified as members of the *A. fumigatus* complex. The rates of correct ID at the species level were 74% and 78.1% at cutoff values of 2.0 and 1.7, respectively. Of isolates of cryptic species (*A lentulus, A. awamori, A. tubingensis, A. tamarii,* and *A. calidoustus*), only two *A. tamarii* isolates were identified correctly for the species cutoff 1.7, and none at a cutoff value of 2.0. **Conclusions:** The Bruker MALDI Biotyper using the Filamentous Fungi Library version 1.0 seems very reliable when used to identify clinical isolates of *Aspergillus* species to the complex level. However, the database must expanded to identify isolates correctly at the species levels, and to identify cryptic species.

Hosp., Dijon, France, [5]Besançon Univ. Hosp., Besançon, France

Abstract Body:

Background: Anti-*Aspergillus* IgG antibodies are important biomarkers for the diagnosis of chronic pulmonary aspergillosis (CPA) and allergic bronchopulmonary aspergillosis (ABPA).**Methods:** In a prospective multicentre study, we compared the performance of a new commercial EIA (Bordier Affinity Products) with those of the Bio-Rad and Virion\Serion EIAs. This assay is novel in the association of two recombinant antigens with somatic and metabolic antigens of *A. fumigatus*. **Results:** A total of 436 serum samples from 147 patients diagnosed with CPA (136 sera/104 patients) or ABPA (94 sera/43 patients) and from 205 controls (206 sera) were tested. We obtained sensitivities of 97%, 91.7%, and 86.1%, and specificities of 90.3%, 91.3%, and 81.5% for the Bordier, Bio-Rad and Virion\Serion test, respectively. The Bordier kit was more sensitive than the Bio-Rad kit ($p<0.01$), which was itself more sensitive than the Virion\Serion kit ($p=0.04$). The Bordier and Bio-Rad kits had similar specificities ($p=0.8$), both higher than that of the Virion\Serion kit ($p=0.02$). The areas under the ROC curves confirmed the superiority of the Bordier kit over the Bio-Rad and Virion\Serion kits (0.977, 0.951 and 0.897, respectively; $p<0.01$ for each comparison). In a subset analysis of 279 serum samples tested with the Bordier and Bio-Rad kits and an in-house immunoprecipitin assay (IPD), the Bordier kit had the highest sensitivity (97.7%), but the IPD had the highest specificity (96.6%). **Conclusions:** The use of recombinant, somatic and metabolic antigens in a single EIA improved the compromise between sensitivity and specificity, resulting in an assay highly suitable for use in the diagnosis of chronic and allergic aspergillosis

Immunohistochemical (Ihc) and In-Situ Hybridization (Ish) Detection of *Aspergillus spp.* in Human Tissue Samples

Author Block:

K. C. Dee, C. J. Clancy, S. Dacic, K. Cieply, S. Yousem, M. H. Nguyen; Univ. of Pittsburgh Med. Ctr., Pittsburgh, PA

Abstract Body:

Background: Invasive aspergillosis (IA) is a disease which carries significant morbidity and mortality to a broad range of patients. The diagnosis of IA is limited by poor sensitivity and specificity of microbiologic cultures, and the poor ability of conventional histopathologic tests to distinguish IA from other invasive fungal infections (IFI). *Aspergillus*-specific IHC and ISH could facilitate direct diagnosis of IA within tissue. **AIM:** The aim of our study was to assess the sensitivity and specificity, via retrospective chart review with tissue culture as gold standard, of *Aspergillus* IHC and ISH. From 5/2010 through 10/2015, 44 tissue specimens from distinct patients with histopathologic evidence of mold were cultured for fungus and processed for IHC and/or ISH. Positive cultures (21 samples; 48%) grew *A. fumigatus* (11), *A. terreus* (2), *A. versicolor* (2), *A. niger* (1), *Scedosporium* (3), *Fusarium* (1) and *Alternaria* (1), while 23 cultures (52%) were with no growth. Tissue source was lung (72%), followed by sinus (17%), bone (6%), larynx and skin (4%). 28 of the patients were immunosuppressed including solid organ transplant recipients (N=13), hematologic malignancy (5), and solid tumor patients receiving chemotherapy (1). **Results:** Overall sensitivity for all *Aspergillus sp.* was 69% for IHC and 67% for ISH. Sensitivity for *A. fumigatus* alone was 80% and 71% for IHC and ISH respectively. If both tests were performed and either IHC or ISH was positive, sensitivity increased to 70% for all *Aspergillus sp*. and to 82% for *A. fumigatus*. The specificity for culture negative specimens was 65% for IHC and 76% for ISH. For the 5 specimens that grew other mold, specificity was 0% for IHC and 20% for IHC. There were 3 false positive samples (IHC and ISH) that grew *Scedosporium apiospermum* (note: 2 of these patients had also grown *A. fumigatus* on recently obtained cultures) and a single false positive each from *Fusarium sp*. and *Alternaria*. **Conclusions:** The sensitivity of IHC and ISH make these tests potentially valuable adjuncts to culture for diagnosing IA. Specificity may be understated in this study, as culture negative samples that were positive by IHC/ISH may represent IA cases that were missed by cultures. Assays require optimization in order to differentiate *Aspergillus* spp. from other acute-angled branching molds.

Comparative Performances Of 2 Pcr Assays For The Detection Of *aspergillus* In Bronchoalveolar Lavage Fluid During The Diagnosis Of Invasive Aspergillosis

Author Block:

P. COMACLE, S. BELAZ, F. ROBERT-GANGNEUX, S. CHEVRIER, **J-P. GANGNEUX**; CHU Pontchaillou, Rennes, France

Abstract Body:

Background: *Aspergillus* detection in the BAL fluid is one of the criteria for the diagnosis of proven and probable invasive aspergillosis (IA). Beside mycology (direct examination and/or culture) and galactomannan (GM) detection that are identified as EORTC/MSG criteria for probable IA (de Pauw 2008), PCR on pulmonary samples has become an essential argument for the laboratory diagnosis. Various amplification methods have been published but without consensus.**Methods:** The aim of this work was to compare the performance of two amplification targets: *A. fumigatus* mitochondrial gene (AFmito) and 28S rRNA. From 01/2012 to 10/2015, 324 BALF were prospectively collected and tested for mycology examination, GM detection (EIA Platelia assay Biorad, cutoff 1.0 if isolated, and 0.8 if associated to serum GM > 0.5) and AFmito PCR assay. Beside, 28S PCR assay was retrospectively performed on the same DNA extracts (312/324 available DNA). **Results:** According to the 2008 modified criteria of EORTC/MSG for classification of IA, patients were classified as: 1 proven, 47 probable and 11 possible IA. Other patients were classified as 11 with colonization and 256 non-infected. Sensitivity of BALF GM detection, 28S PCR assay and AFmito PCR assay was 58%, 61% and 50%, respectively. Mycology testing (ED +/- culture) had a sensitivity of 33%. Specificity of BALF GM detection, 28S PCR assay, AFmito PCR assay and culture was 94%, 97%, 97% and 98%, respectively. Negative predictive value was 93%, 95%, 92% and 89%, respectively. Concordance between the 2 PCR assays was 97% (kappa coefficient 0.84), whereas it was 88% (kappa 0.40) between 28S PCR and BALF GM and 88% (kappa 0.43) between Afmito PCR and BALF GM. **Conclusions:** 28S PCR assay had the highest performance for the molecular detection of *Aspergillus* in BALF compared to AFmito. The combination of 28S PCR assay and GM detection in BALF allowed to reach a sensitivity of 80% with a conserved high specificity (91%).

Assessment of the Critical Components of a Pan-fungal Pcr Assay

Author Block:

P. D. Khot, **E. S. Slechta**, E. Kish-Trier, K. E. Hanson; ARUP Lab., Salt Lake City, UT

Abstract Body:

Background: Broad-range detection of fungal nucleic acid directly in human tissue has potential utility for the diagnosis of invasive fungal infections. The purpose of this study was to assess impact of primer design, master mix composition and DNA extraction method on interference from environmental contamination.**Methods:** Real Time PCR was performed on the Quant Studio (Life Technologies), with amplicons analyzed by post-PCR melt-curve analysis and Sanger sequencing. Two master mixes were evaluated including a standard mix and a fungal DNA-free custom mix, both from Promega. Primers targeted the 18S, 28S and ITS2 regions. Automated (Promega and Chemagen) and manual (Zymo and MoBio) extraction methods using fresh tissue with were also compared.**Results:** Initial studies were performed with 62 different fungal organisms and the standard master mix. All organism identifications were correct, but the number of specimens detected at <30 qPCR cycles varied by primer set (18S [54/62], 28S [60/62] and ITS2 [61/62]).Background fungal DNA was detected in 0 of 30, 3/30 (40 to 44 cycles) and 29/30 (37 to 43 cycles) of the no template custom mix controls using the 18S, 28S and ITS2 primers, respectively. Replicate testing of the no template standard mix control showed that 0 of 11, 12/12 (33 to 39 cycles) and 11/11 (33 to 43 cycles) contained fungal DNA using the 18S, 28S and ITS2 primers, respectively.Fungal culture-negative tissue and tissue spiked with a suspension of *Aspergillus fumigatus, Candida albicans, Cryptococcus neoformans, Exophiala dermatitidis* or *Absidia corymbifera* were also extracted and analyzed using the ITS2 primers. Results are presented in the **Table**.**Conclusions:** PCR primers targeting the fungal 28S and ITS2 regions, use of a fungal-free master mix and DNA extraction with either the Promega or MoBio kits were associated with optimal test performance.**Table**

Specimen	Extraction Kit Ct (range)			
	Chemagen	Promega	MoBio	Zymo

Publishing Title:

Comparison Of Sequencing The D2 Large-Ribosomal-Subunit (Lsu) Gene (Microseq^{tm}) Versus The Internal Transcribed Spacer (Its) Regions For Identification Of Common And Uncommon Clinically Relevant Fungal Species

Author Block:

S. Arbefeville, A. Harris, P. Ferrieri; Univ. of Minnesota Med. Sch., Minneapolis, MN

Abstract Body:

Fungal infections are still a cause of considerable morbidity and mortality in immunocompromised patients, and their precise identification (ID) can aid in directing antifungal therapy. With the advent of molecular methods, clinical laboratories have alternative approaches for fungal IDs to supplement traditional phenotypic methods, which can be challenging, and may not be accurate. The commercially available MicroSEQ™ D2 LSU rDNA Fungal Identification assay can streamline acquisition of readable D2 LSU rDNA; however, much of the evaluation of D2 LSU has focused on commonly encountered fungi, leaving clinical laboratories uncertain of the ability to differentiate a broader range of fungi. Thus, a comparison of D2 LSU sequence versus the more commonly used ITS regions, as taxonomic identifiers, was performed. Isolates of hyaline, dematiaceous, dermatophytes, mucorales, and other fungi from clinical specimens were investigated. D2 LSU identified 92.5% or 96.2% of the 53 isolates to the genus level and ITS-1+ITS-2 (f-ITS): 94.3% or 98.1%, using GenBank or MycoBank, respectively, when compared to assigned ID. When comparing species-level designations to assigned ID, D2 LSU aligned with 43.4% (23/53) or 49.1% (26/53) of these isolates in GenBank or MycoBank, respectively. By comparison, f-ITS possessed greater specificity, followed by ITS-1, then ITS-2 (species-level ID 73.6% (39/53), 66.0% (35/53), and 60.4% (32/53), respectively) using GenBank; for MycoBank, these values were 71.7% (38/53), 69.8% (37/53), and 71.7% (38/53). Comparing D2 LSU to ITS regions in GenBank or MycoBank at the species level against the assigned ID, f-ITS (23/53 vs. 39/53; $p = 0.0016$ or 26/53 vs. 38/53; $p = 0.017$, respectively) and ITS-1 ($p = 0.019$ or 0.03), exceeded D2 LSU's performance, but ITS-2 ($p = 0.08$ or 0.017) was comparable to D2 LSU using GenBank. Using either GenBank or MycoBank, D2 LSU outperformed phenotypic based ID at the genus-level (92.5% (49/53) vs. 69.8% (37/53); $p = 0.003$ or 96.2% (51/53) vs. 69.8% (37/53); $p = 0.0003$, respectively). Our results indicated that D2 LSU was equivalent to ITS and its components at genus level ID and identified several complex fungal species.

Clinical Benefit of DNA Sequencing for Difficult to Identify Fungi Recovered from Paitents

Author Block:

T. S. Murray[1], R. Feinn[1], V. Ryan[1], D. R. Peaper[2]; [1]Frank H Netter MD Sch. of Med. Quinnipiac Univ., Hamden, CT, [2]Yale Univ. Sch. of Med., New Haven, CT

Abstract Body:

Background: The identification of fungi relies mostly on morphology. Environmental fungi recovered from clinical specimens that fail to form fruiting bodies are often considered contaminants and identified as mold. There is little data regarding the value of DNA sequencing in identifying pathogens when small amounts of these fungi are present. The purpose of this study is to determine the clinical value of DNA sequencing in identifying fungal pathogens for organisms not identified by traditional morphology. We hypothesized DNA sequencing applied to difficult to identify fungi is more likely to identify environmental contaminants when 1 colony forming unit (CFU) is present and more likely to identify pathogens when fungi are present in greater numbers.**Methods:** Over 2 years, sequential clinical fungal isolates from Yale New Haven Hospital sent for DNA sequencing were reviewed to determine whether pathogens were identified. Partial sequencing of the 28sRNA ribosomal subunit identified organisms using either Microseek or GenBank databases. PubMed searches determined whether the organism was a pathogen, probable pathogen (1-3 case reports) or not reported to cause infection. Fischer's exact test compared outcomes between groups using the dichotomous variable of pathogen or not.**Results:** 75 sequences of unique isolates were recovered from 74 patients; 48 respiratory specimens, 17 skin/ hair, 8 tissue , and 2 recovered from urine. 47 likely pathogens, 4 possible pathogens and 24 unlikely pathogens were sequenced. 25 isolates were identified at the species level, 43 at the genus level, and 2 at the level of family. Six were not definitively identified despite quality sequence data. Fungi recovered from tissue (7/8, 87%, p=.06) and skin/hair (14/17,82%, p=.03) were more likely to be pathogenic compared with respiratory fungi (24/48, 50%). There was no correlation between the amount of fungi recovered and the probability of identifying a pathogen (1 CFU, 14/27 pathogens and >4 CFU, 8/16, p=1.0).**Conclusions:** 50% of fungi recovered as a single colony from a clinical specimen and not identified by traditional morphology were likely pathogens. The original hypothesis is incorrect as there is clinical value in applying molecular techniques such as DNA sequencing in the mycology lab to fungi recovered in small numbers.

Sequencer-Based Capillary Gel Electrophoresis (SCGE) Targeting the rDNA Internal Transcribed Spacer (ITS) Regions for Accurate Identification of *Candida, Cryptococcus, Trichosporon* and Other Yeast Species

Author Block:

X. Hou[1], M. Xiao[1], S. C. Chen[2], H. Wang[1], L. Zhang[1], X. Fan[1], Z-P. Xu[1], F. Kong[2], Y-C. Xu[1]; [1]Peking Union Med. Coll. Hosp., Beijing, China, [2]Westmead Hosp., Univ. of Sydney, Sydney, Australia

Abstract Body:

Accurate species identification of *Candida*, *Cryptococcus*, *Trichosporon* and other yeast species is important for clinical management. In the present study, we evaluated a yeast species identification scheme by determining the rDNA internal transcribed spacer (ITS) region length types (LTs) using a sequencer-based capillary gel electrophoresis (SCGE) approach. A total of 156 yeast isolates encompassing 32 species (151 clinical isolates and five reference strains) were first used to establish a reference SCGE ITS LT database. Clinical evaluation of the SCGE ITS LT database was then performed using a further 95 isolates (seven *Candida* and one *Cryptococcus* species). In the initial database, 41 ITS LTs were identified, which distinguished 29 of 32 (90.6%) studied yeast species, with the exception of *Trichosporon asahii*, *Trichosporon japonicum* and *Trichosporon asteroides*. Isolates of eight species revealed different electropherograms and were subtyped into 2-3 different ITS LTs each. Of 95 test isolates representing eight species, 94 (98.9%) were correctly identified to species level, and the remaining one isolate had a novel ITS LT. The SCGE ITS LT assay was able to distinguish between the species of *Candida parapsilosis* species complex, *Candida glabrata* species complex, *Candida haemulonii* species complex and *Cryptococcus neoformans* species complex, but cannot differentiate the three *Trichosporon* species of *T. asahii*, *T. japonicum* and *T. asteroids*, which need further IGS1 region sequencing. In conclusion, yeast identification by SCGE ITS LT is a reproducible, fast and inexpensive alternative for the identification of clinical important yeast species.

Prevalence of Acute Hepatitis A Virus and Hepatitis E Virus in Urban Cities of Sindh, Pakistan

Author Block:

A. Muneer[1], T. Siddiqui[1], M. Nadeem[1], S. U. kazmi[2]; [1]Rahila Res. & Reference Lab (pvt) Ltd., Karachi, Pakistan, [2]IIDRL Lab, Univ. of Karachi, Karachi, Pakistan

Abstract Body:

Background: Hepatitis A virus <HAV> and Hepatitis E virus <HEV> are both transmitted by route, resulting in acute viral hepatitis <AVH> in developing countries. They pose major health problems in our country. This study was done to determine prevalence of HAV and HEV in patients presenting with AVH.**Methods:** A cross-sectional study of 1-year duration was conducted in urban cities of Sindh, Pakistan. Samples were collected from general population of different areas of cities. Serum samples were analyzed for IgM anti-HAV and IgM anti-HEV for the detection of HAV and HEV, respectively using commercially available ELISA kits and then confirmed by PCR method.**Results:** : The seroprevalence of HAV and HEV positive patients were 60% and 20% respectively. There were 240 male samples and 260 female samples between the age group of 2 months to 30 years. It was found that young children from the age of 2 months to 10 years were the most affected population.**Conclusions:** Based on the above data, it is identified that young population of urban cities of Sindh is at the high risk of acquiring hepatitis A and hepatitis E virus due to poor sanitary conditions. This data will be helpful in planning for future vaccination and in improvement of hygiene.

Relationship between Socio-Economic and Nutritional Features and Advanced HIV Disease (AHD) in Newly Diagnosed HIV Patients in a Rural Hospital in Mozambique

Author Block:

X. Kortajarena[1], **M. Á. Goenaga**[1], M. Ibarguren[1], H. Azkune[1], M. J. Bustinduy[1], A. Fuertes[2], R. Galvez[2], L. Garcia-Pereña[3], E. Nacarapa[2]; [1]Hosp. Univ.rio Donostia, Donostia, Spain, [2]Hosp. El Carmelo, Chokwe, Mozambique, [3]Hosp. El Carmelo, Chokwe, Spain

Abstract Body:

Background: WHO estimated that there are 35 million people living with HIV in the world (69% in Sub-Saharan Africa). Some reports have shown the relationship between socio-demographic and nutritional features and AHD. The aim of this report is to know the prevalence and that relationship in our cohort. **Methods:** 1170 HIV new diagnosed 15 years old or older patients were enrolled during 2014 in Carmelo Hospital (Chokwe), a rural town located in Gaza province (Mozambique), with more than 25% of HIV prevalence in adults between 15-49 years old. We collected different socio-demographic and basic nutritional data to know the relationship with AHD, defined as WHO stage III or IV or CD4 lymphocyte count <200/mm3. **Results:** Mean age:37 years old. 41.3% were male. WHO stage:I 53,9%, II 23,2%, III 19% and IV 3,9%. 35.8% do not have access to electricity and 34.2% to water. Mean of hospital arrival time was 49 minutes: 42.5% on foot, 55.4% by public transport and 2.1% by their own vehicle. 82.8% do not have any degree, 12.7% primary degree, 4.1% secondary degree and 0.4% university degree. 51.5% were unemployed. Mean height 162 cms and mean weight 58.6%. Body mass index (BMI): 14% desnutrition (BMI<18.5); 66.2% normal (BMI 18.5-25); 15.6% overweight (BMI 25-30) and 4.1% obese (BMI>30). 65.5% had anaemia (Hb<12): 27.8% mild (Hb 11-12); 55.8% moderate (Hb8-11) and 16.4% severe (Hb<8). CD4 lymphocyte levels: 61.2% <350/mm3 and 36.1% <200/mm3. Gender (male 61.1% vs female 31.4%;p=0.00), employment status (employed 31.8% vs unemployed 54.5%;p=0.00), age(39 vs 36 years old;p=0,00), arrival time to the hospital (52 vs 48 minutes;p=0.019), BMI(20.9 vs 23.4;p=0.00) and hemoglobin (10.1 vs 11.7;p=0.00) were the features independently associated with AHD.**Conclusions:** The percentage of people with AHD were 43.5%. The features associated with AHD were male gender, being older, being unemployed, longer arrival time to the hospital, lower BMI and lower hemoglobin level.

Effects of Pitavastatin on Markers of Arterial Inflammation and Immune Activation in HIV Patients

Author Block:

K. Fitch[1], M. Zanni[1], T. Burdo[2], L. Sanchez[1], C. Sponseller[3], K. Williams[2], J. Aberg[4], S. Grinspoon[1]; [1]Harvard Med. Sch., Boston, MA, [2]Boston Coll., Chestnut Hill, MA, [3]KOWA Pharmaceuticals America, Montgomery, AL, [4]Mt Sinai Sch. of Med., New York, NY

Abstract Body:

Background: HIV patients on chronic ART often exhibit increased arterial inflammation and immune activation. Statin therapy may improve such indices, but few data from randomized, long-term studies are available, particularly with newer statins, such as pitavastatin, which do not have known significant interactions with ART. We previously reported greater effects of pitavastatin than pravastatin to reduce LDL-C in this study (-31% vs. -21% pitavastatin vs. pravastatin, CROI 2014). We now compare changes in markers of arterial inflammation and immune activation. **Methods:** In a randomized, double-blind study, 252 HIV patients on ART > 6 mos (CD4 > 200 cells/μL and HIV RNA <200 copies), and dyslipidemia [(LDL-C ≥130 and ≤220 mg/dL) and TG ≤400 mg/dL)] were randomly assigned 1:1 to receive pitavastatin 4 mg or pravastatin 40 mg PO QD. Inflammatory biomarkers were assessed at 12 and 52 weeks.**Results:** Neither demographics such as age [50 (45, 56) yrs], sex (87% male), BMI [27 (24, 30) kg/m^2], log HIV RNA [1 (1, 1)], Framingham risk score [5 (3, 9) %] nor baseline inflammatory markers were different between groups. Subjects randomized to pitavastatin demonstrated significantly greater reductions in sCD14 (P=0.01), OxLDL (P=0.02) and Lp-PLA2 (P=0.01) compared to subjects randomized to pravastatin, whereas other markers were not different at 52 weeks (Table, P value for Change Between Groups, *P<0.05 for Change Within Groups).**Conclusions:** Pitavastatin significantly lowered sCD14, OxLDL and Lp-PLA-2 over 52 weeks in dyslipidemic HIV patients. These effects were more prominent than seen with pravastatin, a commonly prescribed statin in HIV. Combined with more potent efficacy on LDL-C, these results suggest that pitavastatin may be an effective statin to improve lipids and inflammatory markers in HIV patients. Further studies are needed to determine the effects of pitavastatin on CVD prevention in HIV.

Change in Biomarkers Over 52 Weeks

	Baseline Pravastatin	Baseline Pitavastatin	Change Pravastatin	Change Pitavastatin	P Value(Change Between Groups)
sCD163, ng/mL	948.7 (736.8, 1139.4)	1030.2 (731.1, 1369.3)	-26.8 (-133.4, 128.7)	13.2 (-137.7, 129.9)	0.84

IL-6, pg/mL	1.1 (0.7, 1.7)	0.9 (0.8, 1.4)	0.1 (-0.3, 0.4)	0.0 (-0.3, 0.3)	0.39
MCP-1, pg/mL	142.6 (107.4, 180.7)	142.2 (110.9, 189.2)	-2.5 (-22.3, 22.0)	-2.2 (-30.3, 27.7)	0.89
sCD14, ng/mL	1752.1 (1381.9, 2057.4)	1801.3 (1348.0, 2275.8)	10.22 (-281.2, 307.9)	-144.9 (-482.7, 114.5)*	0.01

Alarming Prevalence of HDV-HBV Co-Infection in Patients at Hepatitis Clinic, Civil Hospital, Karachi, Pakistan

Author Block:

G. Fatima[1], S. Quraishy[2], **S. U. Kazmi**[1]; [1]Immunology and Infectious Disease Res. Lab. - Dadabhoy Inst. of Higher Ed., Karachi, Pakistan, [2]Civil Hosp., Karachi, Pakistan

Abstract Body:

Pakistan is currently facing an epidemic of viral hepatitis caused by B, C and D viruses which share parallel routes of transmission. Hepatitis D virus (HDV) is a small, defective RNA virus that can only replicate in individuals who are already infected with hepatitis B virus. Patients having HBV-HDV co-infection may have more severe outcomes and higher risk of fulminant hepatitis in acute cases and cirrhosis and hepatocellular carcinoma in chronic infections within 5-10 years compared to individuals suffering from HBV mono infection. Worldwide, more than 15 million people are co-infected with this virus. Pakistan and other developing countries still fall among the areas of high endemicity for HDV infection. Since hepatitis B infection is a major public health problem in Pakistan, we investigated the prevalence of hepatitis D virus infection among the HBV positive patients population and associated risk factors. Blood samples were collected aseptically in red top vaccutainer from 12679 patients who reported at hepatitis Clinic of Civil Hospital, , during a period of two years (2013-2014). Demographic data including age, sex and risk behaviors were also recorded. All serum samples were screened for the presence of HBsAg by one step ELISA technique and confirmed by PCR for HBV DNA. Samples from HBV positive patients were processed to determine HDV specific antibodies by Sandwich ELISA technique. A total of 2472 (19.5%) patients with symptoms of hepatitis tested positive for presence HBsAg, HBV DNA .Out of these HBV positive patients, 1954 tested for anti HDV, 693 (35.5%) were found to be positive for HDV specific antibodies . HDV infection was most prevalent in patients on both extremes of age i-e under 10 years and 71-80 years, slightly higher in females than males and majority had a history of drug injections (therapeutic) and previous surgery. **Conclusion:** Our results indicated a very high prevalence of HDV infection among the HBV infected patients which would suggest that all such patients should be tested for HDV infection to avoid serious complications of the disease. Mass screening, HBV vaccination campaigns and awareness sessions about mode of spread can be effective in reducing the burden of HBV and HDV.

Ctr. for Global Hlth.and Med., Kounodai, Ichikawa, Chiba, Japan

Abstract Body:

Background: Epidemiological data of hepatitis C virus (HCV) infection in Mongolia is limited. Acute HCV hepatitis is issue among men who have sex with men (MSM) with various genotype of HCV in East Asia.**Methods:** We evaluated HCV antibody of Mongolian MSM who visited us to take a screening test for human immunodeficiency virus in Mongolia from December 2013 to September 2015. Among HCV antibody positive subjects, we evaluated HCV genotype with direct gene sequencing method of NS5B region. **Results:** Among 501 subjects, 51 (10.2%) were HCV antibody positive and HCV-RNA was detected in 32 (6.4%). Among HCV-RNA detected subjects, 30 (93.8%) were genotype 1b and 2 (6.3%) were genotype 2a. **Conclusions:** HCV genotype distribution of MSM was almost similar to the previous data among healthy-individuals in Mongolia.

How Important Are The HBV DNA Levels Of 2,000 IU/ml In Hbeag-Negative And 20,000 IU/ml In HbeAg-Positive Chronic Hepatitis B Patients with Persistently High Alt Levels to Predict The Liver Damage

Author Block:

E. Yenilmez[1], R. A. Cetinkaya[1], A. Ulcay[1], M. Afyon[1], B. Bektore[1], T. K. Atik[1], M. B. Selek[1], H. Diktas[2], B. Simsek[3], A. Haholu[1], I. Yilmaz[1], V. Turhan[1]; [1]GATA Haydarpasa Training Hosp., Istanbul, Turkey, [2]Tatvan Military Hosp., Bitlis, Turkey, [3]Kasimpasa Military Hosp., Istanbul, Turkey

Abstract Body:

Background: There are few studies of the chronic hepatitis B (CHB) cases with low HBV DNA but persistently high ALT (PHALT) levels..**Methods:** A total of 450 naive patients with CHB (HBeAg-negative:249, HBeAg-positive:201) between 2008 and 2015 who are 19 to 40 years-old and male, were retrospectively enrolled in the study. Liver biopsy was performed after having ALT over 40 U/l persistently at least for six months regardless of the HBV DNA levels. We separated the cases according to the HBV DNA level of 2,000IU/ml for HBeAg-negative and 20,000IU/ml for HBeAg-positive, respectively. Also we formed groups according to HAI scores of 0-3/4-7/8-11/12-18 and fibrosis scores of 0-1/2/3-4/5-6 defined as no-minimal/moderate/significant/ severe, respectively. Than, we tested for the association between these groups using Chi-square test.**Results:** For HBeAg-negative cases, the mean age, ALT, DNA, Ishak's histological activity index (HAI) and fibrosis score was 23.9±0.3, 88.2±5U/l, $1.4x10^7$ IU/ml±$6.4x10^6$IU/ml, 4.08 and 1.44, respectively. For HBeAg-positive cases, the mean age, ALT, DNA, Ishak's HAI and fibrosis score was 22.5±0.2, 107.8±5.8U/l, $1.9x10^9$ IU/ml±$2.6x10^8$IU/ml, 4.72 and 1.61, respectively. For HBeAg-negative cases, there were statistically significant difference between HBV DNA levels <2,000 IU/ml and >2,000 IU/ml groups in HAI and fibrosis level groups defined (p:0.001<0.01 for HAI and p:0.000<0.01 for fibrosis),but the relationship between the groups were concordant but very low in strenght (tau c:0.21 for HAI and tau c:0.24 for fibrosis). For HBeAg-positive cases, there were statistically significant difference between HBV DNA levels <20,000 IU/ml and >20,000 IU/ml groups in HAI and fibrosis levels groups defined (p:0.001<0.01 for HAI and p:0.002<0.01 for fibrosis, but the relationship between these groups were concordant but very low in strenght (tau c:0.15 for HAI and tau c:0.15 for fibrosis).**Conclusions:** Further studies and new guideline recommendations about CHB cases with low HBV DNA are needed to guide clinicians how to monitor these cases.

Publishing Title:

Long-Term Mean Plasma HIV RNA And CD4 Nadir Influence on Liver Stiffness Measurement in HIV-HCV Coinfected Patients and HIV Monoinfected Patients

Author Block:

S. G. Parisi[1], M. Basso[1], R. Scaggiante[1], M. Franzetti[1], S. Andreis[1], A. Cattelan[1], C. Mengoli[1], M. Cruciani[2], M. Andreoni[3], S. Piovesan[1], G. Palù[1], A. Alberti[1]; [1]Padova Univ, Padova, Italy, [2]ULSS 20, Verona, Italy, [3]Roma Univ, Roma, Italy

Abstract Body:

Background: To determine the influence of long-term (36 months before liver stiffness measurement, LSM) mean plasma HIV viremia (mpHIV) and of nadir CD4+ on LSM assessed with transient elastography in HIV monoinfected patients (MOpts) and HIV-HCV coinfected (Copts**).Methods:** The patients had to be HBsAg negative, HCV RNA positive in case of HCV positivity and with a valid LSM performed; pHIV defined undetectable HIV viremia (UV) if no value >50 copies (cps)/ml (no more than 1 blip/year) and as detectable viremia (DV) otherwise. Cut-off for DV mpHIV: less than 1000 cps/ml, (low, L); 1001-10000 cps/ml (intermediate, I), ≥10001 cps/ml (high, H). The cut-off for "normal" LSM was 4 kPa and 7.1 kPa for significant fibrosis. The Chi-squared test ,Fisher test and the Mann-Whitney test were applied as appropriate.**Results:** COpts had higher LSM values than MOpts both in case of UV and of DV ($p<0.0001$). The frequency of pts with normal LSM in higher in MOpts with UV, approaching the significance (34.9% vs 21.3%, $p=0.07$). The difference between Mopts and COpts was significant for each class of pHIV (L $p=0.001$, I $p=0.02$; H $p=0.0003$). Nadir was lower in MOpts with UV respect to MOpts with D ($p=0.01$): in MOpts with normal LSM the difference between UD and DV was not significant (296 vs 310, $p=0.5$) but in MOPS with LSM>4 nadir is lower in pts with UD (270 vs 357, $p=0.01$).**Conclusions:** COpts had higher LSM than MOpts, regardless mpHIV: in MOpts the influence of long-term mpHIV load on LSM seems related to the HIV RNA detectability and not to the HIV RNA level. The possible role of nadir is probably independent from mpHIV.

Figure 1. Main characteristics of the 207 HIV patients, stratified in 4 groups according to HCV serology, HCV RNA and mean plasma HIV viremia of the 36 months before liver stiffness measurement.

Publishing Title:

Role of VACS Index in the Survival of Patients with Substance Use Disorders and HiIV/HCV Infections

Author Block:

A. Sanvisens, P. Zuluaga, D. Fuster, J. Tor, **R. Muga**; Hosp. Germans Trias i Pujol, Badalona, Spain

Abstract Body:

Background: The Veterans Aging Cohort Study (VACS) is an index that includes age, CD4+ cell count, HIV-1 RNA and general indicators of organ system injury. It is designed to predict mortality in a wide range of patient population including HIV-negative patients. We aimed to analyze the VACS index in patients seeking treatment of substance use disorder (SUD).**Methods:** cohort study in patients admitted to treatment between 1997 and 2014 in Badalona, Spain. Characteristics of patients and blood samples were obtained at admission. VACS was computed according to http://vacs.med.yale.edu and stratified by the median; for HIV-negative patients, CD4+ cells and HIV-RNA counted 0 points. Patients were followed-up until December 2014 and cross-checks with death registry were obtained.**Results:** 768 patients included (82% M); median age was 35 years (IQR: 29-43 years); SUD was attributable to opiate, cocaine, and alcohol in 372 (48.5%), 108 (14.1%), and 287 patients (37.4%), respectively. Almost 53% had history of injection drug use. Prevalence of HIV and HCV infection was 23.4% (n=180) and 51.9% (n=399) respectively; 22.6% (n=174) patients were HIV/HCV co-infected. Median CD4+ cell count was 402 cells and median RNA-HIV was 5.200 UI/mL. Prevalence of HAART use was 38%. Median VACS score at admission was 12 points (IQR:5-24 points) and the maximum score observed was 95 points. After median follow-up of 10.6 years (IQR 5.8-14.8 yrs) (7.748 person-years), 18% of patients had died (n=140). Table shows mortality rates and Relative Risk (RR) of death according to viral infections and VACS score:

	Patients* (N=768)	**Deaths (N=140)**	**Follow up (p-y)**	**Mortality rate (x 100 p-y) (95% CI)**	**Relative Risk (95% CI)**
HIV(-) HCV(-)- and VACS ≤12	260	20	2398	0.8 (0.5-1.3)	1
HIV(-) HCV(-) and VACS >12	103	22	659	3.3 (2.1-4.9)	4.0 (2.1-7.4)
HIV(-) HCV(+) and VACS ≤12	122	20	1539	1.3 (0.8-2.0)	1

HIV(-) HCV(+) and VACS >12	103	20	1151	1.7 (1.1-2.6)	1.3 (0.7-2.5)
HIV(+) HCV(+) and VACS ≤12	28	5	325	1.5 (0.6-3.4)	1
HIV(+) HCV(+) and VACS >12	146	53	1610	3.3 (2.5-4.2)	2.1 (0.9-6.0)

*Six HIV+/HCV- patients are not shown in TableAdjusted Cox regression models showed that VACS>12 points, Alcohol Use Disorder and HIV/HCV co-infection were independent risk factors of death (HR: 1.9, 95%CI=1.3-2.9; HR=2.1, 95%CI:1.4-3.3 and HR=2.2, 95%CI:1.3-3.7, respectively).**Conclusion:** VACS predicts mortality in SUD patients with and without HIV infection. Alcohol and drug use disorder should be included in comorbidity indexes to better estimate mortality.

Hepatitis C Virus Genotypes in Patients Attending a Tertiary Care Hospital, Karachi, Pakistan

Author Block:

G. Fatima[1], S. Kumar[2], S. Quraishy[1], **S. U. Kazmi**[1]; [1]Immunology and Infectious Disease Res. Lab., Karachi, Pakistan, [2]Civil Hosp., Karachi, Pakistan

Abstract Body:

Background: Hepatitis C is a blood borne chronic liver disease, caused by the hepatitis C virus (HCV),which may progress to cirrhosis, hepatocellular carcinoma and even liver failure. It is one of the leading cause of morbidity and mortality and a serious public health problem, worldwide as well as in Pakistan. An estimated 130-170 million people worldwide are infected with hepatitis C. No vaccine against hepatitis C is currently available. There are seven major genotypes of the hepatitis C virus, which are indicated numerically from one to seven. HCV genotype-3 is known to be relatively more responsive to available therapy than other types. **Objective:** In this study investigated the frequency of various HCV genotypes present in patients with liver disorders attending Hepatitis Clinics at Civil Hospital - the largest public sector tertiary care hospital of Pakistan . **Methods:** All patients attending Civil Hospital Karachi, Pakistan, during a period of five years (2010-2014) who were positive for Hepatitis C virus RNA by real time PCR were included in the study. Blood samples were collected from the patients in yellow top vaccutainers, and allowed to clot, centrifuged and serum was separated and saved at -40^0C till further testing. HCV genotyping was done by real time PCR according to manufacturer's instructions. Demographic data of all patients was recorded and results were analysed to determine risk factors. **Results:** In order to know the prevalence of hepatitis C virus genotype in our community we determined HCV Genotype for 951 patients who were positive for HCV RNA by real time PCR. It was observed that the most prevalent HCV genotype was "3" for which 713 (75%) patients tested positive , followed by 1a in 63(6.6%) cases. Genotype 3 was distributed in all age groups but females were slightly more affected by genotype 3 than males. **Conclusions:** High prevalence of HCV Genotype 3 strain among inject able drug users (IDUs) due to use of recycled syringes, unsafe blood transfusion is a cause of concern for public health professionals in Pakistan, however timely diagnosis may reduce the chances of serious complications due to comparatively effective therapeutic response to available antiviral treatment. Our observations call for developing effective control of factors contributing to high incidence of disease.

Increasing Incidents of Hbv & Hcv Dual Infection in Sindh Pakistan

Author Block:

B. A. Khan, s. Khan; Dow Univ. of Hlth.Sci., Karachi, Pakistan

Abstract Body:

Introduction: Viral hepatitis, Chronic liver diseases and hepatocellular carcinoma (HCC) are majorly caused by Hepatitis B (HBV) and Hepatitis C (HCV) viruses which shares the same route of transmission thus increasing the risk of dual-infection. The major concern with HBV/HCV dual-infection is that it can cause more severe liver disease and increase risk for the development of HCC. The frequency of HBV & HCV dual infection varies according to the geographical region. Pakistan is highly endemic for HBV & HCV infection. Due to lack of awareness & exposure to high risk activities HBV & HCV infection is significantly boosting. Since both of these viruses shares the same route of transmission, so there is a high risk of HBV & HCV dual-infection which needs to be evaluated **Objective:** To determine the frequency of Hepatitis B virus and Hepatitis C virus dual-infection in Sindh Pakistan using Real Time-PCR. **Methods:** Total 1864 blood samples were collected from suspected male & female patients, ranging from 07 to 70 years. HBV DNA was extracted using Qiagen dsp virus extraction kit and HCV RNA was extracted using kit from Roche followed by real time PCR using Qiagen & roche amplification kit respectively. **Results:** Out of total 1824 patients 1208 (66.2%) were males and 616 (33.7%) were females. HBV DNA was detected in 472 (25.8%) individuals. HCV RNA was found in 464(25.4%) patients. HBV/HCV co-infection was found in 322 (17.6%) samples while 888 (48.6%) were found negative for HBV and HCV. Females were infected more with HCV than HBV while HBV was found more in males. Patients of 21-40 years of age group were most affected for these viral infections as compare to other two age groups. **Conclusions:** This study shows that the frequency of HBV/HCV dual-infection is very high in Sindh Pakistan, the highest prevalence of dual-infection was seen in between 21-40 years of age. The main reason might be that this age group has more exposure to the high risk factors. Therefore extra attention is required to prevent the spread of infection particularly in this age group. Dual-infection of HBV/HCV is significantly boosting in our population. Which causes more severe liver disease therefore special attention is required towards the management and treatment of patients infected with Hepatitis B and C viruses.

Seroprevalence and Phylogeny of Hepatitis B Virus Among Apparently Healthy Blood Donors in Ekiti State, Nigeria

Author Block:

A. O. Oluyege; EKITI STATE Univ. ADO EKITI, Ado-Ekiti, Nigeria

Abstract Body:

Background: Voluntary and non-remunerated blood donors are frequently employed for blood donation and constitute a potential source of transmission of Hepatitis B virus particularly in rural communities in Nigeria. Blood are accepted if the result of the screening for the Hepatitis B surface Antigen and other transfusion transmissible infections is negative. Establishing the phylogeny of HBV is critical to developing infection control strategies. This study was carried out to establish the phylogeny of the HBV among blood donors in Ekiti State. **Methods:** Commercially prepared immunochromatographic test strips used for screening blood donors was employed to detect the seroprevalence of HBsAg in the sera of blood donors. A nested PCR assay targeting a 408 bp stretch within the S ORF was used to detect HBV DNA. The targeted amplicons were purified and sequenced using BigDye chemistry sequencing. HBsAg reference sequences were retrieved from the HBV database and aligned using the CLUSTAL W program in MEGA 5 software. The phylogeny and pair wise distance of the HBsAg were estimated using MEGA 5 software with Kimura-2 parameter model. **Results:** A total of 27 (6.8%) of the 400 sera were positive for HBsAg. The 408 bp amplicon within the S ORF was successfully amplified in only 6 (22.2%) of the HBsAg positive samples. The phylogenetic analysis revealed that all the HBV from blood donors in Ekiti State belong to the genotype E. **Conclusions:** This study confirms the endemicity of HBV, the risk constituted by blood donors and the circulation of genotype E among blood donors in Ekiti State.

Factors Associated to Co-Infection with Hepatitis B Virus or Hepatitis C Virus in Hiv Patients Under Treatment in Mbujimayi in Drc

Author Block:

E. K. Tshibangu, N. Kayiba, T. M. Tshiswaka, **T. G. Disashi**; Univ. of Mbuji-Mayi, Mbuji-Mayi, Congo, Democratic Republic of the

Abstract Body:

Background: Mbujimayi in DRC is an area of high prevalence of infection by the human immunodeficiency virus (HIV) and hepatitis B virus the virus (HBV) and C (HCV) virus which share the common routes of transmission. This study aimed to determine the prevalence of HIV co-infection with HBV and HCV and to identify the its associated factors among patients on antiretroviral therapy in Mbujimayi. **Methods:** Sectional study involves a random sample of 100 patients under treatment. These patients were interviewed and examined. Detremination of HBe and HBs antigens of HBV and anti-HCV antibodies against HCV, used the immunochromatographic test (SD Bioline®). CD4 count was performed by flow cytometry (Alere Pima®). A logistic regression analysis model was used to assess the determinants of HIV co-infection with HBV and / or HCV. The Epi-Info 3.5.1 (CDC®) was used for statistical analyses. **Results:** The frequency of co-infection of HIV with HBV, HIV with HCV, HIV with HBV and HCV was respectively 21% [13.5 to 30.3], 8.8% [3.6 to 17.2] and 3.0 [1.0 to 9.8]. The HBe Ag frequency was 8.7% [1.1 - 28.0] among HIV patient with HBV. None of these patients has been checked for HBV or HCV or received a vaccination or a treatment against HBV, HIV patients co-infected with HBV or HCV have a more severe immunosuppression than other patients (CD4 cells / mm3: 356.3 ± 254.5 vs 499.9 ± 243.1 cells / mm3; p = 0.019). The most determinants of HIV co-infection with HCV or HBV were the past history of jaundice (OR = 7.7 [1.0 to 57.9]; p = 0.049) and the notion of sex without a condom in the last six months (OR = 4.8 [1.1 to 21.4]; p = 0.039). **Conclusions:** HIV and HBVor HCV coinfection are frequent and associated with a poor immune status of patients Mbujimayi. Unfortunately, these co-infections do not seem to be the target of specific diagnostic and therapeutic measures.

Emergence of CMY-2-Producing *Proteus mirabilis* in Companion Animals with UTI: 16 Years Study

Author Block:

C. Marques, A. Belas, L. Telo da Gama, C. Pomba; CIISA, Faculty of Vet. Med. - UL, Lisbon, Portugal

Abstract Body:

Proteus mirabilis is frequently associated with complicated and nosocomial urinary tract infections (UTI) in humans and companion animals. ESBL- and pAmpC-producing bacteria are frequently multidrug-resistant (MDR) and their increase is a worldwide concern. The goal of this study was to characterise the antimicrobial resistance of *P. mirabilis* isolated from companion animals with UTI over a period of 16 years.A total of 155 *P. mirabilis* isolated from companion animals with UTI (1999-2014) were included. Disk diffusion antimicrobial susceptibility testing was performed and CLSI breakpoints were applied. Third-generation cephalosporin (3GC) resistant isolates were screened by PCR and sequencing for the presence of ESBL (CTX-M) and pAmpC (CMY, DHA, MOX, ACT, FOX, MIR) genes. Fluoroquinolone resistance genes *qnr* (A, B, C, D and S) were also tested. Fisher exact test was used for statistical analysis.First detected in 2004, *P. mirabilis* 3GC resistance increased significantly ($p<0.001$) from 2.06% (n=2/97) to 20.37% (n=11/54) when comparing 1999-2006 and 2007-2014 time periods. A significant increase in resistance against amoxicillin/clavulanate ($p<0.01$), fluoroquinolones ($p=0.03$) and gentamicin ($p<0.01$) was also detected. In the 2007 to 2014-time period, resistance frequencies were as follow: 21.82% (n=12/55) amoxicillin/clavulanate, 32.14% (n=18/56) fluoroquinolones and 16.07% (n=9/56) gentamicin. Ninety percent (n=9/10) 3GC-resistant *P. mirabilis* harbored CMY-2 enzyme. All but one *P. mirabilis* CMY-2-producer were isolated from dogs. One *P. mirabilis* DHA-1-producer was also found in a dog. All 3GC-resistant isolates were resistant to three or more antimicrobials and thus were considered MDR. A significant increase in MDR was also detected ($p<0.001$). Only five *P. mirabilis qnr*D-producers were detected among 37 fluoroquinone-resistant isolates.This study shows a significant increase in *P. mirabilis* antimicrobial resistance in companion animals with UTI. The emergence of MDR CMY-2-producing *P. mirabilis* in companion animals raises great public-health concerns. Future epidemiological studies on CMY-2-producing *P. mirabilis* fecal colonization should be conduced in dogs to assess their role as reservoirs.

Comparison of Beta-Lactam Versus Fluoroquinolone Empiric Treatment in *Pseudomonas aeruginosa* Urinary Tract Infections

Author Block:

N. R. Schwarber[1], S. Schmittling[1], S. Waqar[2], S. J. Bergman[3]; [1]HSHS St. John's Hosp., Springfield, IL, [2]Southern Illinois Univ. Sch. of Med., Springfield, IL, [3]Southern Illinois Univ. Edwardsville Sch. of Pharmacy, Edwardsville, IL

Abstract Body:

Background: Data have emerged that improving empiric therapy in urinary tract infections (UTI) can decrease length of stay (LOS). The aim of this study was to evaluate how empiric therapy impacts LOS in UTI caused by *Pseudomonas aeruginosa* (PA). **Methods:** An IRB approved retrospective cohort study was conducted on inpatients admitted from January 1, 2010 through September 30, 2015. Patients with PA urine cultures were identified from the microbiology laboratory and included if they received empiric treatment with either a beta-lactam (BL) or fluoroquinolone (FQ). Exclusion criteria were patients less than 18 years old or non-urinary bacterial infections. The primary outcome was LOS compared between those who received empiric treatment with a BL versus those who received a FQ. Secondary outcomes included differences in mortality, adverse events, rates of *Clostridium difficile* infection, and appropriateness of empiric therapy based on susceptibility results. Analysis was performed using STATA. Non-normally distributed means were logarithmically transformed. **Results:** A total of 44 patients were included in this study with 24 in the BL group and 20 in the FQ group. Baseline characteristics were similar in both groups with regard to age, gender, and presence of urinary catheter. Four patients (20%) were immunosuppressed in the FQ group compared to only one patient (4%) in the BL group. The mean LOS in the FQ group was 7.6 days compared to 5.3 days in the BL group ($p > 0.05$). After regression analysis including age, gender, immunosuppression, urinary catheter, sepsis, and appropriateness of empiric therapy, the FQ group was associated with a LOS 1.04 days longer than the BL group ($p > 0.05$). FQ was associated with 60% appropriate empiric therapy compared to 42% in the BL group. For antipseudomonal BL, however, this number was 100%. No differences in other secondary outcomes were detected. **Conclusion:** In this pilot study, we found a 30% decrease in LOS with BL empiric therapy compared to FQ use. Although not statistically significant, future studies should include a larger sample size to determine if these results can be replicated and assess reasons for the difference.

The Effect of Cranberry Juice on the Human Gut Microbiome: A Placebo-Controlled Trial of Women with Recurrent Urinary Tract Infections

Author Block:

W-C. Chou[1], H. Schreiber[2], K. Kaspar[3], M. Hullar[4], O. Kahsai[4], E. Traylor[4], S. Hultgren[2], C. Khoo[3], A. Earl[1]; [1]Broad Inst., Cambridge, MA, [2]Washington Univ. in St. Louis, St. Louis, MO, [3]Ocean Spray, Middleborough, MA, [4]Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract Body:

Urinary tract infections (UTIs) affect 15 million women each year in the United States alone, with 20-30% of women experiencing frequent recurrent UTIs (rUTIs) that do not resolve even with repeated antibiotic treatment. Studies have shown that women who experience rUTIs and consumed cranberry products were 47% less likely to have another UTI. This study aims to understand how cranberry consumption may reduce rUTI incidence by assessing its impact on the composition of the gut microbial community, the reservoir for UTI-associated pathogens. Seventy-one women with a recent history of rUTI were enrolled and received a cranberry beverage or a placebo daily for 24 weeks. Fecal samples were collected prior to study visits at weeks 0 and 24 and prior to any UTI visit. Using 16S rRNA gene-based metagenomic sequencing, we determined the community structure of the gut microbial community and identified genera that were correlated with the effects of daily cranberry beverage consumption. We found that microbial diversity within samples was not significantly different between cranberry juice and placebo groups, and same subject samples tended to be more similar to each other than to other subject samples regardless of cranberry consumption. However, we identified two genera, *Anaerovorax* ($p=0.0003$) and *Flavonifractor* ($p=0.001$), that were significantly associated with cranberry consumption. Ongoing work using whole genome shotgun metagenomic approaches will help us to further elucidate the functional changes within the gut microbiota associated with cranberry consumption.

Total Laboratory Automation and Maldi-Tof Improves Turnaround Times for Urine Cultures

Author Block:

T. Theparee, S. Das, R. B. Thomson, Jr; NorthShore Univ. Hlth.System, Evanston, IL

Abstract Body:

Rapid microbiological information is essential for patient care. A Bruker matrix-assisted laser desorption ionization time of flight (MALDI-TOF) system was implemented in our laboratory for organism identification followed later by BD Kiestra total laboratory automation (TLA). We compared turnaround times (TAT) for urine cultures before and after implementation to assess these developments.Urine culture data was extracted from our laboratory information system in one month periods representing manual plating and biochemical identification (CONV), manual plating and MALDI (MALDI), early phase implementation of TLA and MALDI (TLA1), and late phase implementation of TLA and MALDI (TLA2). TAT to organism identification (ID) and antimicrobial susceptibility (AST) report were calculated for positive cultures. Results were compared between time periods and organism groups using the Kruskal-Wallis test and Dunn's post test.A total of 1532, 1330, 1214, and 1326 positive urine cultures were extracted for the CONV, MALDI, TLA1, and TLA2 groups respectively. TLA1 and 2 show significantly improved time to ID and AST and reduced TAT variability (interquartile range) compared to MALDI and CONV ($p<.001$). In addition, TLA2 showed significantly improved time to AST compared to TLA1 ($p<.01$). Time to ID significantly improved with MALDI compared to CONV for organisms not identifiable by spot testing ($p<.001$). Time to ID was similar for organisms identifiable by spot testing for all time periods.**Conclusions:** MALDI-TOF and TLA significantly improved TAT to ID and AST with positive urine cultures. Specifically, MALDI-TOF improves time to ID compared to CONV, and TLA plus MALDI-TOF improves time to ID and AST compared to CONV and MALDI. Our analysis also revealed areas for further improvements with TLA.

Risk Factors for Severe Sepsis and Septic Shock in Complicated Pyelonephritis

Author Block:

I. Marquez, V. Buonaiuto, L. Valiente, J. Mora, I. De Toro, A. Plata, B. Sobrino, J. Reguera, J. Colmenero; Hosp. REGIONAL DE MÁLAGA, MÁLAGA, Spain

Abstract Body:

Background: Severe sepsis and/or septic shock are the main factors influencing the prognosis of acute pyelonephritis. However, information about risk factors for severe sepsis in complicated pyelonephritis (CPN) is very scarce. Our aim was to analyze factors associated with the development of severe sepsis or septic shock in a large sample of patients with CPN. **Methods:** We conducted a retrospective cross-sectional observational study including 1507 consecutive patients older than 14 years diagnosed with CPN and admitted to a tertiary hospital between 1997 and 2015. Covariates associated with severe sepsis or septic shock in univariate analysis, were included in a multivariate logistic regression model.**Results:** Of the 1507 patients, 423 (28.1%) fulfilled the criteria for severe sepsis or septic shock at the time of admission. Crude and attributable mortality at 30 days were 17.7% and 11.7% in patients with severe sepsis or septic shock versus 1.7% and 0.6% in patients without severe sepsis or septic shock, $P < .0001$ and $P < .0005$ respectively. An age >65 years, urinary instrumentation in the previous two weeks, the lack of mictional syndrome or costovertebral tenderness, thrombocytopoenia, an ectasia ≥ grade II and bacteraemia were independent risk factors associated with severe sepsis or septic shock.**Conclusions:** The prevalence of severe sepsis and septic shock in patients with CPN is high. Some risk factors for severe sepsis are easy to identify in any Emergency Department. Using these data should simplify the empirical treatment of CPN and avoid unnecessary admissions.

Publishing Title:

Intravenous Eravacycline With Transition To Oral Therapy For Treatment Of Complicated Urinary Tract Infections (Cuti) Including Pyelonephritis: Results From A Randomized, Double-Blind, Multicenter, Phase 3 Trial (Ignite2)

Author Block:

L. Tsai[1], M. Zervos[2], L. Miller[3], P. Tenke[4], A. Marsh[1], J. Mohr[1], K. Luepke[1], P. Horn[1]; [1]Tetraphase Pharmaceuticals, Inc, Watertown, MA, [2]Henry Ford Hosp., Detroit, MI, [3]Harbor-UCLA Med. Ctr., Torrance, CA, [4]Jahn Ferenc South-Pest Teaching Hosp., Budapest, Hungary

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity being developed for the treatment of serious infections, including those caused by multidrug-resistant pathogens.**Methods:** IGNITE2 evaluated the efficacy and safety of ERV vs levofloxacin (LEV) in hospitalized patients with cUTI. Patients were randomized to intravenous (IV) ERV 1.5 mg/kg once daily (QD) or IV LEV 750 mg QD. Patients could transition to ERV 200 mg orally (PO) twice daily or LEV 750 mg PO QD after 3 days if clinically indicated, for a total of 7 days. The primary endpoint was the composite response rate (clinical cure and microbiological success) in the microbiological intent-to-treat (micro-ITT) population at the post-treatment visit (PT, 6-8 days after end of therapy [EOT]) with a non-inferiority margin of 10%.**Results:** 908 patients were randomized, 600 were included in micro-ITT analysis. Although composite response rates were higher for ERV than LEV at EOT (5.5%, 95% CI=-0.5 to 11.4), ERV did not achieve non-inferiority to LEV at PT. In a pre-specified subgroup analysis, the response rate among LEV-resistant pathogens was higher for ERV compared to LEV. Response rates were also higher for ERV among patients who received 7 days of IV study drug. The most common adverse events were nausea and vomiting, 82/455 (18%) and 33/455 (7.3%) for ERV vs 14/450 (3.1%) and 6/450 (1.3%) for LEV, respectively.**Conclusion:** ERV did not achieve statistical non-inferiority compared to LEV but showed higher response rates among patients with LEV-resistant pathogens and those who received 7 days of IV study drug. Further investigation of the change in response between EOT and PT and the efficacy of IV-only therapy is warranted.

Table 1. Composite Response at the PT Visit

Group	ERV	LEV	Difference (95% CI)
All micro-ITT	180/298 (60.4%)	202/302 (66.9%)	-6.5% (-14.1, 1.2)
LEV-R pathogens	43/80 (53.8%)	31/85 (36.5%)	17.3% (2.1, 31.8)
3 days IV	74/131 (56.5%)	91/129 (70.5%)	-14.1% (-25.4, -2.3)

7 days IV	30/51 (58.8%)	26/54 (48.2%)	10.7% (8.5, 29.0)

Intravenous Eravacycline Compared to Intravenous Levofloxacin for the Treatment of Complicated Urinary Tract Infections (cUTI): Subgroup Analysis from a Randomized, Double-Blind, Phase 3 Trial (IGNITE2)

Author Block:

L. Tsai[1], M. Zervos[2], L. Miller[3], P. Tenke[4], A. Marsh[1], J. Mohr[1], K. Luepke[1], P. Horn[1]; [1]Tetraphase Pharmaceuticals, Inc., Watertown, MA, [2]Henry Ford Hosp., Detroit, MI, [3]Harbor-UCLA Med. Ctr., Torrance, CA, [4]Jahn Ferenc South-Pest Teaching Hosp., Budapest, Hungary

Abstract Body:

Background: In IGNITE2, Eravacycline (ERV), when administered as an intravenous (IV) to oral transition therapy, did not achieve the primary endpoint of statistical non-inferiority compared to levofloxacin (LEV) for the treatment of cUTI. Additionally, fewer days of IV therapy was associated with loss of efficacy between the end of therapy (EOT) and post treatment (PT, 6-8 days after EOT) evaluations, particularly among ERV patients.**Methods:** A subgroup analysis of patients enrolled in IGNITE2 who received only IV ERV 1.5 mg/kg once daily or IV LEV 750 mg once daily was performed. All patients who received IV-only therapy were included, regardless of the duration of treatment.**Results:** There were 178 patients who received IV-only therapy; 121 were included in the microbiological intent-to-treat (micro-ITT) population. Baseline demographics were balanced between the 2 groups and included 67% female, mean age 58.3±16.9 years, and 38% pyelonephritis. *Escherichia coli* was the most common pathogen identified (76.5%). The LEV resistance rate was 34.7%. Composite responder rates (clinical cure and microbiological success) at PT are presented in the table. Responder rates among patients with LEV-resistant and LEV-susceptible pathogens are also presented. The most common adverse events were nausea and vomiting, reported in 19/91 (20.9%) and 8/91 (8.8%) subjects in the ERV arm compared to 6/87 (6.9%) and 3/87 (3.4%) subjects in the LEV arm.**Conclusions:** ERV demonstrated comparable efficacy to LEV in a subgroup of patients enrolled in IGNITE2 who received IV-only therapy for the treatment of cUTI and greater efficacy in patients with LEV-resistant pathogens.

Table 1. Composite Response at the PT Visit - IV-Only Therapy

Group	ERV	LEV	Difference (95% CI)
IV-only-micro-ITT	31/57 (54.4%)	27/64 (42.2%)	12.2% (-5.7, 29.3)
LEV-R pathogens	8/19 (42.1%)	3/23 (13.0%)	29.1% (2.1, 53.8)
LEV-S pathogens	23/28 (60.5%)	24/41 (58.5%)	2.0% (-19.5, 23.2)

Publishing Title:

Risk Factors for Change in Microbiological Outcomes between the End of Therapy (Eot) and Post-Treatment (Pt) Evaluations in Patients with Complicated Uti (Cuti) Treated with Eravacycline (Erv): Analysis from a Randomized, Double-Blind, Phase 3 Trial (Igni

Author Block:

L. Tsai[1], A. Das[2], J. Mohr[1], P. Scoble[1], P. Horn[1], A. Shorr[3]; [1]Tetraphase Pharmaceuticals, Inc, Watertown, MA, [2]InClin, Inc, San Mateo, CA, [3]Medstar Washington Hosp. Ctr., Washington, DC

Abstract Body:

Background: IGNITE2 compared ERV to levofloxacin (LEV) for cUTI. Although ERV achieved a higher response rate (clinical cure and microbiological success) at the end of therapy (EOT), ERV did not demonstrate non-inferiority to LEV at the post-treatment evaluation (PT, 6-8 days after EOT). Since response was driven by microbiological outcome, we investigated factors associated with microbiological failure at PT despite initial response at EOT.**Methods:** Outcomes in patients classified as microbiological success at EOT were examined. We compared those who remained successes at PT to patients who converted to failure. Risk factors including demographics, type of infection, study drug, and duration of IV therapy while on study drug were assessed. We employed logistic regression to identify variables independently associated with microbiological failure at PT despite success at EOT.**Results:** In the microbiological-ITT population, at EOT, 90.6% (270/298) and 84.8% (256/302) subjects were microbiological successes in the ERV and LEV groups, respectively. Crude failure rates between EOT and PT were 25.5% and 14.3 %, for ERV and LEV, respectively. Independent variables associated with conversion to failure at PT are shown in the table below. The adjusted Odds Ratios (OR) for loss of efficacy between EOT and PT among patients who received ≤ 3 days IV study drug were 1.61 (95% CI=0.90, 2.88, p=0.1102) and 1.34 (95% CI=0.67, 2.67, p=0.4135) for ERV and LEV, respectively, suggesting an interaction between duration of IV therapy and study drug.

Table. Factors associated with failure at post-treatment visit in multivariate analysis

Factor	**Adjusted OR**	**95% CI**	**p-value**
Treatment	0.68	0.44 - 1.06	0.0900
Diagnosis (AP vs other cUTI)	0.57	0.36 - 0.92	0.0200
Gender	1.55	0.96 - 2.50	0.0716
IV study drug ≤ 3 days	1.45	0.93 - 2.26	0.0977

Conclusions: Treatment with ≤ 3 days of IV ERV was identified as a potentially modifiable, independent risk factor for a change in microbiologic outcome between EOT and PT in patients enrolled in this study. Further investigation of IV-only ERV for the treatment of cUTI is warranted.

Publishing Title:

Outcomes and Development of Resistance of Fosfomycin Use in Extended-spectrum *Beta-Lactamases (Esbl) Enterobacteriaceae* Urinary Tract Infection (Uti) in Geriatric Patients

Author Block:

J. Quek[1], T. Ng[1], C. Teng[2]; [1]Tan Tock Seng Hosp., Singapore, Singapore, [2]Natl. Univ. of Singapore (NUS), Singapore, Singapore

Abstract Body:

Background: There is limited clinical data on oral fosfomycin in the treatment of urinary tract infections caused by *ESBL Enterobacteriaceae*. These *ESBL* organisms are often resistance to ciprofloxacin and co-trimoxazole, limiting the availability of oral treatment. In the geriatric population, renal impairment often limits the use of nitrofurantoin. We evaluated the treatment outcomes and development of resistance of fosfomycin use, for *ESBL Enterobacteriaceae* UTI, in geriatric inpatients in a Singapore hospital.**Methods:** A retrospective study was conducted on all patients who received oral fosfomycin from 1st March 2013 to 30th June 2014 in Tan Tock Seng Hospital. Only patients with *ESBL K. pneumoniae* and *E.coli* UTI were included. Data on patient characteristics, microbiology and outcomes were collected.**Results:** One hundred and fifteen patients received oral fosfomycin. The median age was 79 (IQR, inter-quartile range; 70 - 86) years old and 43 (37.4%) were males. The median Charlson score was 6 (IQR; 4 - 8). 39 (42.6%) had diabetes and median creatinine clearance was 40.4 (IQR; 27.6 - 56.5) mls/min. 77 (67.0%) were cystitis and 38(33.0%) complicated UTI. 71 (67.1%) patients had *E.coli* UTIs while 44 (38.3%) had *K.Pneumoniae* UTIs. 30 (26.1%) received active empiric antibiotics while 37 (32.2%) received an active definitive antibiotic prior to fosfomycin. Majority of patients received a single dose of fosfomycin [88 (76.5)%] with the remaining patients receiving up to 3 doses. Mortality rate was 5.2%. 81 (70.4%) patients had microbiological cure and 33 (28.7%) had recurrence within 3 months; of which, fosfomycin resistant *enterobactericeae* UTI developed in 11 (9.6%) patients. No patient developed adverse drug reactions to fosfomycin.**Conclusions:** Fosfomycin is safe and effective in treating *ESBL Enterobacteriaceae* UTI in the geriatric population. It achieved comparable microbiological cure rates as reported in other studies[1]. However resistance development may be a cause of concern.

Activity of Ceftazidime-avibactam (CAZ-AVI) Against ESBL Positive *Enterobacteriaceae* (Entb) and CAZ-resistant *Pseudomonas aeruginosa* from Urinary Tract Infections (UTI) in Asia/South Pacific, Europe, Middle East/Africa and Latin America in the 2013 INFORM Surveillance Program

Author Block:

G. STONE[1], E. Reiszner[1], R. Badal[2], M. Hackel[2]; [1]AstraZaeneca Pharmaceuticals, Waltham, MA, [2]IHMA, Schaumburg, IL

Abstract Body:

Background: Resistance to β-lactams is increasing worldwide due in part to extended-spectrum β-lactamases (ESBL) among Gram-negative pathogens that cause UTIs, thus reducing treatment options for these infections. Avibactam (AVI) is a novel, non-β-lactam, β-lactamase inhibitor that inhibits Ambler class A, C, and some class D β- lactamases. Combining AVI with ceftazidime (CAZ) may have utility in the treatment of such UTI pathogens.**Methods:** Isolates were collected as a part of the International Network for Optimal Resistance Monitoring (INFORM) global surveillance program. UTI isolates were collected during 2013 as follows: Asia/South Pacific (AP): 766 Entb and 62 *P. aeruginosa* from 8 countries; Europe (E): 1,715 Entb and 184 *P. aeruginosa* from 19 countries; Middle East/Africa (MEA): 323 Entb and 29 *P. aeruginosa* from 5 countries; Latin America (LA): 581 Entb and 55 *P. aeruginosa* from 6 countries. MICs were determined by CLSI broth microdilution method. CAZ-AVI MICs were determined using a fixed concentration of 4 µg/ml of AVI. Entb ESBL+ phenotype was confirmed according to CLSI guidelines. CAZ-AVI FDA susceptible breakpoints: ≤8 µg/mL for Entb and *P. aeruginosa*.**Results:** MIC_{90} values (µg/ml) of CAZ-AVI against selected Gram-negative species (including phenotypically characterized ESBL+ and CAZ-NS *P. aeruginosa*) are shown below.

	MIC_{90} (µg/mL)			
Organism	AP (n)	E (n)	MEA (n)	LA (n)
Klebsiella pneumoniae ESBL -	0.5 (208)	1 (530)	1 (89)	2 (133)
K. pneumoniae ESBL+	1 (68)	1 (233)	1 (50)	2 (81)
Escherichia coli ESBL -	0.25 (334)	0.25 (679)	0.25 (137)	0.25 (240)
E. coli ESBL+	0.5 (121)	0.5 (161)	0.25 (31)	0.5 (75)
P. aeruginosa CAZ-S	4 (54)	8 (149)	32[b] (22)	8 (41)
P. aeruginosa CAZ-NS	NA[a] (8)	64 (35)	NA[a] (7)	16 (14)

[a]NA - Not Applicable[b]CAZ-AVI MICs were ≤8 μg/ml (susceptible FDA breakpoint) for 82% of *P. aeruginosa* isolates in MEA**Conclusions:** CAZ-AVI showed excellent *in vitro* activity against ESBL+ Entb, CAZ-NS and *P. aeruginosa* isolates from urinary tract infections worldwide.

Exploring Antibody Responses to Uropathogenic *Escherichia coli* in Patients with Uncomplicated Utis

Author Block:

C. A. Sarkissian, V. DeOrnellas, A. Sintsova, H. H. L. Mobley; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Urinary tract infection (UTI) is the second most common infection in humans after those involving the respiratory tract. Uropathogenic *Eschericia coli* (UPEC) is the most common causative agent of UTIs in healthy individuals. Although antibiotics have generally been an effective treatment for UPEC infections, the continuous rise in antibiotic resistant strains adds significant urgency to vaccine development programs. Efforts to license an effective vaccine have so far been unsuccessful, and are in part hampered by gaps in our understanding of the immune response to UPEC infection. While some studies, as well as the high incidence of recurrent disease, suggest that antibody responses to bladder infections are weak and ineffective, these responses have not been investigated in sufficient detail. To explore UPEC-induced antibody responses, we obtained sera and bacterial specimens from a patient cohort with uncomplicated UTIs that included both individuals with no prior history of UTIs, as well as those with recurrent infections. When patients' sera were tested against a lysate of UPEC strain CFT073, we found that most patients produced antibodies that are able to recognize multiple CFT073 antigens. The specificity of the responses varied dramatically between patients with recurrent infection and those with no history of UTI. Additionally, using whole cell ELISAs, we found that each patient produced significant levels of antibodies that were specific for that patient's clinical UPEC isolate, and that antibody responses showed varied levels of cross reactivity against clinical strains isolated from other patients. In conclusion, we demonstrate that patients with uncomplicated UTIs show high levels of specific antibodies in their sera, and our future studies will focus on the ability of this antibody response to mediate bacterial clearance.

***Pseudomonas aeruginosa* Urinary Tract Infections in Hospitalized Patients: Mortality and Prognostic Factors**

Author Block:

J. Lamas, L. González, J. Álvarez, A. Arca, J. Bermúdez, I. Rodríguez, M. Fernández, J. De la Fuente; Hosp. Povisa, Vigo (Pontevedra), Spain

Abstract Body:

Background: The aim of this study was to analyze the mortality and predictors of 30-day mortality among hospitalized patients with *Pseudomonas aeruginosa* urinary tract infection (PAUTI), as well as the impact of antibiotic treatment on survival.**Methods:** Patients admitted to our hospital with PAUTI or those diagnosed of PAUTI during hospitalization for other disease between September 2012 and September 2014 were included. Repeated episodes from the same patient and episodes of asymptomatic bacteriuria were excluded. Database with demographic, clinical and laboratory ítems was created. Empirical and definitive antibiotic therapy, antimicrobial resistance and all-cause mortality at 30 and 90 days were included. Kaplan-Meier curves and log-rank test were used to analyze the association of variables with 30 days survival. Multivariate analysis was made using Cox regression.**Results:** 62 hospitalized patients with PAUTI were included, with a mean age of 75 years. 51% were male. PAUTI were comunity adquired in 27% of cases. 8% meet criteria for severe sepsis or septic shock at the time of diagnosis. *Pseudomonas aeruginosa* isolates were multiresistant in 27% of cases. Definitive antibiotic treatment was inadequated in 24,2% of patients. Mortality was 17.7% at 30 days and 33.9% at 90 days. Factors associated with reduced survival at 30 days were chronic liver disease with portal hypertension (P <0.01), diabetes mellitus (P = 0.04) chronic renal failure (P = 0.02), severe sepsis or septic shock (P <0.01), Charlson index > 3 (P = 0.02) and inadequated definitive antibiotic treatment (P <0.01). Independent risk factors for mortality in multivariate analysis were advanced chronic liver disease (HR 77,4; P<0,01), diabetes mellitus (HR 3,6; P=0,04), chronic renal failure (HR 4,1; P=0,03) and inadequated definitive antimicrobial treatment (HR 6,8; P=0,01).**Conclusions:** PAUTI are associated with high mortality in hospitalized patients, which increases significantly in those with severe comorbidity such as chronic renal failure, advanced liver disease or diabetes mellitus. Inadequated antibiotic treatment is associated with poor outcome, which remarks the importance of adjusting empirical antibiotic treatment based on the microbiological susceptibility results.

Persistence and Quiescence in Uropathogenic *Escherichia coli*

Author Block:

E. Pelton, William Law, Paul S. Cohen and Jodi Camberg; Univ. of Rhode Island, Kingston, RI

Abstract Body:

Uropathogenic *Escherichia coli* (UPEC) are the leading cause of urinary tract infections, and 27% of patients experience recurrent infection even after treatment with antibiotics. The bacteria associated with recurrent infections are thought to enter dormancy and survive exposure to antibiotics. Persister cells, which are a subpopulation of cells that are resistant to the cytotoxic effects of antibiotics, have been identified in several pathogenic organisms including UPEC strains. Several mechanisms for stimulating persister cell formation in *E. coli* include toxin-antitoxin systems, starvation, gene regulation by ppGpp, and stochasticity. Here we utilize an assay to promote the development of persistence in the prototypic UPEC strain CFT073 and monitor persistence by measuring survival after treatment with ampicillin. We performed minitransposon mutagenesis using a miniTn5 to generate mutants of CFT073 that are defective for persistence. We screened 300 mutants and identified three that are defective for persistence. In addition to forming persister cells, CFT073 also undergoes metabolite-induced quiescence. Quiescence is a state of dormancy where bacteria exit from the growth and division cycle but remain viable. To understand if the two states of dormancy, persistence and quiescence, are controlled by overlapping or redundant mechanisms, we tested if the persistence mutants are also defective for quiescence. We found that all three mutants isolated undergo quiescence on minimal media when plated at low density, similar to CFT073, but are defective for persistence. These results suggest that persistence and quiescence represent two distinct states of dormancy and may further uncover the mechanisms by which recurrent UPEC infections survive antibiotic treatment in patients with urinary tract infections.

Evaluation of a Biomarker Based Algorithm for Diagnosis of Urinary Tract Infection in Hospitalized Patients

Author Block:

S. Das, E. Usacheva, R. Thomson, L. Peterson; NorthShore Univ. Hlth.System, Evanston, IL

Abstract Body:

Background: Diagnosis of urinary tract infection (UTI) is dependent on the accurate interpretation of a positive urine culture and careful evaluation of symptoms and can be difficult in elderly and patients with comorbidities. Despite best efforts, overtreatment of asymptomatic bacteriuria has reached epidemic proportions jeopardizing antibiotic stewardship efforts. We hypothesized that true infection is associated with host response and evaluated the utility of a urinary biomarker (microRNA 223-3p) of host response as a predictor of UTI among hospitalized patients. **Methods:** In a previous study, we derived our UTI diagnostic algorithm on 113 patients with a spectrum of findings with and without UTI. For this study, we validated the concept on 101 urine specimens from patients admitted for acute care. Clinical and laboratory data was collected from all patients. Total RNA was extracted from 1ml of whole urine and expression of microRNA-223-3p was quantified. Briefly, 10ng of RNA was reverse transcribed using specific primers followed by Taqman® assay. Signals were normalized to U6 housekeeping gene and a comparative threshold cycle (Ct) method ($2^{-\Delta Ct}$) was used to calculate relative miR expression.**Results:** Using clinical and laboratory data, patients were grouped as: a) having UTI per NHSN guidelines or b) with no evidence of UTI. Clinical and/or radiologic evidence of UTI or pyelonephritis was present in 34 patients and 7 patients had evidence of sepsis in addition to UTI. Urine culture was positive in all patients with clinical UTI, but was also positive in 73% of patients without UTI. Similarly, abnormal urinalysis had no correlation with clinical diagnosis of UTI ($p>0.5$). The median expression of miR-223-3p was 5.99 in the UTI group compared to 0.44 in the non-UTI group ($p<0.0001$). When the cut-off value for a positive relative miR 223-3p expression was set at a >2.0, the test was 91% sensitive and specific for detection of UTI. The negative predictive value of the assay was found to be 0.95 (0.86-0.98, 95% CI). The area under the receiver operating characteristic curve (ROC) was 0.905.**Conclusions:** A diagnostic algorithm of miR-223-3p levels in urine could be a valuable tool in screening patients with suspected UTI, with culture being done only on patients exceeding a defined threshold.

Urinary Tract Infection in Renal Transplant Recipients in India

Author Block:

S. Sharma, R. K. Nair, D. Mukherjee; Army Hosp. Res. & Referral, Delhi, India

Abstract Body:

Background: Urinary tract infection (UTI) is the most common bacterial infection faced by renal transplant recipients(RTR). Our objective was to determine the incidence, predisposing factors and microbiological profile of UTI in renal transplant recipients in our centre.**Methods:** This was a cross-sectional observational study in which 210 renal transplant recipients were studied over one year. All patients were analysed in detail and cultures were taken when there was significant WBC count in urine microscopic examination.**Results:** Out of 210 transplant recipients, 69(32.86%) had UTI. Majority(59/69) had undergone live renal transplantation and ten cases had received cadaveric grafts. Forty nine patients had a primary infection while twenty patients had recurrences. The mean age of patients with UTI was 38.63 ± 10 years. The incidence of UTI was higher in females(42.25%) as compared to males(28.06%). Most common causative agent of UTI in RTR was Escherichia coli(72.46%), followed by Klebsiella pneumoniae(13.04%). Staphylococcus aureus(03/69), Pseudomonas aeruginosa(02/69), Proteus mirabilis(02/69), Salmonella enterica(01/69), Acinetobacter spp(01/69) and Enterococcus fecalis(01/69) were also isolated. Gram negative bacilli accounted for 94.20%(65/69) while Gram positive cocci for 5.8%(4/69) of positive cultures. Multidrug resistance was highest in Klebsiella pneumonia(100%). Fifteen transplant recipients with UTI were detected to have underlying urinary tract abnormalities, most common being urethral stricture(60%) and ureteral stricture(13.33%). One patient was detected to have broken double J stent in renal pelvis. Forty eight patients(69.57%) developed acute graft dysfunction secondary to UTI. Female sex($p=0.038$), urinary tract abnormality($p<0.01$), prolonged Foley's catheterization($p<0.01$), prolonged post-transplant hospitalization($p<0.01$), New onset diabetes after transplantation(NODAT)($p<0.01$) and coexisting HCV infection($p=0.012$) were statistically significant predisposing factors for UTI in RTR.**Conclusions:** The incidence of UTI is related strongly with female sex, urinary tract abnormality, prolonged hospitalization/indwelling catheterization and immunomodulatory conditions like NODAT & HCV infection. Patients with these predisposing factors should undergo regular surveillance for UTI.

Antibiotic and Bacteriophage Susceptibility of Uropathogenic "*Klebsiella pneumoniae*"

Author Block:

M. Fursov[1], A. Lev[2], E. Astashkin[2], V. Myakinina[2], N. Kartsev[2], N. Volozhantsev[2], N. Fursova[2]; [1]RCB RAS, Moscow, Russian Federation, [2]SRCAMB, Obolensk, Russian Federation

Abstract Body:

Background: "*Klebsiella pneumoniae"* is one of the causative agents of urinary tract infections (UTI). The progressive increasing antimicrobial multi drug resistance (MDR) among uropathogens during last decades become a healthcare problem worldwide. Phage therapy considered as alternative and complementary method for antibiotic therapy as part of personalized medicine.**Methods:**Three "*K. pneumoniae*" isolates were collected from 23-year man with chronic inflammation of the bladder. Bacterial identification was done using VITEK-2 (bioMerieux, France), MALDI-TOF Biotyper (Bruker, Germany). The antibiotic susceptibility was determined by VITEK-2 (bioMerieux, France). The susceptibility to 30 Klebsiella phages was determined by the spot test. Resistance genes (bla_{TEM}, bla_{SHV}, bla_{CTX-M}, int1) and virulence genes (*rmpA, aer, uge2, wabG, kfu, fimH, allS*) were detected by PCR. Strain genotyping was performed by Random Amplified Polymorphic DNA (RAPD-PCR) method.**Results:** Three "*K. pneumoniae*" isolates X1, X2 and X3 had MDR phenotype and were resistant to 7 functional classes of antibacterials: beta-lactams, aminoglycosides, quinolones, tetracycline, nitrofurantoin, chloramphenicol, and sulfonamides; sensitive to cefoxitin, tigecycline and carbapenems. The mechanism of MDR determined by beta-lactamase genes bla_{CTX-M}, bla_{TEM} and bla_{SHV}, and class 1 integrons. There are three virulence genes in the genomes of all three isolates: *allS, fimH,* and *wabG*. Virulence gene *uge* was detected additionally in X1 and X3 isolates. Intraspecies differences of isolates were identified by genotyping and phagotyping. Isolates X1 and X3 belong to subtype A, and X2 isolate - to subtype B. Subtype A was sensitive to 17 of 30 used phages, and subtype B - to only one phage. Latter bacteriophage had the ability to lyse all three "*K. pneumoniae*" isolates. It was recommended for phage therapy.**Conclusions:** Three studied uropathogenic "*K. pneumoniae*" isolates demonstrate combining of MDR and virulence potentials. Genetic heterogeneity of UTI pathogen was detected in one patient. Definition of resistance spectrum and phage sensitivity allows to combine antibiotic and phage therapy for realization of personalized approach to the treatment of UTI.

European Multicenter Study on Antimicrobial Resistance in Companion Animal Urinary Tract Infection

Author Block:

C. Marques, UTIR-VNET, C. Pomba; CIISA (UIC/CVT/00276/2013), Faculty of Vet. Med.-UL, Lisbon, Portugal

Abstract Body:

Despite the growing concerns about antimicrobial resistance in companion animals (CA), there is a lack of studies comparing resistance between countries. This multicenter study aimed to investigate the geographical and temporal trends of antimicrobial-resistant bacteria in CA with urinary tract infection (UTI) in Europe.Susceptibility data on 22256 bacterial isolates obtained, between 2008-2013, from CA with UTI from 14 European countries were analyzed. The antimicrobial resistance frequency for the most common uropathogens was determined for each country individually for 2012-2013 using clinical breakpoints used in each laboratory, following the example of EARS-Net surveillance program reports. Fully-resistant isolates to three or more antimicrobial categories were considered multidrug resistant (MDR). Temporal trends of resistance were established by logistic regression.Overall, Southern countries (SC) showed higher percentage of antimicrobial resistance in *Escherichia coli*, *Proteus* spp. and *Staphylococcus* spp. than Northern countries (NC). Resistance to third generation cephalosporins (3GC) was high for *E. coli* in SC: Portugal (31.2%), Italy (24.6%) and Spain (21.2%). *E. coli* fluoroquinolone (FLU) resistance was high in Spain (29.7%), Italy (29.0%) and Portugal (24.0%). The lower percentages of 3GC-resistant *E. coli* were found in the Netherlands (3.8%), Denmark (4.3%) and Austria (5.6%). Sweden, Denmark, Belgium and the Netherlands had less than 10% FLU resistant *E. coli*. Less than 16% *E. coli* were MDR in all countries, except Portugal (24.0%), Spain (29.7%) and Italy (29.0%). The Netherlands and Switzerland had a significant increase in *E. coli* amoxicillin/clavulanate (AMC) and gentamicin (CN) resistance, respectively. *Proteus* spp. from Belgium also showed a rising trend in FLU resistance. Belgium had a significant decrease in *E. coli* resistance to all antimicrobials. Denmark (AMC, FLU, trimethoprim/sulfamethoxazole [SXT]), France (3GC, FLU), the Netherlands (3GC, FLU, SXT, MDR) and Sweden (CN, MDR) also had significant decreases in *E. coli* resistance over time.This work brings new insights into the current European antimicrobial resistance scenario of CA UTI-pathogens and reinforces the need for strategies aiming to reduce resistance, especially in SC, where the highest resistance levels occur.

Rapid and Joint Detection of Three Childhood Pneumoniapathogens Using AllGlo Quadruplex Quantitative PCR

Author Block:

d. Yu, Sr.; Hangzhou First People's Hosp., Hangzhou, China

Abstract Body:

Background: Pneumonia caused by an acute respiratory infection (ARI) is a common disease and continues to be the leading killer of children worldwide. Co-infection of *Mycoplasma pneumoniae* (MP), Epstein-Barr virus (EBV) and human cytomegalovirus (HCMV) is a recently developed ARI cause that poses a serious threat to children's health. Therefore, an accurate and rapid test that can simultaneously detect and differentiate among MP, EBV and HCMV should be established to aid in diagnosis. **Methods:** In this study, we established a quadruplex real-time quantitative PCR (qPCR) method to rapidly identify and simultaneously detect a single infection or co-infection of these three widespread children pneumonia pathogens and an internal control in a single tube using AllGlo fluorescent probes. The quadruplex qPCR system was optimized and evaluated in this assay. **Results:** The analysis demonstrated a high sensitivity of 10^1 copies/test, a wide linear range of detection from 10^1 to 10^8 copies/test, and a low coefficient of variation of less than 5%. The amplification efficiencies for MP, EBV, HCMV and the internal control were 1.04, 1.06, 1.03 and 0.96, respectively, and the correlation coefficients (r^2) of the standard curves were all greater than 0.99. In a comparative reagent test, we found no significant difference between TaKaRa™ and Vazyme™ ($p > 0.05$). Moreover, the results of tests on clinical samples using AllGlo quadruplex qPCR and TaqMan uniplex qPCR were in near perfect agreement (kappa value = 0.97). **Conclusions:** The diagnosis of a single infection or co-infection with three children pneumonia pathogens (MP, EBV, HCMV) in a single tube by multiplex quantitative PCR is possible. This assay will improve clinical differential diagnosis capability, and allow better disease surveillance and controlled outcomes. Application of this promising technique for evaluating children with pneumonia as a screening or confirmation tool might enhance clinical decision making during the early stage of pathogen infection, thereby reducing the overuse of antibiotics and improving patient prognosis.

Performance and Cost-effectiveness of Verigene Rp Flex

Author Block:

A. Silva, R. LaCount, L. Ballard, B. Milham; St. Marys Hosp. and Regional Med. Ctr., Grand Junction, CO

Abstract Body:

Background: Until recently, none of the multiplex respiratory pathogen tests alone could provide the flexibility to satisfy the clinician's desire for both targeted and broad respiratory pathogen testing in a cost-effective manner for the lab and patient. Verigene RP *Flex* allows the user to choose any combination of the 16 viral and bacterial targets for an individual sample at the time of test ordering based on the clinician and patient's needs and pay just for the targets reported. In this study, we determined the analytical performance of RP *Flex* using NP washes and NP eswabs and analyzed the cost-effectiveness of flexible testing with RP *Flex* relative to St. Mary's previous respiratory algorithm and use of broad respiratory viral panel (RVP) only. **Methods:** A combination of clinical (n=22), contrived (n=28) and characterized control (n=6) specimens were tested. The clinical NP eswabs and NP wash specimens were prospectively collected between December 2014 and May 2015 and were frozen at -80°C. Contrived specimens were made by spiking UTM, eswab and NP washes with known positive specimens provided by Zeptometrix. The characterized controls were provided by Zeptometrix. The financial analysis was performed using testing volumes and pricing from 2013 and list pricing for RP *Flex* and a comparable RVP. **Results:** Results of the method comparison are presented in Table 1. RP Flex positive and negative agreement was 100% across all sample types. In 2013, a total of 1,234 flu EIA, 76 flu serotypings, 232 RSV EIA, 2 flu/RSV PCR, 1 Adv PCR, 37 EV PCR, 135 pertussis PCR, and 77 respiratory viral panel tests were sent to a reference lab for testing in 2013, totaling $191,523 in charges. Use of a broad RVP in-house at $130 per test for this testing would have cost $226,690. Use of RP *Flex* with flexible pricing would have cost only $94,860.

Comparison of the Simplexa™ and Solana™ Group A Strep Assays

Author Block:

M. England, P. Erdman, J. Merlo, C. Lowe, D. Myers, D. Craft; Penn State Hershey Med. Ctr., Hershey, PA

Abstract Body:

Introduction: Group A *Streptococcus* (GAS) is the most common cause of bacterial pharyngitis and may lead to non-suppurative sequelae associated with high morbidity and mortality. POC rapid antigen tests are highly specific but have poor sensitivity. Backup conventional cultures require 24-48 hours to final report. Molecular assays provide a means for faster and more sensitive reporting. We evaluated the Simplexa™ (Focus Diagnostics) Group A Strep Direct assay and Solana™ (Quidel Corp) GAS assay for their ability to replace culture for rapid antigen negative specimens.**Methods:** We received 252 throat swab specimens for throat culture. Swabs were rinsed in 250 µl of Amies buffer (sample) and planted to BAP and SSA plates for routine workup. The Simplexa™ and Solana™ were then set up with 50 µl of sample each. A second SSA plate was planted with 50 µl of sample to control for proper rinsing. An additional 50 µl was kept for discrepant analysis by the Lyra® Direct Strep Assay (Quidel Corp).**Results:** Overall, the positivity rate was 11-12%. The average patient age was 21.9y (18m-73y), and the highest positivity rate came from patients aged 5-17y (16/98). There were 3 culture positive/molecular assay negative specimens. MALDI-TOF identified 1 as *S. constellatus* and 2 as *S. pyogenes*. The sensitivity and specificity of the Solana™ were 84.4% and 97.7% respectively, whereas the Simplexa™ had a sensitivity of 93.8% and specificity of 98.2%.

	Solana™	Simplexa™	Culture
True Pos	27	30	30
False Pos	5	4	1
True Neg	215	216	219
False Neg	5	2	2
Total	252	252	252

Conclusions: The overall positivity rate (11-12%) of culture and molecular assays suggest that the number of POC false-negative rapid antigen tests is consistent with reported sensitivities (70-85%). Backup culture proved to be a sensitive method for testing GAS and fared better than or equal to the molecular assays. Both molecular assays had high specificity, but were not as

sensitive as expected in this study. Although we analyzed both molecular assays according to an agreed upon procedure, the overall protocol differed slightly from the manufacturers' package insert. We cannot rule out that the changes had an effect on the sensitivity of either assay.

Comparison Of Methods For Dispersion Of *mycoplasma Pneumoniae* Aggregates

Author Block:

A. H. Totten, L. Xiao, D. M. Crabb, T. P. Atkinson; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract Body:

Background: *Mycoplasma pneumoniae* (Mpn), one of the smallest self-replicating prokaryotes, is known to readily adhere to host cells and to form aggregates in suspension. The fact that the organism has only a single membrane, like eukaryotic cells, presents questions as to optimal aggregate disruption method while minimizing cell death *in vitro*. We compared conventional vortex mixing with other methods for disruption of bacterial aggregates and for its effect on cell viability.**Methods:** UAB PO1, a clinical Mpn isolate, was dispersed via vortex mixer, a probe-type ultrasonicator, repeated 27 gauge needle passage and nonionic detergent (0.1% Tween-20). The resulting suspensions were then plated to measure recoverable CFU / mL *in vitro*. Flow cytometry was carried out to examine membrane integrity with the transmembrane potential dye $DiBAC_4$. Wet Scanning Transmission Electron Microscopy (Wet-STEM) was also performed for high resolution imaging of the resultant cell suspensions.**Results:** Comparison between dispersion methods with Mpn showed a 10-fold enrichment of recoverable CFU / mL *in vitro* with sonication compared to other methods. Time course analysis showed significantly lower bacterial CFU with vortexing compared to sonication at all time points. Flow cytometric analysis showed less cellular membrane damage via $DiBAC_4$ staining in sonicated suspensions. Wet-STEM imaging showed markedly improved dispersion with sonication compared to conventional vortex treatment.**Conclusions:** Sonication is superior to vortexing, repeated 27 gauge needle passage, or nonionic detergent for dispersion of Mpn aggregates while preserving cell viability. Preparation of Mpn suspensions for experiments should be done using brief sonication due to the dramatic decrease in CFU induced by extended vortexing.

Publishing Title:

The Evaluation of Two Single-Analyte Assays and One Multi-Analyte Assay Utilizing Specimens Submitted for *B. pertussis* PCR

Author Block:

L. M. Kirkpatrick, A. M. Budgin, J. J. Manaloor, T. E. Davis, R. R. Relich; Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Background: In recent years, the laboratory diagnosis of pertussis has dramatically changed. Once considered the gold standard, culture has largely been replaced by molecular methods. To diagnose *B. pertussis* infection, our institution performs a laboratory-developed assay, which is performed once per day. Although it provides a rapid turnaround time and better sensitivity compared to culture, delays in patient care are possible. Recently, other molecular assays that offer faster turnaround times have become available. To evaluate the clinical impact and cost savings of these tests, we compared our assay to the *illumigene*® Pertussis Assay, the AmpliVue® Bordetella Assay, and the FilmArray® Respiratory Panel (RP). **Methods:** A total of 120 de-identified nasopharyngeal swab specimens submitted for *B. pertussis* PCR and known to be positive or negative were tested using the *illumigene*® and AmpliVue® assays. A smaller subset of these specimens (n = 60) were tested using the RP assay. Flocked nylon swabs submitted in either M6 or BD universal transport media (UTM) were first tested by the standard of care method and then stored at -80°C until testing. Analytical parameters, including sensitivity, specificity, and negative and positive predictive values, were calculated for each assay and compared. In addition, a cost-benefit analysis was conducted.**Results:** The sensitivity and specificity for the *illumigene* and AmpliVue assays were 69% and 85%, and 99% and 98%, respectively. The sensitivity and specificity of the RP for *B. pertussis* were 70% and 100%. Of the positive samples tested by the RP, 40% were also positive for other respiratory pathogens. Of the negative samples, 67% of specimens were positive for respiratory pathogens, including human rhinovirus/enterovirus, *M. pneumoniae*, and human parainfluenza viruses.**Conclusions:** All assays were easy to perform and provided rapid turnaround times. Of the two single-analyte assays, the AmpliVue assay performed best when utilized with UTM, and was the most cost effective alternative to in-house testing. The RP assay provided the most diagnostic value, but was the most costly. Overall, rapid single-plex and multi-plex nucleic acid tests provide clinically-meaningful information in a short turnaround time and offer a cost effective means to diagnose pertussis.

Comparison of Molecular Methods and Rapid Antigen Tests with Culture in Detection of Group A Streptococcus from Throat Swab Samples

Author Block:

N. Putkuri, L. Ivaska, J. Niemelä, V. Peltola, **K. Rantakokko-Jalava**; Turku Univ. Hosp., Turku, Finland

Abstract Body:

Background: The diagnosis of streptococcal pharyngitis is most commonly confirmed with bacterial culture or a rapid antigen test. Neither of the approaches is perfect since either the time span for the final result (24-48h in culture) or the sensitivity of the methods (rapid antigen tests) is insufficient. In this study, rapid and accurate molecular methods were tested for detection of group A streptococcus (GAS) from throat swab samples and compared to five rapid antigen tests and the gold standard culture method. **Methods:** Altogether 85 throat swab samples were collected from children (1 to 16 yrs) presenting at emergency department with acute pharyngitis. Throat swab samples were collected in ESwab™ (Copan), and the leftover was stored in -70°C prior testing. Molecular methods tested were Simplexa™ GAS assay using 3M Integrated Cycler (Focus Diagnostics) and Illumigene® GAS assay (Meridian Bioscience). Rapid antigen tests included QuickVue Strep A Dipstick (Quidel), OSOM Strep A (Sekisui Diagnostics), Alere TestPack +Plus Strep A (Alere Medical Co., Ltd.), 75-75STREPA (Salofa Oy) and Ultimed Strep A (Ultimed) tests. Tests were performed as manufacturer's instructions except that the swab samples were replaced with 50µl of the Eswab transport media. **Results:** Out of 85 samples, 14 GAS positive samples were detected by culture. Both molecular assays proved to be sensitive and specific to detect GAS when compared to culture (Simplexa sensitivity 100% and specificity 94 %, Illumigene 94 % and 96 %). Specificity values were affected by the better sensitivity of the assays compared to culture; both assays established more positive results than had been initially indicated by culture. In practice, Simplexa assay required less hands on time and was easier to set up for testing. All rapid antigen tests were specific but sensitivity varied between 43-91%. QuickVue Strep A Dipstick, 75-75STREPA and Ultimed Strep A tests were the most sensitive tests (sensitivity values 86 %, 91 % and 91 %, respectively). **Conclusion:** Molecular methods are an applicable choice when considering fast and sensitive assay to replace conventional bacterial culture for the detection of GAS.

Improved Lower Respiratory Pathogen Testing from Clinical Sputum Specimens with No Pre-Processing on a Fully Automated Multiplex Molecular Testing System

Author Block:

J. Green[1], B. Graham[1], U. Spaulding[1], M. Rogatcheva[1], M. Jones[1], A. Clark[1], E. Huynh[1], D. Goldgar[1], S. Thatcher[1], B. Buchan[2], M. Faron[2]; [1]BioFire Diagnostics, Salt Lake City, UT, [2]Med. Coll. of Wisconsin, Milwaukee, WI

Abstract Body:

Background: Quantitative Culture (QC) is a reliable method used to identify bacteria or fungi in sputum specimens, but requires extensive procedures (pre-treatments, colony isolation & identification) and time. Semi-quantitative culture (SQC), while less accurate, is commonly used because it is easier and faster. Both methods are limited in their ability to distinguish multiple species, either from background oropharyngeal flora or co-infections (both common in sputum) without extra labor. BioFire is developing a multiplex molecular test to detect lower respiratory pathogenic bacteria, viruses, fungi, and several antibiotic resistance markers in an hour without sample pre-treatments.**Methods:** A prospective study was conducted using 48 residual fresh sputum and endotracheal aspirate specimens submitted for standard of care testing at the Medical College of Wisconsin, USA. Detections and quantity were characterized by 4 independent methods: SQC, QC (not normally performed), and prototype molecular tests with sputum and digested sputum.**Results:** 67% of specimens were positive by prototype FilmArray compared to 44%/52% (SQC/QC) by culture. FilmArray detections were 100%/96% (SQC/QC) concordant with culture while also providing viral (9%) and antibiotic resistance marker (8%) detections not available by culture. The total number of pathogens detected at a meaningful level (≥10^5 cfu/ml) was higher for sputum (treated & untreated) tested on FilmArray than traditional culture; co-detection rates of 2.4 (FA), 0.9 (SQC), and 1.7 (QC).**Conclusions:** Sputum specimens tested without pre-processing on the FilmArray system provide more comprehensive results compared to traditional SQC. QC provides expanded results as compared to SQC, but at the cost of increased processing and time to result. FilmArray identifies more meaningful LRTI pathogens than culture methods, and requires only 2 minutes to load sample into a fully automated proprietary sputum specimen preparation; all of which improves pathogen identification and patent care.*The FilmArray LRTI Panel has not been evaluated by the FDA or other regulatory agencies for* in vitro *diagnostic use*.

A Novel Lamp Platform Enabling Rapid Poc Diagnosis Using a Multi-Well Chip

Author Block:

M. Sato, A. Shoji, S. Semba, N. Hosaka, T. Yonekawa, Y. Segawa, H. Watanabe, T. Notomi; Eiken Chemical Co.,Ltd., Tochigi, Japan

Abstract Body:

Background: In infectious diseases, rapid identification of pathogens is very important for prompt and appropriate treatment. Recently many technologies for Point-of-Care (POC) diagnosis by nucleic acid testing have been emerging. However, there are still high expectations for further improvement of accuracy, rapidity and coverage of pathogens in medical practice. Therefore, we have been developing a novel system of Loop-mediated isothermal amplification (LAMP) platform which enables a 15 minutes detection of multiple pathogens genomes. The system is characterized by a microfluidic chip having 25 wells with dry form reagent for LAMP and an amplification-to-detection device optimized for the chip.**Methods:** The analytical performance of this system was evaluated by using newly designed LAMP primers and probes for the respiratory infectious diseases panel; *Bordetella pertussis* (BP), *Mycoplasma pneumoniae* (MP), *Chlamydophila pneumoniae* (CP) and *Legionella* (LG). Purified DNA was injected into the chip automatically with pumpless injection technology and the reaction completed after 15 minutes under isothermal condition (64°C) in the device. The amplification signal of each well was measured in real time by quenching method. **Results:** Limit of Detection (LoD) test was performed with plasmid DNA having target sequence of BP, CP, MP and LG and LoD for each target was 1.56, 1.88, <0.63 and <0.63 copies per test respectively (5 wells were used for 1 test and 1 well equals to 5µl). The test of specificity and cross-reactivity was performed with purified bacteria genomes from ATCC strains and clinical isolates. As a result of specificity test for 10 BP strains, 5 MP strains, 6 CP strains and 23 LG strains, only the target genome was detected and there was no cross-reaction. There was also no cross-reaction with the other 46 pathogenic bacteria species genome. **Conclusions:** These findings indicate the capability of the system to detect multiple pathogens simultaneously, rapidly and easily with high sensitivity and specificity. Although we reported 4-pathogens panel in this study, the chip is applicable to test up to 25 pathogens including controls. Furthermore our goal is set to develop the fully automated system enabling rapid POC diagnosis (<30min), which integrates this system and nucleic acid extraction system under development.

Semi-quantitative Analysis of Bacterial Pathogens in Bronchial Alveolar Lavage (Bal) Specimens Using the Pilot Filmarray Lower Respiratory Tract Infection (Lrti) Multiplex Molecular Test

Author Block:

M. L. Faron[1], N. A. Ledeboer[1], **H. Seliger**[1], J. Connolly[1], M. Rogatcheva[2], J. J. Gilbreath[2], B. W. Buchan[1]; [1]Med. Coll. of Wisconsin, MIlwaukee, WI, [2]BioFire Diagnostics, LLC, Salt Lake City, UT

Abstract Body:

Background: Pneumonia is a serious medical condition associated with bacterial, viral and fungal agents. Some bacterial agents are normal inhabitants of the upper airway and have fastidious growth requirements. These factors complicate interpretation of bacterial culture results. Quantitative bacterial thresholds have been proposed to aid in assigning clinical significance. We evaluate a pilot, Research Use Only (RUO) version of the FilmArray LRTI Panel (LRTI) and correlate results with quantitative culture.**Methods:** BAL specimens (n=73) were tested using the LRTI and quantitative bacterial culture. LRTI reports semi-quantitative results for 15 bacterial targets, in addition to qualitative results for 14 other bacterial, viral, or fungal agents. LRTI results are reported as "Not Detected" or values of "10^4", "10^5", "10^6", or ">10^7". Quantitative cultures were reported with quantitation of potential pathogens present at 10^3 to 10^5 and ">10^5" CFU/mL. Potential pathogens were not specifically identified if normal flora was present at >10^5 CFU/mL.**Results:** Culture identified 13 potential pathogens, 10 of which were reported 10^4 CFU/mL or greater (i.e. clinically significant). LRTI identified all 13 culture positive specimens; however, semi-quantitative results were at least 10-fold higher for 11/13 targets. This included 3 targets that were reported at a concentration of 10^3 by culture (one each, *S. aureus, S. agalactiae, P. aeruginosa*). An additional 8 targets were reported as positive by LRTI at 10^4-10^7 that were not detected by culture. Five of these (*H. influenza, M. catarhalis, P. aeruginosa, S. marcescens, S. pneumoniae*) were in cultures containing normal oral flora at >10^5 CFU/mL. The remaining 3 cultures had a second pathogen that was predominant, potentially resulting in failure to identify the pathogen of lesser quantity.**Conclusions:** The LRTI Panel was in categorical agreement (i.e. 10^4 or greater) with culture results for 10/13 bacteria reported by culture method. LRTI also identified 8 bacterial targets not reported by culture. The significance of these additional positive results require correlation with clinical outcomes.

Surveillance for Low Pathogenic Avian Influenza Virus Antibodies in Domestic and Peri-Domestic Birds in Two States of Nigeria

Author Block:

A. Adebiyi, D. Oluwayelu, O. Gamra, a. Jagun-Jubril; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Flock surveillance for avian influenza (AI) plays a crucial role in establishing the epidemiological characteristics of the disease especially in countries where vaccination is not practiced. The recent cases of AI in Nigeria are of concern not only to the poultry industry but also to public health. However, current AI surveillance is tilted towards the highly pathogenic disease which may bias understanding of the true extent of involvement of less pathogenic strains such as low pathogenic AI virus (LPAIV) H5, H7 and H9 that have been reported to cause outbreaks of highly pathogenic AI. Therefore, as part of on-going AI surveillance in southwest Nigeria, sera from domestic and peri-domestic birds including Japanese quails, village weavers and laughing dove were screened for antibodies to LPAI viruses (LPAIV).A competitive ELISA was used for detecting AIV-specific antibodies in the sera of 101 unvaccinated Japanese quails from ten flocks in Osun state, as well as 30 village weavers from a live-bird market and one laughing dove caught for human consumption in Oyo state, Nigeria. Haemagglutination inhibiting antibodies against LPAIV were then detected in the ELISA-positive sera using H3N8, H5N2 and H9N7 subtype-specific antigens. In quails, the AI seroprevalence obtained by ELISA was 18.8% (19/101). Of the 19 ELISA-positive samples, 5 were positive for anti-LPAIV H9N7 antibodies only while 11 were positive for anti-LPAIV H3N8 and H9N7 antibodies, and 3 were positive for antibodies against the three LPAIV subtypes, indicating a mixed infection. The laughing dove serum was positive for only anti-LPAIV H9N7 antibodies while all sera from village weavers had no detectable LPAIV antibodies.This study provides serologic evidence of infection with LPAIV H3N8, H5N2 and H9N7 in Japanese quails and laughing dove in southwest Nigeria. The findings highlight the potential role of Japanese quails in the epidemiology of AI and stress the need for continuous monitoring of different avian species in order to provide an early warning system for implementation of AI control strategies. We recommend that quails, which are rapidly gaining popularity as a cheap source of animal protein in Nigeria, should not be reared together with commercial or backyard chickens.

Verification and Impact of a New Influenza A/B Platform at a Major Military Medical Center

Author Block:

L. E. NIELSEN, G. Brusstar, B. Pagaoa, J. Anderson, C. Lanteri, E. Ager; San Antonio Military Med. Ctr., San Antonio, TX

Abstract Body:

Background: Respiratory illnesses caused by Influenza (Flu) A and B are common between Nov-April. Symptoms of Flu are similar to other respiratory viruses, therefore, detection becomes necessary for antiviral therapy, epidemiology, and vaccine development purposes. Several diagnostics platforms are available; many being an enzyme-linked immunoassay (EIA) or real-time polymerase chain reaction (RT-PCR) based systems. During the 2014-15 season, our laboratory tested >5,500 specimens from across the hospital and its six associated outlying clinics using the Quidel Sofia EIA and the GeneXpert Infinity (Cepheid) RT-PCR system with a combined turn-around-time (TAT) of 2 hrs. This year, all suspected Influenza specimens are tested solely on the point-of-care, CLIA-waived Cobas (Roche) lab-in-a-tube (LIAT) system that has combined the TAT (20 min) of an EIA with the sensitivity of RT-PCR. The purpose of this study was to evaluate methods to determine which system(s) are most advantageous for routine Flu testing and highlight the transformation of workload for multi-center patient testing laboratories. **Methods:** Nasopharyngeal swab specimens were tested for the presence of Influenza A and B virus using the Quidel Sofia EIA, the Cepheid RT-PCR, and the Roche LIAT diagnostic platforms following manufacturer's recommendations. Extracted RNA was used to determine limits of detection (LOD) for each platform. Test results were compared for accuracy, sensitivity, TAT, workflow, LOD and cost. **Results:** Concordance between specimens tested using RT-PCR vs. EIA assays were 80% for negative samples, 50% for Influenza A, and 80% for Influenza B supporting the lower sensitivity of EIA platforms and validating the need for RT-PCR testing. TAT was decreased by 83% and cost from $60 using both the Sofia and Cepheid systems to $30 per sample. The lower LODs for Sofia EIA was 1000-times higher than the LIAT system. **Conclusions:** The LIAT RT-PCR assay offers a similar cost and complexity to EIA platforms but increases accuracy and sensitivity of Influenza A/B detection making reliable and accurate point-of-care, CLIA-waived testing possible. This new technology has allowed us to increase the time to patient result and provide testing at all outlying clinics, allowing the provider to prescribed anti-viral therapy while the patient is still in the clinic.

Evaluation of Novel Respiratory Assays on a Fully Automated System for Competitive Inhibition with Co-infection, Cross Reactivity, and Vtm Compatibility

Author Block:

P. Douglass, M. Jost, A. Narwold, D. Li, J. Zowalki, P. Quinones, **C. R. Hentzen**, C. Nugent, D. P. Kolk; Hologic, San Diego, CA

Abstract Body:

Background: Respiratory viral infections remain a leading cause of infectious diseases worldwide. Most respiratory viruses present with similar symptoms and many patients have more than one viral agent. Clinicians rely on accurate and rapid molecular diagnostics to identify virus(es) to ensure appropriate patient management. For multiplexed panels such as the Panther Fusion Flu A/B/RSV and Paraflu Assays (in development), demonstrating reliability in detecting the appropriate virus is required. In this study, the effects of clinically relevant co-infections and commonly found micro-organisms and viruses were assessed to evaluate inhibition and performance in the Flu A/B/RSV and Paraflu Assays. A variety of commercial viral transport media (VTM) were also evaluated to demonstrate assay compatibility. **Methods:** To evaluate competitive interference in clinically relevant co-infections, viral isolates for different target analytes were spiked into simulated clinical matrix (SCM). High (3 log > LoD) and low concentration (0.5 log > LoD) of one or more target were evaluated (12 conditions; n=6/condition). 51 (Flu A/B/RSV) and 56 (Paraflu 1/2/3/4) microorganisms and viruses were tested to assess cross-reactivity. VTM equivalency was evaluated in five commercial and one in-house VTM (n=12 or 24). **Results:** For Flu A/B/RSV and Paraflu Assays, the co-infection/interference study had 100% agreement to expected result for all conditions. No cross reactivity was observed with any non-targeted organism while all control panels were positive for intended target in SCM. The positivity rate for each intended target at a level near LoD was 100% in all six VTMs. **Conclusions:** The Panther Fusion Flu A/B/RSV and Paraflu Assays demonstrated excellent reliability in detecting intended targets at clinically-relevant concentrations in simulated co-infection samples where no competitive inhibition was observed. The assays did not exhibit any cross reactivity or inhibition in the presence of other micro-organisms and viruses. In addition, the assays are compatible with the most commonly used VTMs. These data suggest the Panther Fusion Respiratory Assays are suitable for a modular approach to syndromic testing.

Quantification of Bacterial Pathogens in Lower Respiratory Specimens with a Sample to Answer Automated Multiplexed Molecular Detection System

Author Block:

U. K. Spaulding, D. Nicholes, I. Kavetska, O. Cham, B. Graham, J. Cloud, C. Baker, J. Peterson, A. Demogines, N. Fish, M. Rogatcheva; BioFire Diagnostics, LLC, Salt Lake City, UT

Abstract Body:

Background & Objective: Typical bacteria associated with lower respiratory tract infections (LRTI) are also frequently commensals of the oropharyngeal passage. Semi-quantitative or quantitative culture methods routinely used in labs to distinguish pathogenic loads from commensal carriage have poor sensitivity, and are slow and subjective. Subject to FDA clearance, the FilmArray® LRTI Panel (FA-LRTI; BioFire Diagnostics) is expected to be a rapid (~ 1 hr), sensitive, and objective alternative for identification of bacteria, viruses, & fungi and select antibiotic resistance genes. Additionally, FA-LRTI will provide semi-quantitative results for 15 typical bacteria. This study compared titers estimated by a development version of FA-LRTI to titers obtained from culture and qPCR methods in respiratory samples (bronchoalveolar lavage (BAL) and sputum). **Method**: Performance of FA-LRTI was compared to other methods in a variety of matrices. Initially, titers of 5 bacteria (*H. influenzae, K. pneumoniae, P. aeruginosa, S. agalactiae, S. aureus*) spiked into normal saline (NS) were determined by FA-LRTI and 5 comparator methods including culture and turbidity, as well as 3 qPCR assays/organism. Next, contrived respiratory matrices spiked with a mix of same bacteria at different titers, and 38 residual specimens characterized by clinical labs were tested with FA-LRTI and qPCR. **Results**: FA-LRTI titers of organisms spiked into NS were reported to be within 0.5 to 1 log units of titers from microbiological and qPCR methods. Similar accuracy of quantification was achieved in contrived matrices. In 38 clinical samples (with 37 reported detections), FA-LRTI had 49 reportable detections ($\geq 10^4$ copies/mL) compared to 54 by qPCR assays with 95% agreement of results (within 1 log window for reportable titers) between the two methods for 14 out of 15 targeted bacteria. All but 2 of 37 bacteria reported by clinical lab were detected by FA-LRTI and qPCR assays. **Conclusion**: This study highlights the ability of FA-LRTI to provide meaningful results to aid diagnoses of bacterial LRTI.*The FilmArray LRTI Panel has not been evaluated by the FDA or other regulatory agencies for* In Vitro *Diagnostic use*.

Comparison Between the Alere Binaxnow Influenza A+b Card and the Quidel Sophia Influenza A+b Fia for the Detection of Seasonal Influenza in Rural Hospitals

Author Block:

M. Dodd[1], J. Schmetterer[2], I. Mallawaarachchi[1], K. Culbreath[3]; [1]Univ. of New Mexico, Albuquerque, NM, [2]Presbyterian Hlth.care Services, Albuquerque, NM, [3]TriCore Reference Lab., Albuquerque, NM

Abstract Body:

Background: The diagnostic accuracy of rapid influenza tests very widely with sensitivities greater than 60% for detection of seasonal influenza infections. Utilization of rapid influenza diagnostic tests (RIDTs) may be useful in timely identification of influenza infection enabling appropriate prescribing of antivirals. The purpose of this study is to evaluate the performance of RIDTs used in rural hospitals and determine if there is clinical value to implementing a more accurate test.**Method:** This retrospective study compared the performance of the Alere BinaxNOW Influenza A+B Card (Binax) from Oct 2013-Mar 2014 to the Quidel Sophia Influenza A+B FIA (Sophia) from Oct 2014-Mar 2015 for two rural New Mexico hospitals. Comparing the RIDTs results to RT-PCR, the gold standard, the percent positivity captured and sensitivity was calculated. Descriptive statistics were used to compare demographics between respiratory seasons. Two sample proportion test was used to compare percentages of positive influenza detected by the Binax and Sophia.**Results:** A total of 973 patients were tested during the 2013-2014 respiratory season and 1365 during the 2014-2015 respiratory season with no significant difference between mean age, 45.3 ± 19.8 vs. 46.0 ± 21.4 respectively ($p = 0.432$). Of the 233 influenza A+B positives, the Binax detected 74 (32.5%) positive influenza A and 2 (40%) positive influenza B while the RT-PCR captured an additional 154 (67.5%) influenza A and 3 (60%) influenza B. The Sophia detected 156 (60.5%) positive influenza A and 30 (53.6%) positive influenza B while the RT-PCR captured an additional 101 (39.5%) influenza A and 26 (46.4%) influenza B from the total 313 influenza A+B positives. The overall sensitivity of the Binax was 32.6% and the Sophia was 59.4% ($p = <0.001$).**Conclusion:** Overall, the Sofia was more sensitive than the Binax for rapid detection of seasonal influenza. However, the Sofia assay was significantly less sensitive than the molecular-based assay. These findings suggest that the Sophia may provide clinicians in rural hospitals with a more clinically reliable rapid antigen-based result for their decision to treat when molecular based testing is not as easily accessible.

Evaluation of *Illumigene* mycoplasma Direct Dna Amplification Assay

Author Block:

N. KANWAR[1], M. A. Pence[2], D. Mayne[3], R. Selvarangan[1]; [1]Children's Mercy Hosp. and Clinics, kansas City, MO, [2]Cook Children's Med. Ctr., Fort Worth, TX, [3]Sacred Heart Hosp., Pensacola, FL

Abstract Body:

Background: *Mycoplasma pneumoniae* (MP) is a common cause of community acquired pneumonia in humans. The investigational use only (IUO) ***illumi****gene* Mycoplasma Direct (iMD) DNA amplification assay (Not FDA-Cleared) is a qualitative *in vitro* diagnostic test utilizing loop-mediated isothermal amplification (LAMP) technology for the direct detection of MP DNA in human respiratory specimens.**Objective:** The aim of this multicenter study was to evaluate the performance characteristics of the iMD assay as compared with the FDA-cleared ***illumi****gene* Mycoplasma (iM) assay. Both assays utilize the same LAMP technology and targets. The major improvement of iMD over iM assay is that the Qiagen DNA extraction step is not required for iMD assay. **Methods:** Three sites across United States participated in this prospective study. Subjects with symptoms of upper respiratory illness suggestive of MP were enrolled. Two throat swabs were obtained from each subject, one in M4 transport medium and one in liquid Amies. The liquid Amies swab was tested at each enrollment site by the iMD assay within 72 hours of sample collection. Reference testing with iM was performed by the manufacturer from the non-nutritive liquid Amies media within 14 days of sample collection.**Results:** Among the 385 specimens tested, the iM reference method detected MP in 24 (6.2%) specimens while iMD assay detected 23 (6.0%) samples as MP positive. There were nine false positive and one false negative detections with the iMD assay prior to discrepant evaluation. The overall positive percent agreement and the negative percent agreement was 95.8% (79.8-99.3%) and 97.5% (95.3-98.7%), respectively. The overall percent agreement was determined to be 97.4% (95.3-98.6%).**Conclusions:** The IUO ***illumi****gene* Mycoplasma Direct test results were comparable with the iM assay. The removal of the Qiagen DNA extraction step in the iMD assay simplifies testing, saves time and reduces the expense of detecting MP from throat swabs when compared to iM assay.

Laboratory Evaluation of a Point of Care Molecular Test for the Detection of Influenza A and B

Author Block:

D. Meadows[1], J. Longshore[2], **R. L. Sautter**[3]; [1]Carolinas Lab. Network, Charlotte, NC, [2]Carolinas Path. GP., Charlotte, NC, [3]Carolinas Path. Gp. Retired, Lancaster, SC

Abstract Body:

Introduction: Rapid laboratory identification of respiratory viral agents is becoming increasingly important because of the development and use of antiviral agents and the continued emergence of new respiratory virus strains with potentially far reaching global impact. The Carolinas Medical Center has used PCR for diagnostics on in-patient and immunocompromised patients. In addition culture and Direct Fluorescent antibody (DFA) methods for the detection of respiratory viral agents were used for outpatients not sick enough to be admitted to the hospital. Testing at the point of care (physician office laboratories [POC]) was discouraged due to the poor performance of rapid cartridge methods. Recently, PCR methods have become available that are touted as more accurate than previous POC methods and easy to use.**Objective:** In this study we compared conventional PCR (real time polymerase chain reaction assays- bead based DNA amplification tests (xTAG RVP FAST)] and a rapid PCR method designed to be used in the POC (Roche LIAT).**Method:** All samples were banked previously confirmed strains or fresh collected using nasal wash, flocked swab NP, bronchial washes, or tracheal aspirates samples. The banked strains were confirmed as to their identity using PCR technology or obtained from the NC state public health laboratory. A total of 121 samples were tested. Including 92 strains of Flu A (seasonal flu strains and H1N1 strains), Flu B and all negative Flu samples were positive for other viral agents such as Parainfluenzae, RSV and adenovirus, and metapneumovirus agents were included as samples negative for influenza.**Results:** Overall, the LIAT was tested in 94 positive and 25 Flu negative samples demonstrating a sensitivity/ specificity of 100% (95% CI 95-100%)/ 93% (95% CI= 74-98.7%) respectively as compared to the xTAG RVP FAST assay.**Conclusion:** The LIAT assay is an accurate and reliable method for detecting both FLU A and B infections and offers the advantage of detecting FLU at the point of care in a timely fashion.

Laboratory Evaluation of the Biogx Flu A, Flu B, RSV Assay on the Bd Max™ System

Author Block:

C. Kubasek, S. Silbert, A. Gostnell, **R. Widen**; Tampa Gen. Hosp., Tampa, FL

Abstract Body:

Due to low sensitivity of respiratory viral rapid antigen tests and the long turn-around time of viral culture, many laboratories are using PCR-based methods for detection of respiratory viruses. The objective of this study was to evaluate the detection of Flu A, Flu B and RSV on the BD MAX™ System, using the BioGX Flu A, Flu B, RSV Sample-Ready™ kit (BioGX, Birmingham, AL) and to compare the results obtained to the Simplexa™ Flu A/B & RSV Direct assay (Focus Diagnostics, Cypress, CA), our standard of care procedure. **Methods:** A total of 200 frozen specimens (NP swabs) submitted for routine testing during the 2015 influenza/respiratory season were tested (50 Flu A, 50 Flu B and 50 RSV positive, as well as 50 negative NP samples). All frozen samples were thawed and re-tested by the Simplexa Flu A/B & RSV Direct assay following manufacture's recommendation. In parallel, a 400µL aliquot from each sample was inoculated into a BD MAX Sample Buffer Tube. Extraction and multiplex PCR were performed on the BD MAX System, using the BD MAX™ ExK™ TNA-2 extraction kit (BD, Quebec, Canada) and the BioGX assay. PCR cycling conditions were: 48°C for 900s and 99°C for 120s followed by 15 cycles of 99°C for 10s, 55°C for 26s, 72°C for 12.6s, and another 30 cycles of 99°C for 5s, 55°C for 15s and 72°C for 8.6s. The total run time (extraction and PCR) took approximately 2.5 hours. In the end, results from the standard of care Simplexa Flu A/B & RSV test were compared to the BioGX assay. **Results:** Out of 200 samples tested, 49 were Flu A, 48 were Flu B and 47 were RSV positives, and 56 were negative for Flu A, Flu B and RSV by both PCR based methods tested. Discrepant results between Simplexa and BioGX were observed in just 2 RSV samples, one of them was RSV positive just by the Simplexa assay and the other one, just by the BioGX assay. Samples previously identified as positive for Flu A (n=1), Flu B (n=2) and RSV (n=3), and negative by the BioGX and Simplexa re-testing may have undergone DNA degradation after the freezing-thawing process. **Conclusion:** The BioGX assay performed on the BD MAX System and the Simplexa Flu A/B & RSV Direct assay displayed an excellent overall agreement for the detection of Flu A, Flu B and RSV. Ultimately, the BioGX assay performed on the BD MAX System is an alternative method for respiratory virus detection in clinical samples.

Test Performance Of The Cobas Influenza A/B (Liat), Xpert Flu And The Simplexa Flu A/B Assay For The Direct Detection Of Influenza Virus In Respiratory Specimens

Author Block:

C. Y. Ying, K. Molina, A. Tavares, T. Koyamatsu, W. Kim, M. J. Bankowski; DLS (The Queen's Med. Ctr.), Aiea, HI

Abstract Body:

Background: Influenza is an acute respiratory illness that requires the most sensitive and specific test detection method from the clinical laboratory in the shortest turn-around-time. Molecular amplification testing has offered the best approach over cell culture and antigen testing. Rapid molecular assays can identify patients with Influenza and aid in more effective infection control, prevention and the decision to use anti-viral treatment. This study challenges the test performances of three molecular assays: cobas ® Influenza A/B assay, the Xpert® Flu and Simplexa™ Flu A/B Assay. **Methods:** Nasopharyngeal swabs (n=44 in M4) were collected from patients presenting with upper respiratory tract infections. Specimens were de-linked after initial testing using the Simplexa™ Flu A/B Assay (ASR) in routine use along with extraction using the MagNA Pure LC System. The cobas® Influenza A/B (Liat) Nucleic acid test assay and the Xpert® Flu A/B test performance was challenged with clinical specimens and limit of detection (LOD). Both are direct, rapid *in vitro* diagnostic tests (Liat is also CLIA-waived), which integrate nucleic acid extraction, amplification, and detection in a closed system.**Results:** A total of 44 specimens were tested using the cobas ® Influenza A/B assay and the Xpert® Flu and compared to the Simplexa™ Flu A/B Assay (ASR). The cobas ® Influenza A/B (Liat) assay showed 96.6% sensitivity and 100% specificity compared to the Xpert® Flu with 62.1% sensitivity and 100% specificity. The mean LOD for the Xpert® Flu was approximately 100-fold less sensitive than the Simplexa™ Flu A/B Assay. The cobas® Influenza A/B (Liat) assay showed 97.7% (43/44) agreement with Simplexa™ Flu A/B Assay.**Conclusions:** The cobas® Influenza A/B (Liat) was comparable in test performance to the Simplexa™ Flu A/B Assay compared to the Xpert Flu, which was less sensitive (100-fold). The cobas® Influenza A/B (Liat) assay also offers the best turn-around-time (20 minutes) compared to either the Xpert® Flu (75 minutes) or Simplexa™ Flu A/B Assay (ASR) (150 minutes).

Multicenter Evaluation of Alere™ I Influenza A & B Assay Using Respiratory Specimens Collected in Viral Transport Media

Author Block:

F. Hassan[1], L. Hays[1], A. B. Bonner[2], J. Connolly[3], N. A. Ledeboer[3], R. Selvarangan[1]; [1]Children's Mercy Hosp., Kansas City, MO, [2]Veritas, P.A., Belton, TX, [3]Med. Coll. of Wisconsin, Milwaukee, WI

Abstract Body:

Background: Rapid and accurate detection of influenza virus is critical for proper patient management, especially in out-patient settings during influenza season. Alere™ i Influenza A & B assay is an isothermal nucleic acid amplification test capable of detecting influenza A and B viruses directly from respiratory specimens.**Objectives:** To evaluate the performance characteristics of Alere™ i Influenza A & B assay using nasal and nasopharyngeal swab specimens eluted and transported in viral transport media (M4, M6 and UTM).**Study design**: A prospective, multicenter, clinical trial was conducted at three different sites across USA to evaluate the performance of the Alere™ i Influenza A & B assay using fresh (within 24 hours of sample collection), left over, de-identified clinical specimens obtained from patients (Children =1084 and Adults= 159). The performance of Alere™ i Influenza A & B assay was compared with ProFlu(+) real-time RT-PCR assay considered as the "gold standard". All specimens with discrepant test results were further tested by FDA cleared PCR assay (CDC InfAB PCR) at Alere Scarborough, Inc.**Results:** A total of 1273 samples were enrolled in this study; 30 were excluded from final analysis. Influenza test results by Alere™ i Influenza A & B assay (250 Flu A positive, 105 Flu B positive, 6 Flu A and B positive, and 882 Flu A/B negative) were compared with ProFlu(+) real time RT-PCR results to determine test performance (see table). Following discrepant analysis by CDC developed Inf AB real-time PCR, the sensitivity and specificity of the Alere™ i Influenza A & B assay increased to 98.1% and 99.6% for influenza A, and 93.1% and 98.6% for influenza B, respectively.**Conclusions:** The Alere™ i Influenza A & B assay is an ideal assay for influenza virus detection in patients of all age groups due to its high sensitivity and specificity and ability to produce results within 15-20 minutes from time of sample collection with minimal hands on time.

Target	**True positive**	**True negative**	**False positive**	**False negative**	**%Sensitivity (95% CI)**	**%Specificity (95% CI)**

Development and Evaluation of a Molecular Assay for Improved Detection and Quantification of *Human rhinovirus* Viral Load

Author Block:

K-T. Ng, J-B. Chook, X-Y. Oong, Y-F. Chan, K-G. Chan, N-S. Hanafi, Y-K. Pang, A. Kamarulzaman, K-K. Tee; Univ. of Malaya, Kuala Lumpur, Malaysia

Abstract Body:

Background: *Human rhinovirus* (HRV), a member of the *Picornaviridae* family, continues to dominate as the major cause of acute respiratory tract infections worldwide. Several studies attempted to investigate the correlation between HRV viral load and severity of respiratory illnesses. However, limitations that may affect accurate HRV quantification exist.**Methods:** We developed a one-step real-time reverse transcription-PCR (RT-PCR) assay using oligonucleotides designed based on a comprehensive list of global HRV sequences. The performance of the newly developed assay was first assessed using a 2013 rhinovirus External Quality Assessment (EQA) panel. The assay was then tested on 315 recently collected human enterovirus-positive clinical nasopharyngeal specimens, in parallel with a commercial HRV quantification kit.**Results:** The newly designed oligonucleotides highly specific to the 5′-UTR region showed high PCR efficiency (E=99.6%) and Pearson correlation coefficient (R^2=0.996), detecting and quantifying HRV RNA as low as -0.29 and 0.05$\log_{10}$ copies/µl, respectively. Performance evaluation using the EQA panel yielded a detection rate of 90%. When tested on 315 human enterovirus-positive nasopharyngeal swabs, comprising at least 84 genetically distinct HRV types/serotypes (as identified by the *VP4/VP2* gene phylogenetic analysis), the newly developed assay yielded a detection rate of 100%, detecting all HRV species and types, as well as other non-polio enteroviruses. In contrast, the commercial quantification kit, which failed to detect any of the EQA specimens, only produced a detection rate of 13.3% (42/315) among the clinical specimens. Using the improved assay, it was shown that HRV persists in the upper respiratory tract and sheds for more than a week following acute infection. In addition, HRV-C had a significantly higher viral load than HRV-A and HRV-B at 2-7 days after the onset of symptoms (p=0.001).**Conclusions:** A rapid real-time RT-PCR assay for improved HRV detection and quantification was developed. The availability of such assay for HRV detection and quantification is crucial to facilitate disease management, antiviral development, and infection control.

***Mycoplasma pneumoniae*: Only Who Seeks, Will Find**

Author Block:

S. Zimmermann, P. Schnitzler, A. H. Dalpke; Heidelberg Univ. Hosp., Heidelberg, Germany

Abstract Body:

Background: Underdiagnosing of specific infections has been put forward as an argument for use of broad-spectrum multiplex panels. Moreover, pathogens that have been known to occur in typical patient populations night nowadays spread as a consequence of the achievements of modern medicine. In an independent trial 2352 LRT and sputum samples, which were requested for respiratory viruses, were analysed by a multiplex PCR that also included detection of *Mycoplasma pneumoniae* (Mp). This assay revealed an incidence of up to 1.5% which was in contrast to the previously known incidence of 0.5% in our hospital. To clarify this discrepancy we performed a retrospective study of the participating wards to find out, why *Mycoplasma pneumoniae* was apparently underdiagnosed over the last years. **Methods:** From November 2014 to June 2015 all 2352 respiratory samples that were submitted to the virology department were investigated using the new FTD21 Respiratory PCR panel (Fast Track Diagnostics). This assay included detection of *Mycoplasma pneumoniae*, which normally was diagnosed in the bacteriology department upon specific request. Mycoplasma positive samples of the FTD21 assay were confirmed by the routine in-house Mp-PCR. Demographic data and clinical requests were analysed to find out, why *Mycoplasma pneumoniae* was obviously underdiagnosed in our hospital. **Results:** 23 of 2352 respiratory samples were PCR positive for *Mycoplasma pneumoniae* (1.0%). The incidence peaked in the second quarter 2015 with 1.5%. 21 of these samples were confirmed by our routine in-house PCR (91%); 2 samples were not available for retesting. 16 patients were male (76%) and 11 came from the pediatric hospital (52%). Only in 3 cases the Mycoplasma investigation had been requested specifically by the clinician (14%). In all the other cases the positive finding was only due to the use of a multiplex PCR panel. **Conclusion:** *Mycoplasma pneumoniae* is underdiagnosed in our hospital, especially in the pediatric clinic. This is not due to an insufficient sensitivity of the PCR assay, but the main reason is an absence of clinical suspicion. Amendments in the preanalytics are obligatory to improve the situation.

Irida'S Genomic Epidemiology Application Ontology: Genomic, Clinical and Epidemiological Data Standardization and Integration

Author Block:

E. Griffiths[1], M. Courtot[2], D. Dooley[3], J. Adam[4], F. Bristow[4], J. A. Carrico[5], A. Keddy[6], T. Matthews[4], A. Petkau[4], R. G. Beiko[6], L. M. Schriml[7], E. Taboada[8], G. Van Domselaar[4], M. Graham[4], F. Brinkman[1], W. Hsiao[3]; [1]Simon Fraser Univ., Burnaby, BC, Canada, [2]EMBL-EBI, Hinxton, United Kingdom, [3]BC PHMRL, Vancouver, BC, Canada, [4]PHAC, Winnipeg, MB, Canada, [5]Univ. of Lisbon, Lisbon, Portugal, [6]Dalhousie Univ., Halifax, NS, Canada, [7]Univ. of Maryland Sch. of Med., Baltimore, MD, [8]PHAC, Lethbridge, AB, Canada

Abstract Body:

Background: Successful use of genomics for microbial typing, surveillance and outbreak investigation requires integration with contextual information. Contextual data such as sample information and epidemiology exposure data are often institution-specific and non-standardized, hampering their analysis on a larger scale. Canada's Integrated Rapid Infectious Disease Analysis (IRIDA) project is developing open-source, user-friendly tools such as SNVPhyl, IslandViewer, GenGIS and CARD for incorporating genomic data into epidemiological analyses to support real-time infectious disease surveillance and investigation. Our research efforts include the development of a Genomic Epidemiology Ontology (GenEpiO), a standardized vocabulary interconnected by logical relationships, which is crucial for providing the framework for public health and genomics data integration.**Methods:** To determine the scope and priorities of GenEpiO development, we interviewed public-health stakeholders and domain experts and surveyed reporting forms and databases. Existing, related, ontologies were reused when possible to promote interoperability.**Results:** An OWL file containing harmonized metadata fields and terms describing source attribution, clinical data, sequencing processes, patient histories and exposures was created adhering to the best practices of the Open Biomedical and Biological Ontology Consortium (OBO). GenEpiO was then made more robust through testing using real public health data.**Conclusions:** Implementation of GenEpiO will facilitate data standardization and integration, interoperability, improve querying and facilitate automation of many analyses. Since harmonization of the genomic epidemiology ontology can only be achieved by consensus and wide adoption, IRIDA is currently forming an international consortium to build partnerships and solicit domain expertise.

Nist Canidate Microbial Genomic Reference Materials

Author Block:

N. D. Olson, J. M. Zook, S. A. Jackson, D. Catoe, M. L. Salit, L. Vang; Natl. Inst. of Standards & Technology, Gaithersburg, MD

Abstract Body:

Advances in DNA sequencing has paved the way for the use of whole genome sequencing (WGS) in clinical and public health settings. Genomic reference materials (RMs) are needed to evaluate and benchmark sequencing methods to improve confidence in WGS results. To address this need, the National Institute of Standards and Technology (NIST) is developing candidate genomic DNA microbial RMs for four bacterial strains: Salmonella enterica Typhimurium LT2, Staphylococcus aureus,Pseudomonas aeruginosa, and Clostridium sporogenes PA3679. The four strains were selected with input from the scientific community based on clinical and public health relevance and to represent a range of GC content. A commercial vendor produced 1000 vials from a single lot of genomic DNA for each of the four strains. The genomic material was characterized for homogeneity, purity, and stability. To evaluate the material homogeneity and purity, eight replicate vials were sequenced using two short-read sequencing technologies. Long-read sequencing and two optical mapping technologies were used to generate a de novo genome assembly for each strain. In the absence of an existing pipeline, "Pipelines for Evaluating Prokaryotic References" (PEPR) was developed, ensuring reproducibility and transparency in the characterization process. Whole genome base-level purity was assessed based on the proportion of sequencing data supporting the reference assembly using data from replicate vials. Material homogeneity was assessed based on the similarity in the base-level purity data between replicate vials. Genomic purity, the presence of genomic DNA from organisms other than the RM genus, was assessed using the short-read sequencing data. Overall over 99.9999% of the bases had purity values > 95%, and > 99.5% of the DNA was from the expected organism. Additionally, the material stability was evaluated using pulse-field gel electrophoresis. No DNA degradation was detected after 8 weeks at 4℃. The NIST candidate microbial genomic DNA reference materials and the data generated during the characterization process can be used to evaluate sequencing methods and bioinformatic pipelines, increasing confidence when used in applied settings such as foodborne outbreak investigations.

1000 Genomes and Counting: Preliminary Results from Nctc3000, a Type Culture Reference Genome Project

Author Block:

S. Alexander[1], M. Fazal[1], E. Burnett[2], A. Deheer-Graham[3], K. Oliver[4], N. Holroyd[4], S. Picton[5], J. Parkhill[4], J. Russell[1]; [1]Publ. Hlth.England, London, United Kingdom, [2]Publ. Hlth.England, Salisbury, United Kingdom, [3]Publ. Hlth.England, Potters Bar, United Kingdom, [4]Wellcome Trust Sanger Inst., Cambridge, United Kingdom, [5]Pacific BioSci.s, Menlo Park, CA

Abstract Body:

Background: The NCTC3000 project aims to generate 3000 high quality reference genomes from strains within the National Collection of Type Cultures (NCTC). Annotated and assembled genomes are being made publically available via an E-resource which links sequencing data to all other available strain metadata (provenance, phenotypic characteristics and authentication data). **Methods:** High molecular weight DNA from 1075 bacterial strains was extracted using either the Masterpure or Qiagen midi kit and analysed using the Agilent TapeStation to ensure sufficient quality (>60kb) and quantity (>3 µg). Whole Genome Sequencing (WGS) was performed using the PacBio SMRT® DNA Sequencing technology followed by genome assembly via an automated pipeline. **Results**: To date WGS has been completed on 1075 bacterial strains, from 21 families: Alcaligenaceae (2), Bacillaceae (3), Bartonellaceae (1), Brachyspiraceae (2), Brucellaceae (2), Campylobacteraceae (8), Corynebacteriaceae (1), Enterobacteriaceae (567), Flavobacteriaceae (12), Fusobacteriaceae (6), Helicobacteraceae (3), Legionellaceae (11), Moraxellaceae (8), Mycobacteriaceae (1), Neisseriaceae (11), Nocardiaceae (1), Pasteurellaceae (24), Pseudomonadaceae (23), Rhizobiaceae (1), Sphingobacteriaceae (3), Sphingomonadaceae (1), Staphylococcaceae (167), Streptococcaceae (201) and Vibrionaceae (7) within the NCTC collection. Of those strains sequenced thus far, 161 (15%) are type strains. All WGS data is made publically available (http://www.sanger.ac.uk/resources/downloads/bacteria/nctc/) and 499 genomes have been assembled and annotated. Where assembly has been possible 55.8% of genomes have been closed into a single contig. 55.1% of strains had evidence of one or more plasmids. **Conclusion**: The NCTC3000 project has generated over 1000 reference genomes from strains of medical importance. All sequences generated and associated metadata are being made publically available and it is hoped that these sequences will be used by scientists to support and enhance genomic studies globally.

Towares a Reference Material for Mixed Pathogen Detection via High-Throughput Sequencing

Author Block:

J. G. Kralj, N. D. Olson, S. Jackson; Natl. Inst. of Standards and Technology, Gaithersburg, MD

Abstract Body:

Background: Sequencing-based culture-independent detection of pathogens continues to garner attention in clinical, environmental, and biomanufacturing. Regulatory agencies, such as FDA and CAP/CLIA, seek best practices for establishing competency and effectiveness in sequencing-based pathogen detection methods. We have proposed to establish a standard pool of microorganisms using input from a consortium. The provenance and identity of the microbes would be well-documented, enabling regulatory bodies to "stress-test" device claims. Further, this standard pool will benefit those designing new devices by enabling integration of reference materials during pre-submission development.**Methods**: Our proof-of-concept samples were mixtures of DNA from four sources (NIST candidate microbial genomic reference materials for *S. enterica* subspecies enterica serovar Typhimurium strain LT2, *S. aureus* clinical isolate, *P. aeruginosa* clinical isolate, and *C. sporogenes* PA3679) in a background of human DNA from the "Genome in a Bottle" project. Two mixtures were generated (BioProject PRJNA297045), including an equigenomic (contstant number of genomes) and a log-10 genome copy dilution series. The resulting data was then subjected to 5 taxonomic identification tools to identify and quantify the composition. The number of species detected varied by classification algorithm.**Results**: The equigenomic sample analyses typically identified and quantified all constituents at the genus level. For the log-10 genome dilution series, identifying down to 0.1x (~several hundred reads, or 0.01% of the sample) was possible on all platforms for species-level ID. The number of species detected varied by classification algorithm. Perhaps notable by its absence, E. coli did not appear to contaminate the samples.**Conclusions**: The differences in results generated from highly-characterized DNA were important in so much that it highlights how reference materials can enlighten where sequencing-based identification tools generate uncertainty. Future work will focus on additional organisms that can be used in sequencing-based diagnositics for identifying and examining multiple variables such as near-taxonomic "neighbor" species, G+C content, genome size, and extremophiles. Despite the fact that others have observed similar trends, this ground-up approach will enable

Genetic Diversity of Georgian and Turkey *Brucella* Isolates

Author Block:

K. Sidamonidze[1], W. Su[2], E. Zhgenti[1], N. Trapaidze[3], F. Buyuk[4], M. Sahin[4], E. Celik[4], O. Celebi[4], S. Otlu[4], L. Baillie[5], P. Imnadze[1], A. Kotorashvili[1], M. Nikolich[2]; [1]Natl. Ctr. for Disease Control and Publ. Hlth., Tbilisi, Georgia, [2]Walter Reed Army Inst. of Res., Silver Spring, MD, [3]U.S. Army Med. Res., Tbilisi, Georgia, [4]Univ. of Kafkas, Kars, Turkey, [5]Cardiff Univ., Cardiff, United Kingdom

Abstract Body:

The genus *Brucella* consists of a number of species that infect different mammalian hosts including humans. *Brucella* infection can lead to abortion in many domestic animals, causing economic harm. Human brucellosis is one of the most globally widespread and debilitating zoonotic diseases, and it remains endemic in both Georgia and Turkey. Due to the high infectivity in mammals *Brucella* is classified as a Category B biological threat agent by the United States Department of Homeland Security. Precise genetic characterization of *Brucella* isolates by molecular typing methods can provide useful analysis for the description of strain diversity, detection of clonal groups, trace-back to sources of infection and discrimination of naturally occurring outbreaks from a bioterrorist event. Recent studies have demonstrated that multiple-locus variable-number tandem-repeat analysis (MLVA) is a high resolution genetic subtyping tool that can provide valuable information for brucellosis epidemiological investigations.In this study we assessed the genetic variability of 29 cattle and sheep isolates of *Brucella* isolated in Turkey and 72 animal and human *Brucella* isolates from Georgia, all identified as *B. melitensis* or *B. abortus* based on microbiological and Bruce-Ladder PCRresults. Genotypes were revealed using a MLVA approach with 15 mini-satellite markers based on Huynh et al. 2008, possessing discriminatory capability. Data obtained were analyzed to construct a phylogenic tree using BioNumerics Software (Applied Maths) and relationships between Turkish and Georgian isolates described.Our data showed that these strains are grouped by origin of country and species, but there are two *B. melitensis* of Turkey strains are mixed in Georgian group. This might suggest these two *B.melitensis* strains in Turkey come from Georgia. Our future research will further elucidate the geospatial localities and transmission patterns of *Brucella* strains we have reported here.

Pan-Genome Wide Association Study to Identify Pneumococcal Genomic Variation Associated with Meningitis

Author Block:

Y. Li, B. J. Metcalf, S. Chochua, R. Gierke, T. Pilishvili, L. Mcgee, B. W. Beall, Active Bacterial Core Surveillance Team; CDC, Atlanta, GA

Abstract Body:

Background: *Streptococcus pneumoniae* causes several types of invasive pneumococcal disease (IPD).Specific bacterial factors that predispose the pathogen to causing meningitis over non-meningitis IPD in humans remain unclear.**Methods:** Invasive pneumococcal isolates from 183 meningitis and 2442 non-meningitis patients were sequenced on an Illumina platform. The short reads were mapped onto 3225 non-redundant coding DNA sequences extracted from 20 complete pneumococcal genomes. Three types of variation--single nucleotide polymorphisms (SNPs), insertion/deletions (INDELs), and gene presences/absence (GPA)--were called from mapped sequences and confirmed by *de novo* genome assembly. Association with meningitis was assessed by Mantel-Haenszel test conditioned on patient age. The effect size of candidate variant was examined by logistic regression and stratified analysis.**Results:** A total of 10258 non-synonymous SNPs, 44 INDELs, and 289 GPAs passed quality control. The genomic inflation factor for all 10591 tests was 1.02. After Bonferroni correction, only snp1783187 in the *pbp1b* gene (causing N214T variation in the transglycosylase domain) was significantly associated with meningitis. Other top hits included SNPs in *folE*, *clpC*, *GrpE*, and GPA of *zmpB*. The snp1783187C allele was enriched in meningitis isolates after adjusting for patient age, serotype group (PCV13, PCV13 minus PCV7, and non-PCV13), and penicillin (PEN) susceptibility (adjusted OR=3.10, 95% CI 1.98-4.80). In the serotype-stratified analysis, snp1783187C allele was also enriched in meningitis isolates (common OR = 2.46, 95% CI=1.14-5.30), and no evidence of OR difference among serotypes was found (Breslow-Day test p=0.83).**Conclusion:** Pneumococcal genome variation appears to contribute modestly yet detectably to the development of meningitis over non-meningitis IPD in humans. A *pbp1b* variant showed association with meningitis isolates, which was apparently independent from PEN resistance and incompletely explained by linkage to serotype. The effect of the variant remains to be confirmed by replication studies.*The findings and conclusions in this report are those of the author(s) and do not necessarily represent the official position of the Centers for Disease Control and Prevention.*

Comparative Genomics and Antimicrobial Resistance Determinants of Community-associated *Staphylococcus aureus* Strains in South Texas

Author Block:

G. C. Lee[1], S. D. Dallas[2], Y. Wang[3], R. J. Olsen[4], K. A. Lawson[5], J. P. Wilson[5], C. R. Frei[1]; [1]UT Hlth.Sci. Ctr. and UT Austin, San Antonio, TX, [2]UT Hlth.Sci. Ctr. San Antonio, San Antonio, TX, [3]Univ. of Texas San Antonio, San Antonio, TX, [4]Houston Methodist Res. Inst., Houston, TX, [5]UT Austin, Austin, TX

Abstract Body:

Background: The emergence of CA-MRSA has resulted in an epidemic of skin and soft tissue infections (SSTI) in the U.S. This investigation sought to describe the molecular epidemiology and antimicrobial resistance patterns of *S. aureus* strains in the South Texas community. **Methods:** Whole genome sequencing (WGS) was performed on *S. aureus* SSTI and nasal colonization isolates from patients within 14 primary care clinics in the South Texas from 2007 to 2015. The bacterial genomes were compared to a reference genome FPR3757 (USA300 *S. aureus* strain) to identify single nucleotide polymorphisms (SNPs). SNP-based phylogenetic analyses were conducted using concatenated SNP nucleotides in the core genomes in reference to FPR3757. Multi-locus sequence type (MLST) was determined from WGS data using the *S. aureus* MLST database. The resistome was assembled by identifying antimicrobial resistance determinants related to the phenotypically derived antibiogram. **Results:** Overall, 144 *S. aureus* isolates (112 from SSTIs and 32 from nasal colonization) were sequenced. Seventy-three strains were MRSA and 71 were MSSA. When compared to the reference FPR3757, the strains differed by an average of 3,548 SNPs (range 15 to 47,574). *S. aureus* SSTI strains were predominantly ST-8 (83%) which clustered tightly within a similar clade containing the reference FPR3757, differing by an average of 160 SNPs (range 15-1,215). The remaining isolates comprised mostly of nasal colonization strains and were more divergent from the reference with an average of 12,422 SNPs (2,808-47,574). The majority of *S. aureus* strains harbored genes encoding for resistance to beta lactams (80%) and erythromycin (71%). High-level mupirocin (*ileS)* was only present in 3 isolates (2%). Notably, isolates harboring mutations conferring fluoroquinolone resistance (*gyrA*) clustered tightly together only in the ST-8 clade. **Conclusions:** This study highlights the genomic diversity of *S. aureus* strains in the South Texas community and demonstrates the utility of next generation sequencing to define the diversity and distribution of resistance mechanisms within *S. aureus*.

Resolution Of *legionella Pneumophila* Outbreak-Associated St1 Isolates Using Genome Sequence Analysis

Author Block:

B. H. Raphael, S. Morrison, J. Mercante, N. Kozak-Muiznieks, J. Winchell; CDC, Atlanta, GA

Abstract Body:

Background: Legionella *pneumophila* (Lp) is the causative agent of Legionnaires' Disease (LD), a severe pneumonia that occurs in susceptible populations exposed to environmental sources of Lp. During outbreak investigations, rapid and accurate subtyping of isolates from clinical specimens and potential environmental samples can confirm the source and direct measures to stop the outbreak. Sequence-based typing (SBT) for Lp is based on sequence variations among 7 alleles, and >2,000 sequence types (ST) have been identified. ST1 is the most common ST identified from isolates submitted to CDC from sporadic LD cases and environmental sources. **Methods:** To evaluate the ability of next generation sequencing technologies to improve the resolution of ST1 isolates, genome sequencing using the Illumina MiSeq instrument was performed with ST1 isolates (N=50). These isolates were selected from various clinical and environmental sources including both sporadic LD cases and outbreaks where multiple clinical and/or source isolates collected during an investigation were examined. **Results:** Single nucleotide polymorphism (SNP) analysis of draft genome sequences demonstrated that ST1 isolates form a distinct clade and that isolates associated with clinical and/or environmental sources within individual outbreaks generally form outbreak-specific subclades. Moreover, a whole genome multilocus sequence typing (wgMLST) approach based on sequence variation of 4,472 alleles revealed similar outbreak-specific subclades. Analysis of isolates from 3 LD outbreaks occurring in New York (2-4 isolates per outbreak), revealed that core SNPs within 2 of the outbreaks differed by 0-1 nucleotides while the core SNPs shared between isolates from the third outbreak (determined to be associated with multiple sources) differed by 6 to >400 SNPs. Correspondingly, isolates associated with these outbreaks shared ~93% identical alleles using the wgMLST scheme while isolates within the outbreaks sharing the fewest SNP differences shared >99% identical alleles. **Conclusions:** This work demonstrates that genome sequencing provides improved resolution of ST1-associated outbreak isolates. Finally, use of a wgMLST approach with a centralized allele database provides a robust and reproducible method for genomic analysis of Lp.

Genomic Dissection of Australian *Bordetella pertussis* Isolates from the 2008-2012 Epidemic

Author Block:

A. Safarchi[1], S. Octavia[1], S. Wu[1], S. Kaur[1], V. Sintchenko[2], L. Gilbert[2], N. Wood[2], P. McIntyre[2], H. Marshall[3], A. Keil[4], **R. Lan**[1]; [1]Univ. of New South Wales, Sydney, Australia, [2]Univ. of Sydney, Sydney, Australia, [3]Univ. of Adelaide, Adelaide, Australia, [4]Princess Margaret Hosp. for Children, Perth, Australia

Abstract Body:

Despite high pertussis vaccination coverage, Australia experienced a prolonged epidemic in 2008-2012. The predominant *Bordetella pertussis* genotype harboured pertussis toxin promoter allele, *ptxP3*, and pertactin gene allele, *prn2*. The emergence and expansion of non-expressing *prn* isolates (Prn negative), was also observed. In this study, whole genome sequencing was used to investigate the microevolution and genomic diversity of 22 epidemic *B. pertussis* isolates, including 10 Prn-negative strains with three different modes of silencing of pertactin gene (*prn*::IS*481*F, *prn*::IS*481*R and *prn*::IS*1002*). Five pre-epidemic strains were also sequenced for comparison. Five single nucleotide polymorphisms (SNPs) were common in the epidemic isolates and differentiated them from pre-epidemic isolates. The epidemic SP13 isolates can be divided into five lineages (EL1-EL5) with EL1 containing only Prn negative isolates. Comparison with global isolates showed that three lineages remained geographically and temporally distinct whereas two lineages mixed with isolates from 2012 UK outbreak. Our results suggest significant diversification and the microevolution of *B. pertussis* within the 2008-2012 Australian epidemic.

Influenza Throughout the 2014-2015 Season, with Focus on Influenza A(H3n2)

Author Block:

W. E. Gruner[1], S. H. Sarria[1], L. E. Sinclair[2], S. L. Jones[1], M. L. Powell[2], J. F. Hanson[2], J. P. Smith[1], R. A. Yohannes[2], K. F. Fumia[2], M. A. Edwards[2], H. Vireak[3], J. Dejli[3], D. W. Ellison[4], E. A. Macias[2]; [1]Henry M. Jackson Fndn., Wright-Patterson AFB (WPAFB), OH, [2]United States Air Force Sch. of Aerospace Med. (USAFSAM), Epidemiology Lab. Service, WPAFB, OH, [3]US Navy Med. Res. Unit No. Two (NAMRU-2), Phnom Penh, Cambodia, [4]Armed Forces Res. Inst. of Med. Sci. (AFRIMS), Bangkok, Thailand

Abstract Body:

Background: The DoD Global, Laboratory-based, Influenza Surveillance Program conducts testing on respiratory specimens collected from a world-wide network of sentinel and participating sites using viral culture, molecular diagnostics, and sequencing to detect and characterize influenza viruses.**Methods:** Around 5,700 respiratory specimens were analyzed at USAFSAM from September 2014 to June 2015 for the presence of influenza using the CDC RT-PCR based assays. About 50% of influenza positive specimens were selected based on epidemiological factors for Sanger-based hemagglutinin (HA) sequence analysis. Additional HA sequences were analyzed from partner DoD laboratories at AFRIMS and NAMRU-2. DNASTAR and BioEdit software were used to assemble the raw data, build phylogenetic trees, and perform cluster analysis of influenza viruses. **Results:** 1,009 out of 1,177 isolates were identified as influenza A (86%); 168 were influenza B (14%). Among influenza A, 94% were A(H3N2) and 6% were A(H1N1)pdm09. Based on the observed mutations, 80% of A(H3N2) viruses analyzed were subclade 3C.2a and 20% were clade 3C.3. Within 3C.3, 30% were subclade 3C.3a. Throughout the season, the number of isolates classified as subclade 3C.2a increased from 22% in October 2014 to 100% in August 2015. All of theA(H1N1)pdm09 isolates classified as clade 6B. Seventy percent of influenza B specimens were Yamagata lineage clade 3 and 30% Victoria lineage clade 1A.**Conclusions:** For the 2014-2015 season, influenza A(H3N2) was the predominant circulating subtype at 80% of the specimens sequenced. Influenza A(H1N1)pdm09 and influenza B constituted the remaining 20%. The A(H3N2) subclade 3C.2a, which contains strains that underwent mutational drift from the 2014-2015 A(H3N2) vaccine component, increased throughout the season and was the dominant subclade going into the 2015-2016 season. This DoD surveillance program provided data to the CDC and to the Vaccines and Related Biological Products Advisory Committee.

Publishing Title:

Whole Genome Sequencing as a Tool for Epidemic Investigation of Tattoo-Associated Nontuberculous Mycobacterial Skin Infections

Author Block:

K. Chou[1], D. M. Williams-Hill[1], J. Pettengill[2], E. Strain[2], S. Torres[1], W. B. Martin[1]; [1]US FDA, Irvine, CA, [2]US FDA, College Park, MD

Abstract Body:

Background: Thirty-eight cases of nontuberculous *Mycobacterium* infections were reported associated with tattooing at a tattoo parlor in Florida between December 2014 and April 2015. In an investigation, all tattoo artists involved in the incidents reportedly used distilled water for diluting grey wash inks. Additionally, none of the artists at other parlors who used the same brand of tattoo inks reported any tattoo related illnesses. To determine the source of contamination, we embarked on a trace-back investigation centered on the use of whole genome sequencing and subsequent analysis.**Methods:** Selective recovery of nontuberculous *Mycobacterium* was performed using the following samples: tap water, environmental swabs, and an opened container of tattoo ink directly related to the skin infections collected from the tattoo parlor, as well as 5 unopened containers of tattoo inks of the same brand and lot number collected from other tattoo parlors. Suspect colonies isolated were screened and identified using methodology developed previously. Selected isolates from the above procedures as well as clinical isolates from the skin infections were subjected to whole genome sequencing.**Results:** *Mycobacterium chelonae* was isolated from all 5 of the unopened container of tattoo inks. *M. abscessus* and *M. fortuitum* were isolated from the opened container of ink. *M. phocacium*, *M. mucogenicum*, and *M. abscessus*, were isolated from the tap water. Clinical isolates consist of 3 strains of *M. abscessus* and 1 strain of *M. fortuitum.* One of the most interesting findings from the whole genome sequencing analysis was that there were 2 perfectly matched groups of *M. abscessus* strains each consisted of isolates from the tap water, tattoo ink and skin biopsy.**Conclusions:** In the absence of complete and accurate epidemiological information, our trace-back investigation centered on the use of whole genome sequencing was able to provide data suggesting that the incidents of skin infections were highly likely and at least partially due to use of tap water to dilute tattoo inks for subsequent application. The outcome of the current study confirmed that whole genome sequencing could serve as a useful tool for epidemic investigation of illnesses caused by bacterial pathogens.

Comparison of *Propionibacterium spp.* Detection in Skin Swabs by Variable Regions of the 16s Rrna Gene

Author Block:

M. D. Gonzalez[1], M. A. Wallace[2], A. E. Schriefer[2], D. K. Warren[2], S. A. Fritz[2], C-A. Burnham[2]; [1]Children's Hlth.care of Atlanta, Atlanta, GA, [2]Washington Univ., St. Louis, MO

Abstract Body:

Propionibacterium spp. (*Propi*) are an important component of the skin microbiota. Our objective was to compare the detection of *Propi* from skin using genomic- and culture-based methods. We used Eswabs to sample 5 skin sites: the anterior nares, axilla, inguinal fold, forearm, and lower leg. Of the 15 subjects (10 female) sampled, 8 were community-dwelling and 7 were in the intensive care unit. Specimens were plated to a variety of culture media and incubation environments; specifically for *Propi* anaerobic incubation on Brucella blood agar, and broth enrichment were used. All cultured isolates were identified by MALDI-TOF MS. For all Eswab specimens, DNA sequencing data was obtained for the V2 (n=216), V3 (n=213), V4 (n=200) and V6 (n=219) variable regions of the 16S rRNA gene. Taxonomic classification of the rarified sequencing reads was performed using QIIME against the GreenGenes database, and all subsequent analysis was done on genus level classification data. We found that *Propi* was detected more frequently, and with higher abundance, from the V2, V3, and V6 regions, but was nearly absent in the V4 region (Table 1). A similar bias in V regions was not observed with *Staphylococcus* spp. and *Corynebacterium* spp., which are also members of the skin microbiota (Table 1). A subanalysis of the V3 sequencing data with relative *Propi* spp. read counts at ≥1% (n=114) indicated that 69% (n=79) of these specimens were culture positive for *Propi* spp, confirming the V3 data. None of the culture positive specimens for *Propi* (n=118), had ≥1% of read counts for V4. Our results indicate that the choice of V region for sequence-based skin microbiota studies greatly influences the relative abundance of *Propi* spp. that is detected.

Table 1. Average relative abundance assigned to *Propi* spp.

V region (n)	*Propionibacterium* spp.[a]	*Staphylococcus* spp.[a]	*Corynebacterium* spp.[a]
V2 (216)	0.0443	0.251	0.1226
V3 (213)	0.0578	0.238	0.1490
V4 (200)	0.0002	0.292	0.1525
V6 (219)	0.0856	0.212	0.1479

[a] Average relative abundance is the sum of relative abundance assigned to The specific taxonomic group divided by the total number of specimens with sequencing data for that V region

Publishing Title:

Analysis of the Manila Family of *Mycobacterium tuberculosis* Linage 1

Author Block:

X. Wan, K. Koster, L. Qian, S. Hou, **J. T. DOUGLAS, PhD**; Univ. of Hawaii, Honolulu, HI

Abstract Body:

Tuberculosis (TB) was recognized by WHO in 2014, as world public health emergency, even though significant efforts have been put into TB control programs. With airborne transmission and prolonged latency period, *Mycobacterium tuberculosis* continues to spread worldwide as one of the most successful bacterial pathogens and kills an estimated 1.5 million people every year. In the Pacific region two linages are dominant: lineage 1 characterized by the Manila family found in Filipinos and linage 2 by the Beijing family found in Northern Asians. In this presentation, we present the complete genome sequence and analysis of *Mycobacterium tuberculosis* Manila family in Lineage 1 and a deep comparative analysis of this family with the complete genomes in Lineage 2-4 and animal strains. Manila strain genomes were assembled using gsMapper with Manila 96121 complete genome. Mauve and MUMmer 3 were used for whole genome alignments. BLAST and Markov cluster algorithm were used to cluster CRISPR spacers. Pan-genome was analyzed using both orthoMCL and Roary pipeline. SNP analysis and synonymous/nonsynonymous substitution rates were calculated using kSNP and ParaAT respectively. Principal components analysis were carried out using R. This reveals the unique evolution of this ancestrally derived family and sheds light on virulence an attenuation of TB. *Mycobacterium tuberculosis* lineage 1 is inferred to originate ancestrally on account of presence of 52-bp TbD1 sequence and analysis of single nucleotide polymorphisms. Manila family genomes are closely clustered with animal outgroups based on whole genome alignment, providing further evidence to support the ancestral lineage hypothesis. Principal component analysis of presence-absence of CRISPR spacers suggest that Manila family is in distinct distance from Lineage 2-4. We further identify the truncated *wbi5* gene, an additional operon consisting of paralogous STPK PknH coupled ABC transporter, and 6 uniquely conserved SNPs, which are fixed in Manila strains. These unique features can further serve as biomarkers to identify Manila strains and may explain attenuated virulence and limited transmission in this ancestral lineage.

Whole-Genome Sequencing Reveals the Origin and Rapid Evolution of an Emerging Outbreak Strain *Streptococcus pneumoniae* 12F

Author Block:

W. Deng[1], G. Peirano[2], E. Schillberg[3], T. Mazzulli[1], S. D. Gray-Owen[1], J. L. Wylie[4], D. Robinson[5], S. M. Mahmud[6], D. R. Pillai[2]; [1]Univ. of Toronto, Toronto, ON, Canada, [2]Univ. of Calgary, Calgary, AB, Canada, [3]Winnipeg Hlth.Authority, Winnipeg, MB, Canada, [4]Cadham Provincial Lab., Winnipeg, MB, Canada, [5]Univ. of Mississippi, Jackson, MS, [6]Univ. of Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: *Streptococcus pneumoniae* is a major cause of community-acquired pneumonia and septicemia in adults. The global drug-susceptible capsular serotype 12F, clonal complex 218 caused several outbreaks in the USA between 1989-2008, as well as a recent large outbreak in Manitoba, Canada that resulted in 36 cases of septicemia and 3 deaths. The evolutionary origin of the Canadian outbreak strain and its relationship to the historical US outbreak strains are not known. **Methods:** Whole-genome deep sequencing was performed on isolates from the Canadian outbreak (n=36), the US outbreaks (n=9), and non-outbreak surveys (n=21). Phylogenomic analysis and comparative genomics were used to assess evolutionary relationships and to detect gene content differences between the isolates.**Results:** The Canadian outbreak was closely related to sporadic cases that occurred pre-outbreak in cross-border geographic regions in North Dakota, Iowa and Manitoba. The emerging Canadian strain differed from US ones by acquisition of cell-surface protein and macrolide resistance determinants via incorporation of a 5.3kb mega cassette harboring *msrD* and *mefE*. Furthermore, during 11 months of transmission, this clone evolved rapidly and acquired fluoroquinolone resistance through precise step-wise mutations in both *parC* and *gyrA* , and putative compensatory mutations in *uraA* or *IMPDH* under drug selection. Alarmingly, this drug-resistant clone appears to have spread quickly to other regions of Canada and the USA, and transforms bacterial population structure.**Conclusion:** Whole-genome sequencing revealed an independent emergence and secondary adaptation of a new virulent and drug resistant pneumococcal epidemic clone. Ongoing molecular surveillance is required and measures to prevent its spread should be developed.

Epidemiology of the Pandemic Multidrug-Resistant *E. coli* ST131-H30 and H30Rx Subclones among US Children

Author Block:

A. Miles-Jay[1], S. J. Weissman[2], A. L. Adler[2], X. Qin[2], V. Tchesnokova[1], E. V. Sokurenko[1], D. M. Zerr[2]; [1]Univ. of Washington, Seattle, WA, [2]Seattle Children's Hosp., Seattle, WA

Abstract Body:

E. coli ST131-*H30* and its sublineage, *H30Rx*, have abruptly emerged as the dominant cause of multidrug-resistant extraintestinal *E. coli* infections. The epidemiologic significance of these subclones in children is undefined. We quantified the burden and identified host correlates of infection with ST131-*H30* and *H30Rx* among US children. We conducted a prospective surveillance study at 4 US children's hospitals from 2009-2013. All third-generation cephalosporin-resistant (3GCR) *E. coli* isolated from urine or normally sterile sites of patients ≤ 21 years old were collected. For each 3GCR isolate, 3 subsequent third-generation cephalosporin-susceptible (3GCS) *E. coli* isolates were collected. Demographic and clinical data were abstracted from medical records. ST131-*H30* isolates were identified using *fumC/fimH* genotyping; *H30Rx* isolates were identified using a single nucleotide polymorphism-based PCR. Associations between host factors and infection with ST131-*H30* or *H30Rx* were analyzed using univariable and multivariable log-binomial regression stratified by 3GCR status. In total, 21,799 *E. coli* isolates were identified; 334 3GCR and 994 3GCS isolates were further analyzed. Of the 3GCR isolates, 119 were ST131-*H30*, and of those, 82 were *H30Rx*. Of the 3GCS isolates, 47 were ST131-*H30*, and of those, 5 were *H30Rx*. The estimated prevalence of ST131-*H30* and *H30Rx* among all extraintestinal *E. coli* infections was 5.2% and 0.88%, respectively. Among children with 3GCR *E. coli* infections, age 0-5 years was the only factor associated with ST131-*H30* or *H30Rx* (relative risk [RR]: 1.99, 95% confidence interval [CI]: 1.31-3.03; RR: 2.28 95% CI: 1.37-3.82). Among children with 3GCS infections, age and several factors related to underlying illness were associated with ST131-*H30* in the univariable analyses; in the multivariable analysis, only a negative association with age 0-5 years persisted (RR: 0.49, 95% CI: 0.26-0.94). 3GCS *H30Rx* were not separately analyzed due to small numbers. These are the first estimates of the burden of *E. coli* ST131-*H30* and *H30Rx* among US children. We observed that in children with 3GCR *E. coli* infections, ST131-*H30* is more dominant among children age 0-5 years, while in children with 3GCS infections, ST131-*H30* is more dominant among older children.

Publishing Title:

Diversity of Plasmids Harboring *bla*$_{kpc-2}$ in *Klebsiella pneumoniae*

Author Block:

D. Cejas, A. Elena, M. Nastro, C. H. Rodriguez, A. Famiglietti, **G. Gutkind**, M. A. Radice; Univ. de Buenos Aires, Buenos Aires, Argentina

Abstract Body:

Background: Sporadic emergence of KPC-2 producing *Klebsiella pneumoniae* (KPCKp) displaying susceptibility profiles different to the pandemic ST258, as susceptibility to aminoglycosides and/or fluoroquinolones and/or trimetoprim-sulfametoxazol, has been recently reported.The aim of this study was to characterize *bla*$_{KPC}$ coding plasmids from KPCKp clones different from ST258 in our region.**Methods:** Plasmids obtained from 9 KPCKp isolates recovered during 2010-2014 at a single teaching hospital were included. The isolates showed different pulsotypes in X*ba*I-PFGE and belonged to different sequence types (2/9 were ST392, while the rest were ST502, ST1458, ST17 and ST11). Purified plasmids were characterized by replicon typing according to Carattoli *et al*., and plasmid addiction systems were detected as suggested by Mnif *et al.* MOB-P and MOB-F relaxases coding genes identification was carried out by PCR according to Alvarado *et al.* The genetic context of *bla*$_{KPC-2}$ was investigated by PCR mapping in order to identify the reported transposon Tn*4401*.**Results:** Inc L/M group was detected in 4/9 *bla*$_{KPC-2}$ harboring plasmids, being also identified the Inc F_{IIS} group in one of them. The other plasmids were non typable by the methodology proposed by Carattoli *et al.*, unlike Inc F related replicons were characterized in KPCKp ST258 plasmids. The addiction system ParD-ParE was identified in all studied plasmids. In 2/9 plasmids *p*51 of MOB-P family could be identified, however no MOB-P or MOB-F relaxases could be detected in the others. The genetic context of *bla*$_{KPC-2}$ corresponded to Tn*4401* in 2/9 plasmids. However, the genetic environment of *bla*$_{KPC-2}$ seems to be different in the others, given that the upstream region of *bla*$_{KPC-2}$ could not be amplified.**Conclusions:** This study contributes to the knowledge of *bla*$_{KPC-2}$ plasmids epidemiology in our region. Diversity of plasmid backbones could be responsible for the presence of *bla*$_{KPC-2}$ in different clones of *K. pneumoniae*. In addition to previous reports, this work highlights the continuing evolution of the genetic environment of the *bla*$_{KPC-2}$ gene.

Molecular Epidemiology of *Providencia* spp. Harbouring Ndm Carbapenemase in Argentina

Author Block:

D. F. Faccone, F. Pasteran, E. Albornoz, M. Rapoport, P. Ceriana, C. Lucero, S. Gomez, NDM-Argentina Group, A. Corso; Antimicrobianos, INEI-ANLIS Dr. Malbran, Natl. Reference Lab. (NRL), Buenos Aires, Argentina

Abstract Body:

Background: NDM-producing organisms emerged in Argentina in 2013. Since then NDM spread was mainly due to *Providencia* spp (Prov) isolates. Between 2013-2015 the NRL confirmed 39 Prov: 23 *P. stuartii* (Pst) and 16 *P. rettgeri* (Pre) harboring NDM. **Methods:** Isolates non-susceptible to carbapenems (CBP) and with a positive synergy test between CBP and EDTA discs, were suspicious of MBL production. Strains were identified using MALDI-TOF. NDM-1 was confirmed by PCR and DNA sequencing, genetic relatedness was assessed by NotI-PFGE. Susceptibility was evaluated by disc diffusion and dilution methods (CLSI). Statistical analyses were performed with Statistics Pro. **Results.** Pre was mainly from urine (14/16, 88%) unlike Pst (8/23, 35%) ($p<0.01$). CBP non-susceptibility: 100% imipenem and meropenem and 77% ertapenem (100% Pre vs. 61% Pst [$p<0.01$]). 4/14 (29%) hospitals (hosp) reported Pre or Pst during more than one calendar year. 10/39 (26%) isolates co-produced ESBLs (7 CTXM, 3 PER). Susceptibility only to amikacin was mostly linked to Pst (31% vs 6% [$p <0.01$]). By NotI-PFGE, 4 Pre and 5 Pst clonal types were defined. Each dominant clone included 8/16 (3 hosp) and 11/23 (5 hosp) isolates of Pre and Pst, respectively. 56% of Pre (clones A and B) were found at the same hosp. Pst clone A (5 hosp/4 cities) was associated with increased likelihood of severe infection (bloodstream [$p<0.01$]), to co-produce CTXM [$p <0.01$], or to display an extreme-resistant phenotype. **Conclusions:** Two Pre clones were widely found in a single hosp, while a dominant Pst clone was found in several hosp. The spread of NDM-producing Prov is of high concern due to the limited available therapeutic options.

Prevalence of *qnr* and *aac(6´)-Ib-cr* Genes in Extended-Spectrum β-Lactamase-Producing *Enterobacteriaceae* Clinical Isolates from a Spanish Hospital

Author Block:

M. M. Tavío, F. Artiles, I. Anacarso, C. Poveda, J. B. Poveda; Las Palmas G. C. Univ., Las Palmas G. C., Spain

Abstract Body:

Genes *qnr* and *aac(6´)-Ib-cr* are widespread among *Enterobacteriaceae* clinical isolates producing extended-spectrum beta-lactamases (ESBLs) and may facilitate the selection of quinolone resistance mutations.[1] We evaluated their prevalence in ESBL-positive *Enterobacteriaceae* clinical isolates and ciprofloxacin resistant strains.ESBLs were detected by the double-disk method. The 56 studied ESBL-producing strains included 24 *Escherichia coli*, 19 *Klebsiella pneumoniae*, 5 *Enterobacter cloacae*, 4 *Morganella morganii* and 4 *Proteus mirabilis*. Antibiotic MICs and the effect of the proton motive force inhibitor carbonyl cyanide *m*-chlorophenyl hydrazone (CCCP) on ciprofloxacin MIC were assesed by microdilution method. The presence of *qnr* (A, B, C, D, S) and *aac(6´)-Ib-cr* genes and possible mutations in the Quinolone Resistance Determining Regions (QRDRs) of *gyrA* and *parC* genes were studied.The gene *qnrB1* (7 strains) was predominant, followed by *qnrB6* (3 strains), *qnrS1* (3 strains), and *qnrA1* (1 strain). The *qnr* and *aac(6´)-Ib-cr* genes were more prevalent in plasmids from *K. pneumoniae* strains (53% and 84%) than in those from *E. coli*, *E. cloacae* and *M. morganii* strains (9% and 36%, respectively). No other *qnr* and *aac(6´)-Ib-cr* positive isolate was detected. The *qnr*-positive plasmids were identified nearly 2.3-fold more in ciprofloxacin resistant isolates than in susceptible strains, whereas *aac(6´)-Ib-cr* was spread equally among resistant and susceptible strains. Ciprofloxacin MICs 8- 512 μg/ml were found in 84% of the strains that were associated with single and double mutations in QRDRs at positions 83 and 87 in GyrA and 80 and 84 in ParC. In addition, four mutations at codons Met-52, Ser-83, Asp-87 and Asp-115 in GyrA were found in one *K. pneumoniae* isolate. CCCP induced 2- to 8-fold decreases in ciprofloxacin MICs in 33/56 strains.Our results confirmed that multipe mutations in QRDRs of GyrA and ParC played the most relevant role in ciprofloxacin resistance. The *qnr* genes were more prevalent than *aac(6´)-Ib-cr* gene in ciprofloxacin resistant strains. *K. pneumoniae* clinical isolates were the main reservoir of *qnr* genes. The highest number of mutations in GyrA was found in one *K. pneumoniae* isolate carrying *qnrB1*, *qnrS1* and *aac(6´)-Ib-cr* genes.

Detection of Extended Spectrum Beta Lactamases Resistance Genes Among Bacteria Isolated from Selected Drinking Water Distribution Channels in Southwestern Nigeria

Author Block:

A. T. Adesoji[1], A. A. Ogunjobi[2]; [1]Federal Univ. Dutsin-Ma, Dutsin-Ma, Dutsin-Ma, Nigeria, [2]Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Antibiotic-resistant bacteria present an important public health challenge worldwide. Aquatic ecosystems are recognized reservoir for antibiotic resistant bacteria. Important antibiotic resistance traits include those encoding the Extended Spectrum Beta-Lactamases (ESBL) that provide high level resistance to beta-lactam antibiotics. Information about the molecular basis of ESBL resistant bacteria is scarce for Drinking Water Distribution systems (DWDS) in southwestern Nigeria. Previously described multidrug resistant bacteria from raw, treated and municipal taps of DWDS from selected dams in southwestern Nigeria were assessed for the presence of ESBL resistance genes which include bla_{TEM}, bla_{SHV} and bla_{CTX} by PCR amplification. A total of 164 bacteria spread across treated (33), raw (66) and municipal taps (68), belonging to α-proteobacteria, β-proteobacteria, ɣ-proteobacteria, flavobacteria, bacilli and actinobacteria group were isolated from this study. Among these bacteria, the most commonly observed resistance was for ampicillin and amoxillin/clavulanic acid (61 isolates). Sixty-one isolates carried at least one of the targeted ESBL genes with bla_{TEM} being most abundant (50/61) and bla_{CTX} being detected least (3/61). *Klebsiella* was the most frequently identified genus (18.03%) to harbor ESBL gene followed by *Proteus* (14.75%). Moreover, combinations of two ESBL genes, bla_{SHV}+bla_{TEM} or bla_{CTX}+bla_{TEM}, were observed in 11 and 1 isolates, respectively. The classic bla_{TEM} ESBL gene was present in multiple bacterial strains that were isolated from DWDS sources in Nigeria. These environments may serve as foci exchange of genetic traits between a diversity of Gram-negative bacteria.

Limited Clonal Expansion of Extended Spectrum ß-Lactamase-Producing *Escherichia coli* in a Community

Author Block:

M. Jinnai[1], R. Kawahara[1], D. T. Khong[2], T. N. Nguyen[2], H. T. Tran[2], H. V. Le[2], H. T. Nguyen[2], K. N. Pham[2], S. Ueda[3], Y. Kumeda[1], T. Hamabata[1], T. Nakayama[4], Y. Sumimura[4], Y. Yamamoto[4]; [1]Osaka Prefectural Inst. of Publ. Hlth., Osaka, Japan, [2]ThaiBinh Univ. of Med. and Pharmacy, ThaiBinh, Viet Nam, [3]Univ. of the Ryukyus, Nishihara, Japan, [4]Osaka Univ., Suita, Japan

Abstract Body:

Background: Wide dissemination of the extended spectrum β-lactamase-producing *Escherichia coli* (ESBL-*E. coli*) in communities, particularly in developing countries, is a threat to public health. Recent studies have indicated that the transmission of ESBL genes may be a mechanism underlying the wide dissemination of ESBL-*E. coli*. However, clonal expansion of ESBL-*E.coli* is not studied well. Therefore, we investigated the relationship between ESBL-*E. coli* isolates from different sources such as food, community residents, and clinical samples obtained from patients with urinary-tract infection (UTI) in the same area, Thai Binh, Vietnam.**Method:** In total, 253 samples of retail food (pork, poultry, fish, and shrimp), feces of 194 residents, and urine of 205 clinically diagnosed UTI patients were collected. ESBL production, ESBL-genotype, and phylogeny of all *E. coli* isolates from the samples were examined. Further, we analyzed the diversity of 112 ESBL-*E. coli* isolates by pulsed-field gel electrophoresis (PFGE).**Results and Conclusions:** In total, 69.7%, 89.7%, and 5.6% of food samples, residents, and UTI patients, respectively, were ESBL-*E. coli* positive. Additionally, 95.9% of 642 isolates harbored genes belonged to CTX-M-1 and/or CTX-M-9 group. PFGE analysis revealed the diversity of the ESBL-*E. coli* isolates. However, some isolates from different sources were closely related PFGE patterns. In particular, one cluster contained identical isolates from a food and human. These isolates belonged to the phylogenetic group B2 and harbored the $bla_{\text{CTX-M-27}}$ gene. These results indicate that clonal expansion may have occurred in the community, at least on a limited scale. This is the first report of the identification of the same ESBL-*E. coli* clone in a food and human. Furthermore, close relatedness of ESBL-*E. coli* isolates from different sources indicated the transmission of ESBL- *E. coli* between foods and humans.

The Virulence of Ctx-M-15-Producing *Escherichia coli* Isolates of Different Clonal Lineages at a Tertiary Hospital in Nairobi, Kenya

Author Block:

B. Ghebremedhin[1], D. Mania[2], A. Kimang'a[2], G. Revathi[3], W. König[4]; [1]Witten/Herdecke Univ., Clinic Wuppertal, Witten, Germany, [2]Aga Khan Univ. Hosp., Nairobi, Kenya, [3]Aga Khan Univ. Hosp. Nairobi, Nairobi, Kenya, [4]Univ. Clinic Magdeburg, Magdeburg, Germany

Abstract Body:

Background: Multidrug-resistant *Escherichia coli* other gram-negative isolates have been increasing in rate in sub-Saharan Africa. We investigated the correlation between the prevalent extended-spectrum beta-lactamase (ESBL), the virulence factor genes (VFGs) and the genetic lineages of E. coli at the Aga Khan University Hospital in Nairobi within 1-year period.**Methods:** The *E. coli* isolates (n=130) were gained from clinical specimens, including urine (n=104), blood culture and pus (n= 15), skin and wound swabs. Identification and susceptibility testing of were performed by VITEK 2 and E-test. ESBL and quinolone resistance genes (*aac-(6')-lb-cr*) were characterized by PCR and sequencing. Different virulence factor genes (*cdt, cnf, felA, fimA, hlyA, hlyF, papC, nfaE*) were analyzed by PCR. Clonal analysis was performed by multilocus sequence typing (MLST).**Results:** Among the 130 CTX-M-15-producing *E. coli* isolates 43 were recovered from inpatients and 83 from outpatients. Resistance to ciprofloxacin and gentamycin co-existed in these ESBL isolates. All isolates carried the insertion sequence IS*EcpI*. The predominant ST131 ESBL isolates (n=49; 37.7%) harbored the *aac-(6')-lb-cr* gene and were positive for the virulence factor genes *fimA* (81.6%), *papC* (38.8%), *cnf* (8.1%) and *hlyF* (6.1%). Nearly all ST131 *E. coli* (89.8%) were isolated from urine samples, followed by pus and respiratory specimens. Other clones were determined as ST405 (9.2%) and ST648 (8.5%) which were positive for the virulence factor genes *fimA* (16% and 36%), and *papC* (16% and 9%). These two STs were also mostly isolated from urine samples. Less frequent STs were ST10 and ST23 complex, ST156, ST393, ST940, ST1284 and ST1642 which were mostly negative for all VFGs.**Conclusion:** This is the first comprehensive report on CTX-M-15-producing *E. coli* ST131, ST405 and ST648 strains in Nairobi, found predominantly among outpatients. The high diversity of STs is remarkable among the CTX-M-15 *E. coli*. Noteworthy is the higher virulence of the most prevalent ST131 *E. coli* as compared to other STs. This study highlights the need to intensively investigate the diverse ESBL dissemination in Kenya.

Ctx-M-27 Producing *Salmonella enterica* Serotypes Typhimurium and Indiana Are Prevalent among Livestock in China

Author Block:

W-H. Zhang, Z-L. Zeng, **H-X. Jiang**; South China Agricultural Univ., Guangzhou, China

Abstract Body:

Background: *Salmonella spp*. are one of the most important food-borne pathogens causing digestive tract and invasive infections in both humans and animals. Extended-spectrum β-lactamases (ESBLs) especially the CTX-M-type ESBLs are increasingly being reported worldwide and in China. These studies seldom focused on *Salmonella* isolates from food-producing animals. The aim of this study was to characterize the antimicrobial resistance profiles, serotypes and ESBLs and in particular, CTX-M producing Salmonella isolates from chickens and pigs in China.**Methods:** *Salmonella* isolates were identified by API20E system and polymerase chain reaction (PCR) assay; serotypes were determined using slide agglutination with hyperimmune sera; antimicrobial susceptibility was tested using the ager dilution method; the prevalence of ESBLs genes were screened by PCR; CTX-M-producing isolates were further characterized by conjugation along with genetic relatedness and plasmid replicon type.**Results:** In total, 159 *Salmonella* strains were identified, among which 95 strains were *S. enterica* serovar Typhimurium, 63 strains were *S. enterica* serovar Indiana and 1 strain was *S. enterica* serovar Enteritidis. All of these isolates presented multi-drug resistant phenotypes. Forty-five isolates carried CTX-M genes, the most common CTX-M-27(34), followed by CTX-M-65(7) and CTX-M-14(4).Most $bla_{\text{CTX-M}}$ genes were transmitted by non-typeable or IncN/IncFIB/IncP/IncA/C/IncHI2 plasmids with sizes ranging from 80 to 280 kb. In particular, all the 14 non-typeable plasmids were carrying $bla_{\text{CTX-M-27}}$ gene and had a similar size. PFGE profiles indicated that CTX-positive isolates were clonally related among the same serotype, whilst the isolates of different serotypes were genetically divergent. This suggested that both clonal spread of resistant strains and horizontal transmission of the resistance plasmids contributed to the dissemination of $bla_{\text{CTX-M-9G}}$-positive *Salmonella* isolates.**Conclusions:**The presence and spread of CTX-M, especially the CTX-M-27-positive serovars Typhimurium and Indiana in food-producing animals poses a great threat for public health. Control strategies to limit the dissemination of these strains through the food chain are necessary.

Whole Genome Sequencing Of Shiga Toxin-Producing *e. Coli* In The New York State Public Health Laboratory To Identify Serogroup, Virulence Factors, And Genomic Clusters

Author Block:

S. E. Wirth, T. Quinlan, D. J. Baker, D. Bopp, T. Halse, P. Lapierre, W. J. Wolfgang, K. A. Musser; Wadsworth Ctr., NYSDOH, Albany, NY

Abstract Body:

In the United States, it is estimated that shiga toxin producing *E.coli* (STEC) is responsible for at least 265,000 infections each year. STEC in non-O157 serogroups cause approximately 75% of these infections. At the Wadsworth Center, certain virulence factors and the more common serogroups are currently characterized for each isolate by using up to seven real-time PCR assays. Concurrently, pulsed-field gel electrophoresis (PFGE) is performed to identify the PFGE subtype to aid in epidemiological investigations. The use of multiple molecular tests for identification and typing is time-consuming and expensive.Whole Genome Sequencing (WGS) can yield information regarding virulence factors, serogroup, and genomic subtyping from a single dataset, potentially leading to reduced costs and improved turn around time. Furthermore, genomic subtyping can enhance cluster resolution compared to PFGE information alone. To evaluate WGS as a "one-stop-shop" for STEC identification and typing, we have sequenced and analyzed 200 sporadic and outbreak-associated STEC isolates within serogroups O26, O45, O103, O111, and O145. WGS was performed on an Illumina Miseq^{TM} using 2 x 250 paired end chemistry. After passing quality control metrics, sequence reads were analyzed using an in-house developed bioinformatic pipeline. Serogroup and virulence profiles were assigned from raw reads and assembled genomes. In addition, the pipeline mapped raw reads to a single O26 serogroup reference genome and a SNP-based phylogenetic tree was produced. Isolates belonging to the same serogroup were diverse with 0 to >300 SNPs difference while isolates belonging to different serogroups could be thousands of SNPs apart. However, isolates from five different outbreaks clustered tightly with only 0 to 4 SNPs difference. Furthermore, there is a high degree of concordance between SNP-based phylogenetic clusters, PFGE-defined clusters, and epidemiologically defined outbreaks. Our next steps are to refine the pipeline, investigate the impact of using reference genomes from different serogroups to construct our SNP-based tree, and validate for New York State clinical laboratory approval to report WGS-derived serogroup and virulence data.

PCR-RFLP Based Screening Method for *Salmonella enterica* Serovar Typhi to Detect the H58 Lineage and Related Mutations in *gyrA, gyrB, parC* and *parE* Genes

Author Block:

A. M. Tanmoy[1], S. Baker[2], S. P. Luby[3], S. K. Saha[1]; [1]Child Hlth.Res. Fndn., Dhaka, Bangladesh, [2]Oxford Univ. Clinical Res. Unit, Ho Chi Minh City, Viet Nam, [3]Stanford Univ., Stanford, CA

Abstract Body:

Typhoid fever, caused by *Salmonella* Typhi, is a major cause of severe illness particularly among children and adolescents in South Asia. Since the early 1990s, a dominant multidrug-resistant (MDR) lineage (H58) of this organism has been emerged and spread globally. In addition to the MDR phenotype, a high percentage of H58 isolates also exhibit reduced susceptibility against fluoroquinolones via mutations in DNA Gyrase (*gyrA* & *gyrB*) and Topoisomerase IV (*parC* & *parE*) genes. Currently, detection of lineage H58 depends on genome sequencing, which is prohibitively expensive and time consuming. To address this limitation, we have developed a PCR-RFLP based method to identify the H58 lineage among *S.* Typhi. In addition, we have developed a method to screen the mutations in *gyrA*, *parC*, *gyrB* and *parC*. PCR primers were designed from the NCBI-Genbank *S.* Typhi CT18 sequence. Using NEB-cutter tool, appropriate restriction enzymes were selected based on their cutting site and specificity for the mutations in the PCR generated amplicons. *Spe*I was selected to detect H58, targeting the glpA-C1047T mutation. In case of *gyrA* gene, a previously described method using *Hinf*I enzyme to detect the *gyrA*-83 & 87 mutations was adapted with the addition of *parE*-420. Using the same principle, *Bsa*JI was selected to detect *gyrB*-464 and *Hae*II for *parC*-57 & 80 mutations. These methods were validated using a library of 86 *S.* Typhi isolates, with and without MDR and differing degrees of susceptibility to ciprofloxacin. Our method detected 67 isolates (78%) with H58 lineage of *S.* Typhi. Among them 78% were MDR and 97% had reduced susceptibility or resistance against ciprofloxacin. The H58 isolates had mutation at *gyrA*-83 (97%), *gyrA*-87 (1.5%), *gyrA*-83, 87 (1.5%), *gyrB*-464, (0%), *parC*-57 (0%) and *parC*-80 (2%). Among the non-H58 isolates, the mutation rate was 68%, 26%, 0%, 11%, 5% and 0% to the corresponding genes and codons. Overall, this low-cost and simple method to detect H58 *S.* Typhi and mutations in four genes responsible for reduced susceptibility against fluoroquinolones will be of significance for surveillance and monitoring of drug resistance of *S.* Typhi, specifically in resource poor setting.

Epidemiological Investigation on Uropathogenic *Escherichia coli* to Identify Potential Vaccine Candidate for Urinary Tract Infection

Author Block:

M. Mally[1], C. DebRoy[2], V. Gambillara Fonck[1]; [1]LimmaTech Biologics AG, Schlieren, Switzerland, [2]ECRC (E. coli Reference Ctr.), Pennsylvania, PA

Abstract Body:

Urinary tract infections (UTI) are one of the most prevalent infectious diseases worldwide that have significant impact on quality of life and health care costs. Originating from the gut flora, *Escherichia coli* is the most common cause of community and nosocomially acquired infections leading to acute cystitis, pyelonephritis or urosepsis. While the current standard of care is antimicrobial therapy, uropathogens are getting increasingly resistant to certain types of antimicrobials. Hence, alternative treatment strategies are gaining significant importance. GlycoVaxyn developed a proprietary *in vivo* conjugation technology that enzymatically transfers a complex polysaccharide to a consensus protein sequence that allows the efficient production of a multivalent glycoconjugate vaccine against the relevant O-antigen of *E. coli*. In order to evaluate the prevalence of *E. coli* associated with UTI-and the predominant O-serogroups of the strains in community and hospital settings, GlycoVaxyn (now LimmaTech) performed an epidemiological study in Switzerland characterizing the pathogen causing more than 3,000 cases of- UTI and collected over 1800 *E. coli* strains isolated from urines of humans in order to identify the main O-serogroups associated with urinary tract infection. Our findings confirmed that *E. coli* is the predominant pathogen causing UTI infection and showed that a limited subset of O-serogroups accounted for more than 63% of the *E. coli* isolates. Therefore, the O-antigens associated with the prevalent serogroups may be considered as potential vaccine candidates for UTI. Many of these strains were highly resistant to antimicrobials. While the incidence of fluoroquinolone resistance was 24% among the isolates, 4% of all isolates produced extended-spectrum beta-lactamase. In addition, we observed that the antibiotic-resistance is specifically widespread in *E. coli* O25. These findings support the profile and development of O-antigen specific vaccine for the prevention of E.coli infections. Moreover, the glycoengineering technology has the suitable applicability for the development of such a multivalent vaccine candidate.

Usefulness of a Pcr Assay for the Identification of the *Klebsiella pneumoniae* st258 Epidemic Clone in Latin American Clinical Isolates

Author Block:

S. A. Gomez, M. Rapoport, N. Piergrossi, D. Faccone, F. Pasteran, ReLAVRA-Group, A. Petroni, A. Corso; Serv. Antimicrobianos, Laboratorio Natl. de Referencia (LNR), INEI-ANLIS "Dr. Carlos G. Malbrán"., Buenos Aires, Argentina

Abstract Body:

Background: The worldwide dissemination of ST258 of *Klebsiella pneumoniae* (KP)-KPC producers encouraged investigators to develop a rapid typing method based on the identification of ST258 unique gene *pilv-l,* and phage related protein (*prp)* which is neither specific nor ubiquitous of ST258 *(*Adle*r et. al. DMID 2014, 78:12-15)*. Prompt identification of ST is invaluable for some Latin American (LA) countries where this clone has become endemic. **Objective:** to evaluate a PCR developed for ST258 in KP-KPC clinical isolates from LA. **Methods:** KPC, pilv-l and prp genes were detected by PCR and sequenced following standard procedures. Specific primers were used to detect the 3´end of PilV-like gene which is highly specific of ST258 (product size 320 bp) and *prp* gene (product size 544 bp). ST258 and non-ST258 were defined by Xba-I-PFGE and MLST. A total of 107 KP clinical isolates from 9 LA countries recovered from 2006 to 2015 where tested, of which 44 were ST258 and 63 non-ST258. **Results:** The *pilv-l* gene was present only in ST258 isolates regardless of the presence of KPC (positive predictive value 100%). All *pilvl* negative isolates were non-ST258 (negative predictive value 100%). *prp* results were variable. Remarkably, four ST258 isolates were positive for *pilv-l*, negative for KPC and carried CTX-M (n=3) or NDM (n=1). **Conclusions:** The evaluation of a specific PCR for ST258 unique gene that could replace time and resource consuming methods (MLST and PFGE) was successful for the LA isolates tested. In our setting, *pilv-l* detection is enough to discriminate ST258 from other STs.

Fda-*Escherichia coli* Identification (Fda-Ecid) Microarray: A Pan-genome Molecular Toolbox for Serotyping, Virulence Profiling, Molecular Epidemiology, and Phylogeny

Author Block:

I. R. Patel[1], J. Gangiredla[1], D. W. Lacher[1], M. K. Mammel[1], S. A. Jackson[2], K. A. Lampel[1], C. A. Elkins[1]; [1]FDA, Laurel, MD, [2]NIST, Gaithersburg, MD

Abstract Body:

Most *Escherichia coli* are non-pathogenic and some have a beneficial effect on humans. However, it is important to identify pathogenic strains for clinical diagnosis as well as food safety analysis. Commonly used methods for the identification of pathogenic *E. coli* are either time-consuming and/or provide limited and sometimes incomplete information to make a definitive determination of the potential risk to human health. A high-density custom DNA microarray was designed with informative genetic features extracted from 368 whole genome sequences (WGS) for rapid and high-throughput pathogen identification. The FDA-ECID microarray contains three sets of molecularly informative features that function together to stratify strain identification and relatedness. First, 53 known flagellin alleles, 103 alleles of *wzx* and *wzy*, and 5 alleles of *wzm*, provide extensive utility to perform molecular serotyping. Second, 41,932 probe sets representing the pan-genome of *E. coli* provide strain-level gene content information. Third, approximately 125,000 single nucleotide polymorphisms (SNP) of available WGS were distilled to the most discriminatory 9984 SNPs capable of recapitulating the phylogeny of *E. coli* with greater detail than previously reported for available typing methods. Using this platform, we analyzed 103 diverse *E. coli* isolates with available WGS data, including those associated with past foodborne illnesses, to determine robustness and accuracy. The array was able to accurately identify the molecular O and H serotypes of all isolates tested. In addition, molecular risk assessment was possible with virulence maker identifications, as exemplified with the targeted *stx* and *eae* alleles. Epidemiologically, each strain had a unique comparative genomic fingerprint that was extended to an additional 507 strains with strain-level resolution demonstrated for food and clinical examples. Finally, a 99% phylogenetic concordance was established between microarray analysis and WGS using SNP-level data for advance genome typing. The current study confirms the FDA-ECID microarray as a powerful tool for epidemiology and molecular risk assessment with the capacity to profile the global landscape and diversity of *E. coli*.

Molecular Characterization of Enteropathogenic *Escherichia coli* from Children under Than 5 Years with and without Diarrhea in a Rural Area of Southern Mozambique

Author Block:

D. C. Vubil, A. Amos, M. Garrine, T. Nhampossa, I. Mandomando; Manhica Hlth.Res. Ctr., Manhica, Mozambique

Abstract Body:

Introduction: Enteropathogenic *Escherichia coli* are the major cause of infant diarrhea in developing countries. The pathogenicity of EPEC strains has been associated with expression of diverse virulence genes therefore it is possible that different EPEC isolates hold different pathogenic potentialities.**Objectives:** To determine molecular variability of EPEC virulence genes (*eae*, *bfpA* and *perA*) recovered from children under than 5 years with diarrhea in Manhiça District, southern Mozambique.**Material and Methods:** We genetically characterized a collection of EPEC isolates recovered from children under than 5 years admitted to Manhiça District Hospital from 2007-2010 as part of multi-centric case/ control study of etiology of diarrhea in developing countries. EPEC identification and typing of virulence genes was done by conventional PCR.**Results:** total number of 151 EPEC isolates (48 cases of diarrhea, 103 controls) have been characterized. Typical EPEC (*bfpA* with or without eae) was identified in 97(64%) while atypical EPEC (*eae* only) was found in 54(36%). The operon regulator gene *perA* was found in 73(48%). Fifteen different eae types have been identified. The most found were *eae*-λ with 15(31%) for cases and 23(22%) for controls, followed by *eae*-β1 with 12(25%) for cases and 21(20%) for controls, *eae*-ξR/β2B‡§ with 9(18%) for cases and 12(11%) for controls and *eae*-μB# with 9(18%) for cases and 9(8%) for controls, although were not statistical different.**Conclusions:** This is the first report on molecular characterization of EPEC strains in Mozambique, showing that some virulence genes are likely to be more common among cases of diarrhea than in controls although, its implication in severity remain unclear.

Variation in the Distribution of Shiga Toxin-Producing *Escherichia coli* O157 Genotypes from Humans and Cattle

Author Block:

P. Singh[1], R. Mosci[1], M. Moore[1], K. Jernigan[1], J. T. Rudrik[2], G. H. Loneragan[3], S. D. Manning[1]; [1]Michigan State Univ., East Lansing, MI, [2]Michigan Dept. of Hlth.and Human Services, Lansing, MI, [3]Texas Tech Univ., Lubbock, TX

Abstract Body:

Escherichia coli O157:H7 is an important serotype of Shiga toxin (stx)-producing *E. coli* (STEC), a foodborne pathogen responsible for bloody diarrhea and hemolytic uremic syndrome. According to the CDC, there has been a decline in STEC O157 cases in 2014 as compared to 2006-2008, however it is still predominantly associated with outbreaks relative to other foodborne pathogens. Here, we characterized clinical (N=212) and cattle (N=101) isolates from Michigan (MI) and Texas (TX) in 2007-2012 using single nucleotide polymorphism (SNP) genotyping. SNP genotypes were classified into previously defined clades using a modified Illumina-based GoldenGate assay targeting 80 loci and subsequent phylogenetic analyses. Among all isolates examined, the cattle and clinical isolates clustered into six clusters, which correlated with specific virulence genes. Isolates in clusters 1 and 2 were significantly ($p<0.0001$) more likely to harbor *stx1,2* and *eae*, whereas isolates in clusters 4-6 only had *stx*2 and *eae*. Although previously defined clades (1&2 and 7&9) clustered together, new SNP genotypes within the existing clades were identified. As formerly reported among clinical isolates from MI, clade 8 (39%) and clades1&2 (37%) were still dominant from 2007-2012 followed by clade 3 (21%). Relative to the isolates recovered from 1998-2006, the frequency of clade 8 (22%) isolates has continued to increase in MI, while clade 2 (53%) has decreased. Clade 2 (40%) in cattle predominated followed by clades 8 (27%) and 7 (21%), though the distribution varied between MI and TX. Cattle isolates from MI most commonly belonged to clade 2 (80%) versus 28% from TX. None of the cattle-derived isolates from MI were classified as clade 8 compared to 35% from TX. Further, during the same time period, the high clade 2 frequency among bovine isolates may partly explain the increase in clade 2 frequency observed in clinical isolates. This study demonstrates variation in the circulation of *E. coli* O157 genotypes in MI patient and cattle populations in both MI and TX, which could impact disease frequencies in each location.

Isolation of Six *Enterobacteriaceae* Producing New Delhi Metallo-Beta-Lactamase (Ndm-1) in a Pediatric Patient from Argentina

Author Block:

F. Martino[1], N. Tijet[2], R. Melano[2], F. Pasteran[1], M. Rapoport[1], D. Faccone[1], E. Biondi[3], M. Vazquez[3], A. Corso[1], **S. A. Gomez**[1]; [1]Serv. Antimicrobianos, Laboratorio Natl. de Referencia (LNR), INEI-ANLIS "Dr. Carlos G. Malbrán", Ciudad Autonoma de Buenos Aires, Argentina, [2]Publ. Hlth.Ontario Lab., Toronto, Ontario, Canada, Toronto, ON, Canada, [3]Hosp. de Niños Dr. Ricardo Gutiérrez, Ciudad Autonoma de Buenos Aires, Argentina

Abstract Body:

BACKGROUND: In Argentina, KPC is endemic and represents a severe public health problem, but since 2013, NDM metallo-β-lactamase has emerged in our country, and since then, its detection has been increasing **OBJECTIVES:** To characterize *bla*$_{NDM}$ carrying plasmids recovered from six *Enterobacteriaceae* (ETB) isolated from a single patient **METHODS:** Specie identification was done by MALDI-TOF (Bruker Co). MBL-production were evaluated by the Blue-Carba test (BCT) and synergism between carbapenems and EDTA/SMA discs, respectively. MICs were determined by agar dilution (CLSI 2015). PCR, sequencing and conjugation were performed by standard methods. *bla*$_{NDM-1}$ carrying plasmids were extracted from the transconjugants (TC) with the Qiagen Large-Construct kit and sequenced with the Illumina-MiSeq. Assembly of the contigs was done with the CLC Genomics Workbench software (CLC bio, Qiagen). Open reading frames were predicted and annotated by the RAST server (rast.nmpdr.org), followed by manual curation and searches in the NCBI (www.ncbi.nlm.nih.gov/BLAST) **RESULTS:** A 4 y.o. boy cursing erythrodermic psoriasis with previous hospitalizations and multiple antimicrobial treatments was hospitalized for 137 days until his death due to septic shock. Between day 39 and 132, *K. pneumoniae, E. coli (n=2), C. freundii, E. cloacae and S. marcescens* were isolated from blood, retroculture and rectal swabs. All isolates and TC were resistant to carbapenems. Fosfomycin and minocycline were the most active drugs. All harboured the same ca139 Kb IncF plasmid with 176 ORFs carrying *bla*$_{NDM-1}$, *bla*$_{CMY-6}$, *rmtc, aacA4, aac(6´)Ib-cr, sul1* resistance genes. *bla*$_{NDM-1}$ environment gene order was: *rmtc*-IS*Kpn14*-delta IS*Aba125*-*bla*$_{NDM-1}$-*ble*$_{MBL}$-*trp*F-*tat*-*dct*-GroES-GroEL-*ins*A. These plasmids had 99% identity with 98% of coverage with pNDM-US (CP006661) **CONCLUSIONS:** As far as we know, this is the first report of *bla*$_{NDM}$ in the same IncF plasmid in 6 ETB from a patient, alerting of the potential of the dissemination of this plasmid

Global Molecular Epidemiology of Imp and Vim-producing *Enterobacteriaceae*

Author Block:

Y. Matsumura[1], G. Peirano[2], M. Hackel[3], D. J. Hoban[3], M. R. Motyl[4], R. DeVinney[1], J. Pitout[2]; [1]Univ. of Calgary, Calgary, AB, Canada, [2]Calgary Lab. Service, Calgary, AB, Canada, [3]IHMA, Schaumburg, IL, [4]Merck Sharp & Dohme Corp., Kenilworth, NJ

Abstract Body:

Background: Carbapenemase-producing Enterobacteriaceae (En) is an emerging global threat. IMP and VIM carbapenemases are endemic in certain regions, although international data on molecular epidemiology are lacking. We investigated clinical IMP and VIM-producing En collected from the SMART worldwide surveillance program during 2008 and 2013. **Methods:** Genomic sequencing of 34 IMP and 81 VIM-producing En was performed on Illumina next generation sequencing systems. Carbapenemase genes and their flanking regions were analyzed using ARG-ANNOT database and BLASTN. In silico multilocus sequence typing was used to identify international lineages. **Results:** Most IMP-producing En were obtained from South Pacific (n=18) and Asia (n=14), whereas most VIM-producing En were obtained from Europe (n=71) followed by Africa (n=4). *Klebsiella pneumoniae* and *Enterobacter cloacae* complex were the predominant species, and IMP-26 and VIM-1 were the predominant carbapenemases. *K. pneumoniae* clonal complex (CC) 14/15 was the most prevalent lineage associated with bla_{IMP} (IMP-26, n=9 from Philippines; IMP-6, n=2 from Japan). Among 59 VIM-1-producing En isolates, *K. pneumoniae* CC147 was detected in Greece and Italy and CC17 was detected in Greece and South Africa. *E. cloacae* complex CC78 was present in Greece, Italy, and Spain and CC114 in Greece, Taiwan, and USA. All of the bla_{IMP} and bla_{VIM} genes were situated within class 1 integrons; $bla_{\text{VIM-1}}$-*aacA4* were the most common cassettes being present in 6 species. *K. pneumoniae* with $bla_{\text{IMP-26}}$ contained a novel $bla_{\text{IMP-26}}$-*qacG-aacA4* structure. **Conclusions:** IMP-producing En were distributed among South Pacific and Asia. VIM-1-producing En had global distribution and specific clones (CC 147 and 17) contributed to its spread. This study highlights the importance of surveillance programs using molecular techniques in providing insight into characteristics and global distribution of STs with carbapenemases.

Intestinal Colonization with Extended-Spectrum Cephalosporin-Resistant *Enterobacteriaceae* in HIV-Positive Individuals in Switzerland

Author Block:

J. Pires[1], S. Kasraian[1], R. Tinguely[1], C. Hauser[2], A. Rauch[1], H. Furrer[1], **A. Endimiani**[1]; [1]Univ. of Bern, Bern, Switzerland, [2]Bern Univ. Hosp., Bern, Switzerland

Abstract Body:

Background: The intestinal microbiota of HIV-positive individuals has been shown to be in a state of dysbiosis. This might influence the susceptibility of this population to develop specific gastrointestinal diseases. However, nothing is known about the influence of HIV infection on the intestinal colonization with extended-spectrum cephalosporin resistant *Enterobacteriaceae* (ESC-R-*Ent*). In this study, we aimed to address this research question. **Methods:** So far, 67 HIV-positive volunteers followed by Bern University Hospital have been enrolled (from March 2015 to January 2016). Stools of individuals and their pets (if any) were enriched overnight in LB broth with cefuroxime and plated on BLSE, ChromID ESBL, and Supercarba selective plates. At least 5 ESC-R-*Ent* colonies per sample were recovered. Species ID was assessed using the MALDI-TOF MS. Microarray CT103XL and PCR/DNA sequencing were used to characterize the *bla* genes. Clonality was assessed by MLST. An epidemiological questionnaire was obtained from the volunteers.**Results:** The prevalence of intestinal colonization was 3% (n=2). All ESC-R-*Ent* recovered were *E. coli.* Interestingly, one of the volunteers was colonized with two different *E. coli* clones: a CTX-M-15-producing ST405 and a CTX-M-1-producing ST127. The other one was colonized with a CTX-M-1-producing ST410. All these STs are usually defined as hyperepidemic clones (HiRC). Remarkably, the individual colonized with two clones presents as the only case where the pets living within the same household were also colonized with ESC-R-*Ent*. In particular, one of the cats was colonized with the same CTX-M-1-producing ST127 clone identified in the human, while the other cat with unrelated clone (ST73) and ESBL (CTX-M-15).**Conclusions:** The prevalence of intestinal colonization with ESC-R-*Ent* in the Swiss HIV-population is low. In spite of this, ESBLs and clones identified resemble those frequently associated with HiRC causing serious infections. Moreover, the identification of the same clone within the same household also highlights the potential silent spread of these pathogens between pets and humans in close contact.

Very High Prevalence of Multidrug-Resistant (MDR) *Enterobacteria* in Hospitalized Bacteriemic Patients from Mali

Author Block:

S. A. Sangare[1], A. I. Maiga[1], I. Guindo[2], A. Maiga[3], N. Camara[1], O. Dicko[3], S. Diallo[2], F. Bougoudogo[2], E. Rondinaud[4], A. Andremont[4], I. I. Maiga[3], **L. Armand-Lefevre**[4]; [1]Gabriel Toure Hosp., Bamako, Mali, [2]Univ. of Sci., Techniques, and Technologies of Bamako, Bamako, Mali, [3]Point G Hosp., Bamako, Mali, [4]Bichat Hosp. and UMR 1137 INSERM IAME, Univ. Paris Diderot, Paris, France

Abstract Body:

The worldwide diffusion of MDR enterobacteria, *i.e.* extended spectrum beta-lactamase (ESBL-PE) and carbapenemase producing enterobacteria (CPE), is alarming. Limited data concerning the prevalence of such strains in patients from Sub-Saharan Africa are available. We determined, here, the prevalence of MDR among enterobacteria in bacteriemic patients in two teaching hospitals from Bamako (Mali). **Methods:** During one year, all enterobacteria isolated from blood cultures of patients hospitalized in the Point G Hosp. and in the pediatric units of G. Toure Hosp. (550 and 110 beds) were collected. Identifications and antibiotic susceptibility testing were performed using API 20E ID system and VITEK 2 (Biomérieux) in Mali, and confirmed respectively using mass spectrometry (Bruker) and disk diffusion method in France (Bichat hospital). Results were interpreted according to the EUCAST recommendations. PCR and sequencing were performed on ESBL-PE and CPE to determine the type of enzyme. **Results:** 82 enterobacteria were isolated from 77 patients, [mean age 41.5 year (15-81y) for Point G Hosp. and 3.5 y (3m-13y) for G. Toure Hosp.; sex ratio 1.3], 31 (37.8%) *E. coli*, 26 (31.7%) *K. pneumoniae*, 15 (18.3%) *E. cloacae*, 5 *S.* Enteritidis and 5 others. In all, 58.5% (48/82) of the strains produced an ESBL [20/31 (64.5%) *E. coli*, 20/26 (76.9%) *K. pneumoniae* and 8/15 (53.3%) *E. cloacae*] without any difference between the two hospitals. One *E. coli* produced an OXA-181 carbapenemase. Among the ESBL enzyme, CTX-M groupe 1 was highly prevalent (43/48, 89.6%), the remaining being SHV-7 (n=3) and TEM (n=2). Except for amikacin (2.4%), resistance rates to other antibiotic classes were high, 52.4 % to gentamicin, 75.6% to co-trimoxazol and 53.7% to fluoroquinolones. **Conclusion:** A very high prevalence of ESBL-PE and one CPE were observed in enterobacteria isolated in bacteriemic patients hospitalized in Bamako. Among antibiotics, only carbapenem and amikacin remained frequently susceptible. Theses data need to be taken into account to establish guidelines for bacteremia treatment.

***bla*$_{\text{CTX-M-15}}$ Carried by IncF-Type Plasmids Is the Dominant ESBL Gene in *Escherichia coli* and *Klebsiella pneumoniae* at a Hospital in Ghana**

Author Block:

A. Agyekum[1], A. Fajardo-Lubián[1], D. Ansong[2], S. Partridge[1], T. Agbenyega[2], J. Iredell[1]; [1]Ctr. for Infectious Diseases and Microbiol., The Westmead Inst. for Med. Res., The Univ. of Sydney, Westmead Hosp., New South Wales, Westmead, Australia, [2]Malaria Res. Ctr., Agogo Presbyterian Hosp., Komfo Anokye Teaching Hosp., Sch. of Med. Sci., Kwame Nkrumah Univ. of Sci. and Technology, Kumasi, Ghana, Kumasi, Ghana

Abstract Body:

Escherichia coli and *Klebsiella pneumoniae* producing extended-spectrum β-lactamases (ESBLs) are among the most multidrug-resistant pathogens in hospitals and are spreading worldwide. ESBLs are capable of hydrolysing penicillin, broad-spectrum cephalosporins and monobactams and are mostly of the TEM, SHV or CTX-M-type with the later becoming more predominant over the last decade. ESBLs are often located on plasmids and horizontal transfer of these plasmids, as well as spread of high risk clones, are involved in their dissemination. Investigation of the resistance phenotypes of 101 consecutive clinical *E. coli* (n=58) and *K. pneumoniae* (n=43) isolated at the Komfo Anokye Teaching Hospital in Ghana over three months revealed 63 (62%) with an ESBL phenotype. All 63 isolates had a *bla*$_{\text{CTX-M}}$ gene and sequence analysis showed that 62 of these were *bla*$_{\text{CTX-M-15}}$. *bla*$_{\text{CTX-M-15}}$ was linked to IS*Ecp1* and orf477Δ in all isolates and most isolates also carried *bla*$_{\text{TEM}}$, *aac(3)-II*, *aacA4*cr and/or *bla*$_{\text{OXA-30}}$ genes on IncF plasmids. XbaI/pulsed-field electrophoresis showed heterogeneity among isolates of both species, suggesting that *bla*$_{\text{CTX-M-15}}$ dissemination is caused by horizontal gene transfer rather than clonal spread of these species. The study revealed the dominance and polyclonal spread of *bla*$_{\text{CTX-M-15}}$ among *Enterobacteriaceae* with an ESBL phenotype in a teaching hospital in Ghana.

Molecular Characteristics of CTX-M β-Lactamase-Producing Clinical Isolates of *Escherichia coli* in Japan

Author Block:

R. Nakano[1], K. Hikosaka[2], A. Nakano[1], S. Endo[3], K. Kasahara[1], Y. Ono[4], H. Yano[1]; [1]Nara Med. Univ., Kashihara-shi, Nara, Japan, [2]Graduate Sch. of Med., Chiba Univ., Chiba, Japan, [3]Tohoku Univ. Graduate Sch. of Med., Miyagi, Japan, [4]Teikyo Univ. Sch. of Med., Tokyo, Japan

Abstract Body:

Background: Plasmid-mediated β-lactamase CTX-M-type has become the most prevalent extended-spectrum β-lactamase (ESBL) identified in both nosocomial and community settings. Among CTX-M-type ESBL-producing *Escherichia coli*, CTX-M-15 (which belongs to the CTX-M-1 group)-producing *E. coli* have spread worldwide. In this study, we investigated molecular characteristics of clinical isolates of CTX-M-producing *E. coli* in Japan. **Methods:** Fifty non-duplicate CTX-M-producing *E. coli* isolates were obtained from various hospitals throughout Japan between 2013 and 2015. These specimens were isolated from hospital patients and outpatients. The antimicrobial susceptibility profiles of these strains were determined by CLSI guidelines. β-lactamase genes and MLST were identified by PCR analysis and DNA sequencing. The transferability of $bla_{\text{CTX-M}}$-harboring plasmids was confirmed by transconjugation, and plasmid Inc groups were determined by PCR-based replicon typing. **Results:** Of the 50 isolates, 22 (44%) and 28 (56%) were positive for CTX-M-1 and CTX-M-9 groups, respectively. The other CTX-M group β-lactamases were not detected. Of the CTX-M-1 group, CTX-M-15 was the most prevalent (14/22), followed by CTX-M-55 (5/22) and CTX-M-1 (3/22). Of the CTX-M-9 group, CTX-M-14 was the most prevalent (17/28), followed by CTX-M-27 (9/28) and CTX-M-24 (2/28). ST131 was dominant in the CTX-M-1 group (17/22) and the CTX-M-9 group (20/28). Forty-five isolates were transferable and mostly belonged to the IncF family (30/45), which included some highly conjugative plasmids (conjugation frequency, 10^{-1} per recipient). Distinct molecular characteristics were not observed between isolates from hospital patients and outpatients. **Conclusions:** Our findings indicate that CTX-M-14 and CTX-M-27 of the CTX-M-9 group were predominant in CTX-M-producing *E. coli* in Japan. Subsequently, CTX-M-15 (CTX-M-1 group)-producing *E. coli* was identified as a worldwide pandemic clone. ST131 and IncF-type plasmids were predominant among CTX-M-producing *E. coli* isolates. These findings may lend insight into the spread of these resistance genes among *E. coli*.

Trends Of Extended-Spectrum β-Lactamases In U.S. Hospitals: 2008-2015

Author Block:

C. A. DeRyke[1], V. Gupta[2], X. Sun[2], D. D. DePestel[1], S. Merchant[1], Y. P. Tabak[2]; [1]Merck & Co. Inc., Rahway, NJ, [2]Becton, Dickinson & Company, Franklin Lakes, NJ

Abstract Body:

Background: We sought to determine the trends in susceptibility of non-duplicate extended spectrum cephalosporin-resistant *E coli, K pneumoniae* (KP), and *P mirabilis* (PM) isolates in the ambulatory, admission, and hospital-onset settings.**Methods:** We analyzed automated electronic data in a research database of Becton Dickinson and Company from the same 154 USA hospitals (2008-2015). All non-duplicate *E coli*, KP, and PM isolates (first isolate of a species per 30 day period) from all sources were categorized as Extended-Spectrum β-Lactamases (ESBLs) if confirmed as ESBL-positive per commercial panels or intermediate/resistant to any of the 4 extended spectrum cephalosporins (ceftriaxone, cefotaxime, ceftazidime or cefepime). Non-duplicate positive isolates were categorized into three settings by the specimen collection time: a) Admission: within 3 days of an inpatient admission and no previous admission within 14 days; b) Hospital-onset: 3 days post-admission or within 14 days of discharge; c) Ambulatory (neither a or b).**Results:** Of the 116,415 ESBLs isolates, 70.7 % were *E coli*, 22.4% KP, and 6.9% PM. For settings, 53.6%, 20.6%, and 25.8% were ambulatory, admission, and hospital-onset. The overall ESBL rate was 4.8%; pathogen specific ESBL rates were 4.6% (*E coli*), 6.5% (KP), and 3.5% (PM). From 2008 to 2015, the ESBL rates increased from 2.3% to 6.9% (*E coli*, $p < 0.0001$), 6.2% to 7.1% (KP, $p=0.09$), and 1.8% to 4.2% (PM, $p<0.0001$). The overall ESBLs rates increased in all three settings (all $p<0.0001$, see figure). **Conclusions:** ESBL resistance rates increased steadily from 2008 through 2015 in ambulatory, admission, and hospital settings in the U.S. *E coli* accounted for the majority of all the ESBLs.

Identification of β-Lactamase Genes in Clinical Isolates of *Acinetobacter spp.* Collected from Saudi Arabia

Author Block:

S. Schroeder[1], B. Abdalhamid[2], H. Hassan[2], N. D. Hanson[1]; [1]Creighton Univ., Omaha, NE, [2]King Fahad Specialist Hosp, Dammam, Saudi Arabia

Abstract Body:

Background: Gram-negative organisms resistant to β-lactam antibiotics are a growing problem worldwide. Carbapenems are the most potent β-lactam antibiotics available for therapeutic use, but the spread of carbapenemases are threating the utility of these drugs. Enterobacteriaceae, *Pseudomonas aeruginosa*, and *Acinetobacter spp.* (*AS*) are the most prevalent organisms displaying carbapenem resistance. There are several different types of carbapenemases however, data on the occurrence of OXA carbapenemases in isolates of *Acinetobacter spp.* from the Middle East are lacking. The purpose of this study is to identify the types of β-lactamases in clinical isolates of *AS* collected from Saudi Arabia. **Methods:** 25 *AS* isolates where collected from a hospital in Saudi Arabia between January and September of 2013 and identification was completed using API 20E strips (biomerieux). Meropenem, imipenem, and doripenem susceptibilities were evaluated using agar dilution and interpreted using CLSI criteria. PCR amplification was performed using the Philisa rapid amplification system (Streck) and an in house multiplex PCR to identify $bla_{OXA\text{-}like}$ genes. The ARM-D for β-lactamase ID kit (Streck) was used to detect other β-lactamase genes. **Results:** 20/25 *AS* isolates were resistant to all 3 carbapenems tested while 5 isolates were susceptible. $bla_{OXA\text{-}24\text{-}like}$, $bla_{OXA\text{-}48\text{-}like}$, $bla_{OXA\text{-}58\text{-}like}$, and $bla_{OXA\text{-}143\text{-}like}$ genes where not detected in any isolate. 19 isolates were $bla_{\text{OXA-23-like}}(+)/bla_{\text{OXA-51-like}}(+)$, 5 isolates were $bla_{OXA\text{-}23\text{-}like}(-)/bla_{OXA\text{-}51\text{-}like}(+)$, and 1 isolate was $bla_{OXA\text{-}23\text{-}like}(+)/bla_{OXA\text{-}51\text{-}like}(-)$.In addition to $bla_{OXA\text{-}23\text{-}like}$ and $bla_{OXA\text{-}51\text{-}like}$, bla_{KPC} was detected in 1 isolate. **Conclusions:** This is the first report of a KPC β-lactamase in an *AS* isolate outside of Puerto Rico. 80% of these isolates were resistant to all of the carbapenems tested. These data indicate that many *AS* isolates collected in Saudi Arabia are carbapenem resistant and carry the $bla_{OXA\text{-}23\text{-}like}$ gene . In order to understand the mechanisms associated with carbapenem resistance in *AS*, adequate surveillance is key. Molecular detection of genes responsible for β-lactamase production can help identify the presence and spread of OXA carbapenemase genes in isolates of *Acinetobacter*.

Publishing Title:

Prevalence And Genotype Characterization Of Multi-Drug Resistant Gram Negative Organism Colonization In Patients Presenting To An Oncology Unit

Author Block:

H. Michael, B. Yen-Lieberman, M. Sekeres, T. Fraser; Cleveland Clinic, cleveland, OH

Abstract Body:

Background: Multidrug-resistant organisms (MDRO), such as extended beta-lactamase (ESBL) and carbapenem-resistant Enterobacteriaceae (CRE) are an increasing burden. Emerging rapid molecular tests can implicate resistance genes, and may be more sensitive than culture. We describe our experience using a novel PCR-based test to characterize the point prevalence and genotype distribution of MDRO colonization in oncology patients. **Methods:** Surveillance peri-rectal swabs were collected within 24 hours of admission from 205 patients presenting to an oncology unit. Sample size was defined by swab manufacturer. Real-time PCR detected beta-lactamase genes associated with ESBL (CTX-M) and CRE (IMP, NDM, VIM, KPC, OXA-51, OXA-23, OXA-48). Swabs also underwent selective CRE culture. Positive CRE screens underwent ID/AST testing on Vitek2.**Results:** Figure 1 shows the point prevalence of gram negative MDRO genes. CTX-M was most common at 3.4% (N=7). CRE-associated genes had a point prevalence of 2.9% (N=5). Selective CRE culture was positive on 4 swabs. Specifically, 3/3 swabs with KPC gene and 1/7 swabs with CTX-M yielded growth of carbapenem-resistant *Klebsiella pneumonia.* Selective culture was negative in 6/7 CTX-M swabs, 1/1 VIM-B swab, and a swab with CTX-M, OXA-23, OXA-51.**Conclusions:**A PCR-based screening test identified a low prevalence of gram negative MDRO genotypes in a select oncology population and identified relevant resistance genes. While the KPC gene has traditionally been associated with the CRE phenotype, we observed heterogeneity in CRE determinants.Screening based on selective culture may be insensitive for non-KPC organisms. Multiplex PCR may be a promising strategy.

Enterprise-Wide Clinical Implementation Of Next Generation Sequencing For Quality Improvement & Infection Control: Managing Expectations

Author Block:

E. Lesho[1], R. Clifford[1], F. Onmus-Leone[1], L. Appalla[1], E. Snesrud[1], Y. Kwak[1], A. Ong[1], R. Maybank[1], P. Waterman[2], P. Rohrbeck[2], M. Julius[1], A. Roth[1], J. Martinez[1], L. Nielsen[3], E. Steele[3], P. McGann[1], M. Hinkle[1]; [1]Walter Reed Army Inst. of Res., Silver Spring, MD, [2]Armed Forces Hlth.Surveillance Ctr., Silver Spring, MD, [3]San Antonio Military Med. Ctr., San Antonio, TX

Abstract Body:

Objective: Next generation sequencing (NGS) is increasingly acclaimed to revolutionize clinical practice, but most reports involved a single facility or were supported by heavily resourced genomics institutes. Based on our recent experience, large, geographically dispersed healthcare networks and government-funded public health laboratories are likely to encounter constraints and challenges implementing NGS across their health systems. To increase awareness of these and of the public availability of the sequences, isolates, and specialized database architecture of our health system, we highlight the genomic epidemiology of an extensive collection of carbapenemase-producing bacteria (CPB).**Design:** Prospective surveillance**Setting:** 288-hospital healthcare network of the Department of Defense**Intervention:** Enterprise -wide implementation of NGS for quality improvement**Methods:** All CPB underwent NGS. Laboratory capacity, throughput, and response time were assessed.**Results:** From 2009 to present, 25,000 multidrug-resistant Gram-negative isolates were submitted. 225 contained carbapenemase-encoding genes (most commonly bla_{KPC} bla_{NDM}, and bla_{OXA23}) and were found in 15 species, 146 inpatients (53% male; average age 36.1 years) from 19 facilities. Genetically related CPB were found in more than one hospital. Other clusters or outbreaks were not clonal, and involved genetically related plasmids, while others involved several unrelated plasmids. Relatedness depended on clustering algorithm used. Transmission patterns of plasmids and other mobile genetic elements could not be determined without additional, expensive, and rarely available, single-molecule real-time sequencing.**Conclusion:** If not addressed, lack of standardized definitions and quality control metrics, limitations of short-read sequencing, insufficient bandwidth, and limited availability of ultra-long read platforms will constrain enterprise-wide NGS implementation efforts.

Clinical Characteristics and Outcome in Patients with Bacteremia Caused by Extended-Spectrum β-Lactamase (ESBL)- and Non ESBL-Producing *Escherichia coli*

Author Block:

K. Nagaoka, S. Nakakubo, K. Kamada, S. Konno, N. Ishiguro, M. Nishimura; Hokkaido Univ. Sch. of Med., Sapporo, Japan

Abstract Body:

Background: Extended-spectrum beta-lactamase-producing *Escherichia coli* (ESBL-EC) are recently-emerging pathogens worldwide as a cause of community-acquired infection as well as nosocomial infection. Some previous studies suggested high mortality in those patients with bacteremia caused by ESBL- EC bacteremia. However, there have been few studies which compared the clinical features and/or the outcomes between the patients with bacteremia caused by ESBL-EC and those with bacteremia caused by non ESBL-EC. In this study, we attempted to make a direct comparison between the two groups. **Methods:** We retrospectively analyzed 169 consecutive patients with positive blood culture of EC, who had been diagnosed in Hokkaido University between January 2011 and December 2014. We classified the subjects into two groups; ESBL group (N=39) and non ESBL group (N=130), and compared clinical characteristics of the subjects, laboratory data, and regimens of antibiotics at the diagnosis of bacteremia and finally the clinical outcome between the two groups. **Results:** Compared with the non ESBL-EC group, the ESBL-EC group had received any antibiotics more frequently within 3 months before onset of bacteremia (61.5% vs. 33.1% of all the subjects for each; P<0.01), and was being administered inadequate empirical therapy more frequently (58.0% vs. 4.7%; P<0.01). The prevalence of abscess formation in any site of body was significantly higher in the ESBL-EC compared with the non ESBL-EC group (23.1% vs 4.8%; P<0.01). However, the 30 days' mortality was not significantly different between the two groups (13.5% vs. 14.7%; P=1.00). **Conclusions:** Patients with ESBL-producing EC bacteremia tended to be received inadequate empirical therapy at the diagnosis as compared with those with non ESBL EC bacteremia. Higher prevalence of abscess formation might be influenced by the initial treatment failure in ESBL group. However, the 30 days' mortality rate was not significantly different between ESBL-EC bacteremia and that of non ESBL-EC.

The Epidemiology of *bla*$_{CMY-2}$ in *Escherichia coli*: A Change Over Time?

Author Block:

K. Tagg, A. Ginn, S. Partridge, J. Iredell; The Westmead Inst. for Med. Res., Westmead, Australia

Abstract Body:

Escherichia coli is a leading cause of urinary tract infections, diarrheal diseases and septic shock worldwide and resistance rates, particularly to the β-lactam antibiotics, are rising globally. Resistance to β-lactams in *E. coli* is predominantly mediated by plasmid-borne β-lactamase genes and among the most common is *bla*$_{CMY-2}$ (and minor variants), conferring resistance to both cephalosporins and β-lactamase inhibitors. Understanding the transmission dynamics of genes such as *bla*$_{CMY-2}$ is essential for limiting their further spread, but patterns may vary geographically and local studies are essential. We investigated the epidemiology of *bla*$_{CMY-2}$-like genes in *E. coli* isolates from Sydney, Australia over two time periods (2005-09; 2013-14) to gain insight into the dynamics of their spread. Clinical *E. coli* isolates (n=101) were characterised by multilocus sequence typing (MLST), PCR-based replicon typing, multiplex resistance gene PCR and S1 Southern hybridisation and subsets were analysed using pulsed-field gel electrophoresis (PFGE) or Illumina MiSeq technology. Horizontal spread of IncI1 plasmids appeared to be the predominant mode of transmission in 2005-09, as *bla*$_{CMY-2}$ was carried by closely related plasmids in diverse *E. coli* strains. In contrast, *bla*$_{CMY-2}$ was found in the chromosome in half of the recent *E. coli* isolates (2013-14) and very few of these contained IncI1 plasmids. The majority of these isolates were related by PFGE, likely representing clonal expansion of an ancestor strain. However, at least two corresponded to entirely different sequence types by MLST, suggesting that the movement of this gene to the chromosome has occurred on several occasions. This may be a reflection of persistent antibiotic pressure driving mobile resistance genes to more stable genetic locations or simply the natural tendency of these genes to mobilise to different sites. In either case, the apparent increase in the prevalence of *E. coli* strains with a chromosomal *bla*$_{CMY-2}$-like gene is of major therapeutic concern. These findings suggest that the epidemiology and transmission of *bla*$_{CMY-2}$-like genes in Sydney are complex and may be changing over time, and that multiple surveillance strategies are necessary to effectively control their spread.

Multidrug-Resistant *pseudomonas Aeruginosa* (Mdr-Psa) By Source: 2008-2015

Author Block:

D. D. DePestel[1], C. A. DeRyke[1], X. Sun[2], S. Merchant[1], J. Till[2], V. Gupta[2]; [1]Merck & Co. Inc., Rahway, NJ, [2]Becton, Dickinson & Company, Franklin Lakes, NJ

Abstract Body:

Background: We sought to determine the trends in MDR-PSA isolates by source in the ambulatory, inpatient admission, and hospital-onset settings.**Methods:** We analyzed electronic data in a research database of Becton Dickinson from the same 154 USA hospitals (2008 - 2015). All non-duplicate PSA isolates (first isolate of a species per 30 day period) from all sources were identified as MDR if intermediate or resistant to at least 1 in 3 of the 5 drug classes: ceftazidime or cefepime; ciprofloxacin or levofloxacin; aminoglycosides, carbapenems; and piperacillin or piperacillin/tazobactam. Non-duplicate isolates were categorized into three settings by the specimen collection time: a) Admission: < 3 days of an inpatient admission and no previous admission within 14 days; b) Hospital-onset: 3 days post-admission or within 14 days of discharge; c) Ambulatory (neither a or b)**.Results:** Overall, 14.8% (48,283/326,946) of non-duplicate PSA isolates were MDR-PSA. The MDR-PSA rates by ambulatory, admission, hospital-onset settings were 10.2% (14,950/147,109), 14.9% (10,425/70,067) and 20.9% (22,908/109,770), respectively. The proportion of MDR-PSA isolates by source was 42.4% (respiratory), 31.3% (urine), 18.2% (skin), 3.9% (other), 3.5% (blood), and 0.7% (intraabdominal). While a decrease of MDR-PSA for the overall and for blood, skin, and urine sources was observed (all $p<0.01$), the respiratory source remained high (22.6% to 23.3% ($p=0.78$) and the absolute difference was 10% higher than other sources (all $p<0.01$).**Conclusions:** From 2008 to 2015 the MDR-PSA rates were highest for the hospital-onset settings in the US hospitals. Over 40% of all MDR-PSA were respiratory isolates with an

MDR rate of 23% which was consistent across the study period.

Differential Incidence of *Acinetobacter baumannii* Bacteremia Based on Bodily Source of Colonization

Author Block:

R. Rosa[1], A. Jimenez[2], J. Castro[1], D. Kett[1], N. Namias[1], L. Munoz-Price[3]; [1]Univ. of Miami Miller Sch. of Med., Miami, FL, [2]Jackson Hlth.System, Miami, FL, [3]Med. Coll. of Wisconsin, Milwaukee, WI

Abstract Body:

Background: We previously described the strong impact of colonization with carbapenem-resistant *Acinetobacter baumannii* (CRAB) on the subsequent development of any clinical infection with this pathogen. Now we aim to determine the impact of the initial bodily source of colonization on the subsequent development of bacteremia. **Methods:** Retrospective cohort performed at a 1500 bed county teaching hospital, from November 30, 2010 to November 30, 2011. We included all patients consecutively admitted to the trauma intensive care unit (TICU) who had at least one surveillance culture performed. Rectal and respiratory cultures (if intubated) were obtained upon admission and weekly thereafter. Relative risks were determined using the entire cohort. The outcome variable was CRAB bacteremia, defined as at least one positive blood culture in a four year follow up period.**Results:** A total of 364 patients were included in this analysis: 315 (86.5%) remained surveillance negative and 49 (13.4%) tested positive for CRAB. There were 18 CRAB bloodstream infections detected. The relative risk (RR) for the development of bacteremia among surveillance positive patients against surveillance negative patients was 12.8 (95% CI: 5.05-32.6; $p<0.0001$). There were 21 patients whom tested initially positive in the respiratory tract: 6 developed CRAB bacteremia and 15 remained bacteremia free (RR: 15; 95% CI: 5.3-42.5; $p<0.0001$). Among the 16 patients with only rectal colonization at onset, 4 developed bacteremia and 12 remained bacteremia free (RR: 13.1; 95% CI: 4.1-41.9; $p<0.0001$). Twelve patients were concomitantly positive in the rectum and respiratory tract, two of which developed CRAB bacteremia and the remaining 10 were bacteremia free (RR: 8.7; 95% CI: 1.9-38.9; $p=0.004$).**Conclusions:** The bodily source of CRAB colonization appears to impact the risk to develop CRAB bacteremia; the source with highest risk was the respiratory tract.

Increasing Trends of Antimicrobial Susceptibilities of *Escherichia coli* and *Klebsiella pneumoniae* from Intra-Abdominal Infections in South Korea from 2005 to 2014

Author Block:

I-G. BAE[1], J. Lee[2], S. Kim[1], M. Lee[3], M. Kim[4]; [1]Gyeonsang Natl. Univ., Jinju, Korea, Republic of, [2]Hallym Univ. Med. Ctr., Seoul, Korea, Republic of, [3]Merck Sharp & Dohm Korea Ltd., Seoul, Korea, Republic of, [4]Korea Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: The *Enterobacteriaceae*, including *Escherichia coli* and *Klebsiella pneumoniae*, are major pathogens of intra-abdominal infections (IAIs), and their antimicrobial resistances are increasing worldwide. We evaluated the antimicrobial susceptibilities of *E. coli* and *K. pneumoniae* from patients with IAIs in South Korea.**Methods**: A total of 1,739 aerobic Gram-negative IAIs isolates were collected from two or three medical centers in South Korea participating in the Study for Monitoring Antimicrobial Resistance Trends (SMART) program from 2005 to 2014. We determined the antimicrobial susceptibilities to 12 antimicrobials and the extended-spectrum beta-lactamase (ESBL) status using CLSI broth microdilution. **Results**: Of 1,739 IAI isolates, 548 (31.5%) were *E. coli* and 402 (23.1%) were *K. pneumoniae*. The *E. coli* isolates have retained the excellent activities for amikacin and carbapenems with susceptibility rates of > 90%, but fluoroquinolones showed the lowest susceptibility rates of < 60%. With the exception of cefepime and fluoroquinolones, the trends of antimicrobial susceptibilities of *E. coli* isolates were significantly increased over the study period. The *K. pneumoniae* isolates had the modest activities to most antibiotics except for imipenem. Susceptibility rates to most antibiotics were the lowest between 2005 and 2008, and the rates have been increasing since 2012. There was a statistically significant increase in *E. coli* and *K. pneumoniae* susceptibility in isolates from hospital-associated IAIs. There was no significant change in regards to community-associated IAIs. The rates of ESBL-positive *E. coli* and *K. pneumoniae* were not statistically significant changed. **Conclusions**: Our study showed that antimicrobial susceptibility rates of *E. coli* and *K. pneumoniae* isolates from IAIs have been significantly increased from 2005 to 2014, although prevalence of ESBL-positive isolate were not statistically significant changed.

Exploring the Underlying Mechanism of Action and Ultra-structure Distortion Accomplishes by Newly Synthesized Chalcone Derivatives on *Plasmodium falciparum* Infected Erythrocytes

Author Block:

S. Sinha[1], D. I. Batovska[2], B. Medhi[1], B. D. Radortra[1], A. Bhalla[1], R. Sehgal[1]; [1]Post Graduate Inst. of Med. Ed. and Res., Chandigarh, India, [2]Bulgarian Academy of Sci., Sofia, Bulgaria

Abstract Body:

Background: *Plasmodium falciparum* is the deadliest *Plasmodium* that causes human malaria among other five species and for thousands of year traditional herbs are widely used for the cure of this disease. Chalcones (1, 3, diaryl-2-propen-1-ones), secondary metabolite that's belong to the family of flavonoid has been known for its diverse range of pharmacological activities including anti-*Plasmodial* activity. Though several studies illustrates about their mechanisms by which it shows anti-*Plasmodial* action, but its exact mechanism of action is still in the illusion.**Methods**: The hemozoin (b-hematin) inhibition assay was performed in *Plasmodium falciparum* cultures to determine hemozoin content using drug concentrations at IC_{50} values at the end of 48 h and hemozoin content was estimated by determining the absorbance at 400 nm. Further to observe changes at ultra-structure level, ring-stage parasite-infected erythrocytes of both susceptible and resistant strain were treated with chalcone derivatives at twice their respective IC_{50} values for 24 h and then processed, stained to examined through Transmission electron microscopy.**Results**: The level hemozoin production in case of chloroquine and chalcone treated *Plasmodium* culture was almost same, that is, < 350.00 ng/ml, however the hemozoin content was found to be much less as compared to non-treated *Plasmodium* culture that shows statistically significant data ($p<0.05$). Observation through Transmission Electron Microscopy elucidate about the formation of appendages, vacuole formation and condensation of chromatin as compared to non-treated control. This observation is also compared with chloroquine and artemisnin.**Conclusion**: The present analysis suggests these new chalcone derivatives have same mechanism of action as that of chloroquine, which acts on food vacuole of *Plasmodium*. Also, ultra-structural study of *Plasmodium falciparum* strains in the presence of these chalcone derivatives gives the detail analysis of happening inside the *Plasmodium* that will be beneficial while selecting drug target site.

Population-Dependency of Atovaquone Resistance in *Plasmodium chabaudi* Malaria

Author Block:

J. T. Bram, M. Acosta, D. G. Sim, M. J. Jones, A. F. Read; Pennsylvania State Univ., University Park, PA

Abstract Body:

In choosing treatment regimens that best manage drug resistance, it is important to understand the differences between the origin of resistance and the spread of resistance through microbial populations. It is well known that once resistance has arisen, strong drug use places selective pressure on microbes and leads to the proliferation of resistant phenotypes, often over short treatment periods. However, we know little about the factors that contribute to the origin of drug resistance, particularly within hosts. In this study using in an in-vivo rodent malaria model, we test the basic population genetics principle that mutational events occur more frequently in larger populations, and this contributes to increased rates of evolution (i.e. rate of resistance emergence). Mice were inoculated with equal parasite counts and subsequently drug treated at varying time points to simulate different population sizes, allowing us to examine the effects of population size on resistance emergence. Using the rodent malaria model and the antimalarial (Atovaquone), we found that resistance emergence does depend on parasite population size: proportion of mice harboring resistant parasites increased with parasite densities at the onset of treatment. Thus, treatment of larger parasite populations is more likely to lead to resistance emergence. We hypothesize that this may be due to an increased genetic load found within large populations, increasing the probability of the parasite population containing a resistance-conferring allele.

***Plasmodium* Aldolase Detection Using a Smart Phone and a Microfluidic Chip: Electricity-free Elisa for Malaria Monitoring**

Author Block:

N. S. Gopal[1], R. Raychaudhuri[2], L. M. Brzustowicz[3]; [1]Lawrenceville Sch., Lawrenceville, NJ, [2]Med. Coll. of Wisconsin, Milwaukee, WI, [3]Rutgers Univ., Piscataway, NJ

Abstract Body:

Background: Malaria control efforts are limited in rural areas due to lack of monitoring methods for infected patients. A low-cost system to monitor response without the use of expensive enzyme linked immunosorbent assay (ELISA) equipment and electricity is needed. *Plasmodium* aldolase is a key enzyme in the metabolic pathway of the malaria parasite and is a well-characterized biomarker. However aldolase can only be detected with standard ELISA techniques, which requires the use of expensive antibodies, equipment and training. A three part system to enable electricity-free ELISA was developed consisting of a microfluidic chip, hand crank centrifuge and a cell phone based app to read color values. This new system could offer the same sensitivity as ELISA but with a fraction of the costs. **Methods:** A circular microfluidic chip was fabricated using 3 mm optically clear acrylic and a CO_2 laser. Lamination was performed with 3M 501FL adhesive. A series of passive valves released reagents at precise times based upon centrifugal force generated by a hand crank. Color change was measured with a smart-phone camera application programmed in Java. The microchip was compared to a 96 well sandwich ELISA. The ELISA contained: 1) primary: mouse anti-plasmodium aldolase 2) antigen - recombinant aldolase and 3) conjugate: rabbit polyclonal anti-plasmodium aldolase-horse radish peroxidase. **Results:** Results from standard ELISA were compared to microchip at varying concentrations (1-20 ng/mL). Over 15 different microfluidic patterns were tested, and a final prototype of the chip was created. The prototype microchip was compared to standard sandwich ELISA (n=20) using samples of recombinant aldolase. Color readings of standard ELISA and microfluidic microchip showed equivalent results. We found the lower level of the detection limit to be 0.2 ng/mL (200 parasites/uL).**Conclusions:** The cost of the microfluidic system is approximately $10 per sample compared to over $1000 per sample for a standard ELISA. A low cost microfluidic system could improve access to monitoring in rural areas and help identify resistant strains more quickly. Next steps include validating the assay in malaria patients and endemic malaria negative patients.

Complete Telomere-to-Telomere *de novo* Assembly of the *Plasmodium falciparum* Genome Using Long-Read Sequencing

Author Block:

S. S. Vembar[1], **M. Seetin**[2], C. Lambert[2], P. Baybayan[2], A. Scherf[1], M. L. Smith[2]; [1]Inst. Pasteur, Paris, France, [2]PacBio, Menlo Park, CA

Abstract Body:

Sequence-based estimation of genetic diversity of *Plasmodium falciparum*, the most lethal malarial parasite, has proved challenging due to a lack of a complete genomic assembly. The skewed AT-richness (~80.6% (A+T)) of its genome and the lack of technology to assemble highly polymorphic sub-telomeric regions that contain clonally variant, multigene virulence families (i.e. *var* and *rifin*) have confounded attempts using short-read NGS technologies. Using single molecule, real-time (SMRT) sequencing, we successfully compiled all 14 nuclear chromosomes of the *P. falciparum* genome from telomere-to-telomere in single contigs. Specifically, amplification-free sequencing generated reads of average length 12 kb, with ≥50% of the reads between 15.5 and 50 kb in length. A hierarchical genome assembly process (HGAP), was used to assemble the *P. falciparum* genome *de novo*. This assembly accurately resolved centromeres (~90-99% (A+T)) and sub-telomeric regions, and identified large insertions and duplications in the genome that added extra genes to the *var* and *rifin* virulence families, along with smaller structural variants such as homopolymer tract expansions. These regions can be used as markers for genetic diversity during comparative genome analyses. Moreover, identifying the polymorphic and repetitive sub-telomeric sequences of parasite populations from endemic areas might inform the link between structural variation and phenotypes such as virulence, drug resistance and disease transmission.

Efficacy of Rapid Diagnostic Tests for Malaria in Children of Rural Ghana

Author Block:

N. Griswold[1], T. Dickerson[1], J. Reynolds[1], E. Roberts[1], D. Ansong[2], C. Nkyi[2], J. M. Boaheng[2], E. Amuzu[2], S. Gren[1], M. V. M. Morhe[2], P. A. Kontor[2], O. A. Owusu[2], M. G. Quansah[2], R. Buxton[1]; [1]Univ. of Utah, Salt Lake City, UT, [2]Kwame Nkrumah Univ. of Sci. and Technology, Kumasi, Ghana

Abstract Body:

In 2015, 88% of new cases and 90% of deaths due to malaria were in the WHO African region. WHO recommends prompt parasite-based diagnosis in all patients suspected of malaria before treatment, but the absence of accurate diagnostic tests can result in the treatment of patients who do not actually have malaria, contributing to overtreatment, wasted resources and drug resistance. Historically, making a definitive diagnosis of malaria required microscopic examination of a carefully prepared blood sample by a skilled laboratorian. Malaria rapid diagnostic tests (RDTs) have become available to the public for diagnosis of malaria in rural Ghana and require no laboratory infrastructure, allowing them to be deployed to remote settings. It is unknown how well these locally available RDTs perform compared to standard microscopy for diagnosis of asymptomatic malaria in children.A community based, cross sectional study was performed to establish the prevalence of asymptomatic malaria in children of rural Ghana and determine efficacy of locally available RDTs in the diagnosis of asymptomatic malaria as compared to microscopy.Caregivers of children aged 6 months to 5 years in 6 communities in the Barekese sub-District were informed of the study and invited to participate. Samples of capillary blood were used for RDTs and preparation of thick and thin blood smears for microscopy. RDT results were read and recorded on-site. Slides were sent to the research lab for examination.293 participants enrolled in the study. 112 tested positive, 180 tested negative, and 1 test was inconclusive. Compared to the blood smear, the sensitivity and specificity of the RDT were 96% and 74% respectively. The positive and negative predictive values were 43% and 99% respectively. Additionally, 49 of 64 individuals with false positive tests reported having taken medication for malaria within 14 days of RDT analysis, suggesting a possibility of the subjects having remaining antigens after successful treatment of malaria.There was agreement among 77% of the diagnostic tests, making RDTs a fair alternative to microscopy for diagnosing asymptomatic malaria in young children of rural Ghana.

Efficacy of Artemether-Lumefantrine (ACT) for the Treatment of Uncomplicated *P. falciparum* Malaria in Nepal

Author Block:

P. Ghimire[1], N. Singh[2], G. Thakur[3], K. Rijal[1], B. Karki[4], B. Marasini[5], C. Kafle[1]; [1]Tribhuvan Univ.; WHO Nepal, Kathmandu, Nepal, [2]WHO country office for Nepal, Kathmandu, Nepal, [3]Ministry of Hlth., Kathmandu, Nepal, [4]KIST Med. Coll.; Tribhuvan Univ., Lalitpur, Nepal, [5]Epidemiology & Disease Control Div., MoHP, Nepal, Kathmandu, Nepal

Abstract Body:

Background: A single-arm prospective study to assess the therapeutic efficacy of antimalarial drug Artemether-Lumefantrine in Nepal was conducted during 2013-2014. The efficacy of the ACT was assessed based on clinical and parasitological response to directly observed treatment for uncomplicated *P falciparum* malaria. **Methods:** Giemsa stained thick and thin blood smear, prepared from uncomplicated *P falciparum* malaria patients visiting the selected sentinel sites in Nepal during 2013-2014 and meeting the inclusion criteria including parasitemia of between 1000 to 100,000/µl of blood, were evaluated on day 0,1,2,3,7,14,21 and 28 after ACT treatment, following WHO standardized TES Protocol. Based on the reappearance of fever and or increased parasitemia, the study subjects were classified as resistant or susceptible. Blood specimens collected in specified filter papers during first day of microscopic evaluation were also further analyzed by PCR, looking for K13 propeller gene mutation in parasites, a recently identified molecular marker for ACT resistance, for further confirmation of the resistance.**Results:** A total of 56,013 suspected malaria cases only 106 cases were found to be infected with P falciparum, while 1083 were P vivax cases. Out of 28 P falciparum cases meeting inclusion criteria for enrollment in the study only 24 cases completed the study, and 4 lost to follow up after the enrollment in the study. One out of 24 cases (4%) resulted to be late treatment failure (LTF). However, K13 mutation, a proxy indicator for ACT resistance in parasites was not detected on the day-I blood specimens of the cases, indicating the resistance is not yet reached at molecular level and still at phenotypic resistance.**Conclusions:** Detection of ACT resistant parasite on microscopy is a clear indication of phenotypic resistance in the circulating *P falciparum* parasite. The strengthening the sensitivity of the antimalarial drug resistance surveillance is important to contain the resistance as it appears and to mitigate the effects of emerging antimalarial resistance in the south East Asia region.

Annihilation of *Leishmania* Promastigotes by Daylight Responsive Pegylated ZnO Nanoparticles: A Temporal Relationship of ROS Induced Lipid and Protein Oxidation

Author Block:

A. NADHMAN[1], M. Khan[2], S. Nazir[3], M. Khan[4], G. Shahnaz[5], A. Rao[2], D. Shams[6], M. Yasinzai[7]; [1]NORI Hosp., Islamabad, Pakistan, [2]NORI, Islamabad, Pakistan, Islamabad, Pakistan, [3]Natl. Ctr. for Physics, Islamabad, Pakistan, Islamabad, Pakistan, [4]Khyber Med. Univ., Peshawar, Pakistan, Peshawar, Pakistan, [5]Quaid-i-Azam Univ., Islamabad, Pakistan, Islamabad, Pakistan, [6]Abdul Wali Khan Univ., Mardan, Pakistan, Mardan, Pakistan, [7]Intl. Islamic Univ., Islamabad, Pakistan, Islamabad, Pakistan

Abstract Body:

Background: Lipid and protein oxidation are well-known manifestations of free radical activity and oxidative stress. The current study investigates extermination of *Leishmania tropica* promastigotes persuaded by lipid and protein oxidation because of reactive oxygen species (ROS) produced by PEGylated metal based nanoparticles.**Methods:** Zinc oxide nanoparticles doped with different concentrations of silver (1, 5 and 9%) and copper (1%) were synthesized by a modified Masayuki method. The synthesized Photodynamic therapy (PDT) based doped and non-doped zinc oxide nanoparticles were activated in daylight that produced ROS in the immediate environment.**Results:** The ROS produced by the PDT based nanoparticles were found as the main cause of lipid and protein oxidation. However, no lipid and protein oxidation production was observed in the dark experiments. The major lipid peroxidation derivatives comprise of conjugated dienes, lipid hydroperoxides and malondialdehyde, whereas water, ethane, methanol and ethanol were found as the end products. Proteins were oxidized to carbonyls, hydroperoxides and thiol degrading products. Interestingly, lipid hydroperoxides were produced more than 2-fold of the protein hydroperoxides ($p<0.01$), indicating higher degradation of lipids compared to proteins.**Conclusions:** The *in-vitro* evidence represents a significant contribution of the involvement of both lipid and protein oxidation in the annihilated anti-promastigotes effect of nanoparticles.

***Leishmania amazonensis* Rhomboid Proteases**

Author Block:

O. Gonzalez, S. Ganguly, A. Kucknoor; Lamar Univ., Beaumont, TX

Abstract Body:

Leishmaniasis, is a tropical disease caused by species of Leishmania, which include a wide spectrum of disease in humans characterized by lesions in the skin, mucosal surfaces, and visceral organs. Over 10 million people are affected worldwide by this disease that causes significant morbidity and mortality. *Leishmania* parasites have two developmental stages; amastigotes that live intracellularly in macrophages, and promastigotes that multiply inside the insect vector. Although several studies have looked into the actual mechanisms of transition of promastigotes into amastigotes, details are still unknown. Rhomboids are trans-membrane proteins (serine-like proteases), and are able to cleave substrates within their trans-membrane domains. In this study, we have characterized rhomboid like genes in a cutaneous species- *Leishmania amazonensis,* whose genomes have not been sequenced yet. We used the *Leishmania* genome network database to identify Rhomboid-like gene sequences from the available genome sequences. BLAST, ClustalW, and TargetP servers were used to analyze the sequences. Gene specific primers were synthesized based on the sequence comparison and the species of *Leishmania*. Genomic DNA was isolated from a fresh isolate of *L. amazonensis.* PCR amplification was performed and the amplified products were verified for the size. Total RNA was isolated and mRNA was purified. RT-PCR analysis was performed to confirm gene expression. PCR from genomic DNA resulted in amplification of two putative rhomboid-like genes, from *L. amazonensis (LaRom-2 and LaRom-4).* Sequence analyses revealed that except for the catalytic domain, sequences were significantly different from rhomboids in related species. Using the prediction models, LaRom-2 showed two trans-membrane domains with an N-terminal extension towards the cytoplasmic end while LaRom-4 showed four trans-membrane domains with N-terminal extension towards the extracellular end. Interestingly, RT-PCR analyses showed that these genes showed increased expression during stationary phase of growth compared to early logarithmic stages. The stage-regulated expression of these genes suggests a role during the transition of promastigotes to amastigotes, and possibly during the infection process. Functional characterization of these genes is underway.

Visceral Leishmaniasis in Benishangul-Gumuz Regional State, Western Ethiopia: Re-Emerging or Emerging?

Author Block:

A. A. Hirpa[1], G. Tasew[2], T. Tsegaw[1], A. Kejella[3], A. Mulugeta[4], D. Worku[5], A. Aseffa[1], E. Gadisa[1]; [1]Armauer Hansen Res. Inst., Addis Ababa, Ethiopia, [2]Ethiopian Publ. Hlth.Inst., Addis Ababa, Ethiopia, [3]Benishangul Gumuz regional Hlth. bureau, Assosa, Ethiopia, [4]World Hlth.Organization-Ethiopia, WHO-Ethiopia, Addis Ababa, Ethiopia, [5]KalaCORE-Ethiopia, Addis Ababa, Ethiopia

Abstract Body:

Kala-azar is a growing public health problem in Ethiopia. Benishangul-Gumuz regional state is previously not known to be endemic for the disease. In response to a case report fromthe region, we conducted a rapid assessment survey. A pre-tested questionnaire was used to capture socio-demographic and clinical histories pertinent to Kala-azar. Study participants with complaints of fever and headache for two or more weeks were tested for Kala-azar and malaria. All participants were screened with the leishmanin skin test (LST) and the direct agglutination test (DAT) for exposure to Leishmania, defined as a positive result with either or both tests. Twenty of 275 participants were exposed giving an overall leishmaniasis sero-prevalence rate of 7.3%. Among the 20 positive individuals, 19 were farmers and nine of them reported no travel history outside their district. It appears that Kala-azar is emerging in Dangur and Guba districts of Benishangul-Gumuz regional state, probably in connection with human encroachment into one or several previously out of reach zoonotic foci. We recommend integrated epidemiological surveys for confirmation and early containment of disease transmission in the area.

Epidemiological Studies on Opportunistic Intestinal Parasites of HIV Patients on Antiretroviral Therapy in Imo State

Author Block:

T. N. Njoku-Obi, Spouse; Imo State Univ.,Owerri Imo State, Owerri, Nigeria

Abstract Body:

Background: The major health challenges among HIV-positive individuals is opportunistic intestinal parasites infection due to low immunity. The objective of this study was to determine the prevalence of intestinal parasites infection in HIV-infected patient on anti retroviral therapy in Imo state,Nigeria between February 2013 and December 2014.**Methods:** Stools samples were collected from 220 HIV on cART, 200 HIV not on cART and 100 control group. A structured biodata was used to collect socio-demographic data of the patients. Stool samples were **examined by direct saline, iodine wet mount, formol-ether concentration method, modified Ziehl-Neelsen staining techique and modified Trichrome staining method.Results:** Out of 520 stool samples examined 314 were positive for opportunistic intestinal parasites with overall prevalence rate of (60.3%). The highest rate 200(98.5%) of intestinal parasites were observed among HIV positive non cART patients, followed by HIV positive on cART 200(51.3%) and HIV negative individuals 100(4.0%). *Cryptosporidium parvum* 13(2.5%), *Isospora belli* 14(2.6%), *Microsporidium spp* 14 (2.6%), *Giardia lamblia* 91(17.5%) and *Entamoeba histolytica* 182(35%).**Conclusions:** The prevalence of intestinal parasitic infections remains significicant in HIV-infected patients with or without low CD4 counts in the cART era. Cryptosporidium parvum, Isospora belli and Microsporidium spp are the major opportunistic intestinal parasites observed in HIV / AIDS patients. Therefore,early detection and treatment of these intestinal parasites are very important to enhance the life and well -being of HIV/AIDS patients with or without diarrhoea**.**

Impact of *Entamoeba histolytica* Infection on Acute Appendicitis among HIV-1 Infected Individuals in Japan

Author Block:

T. Kobayashi[1], K. Watanabe[2], Y. Murata[1], H. Gatanaga[1], Y. Kikuchi[1], H. Yano[1], T. Igari[1], S. Oka[1]; [1]Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan, [2]Univ. of Virginia, Charlottesville, VA

Abstract Body:

Background: Amoebic appendicitis is rare, but sometimes life-threatening disease of *Entamoeba histolytica* infection. However, its pathogenesis is still unclear. Here, we assessed the impact of *E. histolytica* infection on the pathogenesis of acute appendicitis among HIV-1 infected individuals in Japan.**Methods:** HIV-1 infected appendicitis cases who received appendectomy from 1996 to 2014 were analyzed. Periodic acid-Schiff (PAS) stain in addition to hematoxylin and eosin (HE) stain were used for histopathological examination. PCR for identifying *Entamoeba histolytica* was performed using extracted DNA from formalin fixed paraffin embedded appendix. Serum cytokines before and at the onset of appendicitis were evaluated by ELISA for whom stock serum samples were available.**Results:** Appendectomy was performed in 57 appendicitis patients in the study period. Anti-amoebic antibody was positive in 32.6%. *E. histolytica* infection was confirmed in 9 cases (15.8%). Sequencing of S^{TGA}-D locus showed 4 different genotypes from 9 positive samples. White blood cell counts were slightly higher in *E. histolytica* positive group (13,760/μL vs. 10,385/μL, p=0.02), although no differences were seen in other clinical, imaging and laboratory findings between *E. histolytica* positives and negatives. One case of *E. histolytica* positives, who didn't receive metronidazole, developed intestinal perforation after surgery. Serum samples before and at the onset of appendicitis were available in 3 cases of *E. histolytica* positives. Interleukin-4 was positive in 2 cases both at the onset and before appendicitis, suggesting chronic subclinical *E. histolytica* infection prior to the appendicitis.**Conclusions:** *E. histolytica* infection was confirmed in 15.8% of the appendicitis cases. After surgery, 1 case developed severe complication by *E. histolytica*. Chronic subclinical infection of *E. histolytica* prior to appendicitis was suspected in some cases, which might influence on the development of acute appendicitis. Further investigations on pathogenesis of amoebic appendicitis are needed to improve the morbidity and mortality.

Publishing Title:

Prevalence and Determinant Factors of Intestinal Parasites among Yekolo Temari Children Attending Traditional Education in the Ethiopian Orthodox Churches in Northern Ethiopia

Author Block:

G. B. Hailu, D. T. Mengiste, A. A. Fissiha, S. B. Dasissa; Mekelle Univ., Mekelle, Ethiopia

Abstract Body:

Background: Yekolo temari are children who are studying traditional education in the Ethiopian Orthodox Churches. These special groups of children are characterized by migration, begging and hardship.**Objective**: To determine the prevalence of intestinal parasites and determinant factors among Yekolo temari children of the Ethiopian Orthodox Churches in Northern Ethiopia. **Method**: A cross sectional study design was employed to assess the prevalence and factors associated with parasitic infection among Yekolo temari children in 2015.Wet mount and kato-katz techniques were used to detect *S.mansoni* and other intestinal parasites. Intensity of infection was estimated from the number of eggs per gram of faeces. SPSS version 20 was used to analyze data. **Result**: 361 children participated in the study with a response rate of 85.6%. Of the study participants, 77.8% were in the age group 16 years and above. One hundred eighty three (50.7%) children were positive for at least one parasite. *E.histolytica* was the predominant parasite followed by *S.mansoni* which were detected in 108(29.9%) and 60(16.6%) of study subjects, respectively. Of the study participants, 139(38.5%) and 37(10.2%) harbored single and dual infections, respectively. The mean intensity of *S.mansoni* infection was found to be 118 eggs per gram (epg) of stool and 38(71.7%) of the study participants had light infection (<epg). Majority (82.5%) used to defecate on open fields and 253(70.1%) did not wash their hands after defecation. Moreover, 308(85.3%) of them reported that they get their food by begging and 58.4% trimmed their fingers. Significant relationships were observed between parasitic infection and environmental/behavioral factors. The likely hood of washing hand after defecation was found to be more protective against parasitic infection by 31.8 % (OR=0.68, 95% CI (1.249, 3.132). Children who used to wear shoes were less likely to be infected by hookworm by 3.7 times (OR=3.649, 95%CI (0.005, 0.147). The presence of dirty materials on finger nails was also found to be a risk factor for infection by 53% (AOR=0.47, 95%CI (1.043, 2.45). **Conclusion**: intestinal parasites are very common among this group of children. Therefore, multiple intervention strategies should be implemented to reduce the burden of these infections.

Evaluation of a New FDA Approved Multiplex Molecular Assay for High Throughput Screening of *giardia Lamblia*, C*ryptosporidium spp*., and *entamoeba histolytica* in the Parasitology Clinical Laboratory

Author Block:

C. A. Lanteri, L. Hamilton, R. Ybarra, C. Valenzuela, A. Maramag, R. Tapia, E. Ager; Brooke Army Med. Ctr., San Antonio, TX

Abstract Body:

Enteric pathogens are responsible for significant morbidity and mortality, causing more than 2 million deaths annually worldwide and >375 million cases of diarrhea leading to 900,000 hospitalizations and 6,000 deaths per year in the United States. Giardia infection can be difficult to diagnose using standard microscope examination and often requires a patient to submit multiple stool samples to achieve optimal sensitivity. More recently, molecular methods, such as polymerase chain reaction (PCR), are becoming increasingly more common in clinical microbiology as they offer superior sensitivity relative to traditional methods. Reliance on labor-intensive techniques, such as acid-fast staining, direct fluorescent antibody, or enzyme immunoassays, is no longer required. We evaluated workflow characteristics and sensitivity of the Becton Dickinson (BD) Max™ Enteric Parasite Panel (EPP), a new FDA approved automated multiplex real-time PCR method to screen stool specimens for *Giardia lamblia*, *Cryptosporidium* (*parvum* and *hominis*), and *Entamoeba histolytica*, relative to standard procedures. Previously, processing and analyzing a typical day's workload (32 stools) required 5 hours of technician time, whereas PCR using the BD Max™ system reduced hands-on time to <30 min for sample preparation (<1 min/sample) and resulted in only 3 hrs total turn-around-time (90 min per batch of 24 samples). In this study, we directly compare sensitivity of the EPP versus traditional methods for detecting parasites in clinical specimens and samples spiked with parasite DNA in unpreserved, Carey-Blair, and 10% formalin fixed stool. Results to date suggest formalin interferes with EPP results, whereas we observed better correlation in detecting positives between traditional methods and the EPP in unpreserved or Carey-Blair specimens. Findings from this study are critical to developing a new testing paradigm incorporating rapid molecular testing to replace and/or augment traditional parasitology diagnostics to improve patient care. Since 95% of stools submitted for examination are negative, use of the EPP to rapidly screen for positives improves workflow, eliminates unnecessary processing, and greatly reduces turn-around-time.

***Dirofilaria* as the Etiologic Culprit of an Orbital Pseudotumor**

Author Block:

T. B. Walls, D. Gondim, B. H. Schmitt, T. E. Davis, R. F. Relich; Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Background: The zoonotic nematode genus *Dirofilaria*, is a frequent infective roundworm of dogs, cats, raccoons and other animals. Humans are uncommon incidental hosts of dirofilariae, and infections generally present as lesions of the breast, genitals, lungs, or conjunctiva. This report describes a case of an orbital pseudotumor caused by *Dirofilaria* infection. **Case:** A 68-year-old man with no significant past medical history presented to his primary care physician with a 3-week intermittent history of redness and swelling in his left eye that began after mowing his lawn. The patient was prescribed an antihistamine, but there was no improvement in his swelling and he subsequently developed a vesicle on the left sclera that increased in size. The patient's eye eventually became swollen shut, prompting a visit to the ED. The patient was given steroids and a CT scan, which demonstrated proptosis with periorbital soft tissue swelling. Differential diagnoses of an orbital pseudotumor or neoplasm were considered. An excision of the lesion was performed and the tissue was sent for histopathologic examination. **Results:** Histopathologic examination of the tissue revealed conjunctival stroma infiltrated by acute inflammation and areas of granulation tissue associated with a parasitic nematode. The cross section of nematode demonstrated the characteristic longitudinal ridges, lateral chords, and multilayered cuticle consistent with *Dirofilaria*. **Discussion:** The removal of the scleral lesion was curative and the patient underwent orbital reconstruction surgery. The microfilariae of *Dirofilaria* spp. are transmitted to hosts through a mosquito vector. Humans are dead-end hosts since the nematodes cannot achieve sexual maturity. Four species of *Dirofilaria* have been identified as pathogens of humans: *D. immitis, D. repens, D. tennius*, and *D. ursi*. While definitive identification is not possible on histologic sectioning, *D. immitis*, commonly known as the dog heartworm, is the most common species found in Europe and North America, and it is the most likely culprit in this case.

***Ixodes persulcatus* is the Principal Vector for U.S. Lineage Parasites of *Babesia microti*-Group in Japan**

Author Block:

A. Zamoto-Niikura[1], H. Hirata[2], C. Ishihara[2], S. Morikawa[1], K. Hanaki[1]; [1]Natl. Inst. of Infectious Diseases, Tokyo, Japan, [2]Rakuno Gakuen Univ., Hokkaido, Japan

Abstract Body:

Protozoan parasites belong to U.S. lineage in *Babesia microti* group are known as main causative agents of human babesiosis in the Northeastern and the upper Midwestern United States. The parasites in the U.S. lineage are distributed as well in various small wild mammals throughout the temperate zone of Eurasia, where at least 5 human cases (1 and 4 from Germany and China, respectively) were caused by the lineage, so far. In Northern Asian countries, including Russia, China and Japan, nucleotide sequences of the U.S. lineage were exclusively reported from *Ixodes persulcatus* tick. Whereas evidence of biologically active parasites in *I. persulcatus* is lacking. To confirm vector competence of this tick species, we attempted to isolate infectious parasites from salivary glands of the field collected female ticks in Japan. Five out of 41 ticks were PCR-positive, and 4 isolates were established by inoculating the specimens into hamsters. Phylogenetical analysis based on the nucleotide sequences of *18S rRNA, β-tubulin* and *CCT7* genes revealed that all isolates were classified in U.S. lineage. The sequences of the 4 isolates and those of the isolates from rodents captured in Japan were identical each other. Antigenically all U.S. isolates from *I. persulcatus* and rodents in japan appeared to be same, demonstrating natural transmission in the endemic region in Japan. To our knowledge, direct evidence that *I. persulcatus* tick carries infectious *B. microti* U.S. lineage was provided for the first time. Together with the previous epidemiological and transmission studies, we concluded *I. persulcatus* is at least one of the principal vectors for U.S. lineage in Japan and presumably in Northeastern Eurasia.

Benchmark Results and Trending Analysis Following Introduction of Nucleic Acid Tests for Diagnosis of Anaplasmosis, Ehrlichiosis and Babesiosis in Central and Northern Wisconsin (2013-2015)

Author Block:

T. R. Fritsche[1], T. N. Marti[1], M. E. Nedd[1], A. M. Schotthoefer[2], B. J. Olson[2], T. S. Uphoff[1]; [1]Marshfield Clinic, Marshfield, WI, [2]Marshfield Clinic Res. Fndn., Marshfield, WI

Abstract Body:

Background: Nucleic acid amplification tests (NATs) for detection of the zoonotic pathogens *Anaplasma phagocytophilum* (AP), *Ehrlichia* spp., and *Babesia microti* (BM) are largely replacing blood smear and serologic analyses as the diagnostics of choice for these tick-borne diseases (TBD). Improved diagnostics are facilitating our understanding of the public health significance and expanding distributions of both pathogens and tick vectors. Here we present results following introduction of NATs in 2013 for the diagnosis of AP, *Ehrlichia* spp. and BM in a regional upper Midwest healthcare system.**Methods:** EDTA blood specimens submitted for testing as part of management of patients with possible TBD included 21,236 and 20,185 requests, respectively, for *Anaplasma/Ehrlichia* spp. and BM during the period 1/1/2013-12/15/2015. Tests included two real-time PCR assays, one targeting the *gro*EL operon with melt-curve analysis for differentiation of AP, *E. chaffeensis* (EC), *E.ewingii*, and a novel pathogen identified tentatively as the *Ehrlichia muris*-like agent (EML; Pritt, N Engl J Med 365:422, 2011; Schotthoefer, J Clin Microbiol 51:2147, 2013), and another targeting a variable region of the BM 18s rRNA gene (Teal, J Clin Microbiol 50:903, 2012).**Results:** Overall, positive tests included 654 (3.08%) AP; 17 (0.08%) EML; 2 (0.01%) EC; and 104 (0.52%) BM. Prevalence rates varied little between 2013, 2014 and 2015 (AP, 3.61%, 2.86% and 2.86%, respectively; EML, 0.06%, 0.11% and 0.06%; EC, 0.03%, 0.00%, 0.00%; and BM, 0.63%, 0.44% and 0.50%). These results confirm the expanding range of the rarer *Ehrlichia* spp. in our state as well as the endemic nature of AP and BM in the upper Midwest.**Conclusions:** Use of NATs for diagnosing certain TBD is a paradigm shift demonstrating superior performance compared to traditional methods. While prevalence rates of these TBD in our largely rural service area remain low (AP, 3.08%; EML, 0.08%; EC, 0.01%; and BM, 0.52%), their presence along with recently described geographic spread of competent tick vectors creates a worrisome public health threat superseded only by Lyme disease, also known to be both endemic and enzootic in our region.

Genital *Chlamydia trachomatis* Infection among Women of Reproductive Age Attending the Gynecology Clinic of Hawassa University Referral Hospital, Southern Ethiopia

Author Block:

E. Tadesse, T. Shimelis, M. Teshome; Hwassa Univ., Hawassa, Ethiopia

Abstract Body:

Urogenital infection with *Chlamydia trachomatis* is one of the most common bacterial STIs world-wide, especially in developing nations where routine laboratory diagnosis is unavailable. This study is, therefore, aimed at assessing the prevalence of *C. trachomatis* infection and its associated factors among women of reproductive age group. A cross-sectional study was conducted in a total of 322 consecutive women aged 15-49 years attending the gynecology clinic of Hawassa University Referral Hospital from November 2014 to April 2015. Structured questionnaires were used to collect data on socio-demography and potential risk factors for the genital infection. Moreover, endocervical swab samples were collected from each patient and analyzed for *C. trachomatis* antigen using RDT kit. The overall prevalence of *C. trachomatis* infection in the study population was 18.9 %. High prevalence rates of *C. trachomatis* infection were in the age group 15-24 years (24.2%), followed by the age group 25-34 years (16.8%). Women who had unprotected sex in the last six months were at higher risk of having the infection compared to those with protected sex . Women educational level, marital status, history of pre-marital sex, and use of contraceptive did not influence the infection status significantly ($p > 0.05$). The high prevalence of *C. trachomatis* infection among women of reproductive age group, especially among those participants who were younger and had practiced unprotected sex highlight the need to target this sub-population with interventions measures so that it's clinical and public health impacts could be minimized.

Accuracy of Automated Rapid Plasma Reagin Test in the Diagnosis of Syphilis in HIV-Infected Patients

Author Block:

T. Nishijima, S. Tezuka, K. Teruya, K. Tsukada, H. Gatanaga, Y. Kikuchi, S. Oka; Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan

Abstract Body:

Background: Whether automated Rapid Plasma Reagin (RPR) test is as accurate as conventional manual RPR test in the diagnosis of syphilis among HIV-infected patients is unknown. **Methods:** We conducted a prospective study to compare automated RPR test [Mediace RPR (Sekisui Medical, Tokyo, Japan)] and conventional manual RPR card test [RPR test SANKO (Sanko Junyaku, Tokyo, Japan)] among HIV-infected patients. HIV-infected patients who were suspected of syphilis based on clinical symptoms/signs or who were routinely screened for syphilis were tested for automated RPR test, manual RPR card test, and conventional *Treponema pallidum* Latex Agglutination (TPHA) test with the same serum. For automated RPR test, samples with the results exceeding the upper detection limit were diluted according to the manufacturer's protocol and re-tested. Manual RPR test result of ≥8 fold increase (FI) and positive TPHA test were defined as diagnosis of syphilis.**Results:** 194 test results for 189 patients were analyzed. 97% were men and 93% were men who have sex with men (MSM), with median age and CD4 of 42 (IQR 37-48) and 512 (366-674), respectively. 88% were taking antiretroviral therapy. Median value of automated RPR test was 1.8 RPR Unit (range 0-4500, IQR 0-16) and that of conventional RPR was 2 (range 0-256, IQR 0-16). Two RPR tests showed excellent correlation (Spearman's coefficient 0.947). 58 (30%) results of automated RPR tests were ≥8, whereas 66 (34%) of conventional tests were ≥8. 65 (34%) patients fulfilled the diagnostic criteria for syphilis. There were 8 false negative cases with a median of automated RPR 6.3 (range 2.4-7.4, IQR 4.3-7.3), whereas there were no false positives, resulting in sensitivity of 88% and specificity of 100%. CD4 counts were not different between those with false negative results and the others (p=0.885), and among false negative cases, only 1 out of 8 patients had CD4 count <200 /μl.**Conclusion:** The results of automated RPR test were well-correlated with that of manual RPR card test among HIV-infected patients. However, automated RPR tests can yield false negative results.

Washington, Seattle, WA

Abstract Body:

Background: GEN-003 is a candidate therapeutic vaccine containing recombinant HSV antigens gD and ICP4 with Matrix M-2 (MM) adjuvant. This Phase 2 study was designed to confirm GEN-003 antiviral activity and select the best dose combination for future trials. We previously reported an immediate reduction in virus shedding and lesions. We now present durability of effect. **Methods:** Healthy adults with genital herpes were randomized to receive 30 or 60 µg of each protein antigen and 25, 50, or 75 µg MM, or saline placebo, 3 times 3 weeks apart. Participants collected twice daily genital swabs for HSV-2 DNA PCR for 28 days prior, after the third vaccination, and at 6 and 12 months following immunization and recorded stop and start dates of every outbreak. Placebo recipients were unblinded and re-randomized to one of the 6 active arms after the post-vaccination swabbing period. **Results**: 310 participants were evaluable. Six months after immunization, HSV-2 shedding was significantly reduced in all vaccine groups containing 60 µg of HSV-2 antigens compared to baseline, with the highest reduction in the 60/75 µg group (58%, $p<0.0001$). In subjects receiving 30 µg of antigens, only the 30/50 µg group had a significant reduction in shedding (50%, $P<0.0001$). All active groups (except 30/25 µg) had a reduction in lesions, ranging from 43% to 69% ($p<0.0001$ vs. baseline). Common side effects included injection site discomfort, fatigue and myalgia. No Grade 4 reactogenicity or related SAEs were observed. **Conclusion:** GEN-003 had significant antiviral activity persisting at least 6 months post dosing with an acceptable safety profile.

Prognosis of Ocular Syphilis in HIV-Infected Patients in the Antiretroviral Therapy Era

Author Block:

M. Tsuboi, T. Nishijima, S. Yashiro, K. Teruya, Y. Kikuchi, N. Katai, S. Oka, H. Gatanaga; Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan

Abstract Body:

Background: The clinical course < prognosis of visual acuity in HIV-infected patients with ocular syphilis in the antiretroviral therapy (ART) era remain unknown. **Methods:** We conducted a single-center retrospective chart review of ocular syphilis in HIV-1 infected patients diagnosed between August 1997 < July 2015. The prognosis of best-corrected visual acuity (BCVA) was analyzed. **Results:** The study subjects were 30 eyes of 20 Japanese men who had sex with men (median age, 41). Loss of vision < posterior uveitis were the most common ocular clinical features (43%) < location of inflammation at presentation (50%), respectively. The median baseline BCVA was 0.4 (IQR 0.2-1.2), including three eyes with hand motion. BCVA ≤0.4 at diagnosis was significantly associated with posterior uveitis or panuveitis (p=0.044), while scleritis was significantly associated with BCVA >0.4 (p=0.048). Seventy-five percent were treated with intravenous benzylpenicillin < 53% were diagnosed of neurosyphilis. After treatment (median follow-up: 21 months), BCVA improved in 89% of the eyes, including all eyes with hand motion, to a median BCVA of 1.2 (IQR 0.8-1.2). Kaplan-Meier analysis showed that >28 days of ocular symptoms before diagnosis was the only factor associated with poor prognosis of BCVA. Three patients (15%) developed recurrence after treatment.**Conclusions:** Prognosis of BCVA in HIV-infected patients with ocular syphilis in the ART era was favorable after proper treatment. Persistence of ocular symptoms for >28 days was associated with poor prognosis. We should consider ocular syphilis in the differential diagnosis of uveitis in order to diagnose < treat it early.

Genomic Analysis of *Neisseria gonorrhoeae* Transmission Between Male Partners

Author Block:

J. C. Kwong[1], E. P. F. Chow[2], K. Stevens[1], T. Tomita[1], T. P. Stinear[1], T. Seemann[3], C. K. Fairley[2], M. Y. Chen[2], B. P. Howden[1]; [1]Doherty Inst. for Infection & Immunity, Melbourne, Australia, [2]Melbourne Sexual Hlth.Ctr., Carlton, Australia, [3]Victorian Life Sci. Computation Initiative, Carlton, Australia

Abstract Body:

Background: Gonorrhoea (NG) is a major public health problem, with rising antimicrobial resistance rates and limited therapeutic options. Recent population genomics studies of NG have provided insight into the genomic epidemiology of antimicrobial resistant NG. We conducted this prospective cohort study to understand the evolution of resistance and the genomics of NG transmission between male partners. **Methods:** Men who have sex with men (MSM) who attended the Melbourne Sexual Health Centre with their partners were recruited to participate in the study. Urethral, pharyngeal and rectal cultures for NG were obtained from all participants though only couples where both partners cultured NG were included in the analysis. Whole genome sequencing of the cultured isolates was performed on the Illumina MiSeq/NextSeq. **Results:** 33 couples were included in the study. Urethral, pharyngeal and rectal isolates within an individual were clonal by *in silico* NG-MAST[1] and MLST[2], and highly similar using core-genome SNP[3] analyses, with a median pairwise SNP distance = 2 SNPs (range 0-13; IQR 1-6). In 32/33 couples, MSM were infected with the same clone as their partner (same NG-MAST and MLST; median pairwise SNP distance = 2 SNPs; range 0-199; IQR 1-6). Pan-genomic comparisons of gene content showed a similar signal. Recombination events accounted for many genetic differences between clones, and resulted in partner isolates differing by >50 SNPs in two couples. Isolates from 4 couples had mosaic *penA* alleles (NG-MAST types 1407, 4822), with phylogenetic analyses indicating transmission of clones with identical alleles conferring reduced susceptibility to extended-spectrum cephalosporins between partners. **Conclusion:** NG isolates were clonal at different sites within individuals and between MSM partners. Our findings illustrate the potential for resistance to rapidly emerge in NG through homologous recombination and show the propagation of antimicrobial resistance through transmission of resistant clones. The results from this study provide important information for future genomic analyses of NG resistance and transmission.

Real-Time Pcr for Rapid Detection of *Neisseria gonorrhoeae* and Resistance Determinants in Clinical Specimens

Author Block:

V. Dona[1], S. Kasraian[1], C. Hauser[2], M. Unemo[3], H. Furrer[2], N. Low[4], **A. Endimiani**[1]; [1]Inst. for Infectious Diseases, Univ. of Bern, Bern, Switzerland, [2]Bern Univ. Hosp., Univ. of Bern, Bern, Switzerland, [3]Örebro Univ. Hosp., Örebro, Sweden, [4]Inst. of Social and Preventive Med., Univ. of Bern, Bern, Switzerland

Abstract Body:

Background: Molecular methods are often used for *N. gonorrhoeae* (NG) detection but antibiotic resistance testing still requires time-consuming phenotypic tests. We developed an assay for use in clinical specimens to both identify NG and detect genetic markers of antibiotic resistance. **Methods:** We designed a mismatch amplification mutation assay (MAMA) real-time PCR targeting sequences for: two NG-specific genes (*opa*, *porA*); *penA* mosaic alleles (D345 deletion, G545S) associated with decreased susceptibility to cephalosporins; single nucleotide polymorphisms conferring resistance to ciprofloxacin (GyrA: S91F), azithromycin (23S rRNA: A2059G and C2611U) and spectinomycin (16S rRNA: C1192U). We applied the real-time PCR to 201 clinical specimens (72 urethral, 56 rectal, and 73 pharyngeal) from 79 patients. We evaluated the performance of our method by comparison with the Aptima CT/NG test and standard MICs obtained with the Etest method. **Results:** The MAMA strategy allowed the detection of resistance mutations by comparing cycle threshold values with reference reactions (*opa* and *porA*). Our assay detected NG-positive samples with the following sensitivity/specificity: urethral, 100/98.2%; rectal, 94.7/100%; and pharyngeal, 90/97.7%. It correctly predicted the ciprofloxacin phenotype (24 with MIC ≤0.032 and 16 with MIC ≥0.064 µg/ml) in all culture isolates from specimens tested by real-time PCR. Two patients tested positive for the presence of a mosaic *penA* XXXIV allele. No samples tested positive for the 16S rRNA gene mutation, in line with the observed spectinomycin MICs. The presence of commensals resulted in false positive results for 23S rRNA gene mutations in 5 pharyngeal specimens. **Conclusion:** Our real-time PCR platform is a promising rapid method to accurately identify NG and predict antimicrobial resistance directly in clinical specimens. The impact of this method on the antibiotic management and outcome of NG infections should be evaluated in the near future.

Resistance Patterns Gram-Negative Uropathogens in St.Paul's Hospital Millennium Medical College

Author Block:

Y. Mamuye, Semaria Solomon; SPHMMC, .Addis Ababa, Ethiopia

Abstract Body:

Background: The resistance of bacteria causing urinary tract infection (UTI) to commonly prescribed antibiotics is increasing both in developing as well as in developed countries. The study was undertaken to report antibiotic resistance pattern among common bacterial uropathogens. **Methods**: A total of 2544 urine samples were processed between September 2012 and 2015. Inoculation was performed onto blood and MacConkey agar symoultaniously. Significant bacteriuia was considered with colony counts greater than 10^5cfu/ml. Antibiotic susceptibility was done by Kirby Bauer disk diffusion method. Data entry and analysis was performed using SPSSv20. **Result**: Of the total 2544 samples, 569(22.4%) showed significant growth. Gram negative organisms totaled 508(20.0%), and 61(2.4%) isolates were gram positive. The most frequently isolated gram negative bacterium was *E. coli* followed by *Protues* and *Klebsiella spp*. 305 (12.5%), 102(4.0%), and 42(1.7%) respectively. Between 2012 and 2013, the resistance rate to Tetracyclin, Ampicilin, Amoxycilin, and Nalidixic Acid was reported as 69%, 64% and 67% respectively. In 2014, the study showed that resistance pattern for all except to tetracycline becomes increased 65%, 78% and 78%. The study also showed an emerging resistance to Ciprofloxacilin and Ceftriaxone especially for common gram-negative bacteria. There was relatively low resistance rate to Nitrofurantoin, Gentamycin, and Trimethoprim-Sulfamethoxazole throughout the years. **Conclusions**: In this study setting resistant rate to Tetracyclin, Ampicilin, Amoxycilin, and Nalidixic Acid were high. Since most isolates were sensitive to Nitrofurantoin, Gentamycin, and Trimethoprim-Sulfamethoxazole, thus clinicians should consider these drugs as appropriate antimicrobials for empirical treatment for UTI.

Serogroup and Genotype Distribution of *Chlamydia trachomatis* in Reactive Arthritis and Urogenital Infections in Jamaica

Author Block:

T. R. Butterfield[1], N. Christian[1], J. F. Lindo[1], D. A. Lyn[2], J. Igietseme[3], M. Smikle[1]; [1]Univ. of the West Indies, Kingston 7, Jamaica, [2]Morehouse Sch. of Med., Atlanta, GA, [3]CDC, Atlanta, GA

Abstract Body:

Chlamydia trachomatis is the most frequent triggering agents of reactive arthritis, a sterile joint inflammation. There are no reports on the serogroups or genotypes of *C. trachomatis* in the Jamaican population. The genotypes and serogroups of *C. trachomatis* were determined in joint fluid from patients with suspected reactive arthritis (n=100) and urine samples from a control group of antenatal women (n=201) using 3 different polymerase chain reaction (PCR) assays. The prevalence of *C. trachomatis* in joint fluid ranged from 25% - 71%. The *C. trachomatis* strains found in joint fluid belonged to 2 serogroups and 4 genotypic groups. The majority of strains from joint fluid (24/26, 92%) belonged to serogroup B while serogroup C accounted for the remaining strains (2/26, 8%). The prevalence of *C. trachomatis* in urine specimens ranged from 25% - 69%. The *C. trachomatis* strains found in the urogenital tract belonged to 3 serogroups and 5 genotypic groups. The majority of strains from urine specimens (23/45, 49%) belonged to serogroup B and the remaining strains belonged to serogroup C (14/45; 30%), serogroup I (2/45, 4%) and serogroup BC (5/45; 17%). Genotypic group 1 accounted for the majority of *C. trachomatis* strains in both synovial fluid (15/25; 65%) and urine (92/125; 73%). Among reactive arthritis patients, *C. trachomatis* positivity was significantly associated with being female (25/44, 57% v. 20/56, 36%; p = 0.035) and 50 years of age and older (14/25, 56% v. 9/36, 25% v. 22/39, 56%; p = 0.011). No direct correlations were observed between serogroups and genotypic groups. A substantial proportion of reactive arthritis cases in Jamaica are Chlamydia induced and strains of serogroup B preferentially affect the joints. The results indicate that further work is needed to determine the relationships between *C. trachomatis* serogroups, genotypic groups and serovars and the selective distribution of serogroup B, compared to other *C. trachomatis* serogroups, in the joints of patients with ReA.

Transcription-mediated Amplification-based Screening of Male Sti Clinic Patients for *Mycoplasma genitalium*

Author Block:

E. Munson[1], D. Wenten[2], S. Jhansale[2], M. Schuknecht[2], N. Pantuso[2], M. Napierala[1], K. Munson[1], A. Steward[1], J. Gerritts[1], D. Hamer[1]; [1]Wheaton Franciscan Lab., Milwaukee, WI, [2]Holton Street Clinic, Milwaukee, WI

Abstract Body:

Background: Transcription-mediated amplification (TMA)-based methods have been shown to outperform culture and DNA-based amplification modalities for detection of *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, and *Trichomonas vaginalis* from rectal and/or pharyngeal sources. Recent data espouse the utility of TMA for detection of *Mycoplasma genitalium* from male demographics. We report on performance of TMA-based assays for detection of sexually-transmitted infection (STI) agents from urine and extra-urogenital sources, with particular focus on *M. genitalium*. **Methods:** Within a 22-month interval, 1494 male patient encounters at a Milwaukee STI clinic resulted in collection of 3732 specimens for *C. trachomatis*, *N. gonorrhoeae*, *T. vaginalis*, and *M. genitalium* TMA screening (Hologic). Positive *M. genitalium* results from extra-urogenital specimens were subject to confirmation via repeat analysis. **Results:** 66 patient encounters were managed with collection of one specimen, of which 18.2% were positive for at least one STI agent. This detection percentage increased to 22.2% with collection of specimens from two sources (618 patient encounters) and to 25.6% with collection of specimens from three sources (810 encounters). 270 encounters (18.1% of all encounters) were positive for detection of *C. trachomatis*, *N. gonorrhoeae*, and *T. vaginalis* in various combinations; addition of *M. genitalium* TMA to the screening panel resulted in 86 additional encounters with detection of at least one STI (31.9% increase in encounters positive for STI detection). 60 of these additional detections emanated from urine collections, while 21 resulted from rectal collections. Overall *M. genitalium* detection rates were 6.6% and 5.7% from urine and rectal specimens, respectively. 91.5% of initially-positive *M. genitalium* rectal specimens repeat tested as positive. 93.8% of males with a rectal specimen testing positive for *M. genitalium* indicated strict homosexual preference. **Conclusions:** Additional specimen source sampling contributes to comprehensive STI screening. Incorporation of extra-urogenital sources into assessment for *M. genitalium* may identify additional male carriers of the STI agent.

Publishing Title:

Aetiological Pathogens of Male Urethritis Syndrome and Vaginal Discharge Syndrome in the Tshwane Area, South Africa

Author Block:

B. Osizigbo[1], M. Ehlers[2], **M. Kock**[2]; [1]Univ. of Pretoria, Pretoria, South Africa, [2]Univ. of Pretoria/Natl. Hlth.Lab. Service, Pretoria, South Africa

Abstract Body:

In South Africa, the burden of STI is high and the most common STI presentations to the public healthcare are male urethritis syndrome (MUS) and vaginal discharge syndrome (VDS). Male urethritis account for over 60% of STIs annually, reported at healthcare facilities in the Gauteng province of South Africa. The main STI pathogens responsible for these two syndromes are *Chlamydia trachomatis, Mycoplasma genitalium, Neisseria gonorrhoeae* and *Trichomonas vaginalis*. In South Africa, STI treatment services are provided by both the public and private sectors. In the former, treatment for STIs is reliant on syndromic management. The success of this depends on early detection and constant monitoring of the aetiological pathogens. The aim of this study was to determine the prevalence of *N. gonorrhoeae, T. vaginalis, C. trachomatis* and *M. genitalium* as aetiological pathogens of MUS and VDS using a multiplex real-time polymerase chain reaction assay. Furthermore, the antimicrobial resistance of *N. gonorrhoeae* clinical isolates to eight antibiotics (penicillin, cefoxitin, ceftriaxone, cefpodoxime, tetracycline, ciprofloxacin, ofloxacin and spectinomycin) and the corresponding minimum inhibitory concentrations (MICs) were determined by using the Kirby Bauer disc diffusion and E-test methods. Finally, *N. gonorrhoeae* multi-antigen sequence typing (NG-MAST) was used to determine the genetic relatedness of *N. gonorrhoeae* clinical isolates. The prevalence of MUS and VDS pathogens in this study was 57% (113/200). Pathogens responsible for urethritis were detected in 77% (48/62) of male participants while VDS were found in 47% (65/138) of the female participants. All isolates were susceptible to third-generation cephalosporins. The NG-MAST method revealed novel as well as previously described sequence types (STs). The NG-MAST ST 11715, 11716, 11717 and 11718 are novel STs. This study showed that *N. gonorrhoeae* is the most common cause of urethritis and vaginal discharge in the Tshwane region. The real-time multiplex PCR assay was rapid and suitable for the detection of all four pathogens at relatively low cost. The findings of this study further support the testing of more than one pathogen in a PCR assay for the laboratory diagnosis of MUS and VDS.

Publishing Title:

***Gardnerella vaginalis* Population Dynamics in Bacterial Vaginosis**

Author Block:

D. W. Hilbert[1], J. A. Schuyler[1], M. E. Adelson[1], E. Mordechai[1], J. D. Sobel[2], S. E. Gygax[1]; [1]Med. Diagnostic Lab., Hamilton, NJ, [2]Wayne State Sch. of Medecine, Detroit, MI

Abstract Body:

Background: Bacterial vaginosis (BV) is the leading cause of vaginal discharge and *Gardnerella vaginalis* is thought to play a key role in disease pathogenesis. *G. vaginalis* population structure consists of four clades which differ with respect to virulence factors and antimicrobial resistance.**Methods:** We performed a longitudinal study, collecting vaginal specimens from women at initial BV diagnosis, after completion of treatment and at a 40-45 day follow-up visit. Women were evaluated for BV by Amsel criteria and Nugent scoring. DNA was extracted from these vaginal specimens and analyzed using quantitative real-time polymerase chain reactions (qPCRs) to determine the concentration of each of the four clades.**Results:** Overall, median concentrations of Clades 1 (1.6 E5) and 4 (1.5 E4) were far higher than those of Clades 2 (1.8 E2) and 3 (3.9 E1). Comparison by Nugent score found that Clade 1 and 4 concentrations significantly increased in a stepwise fashion from normal to intermediate to abnormal flora specimens ($P<0.05$). In contrast, the Clade 2 concentration did not differ between intermediate and abnormal flora specimens and the Clade 3 concentration did not differ between normal and intermediate flora specimens. Out of 78 women successfully treated for BV in the study, 32 (41%) would experience recurrent disease at the 40-45 day visit compared to 46 (59%) who remained cured. Both cured and recurrent BV subjects experienced a 2-3 log reduction in Clades 1 ($P<0.001$) and 4 ($P<0.05$) after treatment. The concentration of Clade 2 was reduced only in cured subjects ($P<0.01$) and Clade 3 only in recurrent BV subjects ($P<0.05$). Recurrent disease was characterized by post-treatment increases in Clades 1-3 ($P<0.05$) but not Clade 4.**Conclusions:** Clades 1 and 4 dominate the *G. vaginalis* niche in the vaginal microbiome, are associated with increasing degrees of abnormal vaginal flora and are suppressed similarly by antimicrobial treatment in both cured and recurrent BV patients. In contrast, Clades 2 and 3 were associated with specific vaginal flora transitions and their suppression by therapy with different patient outcomes.

Clinical Symptoms Associated with *Mycoplasma hominis* in Women Genital Tracts

Author Block:

T. Naserpour Farivar, **S. Saadat**, F. Samiee Rad, T. Dabbaghi Ghaleh, H. Jahanihashemi, H. Bahrami, F. Abbasi; Qazvin Univ. of Med. Sci., Qazvin, Iran, Islamic Republic of

Abstract Body:

Mycoplasma hominis is a commensal bacterium in women's genital tracts but recently the role of this organism as a multi-potential pathogen has been suggested. Some physicians believe that this organism colonizes female's genital tract as normal flora with no detrimental effects. This study has compared the frequency of *M. hominis* in symptomatic and asymptomatic women. 226 women with at least one of the clinical symptoms including infertility, vaginosis, abortion or preterm labor and 42 women with none of mentioned manifestations referred to Kowsar University Hospital in Qazvin/Iran were evaluated for the presence of *M. hominis* in their cervix from November 2012 to December 2014. Conventional culture media including broth and agar were prepared manually and supplemented with yeast extract, horse serum, L-arginine, sucrose and antibiotics and also two separate real-time PCR assays targeting 16S rRNA and *yidC* were used for detection of genetically variable *M. hominis* in endocervical specimens.39 (17.2%) symptomatic patients were infected by *M. hominis* whereas among asymptomatic women only 1 (2.4%) person carried this organism in her cervix. Presence of *M. hominis* in women with infertility and vaginosis was significant ($p < 0.05$). Clinical and analytical sensitivity and specificity of real-time PCR targeting *yidC* as a recently used target for detection of *M. hominis* were 100%. Also clinical sensitivity and specificity of the culture were 91.5% and 100% respectively. To distinguish distribution of *M. hominis* between symptomatic and asymptomatic women most (if not all) of related symptoms should be considered, not just one or two of them. Culture method and molecular based assays for detection of such fastidious and heterogeneous bacteria should be design carefully. In this study distribution of bacteria among symptomatic and asymptomatic women was significantly different. *yidC* can be considered as a reliable candidate gene for detection of *M. hominis* although more investigations are necessary in the other populations. Molecular based techniques such as real-time PCR are high sensitive however culture method for detection of *Mycoplasma hominis* is still valuable and cost effective especially in developing countries.

Age-Specific Prevalence of Cervical *Human papilloma virus* (HPV) Infection and Cytological Abnormalities During the Postpartum Period

Author Block:

S. LEE; Cheil Gen. Hosp. and Women's Hlth.care center, Dankook Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: In Korea, most women are screened for cervical cancer using cytology, but prevalence of human papilloma virus (HPV) infection is not well known. Therefore, this study was conducted to investigate the age-specific prevalence of HPV infection and cytological abnormalities during the postpartum period. **Methods:** Between January 2013 and December 2014, we conducted a cross-sectional study of 1927 patients who had given birth at Cheil General Hospital and Women's Healthcare Center. All participants were screened with liquid based Pap smear and cervical human papilloma virus infection test at one to three months after delivery. HPV testing was undertaken using the Seeplex HPV4A ACE screening kit(Seegene).**Results:** During the postpartum period, 6.7% of the patients (128/1927) had positive test results for HPV and 4.2% (81/1927) patients showed abnormal cytology. Among HPV-positive patients, high-risk HPV DNA prevalence was 97.6% (125/128). Among abnormal cytology group, prevalence of low and high-grade squamous intraepithelial lesions(LSIL, HSIL) were 13.6% and 4.9% (11/81 and 4/81). Total 2.5% of the patients (50/1927) showed abnormalities in both HPV and cervical cytology and 2.9% of the patients (58/1927) had positive HPV test with normal cervical cytology. Total 47 patients with abnormal cytology and/or positive HPV infection had further histological confirmation test by colposcopic biopsy and 17/47 patients (36.2%) revealed LSIL or HSIL. 38.5% of the patients (15/39) with both tests positive and 25.0% of the patients (2/8) with abnormal cytology but negative HPV tests were confirmed to have LSIL or HSIL in colposcopic biopsy. Age-specific prevalence of HPV and cytology were not statistically different and showed a plateau-shaped curve.**Conclusions:** The prevalence of HPV infection was lower than expected in Korean pregnant women. More proportion of the patients with both tests positive was confirmed to have histologic LSIL or HSIL than those with only abnormal cytology. Age-specific prevalence was not different between each age group in normal postpartum women.

High Risk *Human papilloma virus* (HR-HPV) Infection Is Not Associated with Adverse Pregnancy Outcomes

Author Block:

S. LEE; Cheil Gen. Hosp. and Women's Hlth.care center, Dankook Univ. Coll. of medicine, Seoul, Korea, Republic of

Abstract Body:

Background: Human papillomavirus (HPV) is one of the most common sexually-transmitted infections among women in their childbearing years. Recently, HPV is known to be associated with several adverse pregnancy outcomes, for example, preeclampsia and premature rupture of membranes. However, only a few studies have been reported in this topic. Therefore, the objective of this study was to determine the association between high-risk HPV (HR-HPV) and adverse pregnancy outcomes. **Methods:**Between January 2013 and December 2014, we conducted a retrospective cohort study of women with HR-HPV at postpartum compared with those with normal cervical cytology at Cheil General Hospital and Women's Healthcare Center. HPV testing was undertaken using the Seeplex HPV4A ACE screening kit(Seegene). We also compared HPV infection with other genital infections. **Results:**Hundred and twenty five women with HR-HPV were age-matched with 250 women with normal pap smears. Our sample included 53 cases of premature rupture of membranes (PPROM), 30 cases of preterm deliveries before 37 weeks, 43 cases of small for gestational age infant (SGA), 21 cases of gestational diabetes mellitus (GDM) and 3 cases of preeclampsia. In our study group, there were no differences in the prevalence preterm delivery, PPROM, SGA, GDM or preeclampsia. Exposed HR-HPV patients had lower body mass index at the beginning of pregnancy and the rate of emergency cesarean section was lower than normal control (16.8% vs 32.0%, p=0.003). Twelve patients were infected by *group B streptococcus* (GBS) and 11 patients were infected by other sexually transmitted diseases (*ureaplasma, mycoplasma, Chlamydia, E.coli* etc). However, co-infection with other types of bacteria or virus was not more prevalent in HR-HPV infected women.**Conclusions:**HR-HPV infection is known as a very important risk factor for cervical neoplasia, however, according to our study, HR-HPV infection was not associated with any adverse pregnancy outcomes including PPROM and preeclampsia.

High Risk Human Papilloma Virus Subtypes in Women of Karachi Pakistan

Author Block:

W. Yousuf, S. Khan; Dow Univ. of Hlth.Sci., Karachi, Pakistan

Abstract Body:

Introduction: Human Papilloma virus is the major cause of cervical cancer (CC) which is the second most common cancer among women worldwide. Presently, more than 100 HPV genotypes have been identified and about 20 of them have been strongly implicated in the development of ano-genital cancer. In developing country like Pakistan Population-based data for HPV-type distribution is insufficient. The need is to compose and present an up to date data that would be instrumental in improving the therapeutic strategies against HPV. **Objective:** To determine the prevalence of high-risk HPV types in healthy women of Sindh Pakistan. **Methodology:** 360 samples consisting of cervical scrapes were collected from women recruited. Following smearing slides for Pap test, remaining cervical cells were transferred to sterile vials containing phosphate buffered saline, and stored at -20^0C. DNA was extracted from samples and HPV specific PCR was carried out for subtypes 16, 18, 31, 33, 35, 39, 45, 52, 56, 58, 59 and 66. **Results:** Out of 360 normal sexually active women visiting the gynecology clinic evaluated for the presence of HPV 54 (15.42%) were found positive for HPV with general primers which subjected to types specific PCR and 15 (4.2%) of them were found to have high risk oncogenic strains of HPV including genotype 16, 18, 56, 45, 66, 31, 39 and 58. Among the high rich strains three were HPV type 56, three HPV type 18, two each type 45, 66 and 31 and one each was HPV 16, HPV 58 and HPV type 39. **Discussion:** This study was performed to determine the prevalence of high risk HPV among normal Pakistani women. The study will help to evaluate the available vaccine and guide the vaccine production in future that could be effective for the local population. In our study we found HPV subtypes other than 16 and 18. Therefore, only the use of available vaccine will not be sufficient to protect the spread of the local strains. There is no question that early detection will continue to be a key element even once a vaccine is available.

High Rate of Colistin Dependence in *Acinetobacter baumannii* Isolates from South Korea

Author Block:

Y-K. Hong[1], J-Y. Lee[1], Y. Wi[2], K. Ko[1]; [1]SungKyunKwan Univ. Sch. Of Med., Suwon, Korea, Republic of, [2]Div. of Infectious Diseases, Samsung Changwon Hosp. Sungkyunkwan Univ. Sch. of Med.,, Changwon, Korea, Republic of

Abstract Body:

Background: Colistin is currently considered the last option for multidrug-resistant *Acinetobacter baumannii* infection. However, colistin resistance in *A. baumannii* is increasing worldwide. We report the in vitro development of colistin dependence in not few colistin-susceptible *A. baumannii* isolates after exposure to colistin. **Methods:** We performed colistin susceptibility testing for 170 *A. baumannii* isolates collected from intensive care units of a Korean hospital in 2015 and examined colistin dependence among colistin-susceptible isolates by using the population analysis and colistin disc method. Multilocus sequence typing (MLST) was performed for the isolates developing colistin dependence. For 45 patients with *A. baumannii* infection, we compared 3-day and 7-day treatment failure in patients with and patients without colistin-dependent strains, 18 and 27 patients, respectively.**Results:** Among 170 *A. baumannii* isolates, 21 (12.4%) were resistant to colistin. We found that 49 of 149 colistin-susceptible *A. baumannii* isolates (32.9%) developed colistin dependence. The 49 isolates developing colistin dependence showed six STs in MLST. The ST208 (28 isolates, 57.1%) had the most common. Three-day and 7-day treatment failure in patients with and patients without colistin-dependent strains were 66.7% versus 37.0% (3-day; $p = 0.051$) and 44.4% versus 25.9% (7-day; $p = 0.197$).**Conclusions:** In vitro development of colistin dependence after exposure to colistin may not be rare phenomenon in *A. baumannii*. Fast substitution of antimicrobial agents may be required if colistin treatment is ineffective and colistin dependence is identified.

Assessing The Efficacy Of Silver-Doped Antimicrobial Coatings On Prosthetic Liners

Author Block:

J. M. Haglin[1], A. V. Hayda[2], **D. Garcia**[2], J. Jarrell[3], R. Hayda[2], C. Born[2]; [1]Brown Univ., Providence, RI, [2]Rhode Island Hosp., Providence, RI, [3]BioIntraface, Inc., North Kingston, RI

Abstract Body:

Abstract: Approximately 185,000 patients undergo an amputation each year, with an estimated 50 percent increase in the next 35 years[1,2]. One of the leading issues facing amputee patients is late developing antibiotic-resistant bacterial infections in the stump of the patient. The enclosed design of the prosthetic socket often causes friction, sweat and debris build-up at the prosthetic-stump interface. Coupled with body heat, these factors result in a favorable condition for skin irritation, bacterial growth and eventual infection and chronic malodor. In this study, we characterized the efficacy of a silver-doped, titanium dioxide-polydimethylsiloxane coating at preventing bacterial growth on orthopaedic liners as a possible solution to the complex issue facing prosthesis wearers.**Methods:** This study utilized seven commonly encountered pathogens: Coagulase-Negative *Staphylococcus epidermidis*, Methicillin-sensitive *Staphylococcus aureus*, Methicillin-resistant *Staphylococcus aureus*, *Propionibacterium acnes*, *Enterococcus faecalis*, *Pseudomonas aeruginosa*, and Multi-Drug Resistant *Acinetobacter baumannii*.Kirby Bauer Assay was conducted using 4 different types of commercially available prosthetic liners and 9 different conditions of coating. Liner plugs were plated on a lawn of bacteria with a set concentration of $1E^6$ CFU/mL. Area inhibition was measured over 72 hours.Efficacy of the coating was determined via dose response curves against each pathogen independent of the prosthetic liners at aconcentration of $1E^7$ CFU/mL. Data was analyzed using ImageJ.**Results:** The silver-doped coating has antimicrobial effects on each of the seven pathogens assessed. On prosthetic liners, the coating is effective at preventing bacterial growth for at least 72 hours. The 95% 10X preparation of the coating was found to be the most effective at killing and preventing bacterial colonization.**Conclusion:** The coating conditions tested display a pattern of bacterial inhibition and continuous protection which point towards the 95%10X condition being the most promising as an antimicrobial coating in prosthetic liners. The identified conditions promise to be an effective tool towards mitigating infections and malodor found in the stump-liner interface.

Microorganisms Recovered From Adult Patients With Cystic Fibrosis

Author Block:

K. Lucey, R. Harbeck; Natl. Jewish Hlth., Denver, CO

Abstract Body:

Chronic, pulmonary infections are the most prominent cause of the increased morbidity and mortality in cystic fibrosis (CF). *Pseudomonas aeruginosa* remains the main pathogen in adults, but other Gram-negative bacteria such as *Achromobacter xylosoxidans* and *Stenotrophomonas maltophilia* have been shown to play an important role in this lung disease. We reviewed the organisms identified from respiratory specimens from CF patients collected over a three year period to determine if there were shifts in the populations of microorganisms.Culture and identification of microorganism followed standard procedures. In brief a 10% solution of sputolysin was added to the respiratory sample to break down the mucus. The sample is then diluted to 1.0 x10-3 and plated onto three selective plates; Mannitol Salt Agar, Burkholderia cepacia Selective Agar, and Chocolate Agar with Bacitracin. Serial dilutions of the sample were plated on 5% sheep blood agar and MacConkey agar. After 16-18 hours of incubation in at 37^0C, 5% CO2, the culture was examined for bacterial growth and the organisms identified by standard biochemical assays or by commercial identification systems.Between 2012 through 2015, 4996 organisms were identified from CF cultures. Of this total, 30% of the cultures were positive for *Pseudomonas aeruginosa*, 23% were positive for *Staphylococcus aureus* and 9% were positive for methacillin-resistant *Staphylococcus aureus* (MRSA). Non-lactose fermenting gram negative rods were present in 8% of the cultures with *Stenotrophomonas maltophilia* and *Achromobacter (Alcaligenes) xylosoxidans* being the two predominating organisms. Mold was recovered in 7% of the cultures with the majority identified as *Aspergillus*. Other organisms isolated, each with a percent less than 7%, included *Pseudomonas* species, *Burkholderia cepacia*, *Haemophilus influenza*, group A streptococcus, yeast, and enteric gram negative rods .In our adult CF patient population *Pseudomonas aeruginosa* was the most predominant organism identified in CF respiratory cultures followed by *Staphylococcus aureus*. Interesting the percentage of MRSA, nonlactose fermenting gram negative rods, *Burkholderia cepacia* and group A strep remained unchanged while the other organism identified either increased or decreased in percentage from year to year.

Variation Of Biofilm Forming Ability Of Aggr-Positive *escherichia Coli* Strains

Author Block:

N. Imuta, T. Ooka, K. Yoshiie, J. Nishi; Kagoshima Univ. Graduate Sch. of Med. and Dectal Sci., kagoshima, Japan

Abstract Body:

Background: Enteroaggregative *Escherichia coli* (EAEC) cause acute or persistent diarrhea and their adherence to the intestinal mucosa is characterized by the formation of a thick biofilm. Although the gold standard method for EAEC identification is the HEp-2 cell adherence assay, the transcriptional regulator AggR is widely used as a genetic marker of typical EAEC for PCR detection. Recently, we have found that some *aggR*-positive *E. coli* strains did not form strong biofilm. Therefore, we examined the correlation between the biofilm forming ability and prevalence of virulence genes among the *aggR* gene-positive *E. coli* strains. **Methods:** A total of 58 *aggR*-positive *E. coli* strains were used, and they were isolated from diarrheal children since 2011 through 2013 in Kagoshima, Japan. Biofilm formation is assessed by microtiter plate assay, and strains were classified into two groups according to the biofilm index: the biofilm group ($OD_{570}\geq 0.2$) and the non-biofilm group ($OD_{570}<0.2$). They were also examined for virulence genes of EAEC (plasmid; *aatA*, *aap*, *aggA*, *aafA*, *agg3A*, *hdaA*, *aaf5*, *pet*, *sepA* and *astA*, chromosome; *sat*, *pic* and *aaiC*) and UPEC (*sfa*, *pap* and *afa*) by PCR. **Results:** Thirty (51.7%) strains belonged to the biofilm group (range, 0.209-2.53), while 28 strains (48.3%) belonged to the non-biofilm group (range, 0-0.098). In the biofilm group, *aap* (96.7%) was the most frequently detected gene followed by *aaiC* (90.0%), *aatA* (83.3%) and *pic* (80.0%). In contrast, *aaf3* (60.7%), *pap* (60.7%) and *sfa* (42.9%) were frequently found in the non-biofilm group. The biofilm group strains predominantly harbored both plasmid and chromosomal genes of EAEC, while the non-biofilm group strains mainly possessed UPEC virulence genes. **Conclusions:** Approximately half of *aggR*-positive *E. coli* strains did not form the characteristic biofilm of EAEC in our district. It was supposed that the *aggR* gene was horizontally transferred from EAEC to UPEC. Not only the *aggR* gene but also other EAEC virulence genes or biofilm formation are required to identify EAEC.

Increased Nasopharyngeal Density And Concurrent Carriage Of *streptococcus Pneumoniae, Haemophilus Influenzae And Moraxella Catarrhalis* are Associated With Pneumonia In Febrile Children

Author Block:

S. Chochua[1], V. D'Acremont[2], C. R. Hanke[1], D. Alfa[1], J. Shak[1], M. Kilowoko[3], E. Kyungu[4], L. Kaiser[5], B. Genton[2], K. P. Klugman[1], **J. E. Vidal**[1]; [1]Emory Univ., Atlanta, GA, [2]Swiss Tropical and Publ. Hlth.Inst., Basel, Switzerland, [3]Amana Regional Referral Hosp., Dar es Salaam, Tanzania, United Republic of, [4]St-Francis Hosp., Ifakara, Tanzania, United Republic of, [5]Univ. of Geneva, Geneva, Switzerland

Abstract Body:

Background: We assessed nasopharyngeal (NP) carriage of five pathogens in febrile children with and without acute respiratory infection (ARI) of the upper (URTI) or lower tract, attending health facilities in Tanzania.**Methods:** NP swabs collected from children (N= 960) aged 2 months to 10 years, and with a temperature ≥38°C, were utilized to quantify bacterial density of *S. pneumoniae (Sp), H. influenzae (Hi), M. catarrhalis (Mc), S. aureus (Sa) and N. meningitidis (Nm)*. We determined associations between presence of individual species, densities, or concurrent carriage of all species combination with respiratory diseases including clinical pneumonia, pneumonia with normal chest radiography (CXR) and endpoint pneumonia.**Findings:** Individual carriage, and NP density, of *Sp*, *Hi* or *Mc*, but not *Sa or Nm*, was significantly associated with febrile ARI and clinical pneumonia when compared to febrile non-ARI episodes. Density was also significantly increased in severe pneumonia when compared to mild URTI (*Sp*, $p<0.002$; *Hi* $p<0.001$; *Mc*, $p=0.014$). Accordingly, concurrent carriage of Sp^+, Hi^+ and Mc^+, in the absence of Sa^- and Nm^-, was significantly more prevalent in children with ARI ($p=0.03$), or clinical pneumonia ($p<0.001$) than non-ARI, and in children with clinical pneumonia ($p=0.0007$) than URTI. Furthermore, Sp^+, Hi^+ and Mc^+ differentiated children with pneumonia with normal CXR, or endpoint pneumonia, from those with URTI and non-ARI cases.**Interpretation:** Concurrent NP carriage of *Sp, Hi* and *Mc* was a predictor of clinical pneumonia and identified children with pneumonia with normal CXR and endpoint pneumonia from those with febrile URTI or non-ARI episodes.

Increased Rate of *Gordonia* Species Identified from Clinical Isolates in New York State

Author Block:

K. Mitchell, L. Mingle, J. Cole, N. Dumas, K. Musser; New York State Dept. of Hlth., Albany, NY

Abstract Body:

Gordonia species are gram-positive, partially modified acid-fast bacilli commonly found in the environment, which have recently been described as emerging pathogens, causing disease primarily in immunocompromised patients. *Gordonia* species are often difficult to identify at both a genus and species level by conventional culture and biochemical analyses and can be misidentified as *Rhodococcus, Corynebacterium,* or *Nocardia* species. Molecular identification of *Gordonia* species using 16S rDNA gene sequence analysis improves the rate of identification, however several of the species cannot be differentiated using this method. The Wadsworth Center (WC) serves as the diagnostic reference center for the detection and identification of bacteria for New York State. From 2001 to 2014 the average the number of specimens received and identified as *Gordonia* species annually was 3.57, however in 2015 the number of specimens identified quadrupled to 16. The 16 isolates originated from 11 different hospitals and from various specimen types including blood, sputum, bronchial wash, corneal scrapings, and wound biopsies. Patients ranged in age from 3 months to 83 years old and were equally distributed between males and females. Of the 16 isolates received, 31% were able to be definitively identified to the species level, while the other 69% were unable to be differentiated between different species using MALDI-TOF MS, biochemicals, and 16S rDNA sequence analysis. The *Gordonia* species received in 2015 by WC that were not readily distinguished by 16S rDNA sequence analysis were *G. sputi*, *G. aichiensis* and *G. otitidis*. Interestingly, amongst these three species the biochemical profiles are significantly different, however the WC isolates do not match the biochemical profiles of any of the type strains. This recent increase in *Gordonia* isolates received may be the result of new test systems in clinical laboratories such as the MALDI-TOF MS or indicate an increase in infections with *Gordonia* species. Studies are underway to identify new genetic targets which may be utilized for more rapid identification methods of these emerging pathogens.

Comparison of Virulence Factors in Pigmented and Non-Pigmented *Pseudomonas aeruginosa* by Using phenotypic and Genotypic Tests

Author Block:

S. Macin[1], **Y. Akyon**[2]; [1]Şırnak State Hosp., Sırnak, Turkey, [2]Hacettepe Univ., Ankara, Turkey

Abstract Body:

Background: The incidence of *Pseudomonas aeruginosa* has been increased in recent years and its virulence factors are various. The aim of this study was to compare the differences in the virulence factors of pigmented and non-pigmented *P. aeruginosa* isolates. **Methods:** Isolates of patients that were identified as *P. aeruginosa* were included into the study. The isolated *P. aeruginosa* strains (n: 100) were divided into two main groups equally according to their pigment production. Antibiotic susceptibility tests of all strains were performed by disk diffusion method according to CLSI (Clinical and Laboratory Standards Institute) standards. DNase, protease, elastase, haemolysis and motility tests were performed as phenotypic tests. The presence of several virulence-associated genes encoding exotoxins T (*exo*T), S (*exo*S), U (*exo*U) and Y (*exo*Y) and quorum sensing mediators (*rhl*A and *rhl*B) were assessed by Real-time PCR method for genotypic identification. The relationship between pigment production, antibiotic resistance and virulence factors were examined.**Results:** There was no significant difference between pigmented and non-pigmented isolates when elastolytic activity and mucus production were compared. Pigmented isolates produced significantly more ($p \leq 0.05$) protease and haemolysis activity. Motility was present in pigmented isolates more frequently than in non-pigmented isolates. DNase activity was significant in pigmented isolates then non-pigmented isolates ($p \leq 0.05$). Antibiotic resistance was present more frequently in non-pigmented isolates than pigmented isolates. Pigmented isolates had more frequently and significant more ($p \leq 0.05$) virulence-associated genes rhlB, *exo*S, *exo*Y ($p \leq 0.05$). *Exo*T was present in pigmented isolates more frequently than in non-pigmented isolates.**Conclusions:** The results of this study suggest that both phenotypic and genotypic virulence factors are associated with the pigment production in *P. aeruginosa.* Pigment production is easy to determine, which might be a good starting point to identify the virulence status of an isolate.

Kim[1], Korea Infectious Diseases (KIND) Study Group; [1]Seoul Natl. Univ Bundang Hosp., Seongnam-si, Korea, Republic of, [2]Seoul Natl. Univ Coll. of Med., Seoul, Korea, Republic of, [3]Natl. Hlth.Insurance Corp. Ilsan Hosp., Goyang-si, Korea, Republic of

Abstract Body:

Background: Panton-Valentine leukocidin (PVL) is a virulent cytotoxin which is known as one of indicators of community-associated methicillin-resistant *Staphylococcus aureus* (CA-MRSA) infection. This study was performed to evaluate the prevalence and clinical and molecular characteristics of PVL (+) invasive *S. aureus* (ISA) infections in Korea. **Methods:** A total of 1,962 non-duplicate *S. aureus* isolates, which were obtained from 2,533 cases in two prospective multicenter Korean surveillance studies for ISA infections in 2009-2011 and in 2012, were screened for possession of *pvl* gene. Clinical data were collected and multilocus sequence typing (MLST), staphylococcal cassette chromosome *mec* (SCC*mec*) typing, accessory gene regulator (agr) typing, and PCR for arginine catabolic mobile element (ACME) was performed for PVL (+) *S. aureus* isolates. **Results:** Among 1,962 *S. aureus* isolates, 28 (1.4%) showed PVL (+). Of these, 19 (67.9%) were MRSA: 8 community-associated and 11 healthcare-associated. In 28 cases of PVL (+) ISA infection, 17 (60.7%) were male patients and median age was 63 years old (range 13-93). Sixteen patients (57.1%) had no underlying comorbidities. Primary sites of infection were skin and skin structure (9), respiratory tract (9), bone and joint (4), cardiovascular system (4), and unknown (2). Thirty day mortality was 41.7% (10/24). In PVL (+) MRSA, ST8 or ST8 variant (ST8v)-SCC*mec* IVa-agr type 1 strain was most prevalent (11/19, 57.9%), 9 of which possessed ACME, but some minor clones such as ST30-SCC*mec* IVc-agr 3 (2), ST938-SCC*mec* IV-agr 3 (2), ST59-SCC*mec* V-agr 1 (1), ST188-SCC*mec* V-agr 1 (1), ST234-SCC*mec* IV-agr 3 (1), ST1232-SCC*mec* V-agr 1 were also present. **Conclusions:** The PVL (+) ISA infection was very rare in Korea and the most common types of infection were skin and skin structure infection and pneumonia. The possession of PVL toxin was not a distinguishable characteristic in CA-MRSA infection and the PVL (+) MRSA strains showed diverse genetic background with a predominance of ST8/ST8v-SCC*mec* IVa-agr 1 strain in Korea.

***Staphylococcus aureus* Bacteremia (SAB) due to Soft Tissue Infection: Comparison between Monobacterial (M-SAB) and Polymicrobial (P-SAB) Cases**

Author Block:

R. Khatib, M. Sharma, K. Riederer; St John Hosp. & Med. Ctr., Grosse Pointe Woods, MI

Abstract Body:

Background: *S. aureus* causes a wide spectrum of soft tissue infections (STI), often as a single pathogen. The characteristics of patients with STI-associated P-SAB are not well defined.**Methods:** We reviewed SAB among adults between 2002 and 2015, selected patients with STI and compared cases with P-SAB and M-SAB.**Results:** We encountered 275 STI-associated SAB among 1674 SAB (16.4%). Other organisms were present in 27 instances, 16 (5.8%) were STI-associated P-SAB. Eleven cases where not counted as P-SAB including ten with a commensal organism regarded as a contaminant, and one with persistent SAB and an unrelated nosocomial *Acinetobacter* bacteremia infection acquired five days after admission. No significant differences were noted between P-SAB and M-SAB in patient characteristics including age (63.1 ±13.5 vs. 58.0 ±17.2 years), the frequency of diabetes (62.5% vs. 40.9%), and hemodialysis-dependence (6.3% vs. 8.1%) but the majority of P-SAB (13/16; 81.3%) were due to necrotizing infections. Among patients with necrotizing infections, P-SAB was noted in 7/30 (23.3%) sacral decubiti, 5/34 (14.7%) foot/leg foci, and 1/3 (33.3%) Fournier' gangrene. P-SAB tended to be more often due to MRSA (81.3% vs. 61.4%; p=0.2), and hVISA (9.1% vs. 4.7%; p=0.3) and was much more frequently caused by SCC*mec* type II (66.7% vs. 23.0% [M-SAB]; $p<0.001$). Overall mortality rate was much higher in P-SAB (68.8% vs. 22.4%; $p<0.001$).**Conclusions:** P-SAB is uncommon in STI-associated SAB, but accounts for a sizable portion of necrotizing infections and is associated with higher mortality. Additional studies of patients with necrotizing infections, including non-bacteremic cases, are needed to better determine the incidence of *S. aureus* and the benefit of including anti-staphylococcal antibiotics in the empirical management strategy.

Characterization of Colonizing Strains of Group B *Streptococcus* in Toronto, Canada

Author Block:

S. Teatero[1], I. Martin[2], W. Demczuk[2], A. McGeer[3], Toronto Invasive Bacterial Disease Network, N. Fittipaldi[1]; [1]Publ. Hlth.Ontario, Toronto, ON, Canada, [2]Natl. Microbiol. Lab., Winnipeg, MB, Canada, [3]Mount Sinai Hosp., Toronto, ON, Canada

Abstract Body:

Background: Group B *Streptococcus* (GBS) causes invasive disease in both adults and neonates. This opportunistic pathogen colonizes the intestinal and/or genital tract of approximately 20% of humans. The link between colonization and adult GBS disease is poorly understood. However, GBS-colonized mothers can transmit the organism vertically to newborns. Understanding the population structure of colonizing GBS strains may therefore reveal trends in invasive GBS infections. **Methods:** Our GBS sample comprised 102 GBS isolates recovered in December 2014 from vaginal/rectal swabs from healthy pregnant women in the metropolitan region of Toronto/Peel, Canada. Strains were serotyped by latex agglutination and PCR, and antimicrobial susceptibility to erythromycin, clindamycin and tetracycline was determined according to CLSI standards. We also performed multilocus sequence typing (MLST) on all strains, and used whole-genome sequencing and bioinformatics tools to study recombination leading to capsular switching in selected strains. **Results:** The most frequently identified serotypes among the GBS colonizing isolates were III (27%), V (25%), and Ia (21%). Notably, 6% of the carriage isolates were serotype IV, an emerging serotype that we recently identified as an important cause of invasive disease in Toronto. The most frequently found MLST types were ST17, ST23, ST19, and ST1. Interestingly, strains of four different serotypes belonged to MLST sequence type 1. Further examination revealed capsular switching in this group of organisms due to single-recombination events in four strains. We also found examples of large-scale genomic recombination among ST1 strains. Overall, we observed a high rate of tetracycline resistance (88%), while resistance to erythromycin and clindamycin was found in 36% and 25% of the strains, respectively. **Conclusions:** Our results provide a portrait of colonizing GBS strains circulating in Toronto, Canada. The serotyping and genotyping results closely mirror those we recently described among invasive GBS in the same area. Emergence of serotype IV strains and the occurrence of frequent capsule switching have implications for GBS vaccine developments.

Xdr *Acinetobacter baumannii* and *Pseudomonas aeruginosa* Associated with Meningitis in Brazil

Author Block:

A. S. Ballaben[1], J. C. Ferreira[1], R. Galetti[1], D. O. Garcia[2], P. Silva[3], A. L. C. Darini[1]; [1]Sch. of Pharmaceutical Sci. of Ribeirão Preto - USP, Ribeirão Preto, Brazil, [2]Adolfo Lutz Inst., São Paulo, Brazil, [3]Adolfo Lutz Inst., Ribeirão Preto, Brazil

Abstract Body:

Non-fermenting gram-negative bacilli (NFGNB) have established themselves as an important nosocomial pathogen over the last decade and have been responsible for numerous complications such as meningitis. Carbapenemases resistance genes in NFGNB have been described both inserted into chromosome and plasmids. The aim of this study was to characterize molecularly and epidemiologically carbapenem resistant NFGNB isolated from cerebrospinal fluid and blood of patients with meningitis in different hospitals in São Paulo state, from 2007 to 2014. These bacteria were isolated at Adolfo Lutz Institute, a reference laboratory. Twenty *Acinetobacter baumannii* and 11 *Pseudomonas aeruginosa* were studied. The genes conferring resistance to carbapenems antibiotics and plasmid groups of *A. baumannii* (AB-PBRT) were investigated by PCR and the relationship was established by PFGE, using Tenover criteria. 80% of *A. baumannii* were extreme drug resistant (XDR) and 20% were multidrug resistant (MDR). All *A. baumannii* (confirmed by *rpo*B sequencing) produced the intrinsic $bla_{\text{OXA-51-like}}$ gene while 17/20 presented $bla_{\text{OXA-23-like}}$ gene which is spread worldwide among this microorganism. After PFGE analysis, was found a high clonal diversity. Plasmids of Groups 6 and 8 were found in two and three isolates, respectively. The two Group 6 isolates were not genetically related. Two isolates of Group 8 were from the same hospital and were genetically related while the other isolate was not. It is the first report about *A. baumannii* plasmids typing by AB-PBRT in Brazil; Group 6 has been reported in Europe countries, Australia and North Africa while Group 8 only in China. 82% of *P. aeruginosa* were XDR while 18% were classified as MDR. The isolates were clustered in 6 different pulsotypes. Only one isolate presented $bla_{\text{IMP-16}}$ which was classified in a separate pulsotype. Hence, the demonstrated results with clinical isolates of NFGNB reinforce the evidence that these bacteria are high and dangerous potential pathogens especially when associated with meningitis. This scenario is increasingly concerned by the ability of these pathogens acquires mobile genetic elements.

***Globicatella Sanguinis*: A Rare Human Pathogen with an Expanding Spectrum of Disease**

Author Block:

A. O. Miller[1], M. W. Henry[1], B. Abraham[2], S. Whittier[3], B. J. Hartman[2], K. F. Maloney[4], F. Wu[3], B. D. Brause[1], P. Della-Latta[3], T. J. Walsh[2], A. N. Schuetz[2]; [1]Hosp. for Special Surgery, New York, NY, [2]Weill Cornell Med., New York, NY, [3]Columbia Univ. Coll. of Physicians and Surgeons, New York, NY, [4]Univ. at Buffalo, Buffalo, NY

Abstract Body:

Background: Commercial phenotypic methods may not consistently identify uncommon bacterial species. Two clinical cases, in which ceftriaxone-resistant, aerobic, alpha-hemolytic, *Streptococcus*-like pathogens were not able to be identified phenotypically, led to further molecular identification, and to a review of the clinical and microbiologic characteristics of the species, *Globicatella sanguinis*.**Methods:** Two ceftriaxone-resistant, aerobic, alpha-hemolytic clinical strains (from two patients with a prosthetic hip infection and a bacteremia) were analyzed with standard clinical automated and manual phenotypic techniques, and then with 16s rRNA and *sodA* PCR. The entire medical literature on *Globicatella* was surveyed.**Results:** Standard phenotypic methods failed to identify the isolates consistently. 16s PCR yielded sequences that were adequate for genus, not species, identification. *SodA* sequencing was required for species-level clarity. *G. sanguinis* is an uncommon cause of infections of the urine, meninges, and blood; no prior reports of orthopedic infection were found.**Conclusions:** Phenotypic methods fail to identify some uncommon pathogens. Advanced molecular techniques expand the spectrum of illness associated with rare organisms, such as *G. sanguinis*, which until now not a known cause of orthopedic foreign body infections. When assessing an alpha-hemolytic streptococcal pathogen with elevated MICs to third-generation cephalosporins, *G. sanguinis* should be considered. Microbiologists and clinicians alike should be alert to new, clinically-relevant findings as the increasing prevalence of advanced microbiologic identification techniques leads to better understanding of the role of uncommon pathogens in common diseases.

Virulent Characteristics of Multidrug Resistant *E. coli* from Zaria, Nigeria

Author Block:

J. A. Onaolapo; Ahmadu Bello Univ., Zaria, Zaria, Nigeria

Abstract Body:

Most multidrug resistant *E. coli* isolates (resistant to more than 3 classes of antibiotics) exhibit co-virulent characteristics that contribute to mortality and morbidity as a result of resistance to commonly prescribed antibiotics in the clinics. This study evaluated phenotypically some virulent characteristics in *E. coli* that contribute to the expressed MDR properties of *E. coli* using standard microbiological methods. Eighty seven *E. coli* isolates were confirmed as *E. coli* from urinary tract infection and diarrhea patients in selected hospitals in Zaria Nigeria using Microgene identification kit, out of which 58.6% (51) were observed to be MDR. Significant number of the MDR isolates (70.6% (36)) were extended spectrum beta-lactamase producers, 45.1% (23) were resistant to cefoxitin and produce ampC. While further analysis on the isolates showed that 23.5% (12) were biofilm producers, 47.1% (24) were heteroresistant to cefoxitin while 5.9% (3) produced carbapenemase. This study showed that most MDR *E. coli* from UTI and diarrhea could exhibit more than one virulent characteristics. Hence, isolates with MDR should be subjected to various tests in other to validate the mechanisms of resistance. This will encourage better treatment options and good periodic surveillance in prescription and dispensing of antibiotics in clinical settings.

Impact of Outer Membrane Protein *ompc* and *ompf* on Antibiotics Resistance of *E. coli* Isolated from Uti and Diarrhea Patients in Zaria, Nigeria

Author Block:

J. C. Igwe; Natl. Biotechnology Developement Agency, Abuja, Nigeria, Abuja, Nigeria

Abstract Body:

Multidrug resistant (MDR) *E. coli* associated infections remains one of the most bacteria infections that have contributed significantly to increased morbidity and mortality in clinical settings. One of the known resistant mechanisms of MDR bacteria is reduced cell wall permeability, which is controlled by outer membrane protein OmpF and OmpC. This study evaluate the difference in molecular weight of outer membrane protein of MDR *E. coli* isolated from UTI and diarrhea patients in Zaria, Nigeria and antibiotic susceptible ATCC29522 strain using standard microbiological and molecular techniques. Eighty seven (87) confirmed *E. coli* isolates from UTI and diarrhea patients in selected hospitals in Zaria, Nigeria were evaluated for MDR using 15 antibiotics commonly prescribed for *E. coli* associated infections. The results showed that the 21 suspected multidrug isolates were 100% susceptible to Imipenem and Amikacin, and 28.6% susceptible to Nitrofurantoin but highly (100%) resistant to Amoxicillin, Ofloxacin, Ciprofloxacin, Cefpodoxime and Ceftaxime, 95.2% resistant to Cefpirome, 85.7% to Tetracycline and Sulphamethonidazole-Trimethroprim, 76.2% to Gentamicine, 66.7% to Chloramphenicol, 61.9% to Aztreonam and 57.1% to Ceftriaxone. Cell wall protein evaluation using SDS-PAGE showed that both the MDR isolates and susceptible strain had equal OmpC bands at 38kDa while the OmpF varied from one MDR isolate to another compared with the ATCC29522 used as control. This study contributes to other findings that a decrease in cell wall outer protein OmpF could contribute to high resistance to antibiotics.

Biofilm Formation among the Clinically Relevant *Pseudomonas aeroginosa*: An Evaluation of Two Different Screening Methods

Author Block:

S. Javed; Jinnah Univ. For Women, Karachi, Pakistan

Abstract Body:

Background: *Pseudomonas aeroginosa* is an opportunistic bacterial pathogen with an ability to produce biofilm. Biofilms are the matrices of microorganisms embedded in their own microbial originated extracellular polymeric substances (EPSs). Microorganisms growing in a biofilm are associated with various chronic infections in humans and they are highly resistant to antimicrobial agents and environmental stresses. **Aim:** The aim of the present study was to evaluate two methods for detection of biofilm development in *Ps. aeroginosa*. **Materials & Methods:** For the detection of biofilm formation, 112 clinical isolates of *Pseudomonas* spp. were screened by Tissue culture plate (TCP) and Tube method (TM) method. **Results:** Of the 112 *Pseudomonas* spp. 72(64.28%) displayed a biofilm-positive phenotype under the optimized conditions in the TCP method and strains were further classified as high 32 (28.57 %) and moderate 20 (17.8 %) while in 20 (17.8 %) isolates weak or no biofilm was detected. Though Tube Method associated well with the Tissue Culture Plate test for 20 (17.85 %) strongly bio-film producing strains. Although, weak producers were more difficult to distinguished from biofilm negative isolates. **Conclusion:** The TCP method was found to be most sensitive, precise and reproducible screening method for detection of bio-film formation by Pseudomonas and has the advantage of being a quantitative model to study the adherence of Pseudomonas on biomedical devices.

The Role of Cornyeform-like Bacteria in Clinical Infections

Author Block:

S. M. Leal, Jr., P. Gilligan; Univ. of North Carolina, Chapel Hill, NC

Abstract Body:

Pleomorphic gram positive rods are part of the human skin microbiome. Often presumptively identified in clinical samples as diphtheroids using phenotypic characteristics, they frequently are dismissed as contaminants. The majority of diphtheroids belong to either the genus *Corynebacterium* or other coryneform-like genera. However, MALDI-TOF MS enables their speciation. In this study we performed a retrospective microbiological culture data review of patients from 2012-2015 growing gram positive rods with speciation by MALDI-TOF (98.2%) or 16S rRNA (1.8%) analysis. Our data set included 810 isolates from 15 genera constituting 45 bacterial species. The most frequent isolates were *Propionibacterium acnes* (35%), *C. striatum* (19%), and *Actinomyces neuii* (7%) followed by multiple *Corynebacterium* species. Site-specific laboratory criteria were utilized to determine true infection versus contaminant. Utilizing these criteria we show that 10% of all isolates met the criteria for true infection and 90% were contaminants. The percentage of isolates causing true infection were: anaerobic wounds (3%), aerobic wounds (2%), blood (11%), urine (41%), cerebrospinal fluid (31%), ophthalmologic cultures (20%), and sterile sites (33%). Speciation of these organisms revealed true infection with 23% of *C. kroppenstedtii* isolates from breast tissue, 56% of *C.striatum* isolates in the blood and 61% in the urine. Additionally, true infection was noted in 36% of *C. aurimucosum*, 75% of *C. urealyticum*, and 58% of *Actinomyces neuii* isolates from the urine. Lastly, 80% of *Propionibacterium acnes* isolates from CNS shunts were associated with true infection versus only 5% of isolates from lumbar punctures. Taken together these findings indicate that speciation of diphtheroids via MALDI-TOF is essential to accurately determine whether the isolate is a known or suspected pathogen versus contaminant and caution should be taken with presumptive identification of these organisms in routine laboratory practice.

Group A Streptococcal (Gas) Carriage in Childhood Tic Disorder and Tourette'S

Author Block:

D. Patel[1], T. Hedderly[2], M. Woods[2], D. Martino[3], T. Murphy[4], I. Heyman[4], A. Schrag[5], G. Kapatai[1], A. Efstratiou[1]; [1]Publ. Hlth.England, London, United Kingdom, [2]Evelina London Children's Hosp., London, United Kingdom, [3]King's Coll. Hosp., London, United Kingdom, [4]Great Ormond Street Hosp., London, United Kingdom, [5]Univ. Coll. London, London, United Kingdom

Abstract Body:

Paediatric Acute-onset Neuropsychiatric Syndrome (PANS) includes acute onset OCD with the potential association of tics with clinical evidence of an infection, often GAS. However, the role of GAS in mediating symptoms is unknown. Our study investigated bacterial genetic factors which may play a role in mechanisms that create vulnerability for tic development through complex host-pathogen interactions and may aid development of targeted therapeutic interventions.Pan-European GAS strains were isolated as part of the European Multicentre Tics in Children Studies. Children with tic disorders were recruited to the COURSE cohort (ages 3-16) assessing symptom fluctuations and unaffected siblings were recruited to the ONSET cohort (ages 3-10) monitoring onset of tics. Whole-genome sequencing (WGS) was performed using an illumina HiSeq platform. In-house bioinformatics pipelines were used for mapping and determining multilocus sequence type (MLST) and *emm* type. Multiple alignments were performed on isolates between cohorts and within a cohort between children with and without an onset or exacerbation of tics.A GAS positivity of 31% was observed among all 42 ONSET children and among those with an onset of tics. Similarly a 12% GAS positivity was observed among the 63 COURSE children and among those with an exacerbation of tics. GAS isolates from ONSET or COURSE children were genetically similar; 7/8 *emm* types and 9/10 MLST types were found in both cohorts. Manual sequence variant analysis identified no variants exclusive to isolates from either cohort or children who experienced an onset or exacerbation of tics.A higher rate of GAS carriage was observed among the unaffected siblings than the tic-affected children which may be due to age or other unexplored factors. No genetic difference was observed between isolates from each cohort and between children with and without an onset or exacerbation of tics. Therefore the role of GAS in PANS remains elusive and requires in-depth exploration. Further investigation of WGS data is underway which may identify specific genes or virulence markers associated with tic disorders.

The Genus *Eikenella* is Heterogenic, Based on Whole Genome Sequencing Analysis

Author Block:

A-M. Bernier[1], T. Burtz[2], D. Wiebe[2], V. Laminman[2], K. Bernard[2]; [1]Université de Saint-Boniface, Winnipeg, MB, Canada, [2]Natl. Microbiol. Lab., Winnipeg, MB, Canada

Abstract Body:

Background: The genus *Eikenella* has a single species, *E. corrodens;* this rare human pathogen is a facultatively anaerobic Gram-negative rod and member of the HACEK group. Eight strains consistent with *E. corrodens* biochemically and with >99% identity by 16S rRNA gene sequencing [16S] were compared with 13 isolates from sterile body fluids/sites closest to but discernable from (97.0%-98.9% by 16S) *E. corrodens.* All 21 *E. corrodens* or *Eikenella*-like isolates were studied by whole genome sequencing (WGS) to see if the 13 strains represented 1 or more new *Eikenella* species or unusual *E. corrodens* biotypes.**Methods:** 8 *E. corrodens* and 13 isolates close to but distinct from the *E.corrodens* TS were studied using standard biochemical and cellular fatty acid (CFA) methods. Comparative whole genome sequencing was performed in paired-end runs using the MiSeq Sequencer (Illumina1.9, 2x 300 cycles). Genomes were assembled using Spades (version 3.5.1) and JSpecies was used to calculate Average Nucleotide Identity values (ANIb and ANIm) and correlate indexes of tetra-nucleotide signatures (TETRA values).**Results:** ANib and ANIm values > 95% identified 4 distinct groups, with G+C values ranging from 55.5 to 58.5% and genome lengths of 1.8 to 2.5 Mb. The 8 isolates closest by 16S to the *E. corrodens* TS grew best in 5% CO2 and were consistent with that species biochemically, by CFAs and by WGS. The 13 other isolates had enhanced growth under strictly anaerobic conditions, grew poorly or not at all in air or 5% CO2, and were found by WGS to fall into 3 distinct groups/possible novel species. The 1st consisted of 10 strains, the 2nd was 2 strains/1 patient (130454/130455) and the 3rd a single isolate (02A017).**Conclusions:** 1) the genus *Eikenella* is heterogenic and additional aerotolerant or anaerobic species may exist; 16S relationships were a reasonable predictor for WGS comparisons. 2) ANIb values identified three new taxonomic groups related to but distinct from, *E. corrodens*.3) The 3 new *Eikenella* taxon groups had a range of G+C mol% of 55.5 to 58.5% and genome lengths from 1.8 to 2.54 Mb.

Tondella[1]; [1]CDC, Atlanta, GA, [2]Haiti Ministere de la Sante Publique et Population, Port-au-Prince, Haiti, [3]CDC, Port-au-Prince, Haiti

Abstract Body:

Respiratory diphtheria is a vaccine preventable disease that is caused by toxigenic *Corynebacterium diphtheriae*. Haiti, a country with childhood DTP3 coverage <80% and endemic for diphtheria, experienced an increase in reported cases starting in December 2014. Between December 24, 2014 and December 11, 2015, 66 throat swabs and three isolates from 80 patients (42 % males; median age, 7 years (range: 1-50 years); 85% without documented DTP vaccination history with ≥1 dose; and from 7 of 10 departments) were tested at the Centers for Disease Control and Prevention. All 66 swabs were tested by real-time PCR for the presence of the A and B subunits of the diphtheria toxin gene (*tox*); 60 (91%) swabs were cultured on Tinsdale and sheep blood agars. Isolates were further tested for toxin production using the modified Elek assay and were genotyped using multi-locus sequence typing (MLST). Cases were considered confirmed upon recovery of toxigenic *C. diphtheriae*, and probable if culture was negative but had diphtheria-like symptoms and were PCR-positive for *tox*. In total, 34 swabs and all 3 isolates (54%) were PCR-positive for *tox*; 17 *tox*-positive swabs and the 3 isolates (29%) were culture-positive for *C. diphtheriae* biovar *mitis*. All 20 isolates produced toxin. Therefore, 20 (29%) of cases tested were confirmed and an additional 17 (25%) were classified as probable. By MLST, 4 of 20 isolates were sequence type (ST) 31, a ST seen in prior outbreak strains from Haiti and Dominican Republic dating back to 2004. Overall case fatality was 29%. Continued surveillance and testing are needed to inform vaccination policy to prevent outbreaks of this forgotten disease.

Plant Natural Products Potentiate Antimicrobial Activity of Antibiotics Against *Pseudomonas aeruginosa*

Author Block:

H. Prithiviraj[1], G. Kulshreshtha[2], B. Prithiviraj[2]; [1]Cobequid Ed.al Ctr., Truro, NS, Canada, [2]Dalhousie Univ., Truro, NS, Canada

Abstract Body:

The problem associated with the use of antibiotics is the development of antibiotic resistant strains of bacteria. One way of reducing the development of antibiotic resistance is to reduce the amount of antibiotics used for treating infectious diseases. In other words, can we enhance the potency of antibiotics? In the traditional medicine a number of plant products have been used to treat bacterial infections. A study was conducted to test if natural compounds that occur in food and in traditional medicine enhance the activity of antibiotics. The antimicrobial effect of four natural compounds; caffeine, quercitin, curcumin and piperine were tested against *Pseudomonas aeruginosa* PA14. Curcumin and piperine exhibited antimicrobial effect at a low concentration of 25µg/ml. The antimicrobial effect of combination of antibiotics tetracycline and streptomycin at MIC_{25} and MIC_{50} and curcumin and piperine were tested. Both the compounds significantly enhanced the potency of antibiotics. Curcumin showed the most promising effect. Since curcumin showed a high synergetic activity with antibiotic, possible mechanism(s) by which curcumin caused this effect was investigated. Curcumin significantly reduced the *P. aeruginosa* ability to form biofilm. Lower concentration of tetracycline increased the expression of genes that play a role in biofilm formation, quorum sensing, and virulence suggesting that this may be one of the mechanisms bacteria become resistant to antibiotics. When lower concentration of tetracycline was mixed with curcumin the expression of quorum sensing genes were significantly reduced. The combination of lower concentrations of tetracycline (MIC_{25} and $MIC_{50)}$ and curcumin was used in the *P. aeruginosa* - *C. elegans* pathosystem model to test its effect on infection. The combination increased worm's survival against the bacterial infection. Curcumin (12 and 24µg/ml) when combined with tetracycline (MIC_{50}) significantly reduced the mortality of the worms. These treatments were much more effective than full strength tetracycline. In conclusion, curcumin showed synergistic effect with antibiotics and improved efficacy of antibiotics against *P. aeruginosa*.

Antibacterial Activity of Pomegranate Wastes to Control the Food Borne Pathogens

Author Block:

U. Farooq; Univ. of Sargodha, Sargodha, Pakistan

Abstract Body:

Food born infectious diseases due to pathogenic microorganism is a global issue in the current scenario. Among these diseases, the infections caused by *Escherichia coli, Pseudomonas aeruginosa, Staphylococcus aureus,* and *Enterococcus feacalis* are most prevalent in the societies. In such alarming situations, the scientists have focused their attentions to control these pathogens through natural ways as the use of antibiotics lead towards many complications. The present study was planned to explore natural and stronger mode of treatment against food borne infectious diseases, a comparative antibacterial study was conducted between aqueous extracts of pomegranate (*Punica granatum*) peel and seeds against above mentioned food-borne pathogens.High yield of aqueous extracts of pomegranate peel and seed was obtained by optimization of extraction conditions (temperature and time) using response surface methodology. The optimization study was based on highest yield of extracts. Antibacterial potentials of the extracts (pomegranate peel and seed) were examined by using disc inhibition zone technique and the results were also compared with commercial antibiotic (Ciprofloxacine).The studied extracts possessed strong antibacterial activity against the tested microorganisms. But the maximum antibacterial activity was shown by peel extract as compared to seed extract. The strong antibacterial activity of peel was shown against *Escherichia coli* with average zone of inhibition 19.5 ± 0.93mm followed by seeds 7.12 ± 0.99mm. The comparison with commercial antibiotic showed that the antibacterial activities of peel extract were comparable with commercial antibiotic (21.12 ± 0.23mm) as compared to seed extract. Results also showed that among all the pathogens *Enterococcus feacalis* was appeared to be the most resistant with inhibition induced by the extracts of peel 14.87 ± 0.13mm and seeds 7.12 ± 0.19mm.It may be concluded from the results that the pomegranate peel proved to be a stronger antibacterial agent as compared to pomegranate seed and also parallel to commercial antibiotic.Keywords: Pomegranate, antibacterial activity

Lipophilic Green Tea Polyphenols as Potential Inhibitor for Endospore Germination in *Bacillus* spp

Author Block:

B. Ali[1], L. H. Lee[1], T-C. Chu[2]; [1]Montclair State Univ., Montclair, NJ, [2]Seton Hall Univ., South Orange, NJ

Abstract Body:

Background: *Bacilli* possess the ability to form endospores when placed under unfavorable conditions. Due to their highly resistant characteristics, endospores allow the bacteria to survive for extended periods that create high concern in the food and medical industries. The preliminary study suggested that the tea polyphenols can inhibit endospore germination in *Bacillus* spp. *B. cereus* is one of the most prevalent bacterial species found in contaminating food and beverages. In this study, a time-kill experiment was carried out to determine the minimal treatment time resulting in 95-100% of germination inhibition. In addition, the antibacterial and antispore effects of the tea polyphenol in food and milk were determined. **Methods:** For the time kill-study; *B. cereus* endospores were treated with modified crude lipophilic green tea polyphenols (cLTP) and purified lipophilic green tea (pLTP) at 1% and 5% concentrations for 5, 10, 15, and 30 minutes, respectively. Colony-forming unit (CFU) was recorded after incubated at 37°C for 24 hours and the percent of inhibition was determined. The same methods were used for the food and milk study and were only treated with 5% pLTP for 60 minutes and 24 hours. Scanning Electron Microscopy (SEM) and Transmission Electron Microscopy (TEM) were used to study the internal and external structure of spores. **Results:** The time-kill result indicated that the minimal kill time was 15 minutes for both tea polyphenols. The average inhibition rate for the 15-minute treatment time was 98.7% for 1% cLTP, 99.6% for 1% pLTP, 99.9% for 5% cLTP and 100% for 5% pLTP, respectively. The EM results indicated that the endospore coat was significantly destructed after treatment. **Conclusion:** These results suggested that cLTP and pLTP play a vital role in inhibiting endospore germination. Therefore, these natural compounds may aid in preventing food and beverage spoilage caused by spore-forming bacteria.

Inhibition of *Streptococcus mutans* Biofilm Formation by Propolis, Green Tea, and Miswak

Author Block:

J. E. Callahan, J. Bryan, N. Molineros, M. Salmon; Saint Peter's Univ., Jersey City, NJ

Abstract Body:

Background: Bacteria growing in biofilms demonstrate higher resistance to antimicrobial agents than their planktonic counterparts. *Streptococcus mutans* is among the earliest colonizers existing on the tooth surface biofilm known as dental plaque. Within this community, *S. mutans* functions by lowering the oral pH, leading to erosion of tooth enamel and resulting in dental caries. Previous studies in various cultures have demonstrated the antibacterial nature of natural plant-based remedies including propolis, green tea *(Camellia sinensis)*, and miswak *(Salvadora persica)*. We hypothesized a similar inhibitory effect on *S. mutans* and evaluated the role of these agents on its biofilm formation. **Methods:** Developing *S. mutans* biofilms were grown under microaerophilic conditions in a sucrose based-minimal media, using 24-well polystyrene plates. Biofilms were exposed to various concentrations of Propolis (0-20% v/v), green tea (0-20% v/v), and miswak (0-20% w/v). Following incubation, wells were examined for biofilm formation, using a standard crystal violet assay. Each condition was incubated in triplicate and repeated a minimum of 3 times. **Results:** Biofilms treated with propolis exhibited decreased biofilm mass (-0.33-fold, $P<0.0001$) when added at 20% w/v and (-0.50-fold, $P<0.0001$) when added at 30% as compared to the control. Treatment with green tea exhibited a (-0.95-fold $P<0.0001$) change at all values added (5-20% v/v) relative to the control. Addition of miswak to the developing biofilm demonstrated a (-0.95-fold $P<0.0001$) change in biofilm mass when added at concentrations (5-20% v/v). **Conclusions:** Our findings support the inhibition of cariogenic *S. mutans* biofilms by propolis, green tea and miswak. These easily accessible and natural plant-based remedies may provide necessary caries biofilm infection control in many areas of the world.

Inhibition of Growth and Biofilm Formation of *Streptococcus pyogenes* by Herbal Extracts

Author Block:

N. M. Wijesundara[1], R. Davidson[2], H. P. V. Rupasinghe[1]; [1]Dalhousie Univ., Truro, NS, Canada, [2]Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Background: Streptococcal pharyngitis caused by *Streptococcus pyogenes*, remains an important public health concern. A renewed interest in alternative herbal medicines, particularly as potential antimicrobial agents, has become increasingly important given the lack of new drug development. **Methods:** In this study we evaluated the antibacterial and anti-biofilm formation activities of 32 phytochemical extracts of 12 selected Canadian medicinal plants against three strains of *S. pyogenes* (ATCC 19615, ATCC 49399) and a clinical isolate using broth dilution assay, kill-curve assay, anti-biofilm formation assay and scanning electron microscopy (SEM).**Results:** Ethanol extracts (EE) demonstrated a range of minimum inhibitory concentrations (MICs) between 62.5 and 1000 g/mL while minimum bactericidal concentrations (MBCs) ranged from 125-1000 µg/mL. Among aqueous extracts (AE), licorice root, oregano flowering shoots and thyme flowering shoots were the most active, with MICs ranging from 1560 to 12,500 g/mL. The MBC was 6250 g/mL. Essential oils (EO) prepared from oregano flowering shoot and sage leaves showed significantly lower MIC and MBC values, ranging from 250-500 g/mL and 500 g/mL, respectively. The comparator penicillin G remained the most active compound against planktonic *S. pyogenes* with a MIC and MBC of 0.0078 and 0.0156 µg/mL, respectively. Oregano EO was demonstrated rapid killing kinetics against *S. pyogenes* (5 min of exposure) whereas sage EE, sage EO, echinacea flower EE and licorice root EE were also eliminated of the initial bacterial inoculum after 3-4 hr of exposure. However, penicillin required 24 hours to achieve the same degree of kill. Anti-biofilm formation and SEM analyses of biofilms revealed that the minimum biofilm inhibitory concentrations (MBICs) of the extracts ranged from 31.5 to 6250 µg/mL.**Conclusions:** Overall, EO from oregano flowering shoots and sage leaves as well as EE of licorice root, echinacea flower and sage leaves demonstrated promise as potential new alternate agents in the management of streptococcal pharyngitis.

Antibacterial and Anti-Hemolytic Effect of Proteins and Polyphenolic Compounds of Honey from *Melipona beecheii* against *Enterohemorrhagic e. coli*

Author Block:

L. Pool Yam, J. Ramon Sierra, J. Ruiz Ruiz, D. Magaña Ortiz, E. Ortiz Vazquez; Inst. Tecnológico de Mérida, Merida, Mexico

Abstract Body:

Background: Current studies, based on ethnographic knowledge, have reported that honey from *Melipona beecheii*, a stingless bee from Yucatan, has antibacterial activity against several pathogens including *E.coli* strains. At this respect, foodborne diseases are a worldwide problem and *E. coli* O157:H7 is the main serotype associated with outbreaks of hemorrhagic colitis and hemolytic uremic syndrome. This bacterium has different mechanisms of infection that are involved in the colonization of digestive tract cells. The main objective of this study was to evaluate the antibacterial and anti-hemolytic effect of proteins and polyphenolic compounds from honey of *Melipona beecheii* against *E. coli* O157: H7**Methods:** The proteins (P) were extracted using phosphate buffer and polyphenolic compounds (PC) were extracted using Amberlite X-2. The antimicrobial activity and minimum inhibitory concentration of *M. beecheii* honey, P and PC samples were determined by the disk diffusion and micro-dilutions methods. Strains *E. coli* 25922 and *E. coli* O157:H7 were used. Hemolytic activity of bacteria was evaluated employing red blood cell. The virulence genes of *E.coli* O157:H7 were detected by PCR. **Results:** *M. beecheii* honey, P and PC samples inhibited the growth of both *E.coli* strains. The MICs of honey, P and PC against for *E. coli* 25922 were 19% (v/v), 70 µg/mL, and 160 µg/mL, respectively. The values for *E. coli* O157:H7 were 17% (v/v), 55 µg/mL and 180 µg/mL. Remarkably, the hemolytic activity of the O157: H7 was 100%, but in the presence of honey this decreases to 5.7%. This phenomenon was also observed in *E. coli* 25922, in this case the hemolysis was reduced from 2.1% to 0.99%. Virulence genes were detected using PCR standard protocols to confirm that the hemorrhagic strain was employed in experiments. **Conclusions:** *Melipona beecheii* honey, protein extract and polyphenolic compounds extracts inhibit the growth of both *E. coli* strains. Honey decreased hemolytic activity of *E. coli* O157:H7, possibly proteins and polyphenols in honey inactivated the hemolysin and thereby protected blood cells. Further investigation is needed for the isolation and structure elucidation of bioactive proteins and polyphenols in *M. beecheii* honey.

Efficacy of Trans-cinnamaldehyde and Eugenol in Reducing *A. baumannii* Adhesion to and Invasion of Human Keratinocytes and Controlling Wound Infections *In Vitro*

Author Block:

D. P. Karumathil, **M. Surendran Nair**, K. Venkitanarayanan; Univ. of Connecticut, Storrs, CT

Abstract Body:

Background: *Acinetobacter baumannii* is a multi-drug resistant, nosocomial pathogen causing a variety of disease conditions, especially wound infections in humans. After *A. baumannii* outbreaks in military combat personnel in Iraq and Afghanistan, reports of *A. baumannii* wound infections are increasingly recognized. *A. baumannii*'s ability to form biofilms and colonize epithelial cells potentially makes it difficult to treat skin and soft-tissue infections of this pathogen. Thus, in light of the multidrug resistance and biofilm producing capacity, new strategies for controlling *A. baumannii* wound infections are necessary.**Methods:** This study investigated the efficacy of two natural, plant-derived antimicrobials (PDAs), namely trans-cinnamaldehyde (TC) and eugenol (EG) for decreasing *A. baumannii* adhesion to and invasion of human keratinocytes (HEK001). Moreover, the efficacy of two PDAs for inhibiting *A. baumannii* biofilm formation was determined using an *in vitro* collagen matrix wound model. In addition, the effect of TC and EG on *A. baumannii* biofilm architecture was visualized using confocal scanning microscopy. Further the effect of both PDAs on *A. baumannii* genes critical for biofilm synthesis was determined using real-time quantitative PCR (RT-qPCR).**Results:** Both TC and EG significantly reduced *A. baumannii* adhesion to HEK001 by ~2 to 2.5 $\log_{10}$ CFU/ml ($P < 0.05$), and invasion by ~2 to 3 log CFU/ml, compared to the controls ($P < 0.05$). Further, after 24 and 48 h, TC inhibited biofilm formation by ~1.5 and ~2 to 3.5 $\log_{10}$ CFU/ml, while EG decreased biofilm-associated bacteria by ~2 and ~3.5 $\log_{10}$ CFU/ml, respectively, compared to controls ($P < 0.05$). Confocal microscopy revealed that TC and EG resulted in the death of biofilm-associated *A. baumannii*, and disrupted the biofilm architecture. RT-qPCR results indicated that the two phytochemicals significantly down-regulated the transcription of genes associated with *A. baumannii* biofilm production. The results suggest that both TC and EG could potentially be used to treat *A. baumannii* wound infections; however, their efficacy in *in vivo* models needs to be validated.

Reciprocal Cooperation of Phytochemicals against *Borrelia burgdorferi* and *Borrelia garinii*

Author Block:

A. Goc, A. Niedzwiecki, M. Rath; Dr. Rath Res. Inst. BV, Santa Clara, CA

Abstract Body:

Background: Lyme borreliosis is a tick-borne disease caused by the spirochete *Borrelia burgdorferi* sensu lato. Throughout nature, phytochemicals represent a growing theme in antimicrobial defense, however, little is known about their anti-borrelaea reciprocal cooperation. To better understand this subject, we studied the efficacy of selected phytochemicals such as flavones and fatty acids to ascertain the type of their related cooperation against *Borrelia sp*. **Methods:** Phytochemicals such as baicalein, luteolin, 10-HAD, and glycerol monolaurate were tested in different "two-agent" combinations for their *in vitro* effectiveness against vegetative (spirochetes) and dormant (rounded bodies, biofilm) forms of *Borrelia burgdorferi* and *Borrelia garini,* using dark field and fluorescence microscope. Antibacterial effects of these agents' cooperation were evaluated at their MIC values and three dilutions above (2-6 X MIC) as well as three dilutions below their MICs (1/2-1/8 X MIC), according to checkerboard assays, and defined by fractional inhibitory concentration index. Additionally, a Student t-test statistical analysis was performed for further validation. All experiments were performed in triplicates. **Results:** The results showed that the combination of baicalein with luteolin exhibited synergistic anti-spirochetal as well as additive effects against rounded forms and biofilm of both studied *Borrelia sp,* whereas their respective cooperation with tested fatty acids showed to be additive against spirochetes and indifferent against other morphological forms. Moreover, additive anti-spirochetal and anti-biofilm effects were observed when monolaurin was used in combination with 10-HAD. Antagonism was not observed in any of the cases. **Conclusions:** The data obtained from this *in vitro* study revealed the intrinsic anti-borreliaea activity of tested combinations of flavones and fatty acids, respectively. Therefore, they might represent valuable adjuvants for antimicrobial chemotherapy.

Characterizing the Antibacterial Properties and Transcriptional Alterations Induced by Lemongrass Oil in *Staphylococcus aureus*

Author Block:

C. J. Christensen, K. L. Anderson; Concordia Univ., Ann Arbor, MI

Abstract Body:

Essential oils have risen in popularity as "all natural" alternatives used to treat a myriad of conditions. However, the precise mechanisms by which essential oils are effective are not well understood. To begin to elucidate the antibacterial properties of essential oils, we tested the effectiveness of Lemongrass Oil (LGO), Tea Tree Oil (TTO), and Willow Bark Extract (WBE) against *Staphylococcus aureus* growth. To do so, a Methicillin-Resistant strain of *Staphylococcus aureus* (USA300) was exposed to each oil using Kirby-Bauer disk diffusion assays. Of the oils, LGO had the greatest zone of inhibition. Thus, further studies were conducted only with LGO and its chemical component Citral. The Minimum Inhibitory Concentration (MIC) of both LGO and Citral was determined in macro-broth cultures; exposure to increased concentrations of each resulted in dramatic cell death as determined by kill curve assays. To begin to determine the molecular mechanisms underlying the observed antibacterial effects, we exposed cells to a sub-inhibitory concentration Citral for 30 min and hybridized the RNA to Affymetrix GeneChips® in order to identify any transcriptional changes that occurred. Results indicated that 8 and 9 transcripts were up- or down-regulated (at least 2-fold), respectively, in Citral-treated cells when compared to mock-treated samples. These transcripts represent virulence factors, hypothetical proteins, and intergenic regions. Current studies are designed to elucidate the function that the affected intergenic regions may play in gene regulation. Taken together, these results demonstrate that LGO exhibits antibacterial properties against a highly pathogenic bacterial species that is exceedingly resistant to the currently available antibiotics. The underlying transcriptional changes induced by Lemongrass Oil are under further examination.

Anti-halitosis Effects of *Amomum compactum* Essential Oil Against *Actinomyces viscosus*

Author Block:

Y. Yanti, M. Tjakra, B. W. Lay; Atma Jaya Catholic Univ., Jakarta, Indonesia

Abstract Body:

Background: Halitosis (oral malodour) has been a problem for many years. About 20-60% of the population has a chronic halitosis on regular basis. The microbial activities are the main cause of oral disease. The activities from the microbes also cause halitosis through the accumulation of volatile sulphur compounds (VSCs), diamines, and short-chain fatty acids. *Amomum compactum* (Java cardamom) is one of the tropical spices that also known as "the Queen of spices" because of its unique taste and aroma. In India, *A. compactum* has been traditionally used to fight bad breath naturally. This study was aimed to test the activity of essential oil from *A. compactum* toward *Actinomyces viscosus* by using VSCs, pH-stat, and biofilm assays.**Methods:** Several steps had been conducted, including essential oil extraction from *A. compactum*, quantitative analysis of essential oil inhibition effects toward pH-stat, quantitative analysis of essential oil inhibition effects toward *A. viscosus* biofilm prevention and eradication, qualitative analysis of VSCs producing oral bacteria and also essential oil inhibition effects toward VSCs.**Results:** For acid production system, *A. compactum* essential oil showed inhibition activity to acid production of *A. viscosus* by pH-stat assay. *A. viscosus* was able to produce acid rapidly in 20 minutes, resulting in pH 5.44 from neutral pH (7.00). At 100 µg/mL, *A. compactum* essential oil exerted the highest inhibition of acid production. Regarding its antibiofilm effect, *A. compactum* essential oil demonstrated both preventive and eradication effects against *A. viscosus* biofilm formation and the established biofilm compared to that of ampicillin standard. At 40 µg/mL, essential oil removed up to 50% of the established biofilm. In contrast, essential oil at higher concentration (80 µg/mL) prevented ~50% of biofilm growth. In terms of VSCs results, *A. compactum* essential oil showed similar effect with ampicillin on inhibiting VSCs production from *A. viscosus*.**Conclusions:** *A. compactum* essential oil exerted anti-halitosis activity toward *A. viscosus* by preventing and eradicating oral biofilm, inhibiting acid formation, and reducing VSCs production *in vitro*.

Targeting Common Staphylococci Species in Prosthetic Joint Infections with Tea Polyphenol

Author Block:

C. Chen; Montclair State Univeristy, Egg Harbor Township, NJ

Abstract Body:

Background: Normal human microbial flora such as *Staphylococcus aureus (S. aureus)* and *Staphylococcus epidermidis (S. epidermidis)* may enter the system through wounds or surgical implants. Both species are biofilm forming and the most problematic pathogens in prosthetic joint infections (PJI). Studying the effects of different tea polyphenols on Gram-positive staphylococci species may provide a novel approach in inhibiting biofilm accumulation in prosthetic joint area.**Methods:** Crude lipophilic tea polyphenols (cLTP) and purified lipophilic tea polyphenols (pLTP) at different concentrations (200 ug/ml, 250ug/ml and 500ug/ml) were used to study their effects on biofilm inhibition. Congo red agar (CRA) method was developed to analyze biofilm inhibition qualitatively, in the presence of tea polyphenols. Crystal violet (CV) assays were used to quantitatively analyzed percent of biofilm inhibition in relation to the controls. Scanning electron microscopy (SEM) was used to observe biofilm and morphological changes of cells treated with cLTP and pLTP. Fluorescent microscopy was used to study cell viability. Colony forming units (CFU) was carried out to analyze overall population density and growth rate. **Results:** CRA analysis suggested biofilm formation was repressed in the presence of cLTP/pLTP, at concentrations of 250 ug/ml and 500 ug/ml in both Staphylococci species. CV results indicated that significant reduction with 97.4% biofilm inhibition at 250 ug/ml and 73.2% at 500 ug/ml for *S. aureus and S. epidermidis*, respectively. Fluorescent microscopy revealed population density and cell viability was significantly reduced for both species. SEM also showed population and biofilm reduction at 250ug/ml of pLTP. CFU test with 250 ug/ml of pLTP recorded significant inhibition of *S. aureus and S. epidermidis* growth with 100% and 99.7% inhibition respectively.**Conclusion:** These results suggested that pLTP might be potent in treating prosthetic joint infection as a novel alternative treatment to antibiotics. Studies showed that there was no recurring growth or biofilm formation after several days, thus suggested that pLTP could be a potential solution to reduce chronic infections in patients.

Minimun Inhibitory Concentration of Proteolytic Fraction from Royal Jelly against *E. coli, s. aureus* and *V. cholerae*

Author Block:

E. Lopez Baños[1], D. Magaña Ortiz[2], J. Ruiz Ruiz[1], J. Ramon Sierra[1], **E. Ortiz-Vázquez**[1]; [1]Inst. Tecnológico de Mérida, Mérida, Yucatán, Mexico, [2]Inst. Tecnológico de Mérida, Mérida, Mexico

Abstract Body:

Background: Royal Jelly is a honeybee secretion that is used in the nutrition of larvae and adult queens; this food is composed of 12.5 % protein, 67-5% water, 11% carbohydrates and 5% lipids. Several reports have validated the relationship between continuous consumption of royal jelly and health, mainly attributed to its multiple biological activities.. The aim of this study was to determine the antibacterial potential of the proteolytic fraction of royal jelly and to evaluate its action mechanism. **Methods:** Royal jelly samples were collected directly from hives in the state of Yucatan, Mexico. Strains used were *E. coli* ATCC 25922, *S. aureus* ATCC 25923 and *V. cholerae*. The protein extraction was performed according to Schmitzová (1998). Protein extract was purified by size-exclusion chromatography (Sepharose-G200). The antibacterial effect of protein fractions was tested by disk diffusion method (Schwalbe et al., 2007). MICs were determined using CLSI Microdilution method. Proteins were analyzed by SDS-PAGE (Bizani et al., 2005). Proteolytic activity was determined using substrate-gel electrophoresis (Abreu-Payrol et al., 2005). Growth inhibition kinetics was performed according to Schneider et al. (2010).**Results:** Three peaks were obtained by size-exclusion chromatography from the royal jelly protein extract peak 1 and 2 had protein content. The peak 2 (RJP2) showed proteolytic activity and antimicrobial activity against the strains tested, with inhibition diameters of 1.10 cm (*E. coli*), 1.5 (*S. aureus*), 1.9 cm (*V. cholerae*). The SDS-PAGE gel of the RJP2 showed seven different bands from 10 to 72.8 kDa. The MICs of Royal Jelly, Protein extract and RJP2 were 212, 9.2 and 0.136 mg/mL for *E. coli*, 87, 1.4 and 0.086 mg/mL for *S. aureus* and 62, 4 and 0.091 mg/mL for *V. cholerae***Conclusions:** The proteolytic fraction of the Royal jelly is the main group of proteins that confer the antibacterial activity against gram positive and gram negative strains. The low values of MIC of the proteolytic fraction suggest the high potential of this kind of proteins obtained from Royal Jelly.

Plasmid Profile of Vancomycin-Resistant *Staphylococcus aureus* and Their Antibacterial Susceptibility to Extracts of *Vernonia amygdalina*

Author Block:

J. O. Oluyege, D. Oguntoye; Ekiti State Univ., Ado-Ekiti, Nigeria

Abstract Body:

Susceptibility of vancomycin resistant Staphylococcus aureus (VRSA) strains isolated from clinical and environmental sources to the extracts of *Vernonia amygdalina*, a Nigerian medicinal plant and to conventional antibiotics was investigated. Three hundred (300) strains of *Staphylococcus aureus* were isolated from clinical and environmental sources out of which 20 vancomycin-resistant strains were obtained. The clinical/enviromental isolates exhibited antibiotic resistance patterns in the following order: ofloxacin (0%/0.7%), gentamicin (0.7%/0%), vancomycin (10.7%/8.0%), erythromycin (60.7%/48.7%), ceftriaxone (68%/60.7%), cefuroxime (91.3%/90.7%), ceftazidim (93.3%/93.3%), cloxacillin (100%/100%) and augmentin (100%/96.7%). The VRSA isolates from clinical and the environmental sources harbored 1-3 plasmid-DNAs with molecular sizes ranging from 250-2500 kilobase pairs. The zone of growth inhibition exhibited by the extracts of *Vernonia amygdalina* ranged from 10mm to 20mm at concentrations of 20-40mg/ml. It is noteworthy that community acquired VRSA can also be found outside clinical environments while gentamicin and ofloxacin could be effective for the treatment of VRSA infections. This piece of work also revealed that antibacterial phytochemicals may be elucidated from extracts of *Vernonia amygdalina* for the treatments VRSA infections.

Melanoidins of *Melipona beecheii* Honey Have Antibacterial Effects Against *E. coli* Atcc 25922 and *Staphylococcus aureus* Atcc 25923

Author Block:

J. Ramon Sierra, J. Ruiz Ruiz, D. Magaña Ortiz, E. Ortiz Vazquez; Inst. Tecnológico de Mérida, Merida, Mexico

Abstract Body:

Background: Melanoidins are the final products of Maillard reactions and they have remarkable properties as food preservatives, antioxidants and prebiotics. Interestingly, previous reports have demonstrated the presence of melanoidins in Apis mellifera honey. However, most of properties of honey melanoidins remain unknown. Since prehispanic times, honey of stingless bee Melipona beecheii has been employed for the treatment of many diseases. The main purpose of this work was to study the antibacterial effect of Melipona honey melanoidins against pathogenic bacteria such Escherichia coli and Staphylococcus aureus. **Methods:** TThe melanoidin extract of Melipona honey was obtained using phosphate buffer and concentrated with a Millipore membrane with cut-off 3 kDa. After this, the proteins present in this extract were quantified using Bradford method employing BSA as standard. In order to obtain the fractions of melanoidins, the extract was separated using acrilamide gels in non-reducing conditions and the fractions were directly excised from this gel. The antimicrobial activity and minimum inhibitory concentration of Melipona honey and the melanoidin fractions obtained were determined using the disk diffusion and micro-dilutions method against E. coli ATCC 25922 and S. aureus ATCC 25923. **Results:**Three fractions of melanoidins were observed in non-reducing gels and all of them were tested in order to determine its antibacterial effect. Only one fraction was able to inhibit the growth of the two pathogenic bacteria tested. Using only 100 µg/ml of protein in melanoidin extract antibacterial effect was detected in disk diffusion method. The MICs of Melipona honey and melanoidin fraction were 17%, 23 µg/ml and 19 µg/ml for *S. aureus* 25923 whereas for *E. coli* 25922 were 19%, 21 µg/ml, and 22 µg/ml respectively. **Conclusions:** Melipona honey and one of three fractions of melanoidins observed were able to inhibit the growth of both pathogenic strains. This is the first report of the antibacterial properties of melanoidins in Melipona honey and future research could establish if the fraction tested contain antibacterial proteins or biological active flavonoids.

Avidocin-CDs: Novel Engineered Bacteriocins Use Phage Receptor Binding Protein to Target S-Layer Protein a Variants on the *Clostridium difficile* Cell Surface

Author Block:

J. A. Kirk[1], D. Gebhart[2], A. Buckley[3], S. Lok[2], D. Scholl[2], G. Douce[3], R. Fagan[1], **G. Govoni**[2]; [1]Univ. of Sheffield, Sheffield, United Kingdom, [2]AvidBiotics Corp., South San Francisco, CA, [3]Univ. of Glasgow, Glasgow, United Kingdom

Abstract Body:

Background: *C. difficile* is an opportunistic pathogen that takes advantage of dysbiosis in the gut to proliferate and cause disease. There is a need for anti-*C. difficile* agents that can eliminate or block infection without off-target effects and disruption of the gut microbiota. We recently demonstrated that an engineered bacteriocin retargeted with the *ptsM* prophage gene specifically killed ribotype 027 strains *in vitro* while preventing colonization of susceptible mice and not altering healthy microbiota *in vivo* (ref 1).**Methods:** Homologues to PtsM with different predicted specificities were identified in the genomes of *C. difficile* bacteria and phage. New Avidocin-CDs were constructed using a selection of PtsM homologues and tested for killing on a panel of 78 *C. difficile* strains. R20291 (027) mutants insensitive to Av-CD291.2 were isolated and characterized for defects. Complementation of the mutations with wild-type allele validated association between mutations and defect phenotypes. Mutants heterologously expressing non-027 *slpA* alleles were tested for sensitivity to the different Avidocin-CDs.**Results:** Each Avidocin-CD tested killed a different subset of strains with Av-CD027. 2 having the broadest coverage (killed 50% of the strains tested). Rare R20291 mutants ($<10^{-9}$) insensitive to Av-CD291.2 had point mutations in the *slpA* gene that resulted in loss of SlpA protein on the cell surface. *In vitro* these mutants exhibited low spore production and increased sensitivity to lysozyme and anti-microbial peptides. *In vivo* the *slpA* mutants were avirulent (100% survival) in a hamster model of CDI. Expression of non-027 *slpA* alleles in the mutant resulted in a gain of sensitivity to other Avidocin-CDs. In total, Avidocin-CDs were constructed that killed strains expressing SlpA variants from 10 of the 12 known S-layer cassettes. A cocktail of Avidocin-CDs could effectively target >95% of the clinical *C. difficile* isolates with a known ribotype.**Conclusions:** Avidocin-CDs represent an anti-bacterial platform capable of producing targetable, precision anti-*C. difficile* agents that can prevent or treat CDIs without disrupting indigenous microbiota.

Comparison of Cytomegalovirus (CMV) UL89 Gene Mutations Selected *In Vitro* after Exposure to 3 Terminase Inhibitor Compounds

Author Block:

S. Chou; Oregon Hlth.and Sci. Univ., Portland, OR

Abstract Body:

Background: Terminase inhibitors 275175X (175X, a benzimidazole) and tomeglovir (TGV, Bay38-4766) were studied in preliminary clinical trials, while letermovir (LMV) is in Phase III trial for prevention of CMV disease in stem cell recipients. The spectrum and overlap of CMV mutations conferring resistance to these compounds is not well defined, but UL56 gene mutations are the most common pathway of LMV resistance, and the UL89 gene mutation D344E is associated with resistance to benzimidazoles. This study seeks to compare the UL89 mutations elicited by the 3 inhibitors. **Methods:** Published procedures were used for serial culture passage of a cloned CMV exonuclease mutant under drug starting near 50% inhibitory concentration (EC50) and increasing as permitted by viral growth. Emerging UL56 and UL89 mutations were detected by DNA sequencing of culture extracts, and were evaluated by recombinant phenotyping for the degree of resistance and cross-resistance conferred. **Results:** 6 expts with 175X all selected for UL89 D344E at a median of 7.5 passages, with UL89 C347S later adding to or replacing D344E in 2 cases. 8 expts with TGV selected for UL89 H389N in 1 case at passage 8, and V362M in all cases at a median of 12 passages. UL89 mutation was found in 2 of 17 expts with LMV at passages 13-25, adding to published UL56 mutations that evolved within 5 passages in all cases. In 1 case, UL89 N320H and M359I were detected (on separate genomes); the other evolved UL89 D344E. Recombinant phenotyping showed that D344E conferred 10x increased EC50 for 175X, slightly (1.5-2x) increased EC50 for LMV and TGV, and it slightly increased the LMV EC50 of the UL56 mutant F261L when combined. C347S conferred 25x increased EC50 for 175X only. H389N and V362M conferred 15x and 50x increased EC50 respectively for TGV only. Low-grade (≤3x) increased EC50s were observed for 175X, LMV and TGV (N320H) or LMV and TGV (M359I). **Conclusion:** Distinct UL89 mutations are consistently selected to confer substantial resistance to 175X and TGV. UL89 mutations are newly revealed as an uncommon accessory pathway of LMV resistance, fractionally increasing the level of resistance arising from preferred UL56 mutations. The proximity of UL89 mutations selected by all 3 drugs, with some conferring low-level cross-resistance, suggests targeting of a similar terminase functional locus with interfacing UL89 and UL56 components.

Letermovir Is Active Against the Four Major Cytomegalovirus (CMV) gB Subtypes

Author Block:

C. M. Douglas[1], X. D. Zhang[1], D. J. Holder[1], P. Lischka[2]; [1]Merck & Co., Inc, Kenilworth, NJ, [2]AiCuris GmbH & Co KG, Wuppertal, Germany

Abstract Body:

Letermovir, an inhibitor of CMV terminase, is being evaluated for prevention of clinically significant CMV infection in adult CMV seropositive allogeneic hematopoietic stem cell transplant recipients. There are four major glycoprotein B (gB) subtypes associated with CMV infections in immunocompromised patients (gB1, gB2, gB3, and gB4). It has been reported that there are significant differences in the incidence of death due to myelosuppression between gB subtypes in CMV-infected marrow transplant recipients (1997 Blood **90**: 2097-2102). We evaluated the impact of gB subtype on letermovir susceptibility for 66 low-passage clinical CMV isolates. The gB subtype was determined by genotyping ORF UL55 (bp 1319-1596) and phylogenetic tree analysis, and letermovir susceptibility was measured using GFP- or plaque reduction assays. Letermovir EC_{50} values ranged from 0.7 to 6.1 ng/mL, and the distribution of gB subtypes among the 66 isolates was 29/24/10/3 for gB 1/2/3/4, respectively. The F-Test from an ANOVA model for testing the null hypothesis that there is no mean difference in EC_{50} of letermovir susceptibility among any of the four gB subtypes yielded a p-value of 0.44. The largest estimated ratio of mean EC_{50} values was 1.56 for gB4/gB2, with a 95% confidence interval of (0.74, 3.31). All of the 95% confidence intervals for pairwise ratios between gB subtypes contain the null value of ratio = 1. We conclude that letermovir has potent in vitro antiviral activity against CMV irrespective of the gB subtype.

Publishing Title:

Mbx-400, Active Against Betaherpesviruses, Does Not Cause Genotoxicity in *In Vitro* and *In Vivo* Models

Author Block:

J. Brooks, T. Bowlin; Microbiotix, Inc., Worcester, MA

Abstract Body:

Background: MBX-400 is currently in clinical development for betaherpesvirus-related disease. MBX 400 has demonstrated good *in vitro* potency against cytomegalovirus (CMV) and human herpesviruses 6A and 6B (HHV6A/B), with EC_{50} values of 1.2, 1.3 and 2.5 µM, respectively (Prichard, 2013). Preclinical studies support the initial clinical program and have demonstrated a margin of safety that supports human use (Bowlin, 2009). A standard battery of genetic toxicology tests, suitable to support an Investigational New Drug Application (IND), were performed to evaluate the potential for genotoxicity. **Methods:** Genetic toxicity was evaluated using four assays that have been well described: an Ames assay, a rat micronucleus assay, a Chinese hamster ovary assay and a rat Comet assay. The Ames assay was conducted using MBX-400 concentrations of 33.3 to 5000 µg per plate (with and without S9). The rat micronucleus assay was evaluated in the bone marrow of Sprague Dawley rats 24 and 48 hours after a single dose of MBX-400 at 500 to 2000 mg/kg. In the Chinese hamster ovary assay, cultures were treated for 3 hours with and without S9 at concentrations ranging from 6.78 to 1000 µL. The Comet assay was conducted using liver and kidney cells from male Sprague Dawley rats following two daily doses of MBX-400 at 500 to 2000 mg/kg/day.**Results:** MBX-400 did not induce reverse mutations in an Ames assay. In a rat micronucleus assay, MBX-400 did not cause significant increases in polychromatic erythrocytes nor bone marrow toxicity. Exposure to MBX-400 did result in chromosomal aberrations both with and without metabolic activation in a Chinese hamster ovary assay. In order to better characterize the potential nature of the aberrations, a rat Comet study was performed, which evaluated DNA damage in the liver and kidney following exposure to MBX-400. MBX-400 did not induce DNA damage in this study.**Conclusions:** The overall genetic toxicology assessment indicates that MBX-400 does not have mutagenic potential. The Chinese hamster ovary assay is known to provide false positive results. The results from this assay could not be confirmed in a subsequent Comet assay. Therefore, unlike ganciclovir, the current standard treatment for CMV infection, MBX-400 has not demonstrated the potential for genotoxicity.

Prophylactic Efficacy of Quercetin-3-β-O-D-Glucoside Against Ebola Virus Infection

Author Block:

X. Qiu[1], R. Kozak[1], A. Kroeker[1], S. He[1], J. Audet[1], M. Mbikay[2], M. Chretien[2]; [1]Natl. Microbiol. Lab., Publ. Hlth.Agency of Canada, Winnipeg, MB, Canada, [2]Clinical Res. Inst. of Montreal, Montreal, QC, Canada

Abstract Body:

Background: Ebola outbreaks occur on a regular basis, with the current outbreak in West Africa being the largest ever recorded. It has resulted in over 11 000 deaths in four African countries and has received international attention and intervention. Although there currently are no approved therapies or vaccines, many promising candidates are undergoing clinical trials and several have had success in promoting recovery from Ebola. However, these prophylactics and therapeutics have only been designed and tested against the species of Ebola that causing the current outbreak. Future outbreaks involving other species would require reformulation and possibly redevelopment. Therefore a broad spectrum alternative is highly desirable. **Method and Results:** Using a variant of *Ebola virus* (EBOV) that expresses green fluorescent protein, a flavonoid derivative called Quercetin-3 β-O-D-glucoside (Q3G) has been identified to have antiviral activity in vitro. Similar results were also found with *Sudan virus* (SUDV). Furthermore, we have evaluated the protective efficacy of Q3G as prophylactic and/or post-exposure treatment agent in a mouse-adapted EBOV model. The results showed that Q3G not only can fully protect mice from EBOV infection when given 30 minutes prior to infection, but also can partially protect mice when the treatment was initiated at 24 hour or 48 hours post challenge. **Conclusion:** This study serves as a proof of principle that Quercetin-3-β-O-D-glucoside has potential as a prophylactic/treatment agent against Ebola virus infection.

Gold Nanorods Reduce Respiratory Syncytial Virus Infection in BALB/c Mice

Author Block:

S. Bawage[1], P. Tiwari[1], A. Singh[2], S. Dixit[1], S. Pillai[1], V. Dennis[1], S. Singh[1]; [1]Alabama State Univ., Montgomery, AL, [2]Univ. of South Alabama, Mobile, AL

Abstract Body:

Respiratory Syncytial virus (RSV) is one of the leading causes of respiratory illness in the infants, children and older adults. RSV causes severe pneumonia and bronchitis to which only symptomatic treatment is prescribed along with the antiviral drug ribavirin. There is no vaccine in the market for RSV specific treatment; therefore there is a need for new approach to address the problem. The field of nanomedicine against pathogenic viruses was unexplored until last two decades, however, their potential for application has gained interest in recent years. Metallic nanoparticles (silver and gold) have shown antiviral activities *in vitro* against respiratory viruses like influenza, parainfluenza and adenoviruses. Here, we show the antiviral activity of gold nanorods (GNRs) against RSV and try to understand the mechanism of inhibition. Our preliminary study has demonstrated RSV inhibition by GNRs *in vitro* by 82%, therefore we carried out mice experiments to demonstrate the efficacy *in vivo*. Mice treated with GNRs showed almost 50% reduction of RSV (plaque assay), when compared to the RSV infected mice. The histology report of lungs showed that GNRs did not cause any notable pathology. However, there was infiltration of leukocytes as the GNRs were present in the extracellular matrix. Transmission electron microscopy showed that GNRs were contained in the cytoplasmic vesicles resulting from the phagocytosis of extracellular GNRs. Antiviral gene response (84 genes) indicate the up-regulation of TLR, NLR and RLR pathways against GNRs and RSV treatment, particularly OAS2, Mx1, Cxcl9, Cxcl10 and Cxcl11. Cytokine analysis of lung homogenate, bronchoalveolar lavage and serum showed increased production of inflammatory cytokines (IL-12, IL-9, IL-13, IL-17) for the RSV and GNR-RSV mice group. Restimulation of splenocytes with RSV, GNR, GNR-RSV did not produce significant cytokines (IL-6, IL-8, IL-10, IFN-γ, TNF-α). Our study demonstrates inhibition of RSV in mice by GNR mediated innate immune response.

Valacyclovir as Initial Treatment for Acute Retinal Necrosis: A Pharmacokinetic Modeling and Simulation Study

Author Block:

A. Jain[1], T. Liu[2], M. W. Fung[3], V. Ivaturi[2], C. Vinnard[1]; [1]Drexel Univ. Coll. of Med., Philadelphia, PA, [2]Ctr. for Translational Med., Sch. of Pharmacy, Univ. of Maryland, Baltimore, MD, [3]Univ. of Pennsylvania Hlth.System, Philadelphia, PA

Abstract Body:

Background: Acute retinal necrosis (ARN) is a feared complication of infectious retinitis most commonly caused by varicella zoster virus (VZV), herpes simplex virus 1 (HSV-1), or herpes simplex virus 2 (HSV-2). We performed a pharmacokinetic modeling and simulation study using previously published data to evaluate the vitreal penetration of oral valacyclovir for the treatment of ARN, under various dosing scenarios. **Methods:** We compared different oral valacyclovir dosing regimens with intravenous acyclovir. The vitreous compartment was modeled as an effect compartment, and paired serum and vitreal acyclovir concentrations were obtained from previously published data of adult patients with ARN undergoing vitrectomy. The efficacy threshold for vitreal acyclovir concentrations was based on the previously reported IC_{50} values for VZV, HSV-1, and HSV-2. **Results:** Based on the time required to attain minimum vitreal acyclovir concentrations (C_{min}) greater than the highest reported IC_{50}, valacyclovir 1.5 g every 8 hours performed similarly to intravenous acyclovir 700 mg every 8 hours. In contrast, the standard dosing regimen for herpes zoster, valacyclovir 1 g every 8 hours, required 8 days for the C_{min} to exceed the target value. **Conclusion:** Modeling and simulation data support oral valacyclovir for the treatment of ARN, although the required dosing exceeds the recommended FDA dose size for herpes zoster. **Figure.** Mean simulation of vitreal acyclovir concentrations under different dosing scenarios of oral valacyclovir, compared with intravenous acyclovir.

Safety and Tolerability of High-Dose Oral Valacyclovir during a Shortage of Intravenous Acyclovir

Author Block:

M. M. McLaughlin[1], J. S. Esterly[2]; [1]Midwestern Univ., Downers Grove, IL, [2]Chicago State Univ. Coll. of Pharmacy, Chicago, IL

Abstract Body:

Background: Intravenous acyclovir (IVA) is the drug of choice for viral meningitis (VM) caused by herpes viruses. A national shortage of IVA from 11/20/12-09/03/13 mandated restricting this agent at Northwestern Memorial Hospital (NMH) for use only in patients with confirmed VM. Pharmacokinetic data suggests similar serum concentrations to IVA can be achieved with high-dose, oral valacyclovir (HDVA); however, there is a lack of data as to the safety and tolerability of HDVA. In certain cases, patients received HDVA empirically to conserve IVA for patients with confirmed VM. The objective of this study was to assess the safety and tolerability of HDVA as an alternative to IVA for patients with suspected VM during an IVA shortage. **Methods:** Subjects were considered for analysis in this retrospective study if they were ≥18 years of age, and received HDVA from 11/20/12-09/03/13 at NMH for suspected or proven VM. HDVA was defined as any dose exceeding the product label recommended doses for given indications and patient renal function (e.g. >6 gram/day for normal renal function). Pertinent patient variables were collected and outcome measures assessed included ADRs from HDVA and neurological sequelae. **Results:** Overall, 18 patients were included in the study. The average patient included in this study was a 49 year old (SD 17.3), immunocompromised, Caucasian male, modified APACHE II of 14.9 (SD 7.2), with a median hospital stay of 6.5 days (IQR 4-32). The most common presenting symptom suggestive of VM was altered mental status (n=15) followed by nuchal rigidity (n=7). 17 patients had a lumbar puncture and there were 4 definitive cases and 6 physician diagnosed cases of VM. Six (33.3%) patients experienced at least one ADR to HDVA (headache, n=1; nausea, n=1; rash, n=1; and thrombocytopenia, n=5). There were no discontinuations or any symptomatic therapy necessary to treat any of the ADRs. In total, 8 patients ultimately received IVA for treatment of VM and there were 2 patients that had neurological sequelae. **Conclusion:** HDVA appears to have been safe and well tolerated by patients with suspected VM and may be an option with IVA is unavailable. Future study is needed to elucidate treatment outcomes and the most appropriate dosing regimen for HDVA.

Ribavirin for Respiratory Syncytial Virus: Mortality Rate and Risk Factors for Mortality Following Treatment

Author Block:

N. N. Pettit, Z. Han, J. delaCruz, A. Charnot-Katsikas, K. Beavis, J. Pisano; Univ. of Chicago Med., Chicago, IL

Abstract Body:

Background: Respiratory Syncytial Virus (RSV) is a common cause of viral pneumonia and is associated with high rates of mortality in immune-compromised (IC) patients. Ribavirin (RBV) is the mainstay of treatment with efficacy data available for oral and aerosolized administration. At our hospital, the rate of RSV positivity is 92-103 cases/yr, with 6-12% of these patients receiving RBV. To assess the clinical efficacy of RBV for RSV in IC patients, we sought determine the rate of and identify risk factors for mortality among those treated with RBV.**Methods:** All adult inpatients with RSV positive PCR and that received oral RBV (PORBV) or aerosolized RBV (aRBV) between 3/1/2013 - 3/1/2015 were included. The primary endpoint was 30 day all-cause mortality. A regression analysis was performed to identify risk factors for mortality.**Results:** A total of 26 patients received RBV (2 PORBV, 24 aRBV). Overall 30 day all-cause mortality was 19.2% (n=5). Mean duration of RBV was 5.1 $\pm$ 3 days. Most patients had a lower respiratory tract infection (LRTI) (n=18) at time of treatment. Risk factors assessed for mortality are shown in table 1.

Table 1: Risk Factor Analysis			
Risk factor	Survival 30d (n=21)	Non-survival 30d (n=5)	P value
Age (mean)	55.8	61	0.54
Stem-cell transplant (SCT)	8 (38)	4 (80)*	0.12
Solid organ transplant	8 (38)	1 (20)	0.42
LRTI	14 (67)	4 (80)*	0.50
IVIG	8 (38)	1 (20)	0.42
IgG <800 mg/dL	14 (67)	4 (80)*	0.50
Mixed Viral Infection	3 (14)	1 (20)	0.60
Duration RBV	4.5 $\pm$ 2.2	7.4 $\pm$ 4.9	0.17

SCT and duration RBV met a priori ($p<0.2$) for inclusion in multivariate regression (MV) analysis, no significant association with mortality was identified.
* 3 of 4 patients had all 3 risk factors: SCT and LRTI and IgG <800 mg/dL.

Conclusions: Our observed mortality rate is similar to available literature showing a rate of 18.5% among IC patients with RSV treated with RBV. None of the risk factors assessed were statistically associated with mortality, however the small sample size precludes definitive conclusions. A larger proportion of patients with the mortality outcome were SCT patients, had a an IgG <800 and LRTI at baseline, suggesting these characteristics may place a patient at greater risk for mortality even with RBV treatment. Additionally, adjunctive use of IVIG was more commonly implemented in the surviving group, indicating a potential role for IgG repletion to reduce mortality risk.

Effectiveness & Safety of New Direct-Acting Antivirals for the Treatment of Hepatitis C Infection in Coinfected Hiv/Hcv Population: Results in Routine Clinical Practice

Author Block:

E. Chamorro-de-Vega, C. Rodriguez-Gonzalez, A. Gimenez-Manzorro, A. Herranz-Alonso, M. Sanjurjo-Saez, GRUVIC Study Group; Gregorio Maranon Univ. Hosp. - Hlth.Res. Inst. Gregorio Maranon, Madrid, Spain

Abstract Body:

Background: The new Direct-Acting Antivirals (DAAs) for Hepatitis C Virus (HCV) infection have dramatically changed the therapeutic landscape. However, data on effectiveness and safety of these combinations in coinfected HIV/HCV patients population are lacking. The objective was to provide preliminary data on effectiveness and safety of DAAs for the treatment of HCV infection in the HIV/HCV coinfected population when used under routine clinical practice.**Methods:** Study design: descriptive, prospective. Inclusion criteria: all HIV/HCV coinfected patients who finished their treatment with DAAs before December 31st 2015. The primary effectiveness end point was a Sustained Virologic Response 12 weeks after the end of treatment (SVR12). Safety was evaluated by the incidence of Adverse Drug Events (ADEs), including laboratory abnormalities. These data were collected at baseline and every 4-week visits during treatment.**Results:** Of the 175 patients enrolled, 61.7% had genotype 1 infection (66.7% genotype 1a), 21.1% genotype 4, 16.6% genotype 3 and 0.6% genotype 2. Overall, 73.1% were men, 50.9% had been previously treated for HCV, and 63.4% had cirrhosis (12.0% decompensated). 56.6% of the patients received SOF/LPV, 18.9% OBV/PTV/r+DSV and 13.7% SOF+DCV. Ribavirin was added in 50.0% of the patients. The duration of treatment was 12 weeks in 45.1% of the patients. SVR12 was achieved by 78/86 of the patients (90.7%; IC95% 84.0-97.4) (no data for SVR12 available for the remaining patients yet). Eight patients did not achieve SVR (3 virologic relapses, 1 virologic failure, 2 deaths -not drug-related-, 1 interruption due to ADEs and 1 desertion). Only 1 ADE of grade 3 was identified (insomnia). The three most common ADEs were: anemia (38.9%), asthenia (29.1%) and headache (26.9%). The haemoglobin level was less than 10 g/dL in 5.1% of patients. **Conclusions:** Preliminary data corroborates high effectiveness and a good safety profile of DAAs regimens in HIV/HCV coinfected population when used under routine clinical practice.

Outcomes of Veterans Treated for Hepatitis C Infection with Interferon-Free Regimens

Author Block:

M. Segarra-Newnham, G. A. Fox-Seaman, T. J. Church; VA Med. Ctr., West Palm Beach, FL

Abstract Body:

Background: Five percent of veterans have hepatitis C virus (HCV). Interferon-free regimens have higher response rates and improved adherence. Our Veterans Affairs Medical Center (VAMC) has treated HCV infection in a nurse practitioner (NP)-based clinic for over 15 years. Treatment is selected by the NP in consultation with a clinical pharmacy specialist. Direct acting antivirals (DAA) such as ledipasvir/sofosbuvir (LDV/SOF) and ombitasvir/paritaprevir/ritonavir plus dasabuvir (PrOD) increase sustained virological response (SVR) particularly for patients with genotype (GT) 1 infection and in both treatment-naïve and treatment-experienced patients. **Purpose:** Determine outcomes including SVR 12 weeks after DAA treatment completion with viral load (VL). **Methods:** A retrospective chart review of patients treated with a DAA from January 2015 to December 2015 was conducted. Data collected included medication prescribed, hepatitis C GT, FIB4 score, cirrhosis, previous HCV therapy, SVR12 and discontinuation rates. **Results:** A total of 322 patients (avg age 62; 97% men) and median FIB4 score of 2.15 were treated during 2015. Twenty-one patients had GT2 with 4 patients having SVR12 evaluations (3/4 negative VL). One had GT4 and is still on treatment. Nineteen GT3 patients were treated with 8 having SVR12 evaluation. Four were treatment failures; all with cirrhosis and 2/4 treatment-experienced. The other 11 patients are pending SVR12 check. A total of 281 GT1 patients started treatment; 91 (32%) with cirrhosis. Of 281 GT1 patients, 208 (74%) were treatment-naïve and 56 (27% of naïve patients) had cirrhosis. Of 73 treatment-experienced patients, 35 (48%) had cirrhosis. Outcomes for GT1 patients are listed in table 1.

Treatment given	Started[a]	Rx complete/Pending SVR12	On treatment	SVR12 (neg VL)
LDV/SOF-based	250[b]	104	69	69/75 (92%)[c]
PrOD-based	31	20	5	3/5 (60%)

[a]3pts d/c rx due to side effects (2 LDV/SOF and 1 PrOD). [b]84 prescribed 8wks due to VL < 6M at baseline [c]15/17 (88%) 8 wks rx had neg VL 16wks post rx **Conclusions:** HCV infected patients treated with LDV-SOF at our clinic had high rates of response, similar to those seen in clinical trials. Response to PrOD regimen was lower than anticipated but with small number of patients evaluated.

Identification of a Novel Antiviral Compound Targeting the Main Protease of Middle East Respiratory Syndrome Coronavirus

Author Block:

H. Shuai, S. Yuan, B-j. Zheng; The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Middle East Respiratory Syndrome Coronavirus (MERS-CoV) is a newly discovered positive single stranded RNA virus which can cause severe pneumonia.MERS-CoV has caused a higher fatality rate (up to 35%). Besides, MERS patients might experience more severe clinical symptoms, such as renal failure. Importantly, the risk of pandemic caused by human adapted MERS-CoV mutant can not be excluded. Currently, no specific or effective antiviral therapy against MERS-CoV is available yet. Main protease (nsp5), which is highly conservative among the *Coronaviridea* family, mainly functions to release the essential viral nonstructural proteins for forming replication/transcription complex (RTC), thus is crucial to the replication of coronavirus, making it an ideal druggable target for development of antivirals. We screened compounds library to target MERS-CoV nsp5. Recombinant nsp5 was expressed using the E.coli system and its biological activity was verified by fluorescent resonance energy transfer (FRET) assay. A total of 879 compounds, previously enriched against SARS-CoV , were screened and we found a novel compound with >50% inhibition of enzyme activity at the concentration of 50μg/mL. The compound showed reduced cytopathic effect (CPE) on Vero-E6 cells at 48h post-infection (p.i.) and 50% inhibitory concentration (IC_{50}) was 3μM. Plaque assay further confirmed that viral titer in supernatant of Vero-E6 cell culture decreased about 4 logs at 24h p.i. at concentration of 12.5μM. Cell viability assay showed that 50% cytotoxicity concentration (CC_{50}) was 75μM at 48h after inoculation. The selection index (SI) of the compound is 25. Western blotting showed that nucleotide protein (NP) decreases in a dose-dependent manner in MERS-infected Vero-E6 cells at 24h p.i., indicating virus replication is reduced. Moreover, the compound showed cross-protection towards SARS-CoV. In conclusion, our work has provided valuable in developing viral protease inhibitor based antivirals for prophylaxis and therapy of infections by coronaviruses such as MERS-CoV and SARS-CoV.

A Sensitive Fluorescence Polarization Screen to Identify Rna Virus Replication Inhibitors

Author Block:

P. J. Nash[1], G. Liu[1], D. W. Leung[2], T. L. Bowlin[1], C. F. Basler[3], G. K. Amarasinghe[2], **D. T. Moir**[1]; [1]Microbiotix, Inc., Worcester, MA, [2]Washington Univ. in St. Louis, St. Louis, MO, [3]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract Body:

Background: Ebola hemorrhagic fever is a highly lethal emerging infectious disease caused by Ebola virus (EBOV), which resulted in 15,215 confirmed cases and 11,300 deaths in 2014-2015. To address the acute medical need for effective therapeutics, we devised and executed a novel high throughput screen to identify small-molecule inhibitors of the essential interaction between EBOV nucleoprotein (NP) and its polymerase co-factor, eVP35. A 29 amino acid peptide at the N-terminus of eVP35 (NP binding peptide, NPBP) is sufficient for interaction with NP (Leung et al., 2015) and is able to suppress EBOV replication, suggesting the NPBP binding pocket as a potential drug target. Conservation of the essentiality of the interaction between the viral nucleoprotein (N or NP) and the polymerase (L) co-factor protein (P or VP35) for replication of paramyxoviruses and filoviruses indicates that this class of targets might be broadly useful for antiviral screening. **Methods:** A fluorescence polarization assay (FPA) was developed to detect inhibition of the interaction between EBOV NP and FITC-labeled VP35-NPBP and used to screen 200,000 compounds. Secondary assays included an unrelated FPA counter-screen to detect inhibitors of a FITC-labeled peptide containing an ETGE domain with purified human Keap1 protein containing a Kelch domain, an orthogonal NP/VP35-NPBP biolayer interferometry (BLI) assay, a cytotoxicity evaluation, and a minigenome assay for EBOV RNA synthesis (Edwards et al., 2015). **Results:** A total of 1,065 compounds were primary hits (0.5%), 498 (0.25%) were confirmed in the primary and counter screens, and 39 (0.02%) were reordered and tested in FPA dose responses. A total of 7 compounds (0.004%) displayed significant inhibition (IC_{50} values ranging from 2-35 μM) of the NP/VP35-NPBP interaction and were validated in all secondary assays. Evaluation in the minigenome assay demonstrated that two of the inhibitors reduced RNA replication significantly at non-cytotoxic concentrations. **Conclusions:** The EBOV NP/VP35-NPBP FPA exhibited excellent sensitivity, reproducibility, and ease of execution. The successful identification of selective NP/VP35 inhibitors supports using this approach for additional RNA viruses.

In Vitro* Activity of Wck 5999, a Carbapenem/β-Lactamase Inhibitor Combination Tested Against Contemporary Kpc-Producing *Enterobacteriaceae

Author Block:

M. Castanheira, P. R. Rhomberg, B. A. Schaefer, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: KPC serine-carbapenemases are prevalent worldwide and are usually resistant to all β-lactams and often resistant to other antimicrobial classes. WCK 5999 is a combination of meropenem (MEM) and WCK 4234, a β-lactamase inhibitor with enhanced inhibitory activity against class D oxacillinases (including carbapenem hydrolyzing) as well as activity against class A and C. We tested MEM-WCK 4234 against 137 Enterobacteriaceae isolates producing KPC enzymes of six bacterial species. **Methods:** 137 clinical KPC-producing isolates collected during 2013-2015 from USA hospitals were susceptibility tested against MEM-WCK 4234 (WCK 4234 at fixed 4 and 8 µg/mL), MEM and WCK 4234 alone according to CLSI guidelines. The presence of bla_{KPC} was determined by PCR/sequencing.**Results:** MEM alone ($MIC_{50/90}$, 8/>64 µg/mL) had a very limited activity based on CLSI interpretative criteria (≤1 µg/mL). MIC_{50} values for MEM-WCK 4234 were ≤0.03 µg/mL for both inhibitor concentrations and MIC_{90} was 0.25 and 0.12 µg/mL for fixed 4 and 8 µg/mL, respectively. MEM-WCK 4234 inhibited 97.8 and 99.3% of the isolates at ≤1 µg/mL using fixed 4 and 8 µg/mL of inhibitor, respectively. Highest MEM-WCK 4234 MIC value among KPC-producing *K. pneumoniae* (n=111, $MIC_{50/90}$, ≤0.03/0.25 µg/mL) was 4 µg/mL (only one isolate) when tested at fixed 4 µg/mL of inhibitor and 2 µg/mL using fixed 8 µg/mL of WCK 4234. All four KPC-producing *E. coli* and one *C. freundii* isolates tested were inhibited by MEM-WCK 4234 at ≤0.03 µg/mL and 5 *K. oxytoca* and 12 *E. cloacae* tested were inhibited at ≤0.5 and ≤1 µg/mL, respectively. MEM-WCK 4234 MIC results for two *S. marcescens* tested were ≤0.03 and 2 µg/mL and ≤0.03 and 4 µg/mL when using WCK4234 at fixed 4 and 8 µg/mL, respectively. WCK 4234 had no activity against the isolates tested (MIC_{50}, >32 µg/mL).**Conclusions:** MEM-WCK 4234 displayed promising activity against a collection of very recent (2013-2015) KPC-producing isolates collected from USA hospitals, regardless of the inhibitor concentration used. This combination (WCK 5999) was eight- to >256-fold (mode, 128-fold) more active against KPC-producing isolates when compared to MEM alone. The emergence of pan-drug resistant KPC-producing isolates highlight the need for new therapeutic options for these isolates and the further development of WCK 5999 is warranted.

Activity of the New Carbapenem/β-Lactamase Inhibitor Combination Wck 5999 Against Gram-negative Isolates Producing Oxacillinases (Oxas)

Author Block:

M. Castanheira, P. R. Rhomberg, J. M. Lindley, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: OXAs are class D serine β-lactamases that can display hydrolytic activity against cephalosporins and/or carbapenems. OXAs with extended- (ESBL) or narrow-spectrum (NS) are detected among Enterobacteriaceae (ENT) and *P. aeruginosa* (PSA). OXAs with carbapenemase (carb) activity were common among *Acinetobacter* spp. (ASP) and ENT. We tested WCK 5999, a combination of meropenem (MEM) with the β-lactamase inhibitor WCK 4234, against 118 OXA-producing isolates. **Methods:** 82 isolates producing OXA-carb (55 ASP and 27 ENT) and 36 isolates producing OXA-ESBL/NS (29 ENT and 7 PSA) were tested. Susceptibility (S) testing was performed according to the CLSI guidelines for MEM-WCK 4234 (WCK 4234 at fixed 4 and 8 μg/mL), MEM and WCK 4234. The presence of OXA-encoding genes was previously determined by PCR/sequencing.**Results:** Overall, MEM-WCK 4234 inhibited all ENT producing OXAs at ≤0.5 and ≤0.25 μg/mL using WCK 4234 at fixed 4 and 8 μg/mL, respectively. MEM alone inhibited only 64.3% of these isolates at the CLSI S breakpoint. All OXA-ESBL/NS were inhibited by MEM-WCK 4234 at ≤0.12 μg/mL, regardless of the inhibitor concentration and 89.7% of these strains were MEM S. MEM inhibited only 37.0% of the ENT isolates producing OXA-carb (OXA-48-like); however, MEM-WCK 4234 inhibited all OXA-Carb ENT isolates at ≤0.5 or ≤0.25 μg/mL (WCK 4234 at fixed 4 and 8 μg/mL, respectively). All OXA-producing ASP were resistant to MEM (MIC_{90}, >64 μg/mL), but MEM-WCK 4234 at fixed 8 μg/mL inhibited 65.5 and 90.9% of these isolates at ≤2 and ≤4 μg/mL, respectively. MEM-WCK 4234 had higher activity against more prevalent OXA-23-producing ASP when compared to isolates producing OXA-24. MEM-WCK 4234 (fixed 8 μg/mL) inhibited 84.4 and 96.9% of the OXA-23 isolates and 29.4 and 76.5% of the OXA-24 isolates at ≤2 and ≤4 μg/mL, respectively. Based on a small set of isolates (n=7), the activity of MEM-WCK 4234 was limited against PSA isolates producing OXA-ESBL/NS.**Conclusions:** MEM-WCK 4234 displayed enhanced activity against ENT and ASP isolates producing OXAs with carbapenemase activity when compared to MEM. The activity of MEM-WCK 4234 was very good against ENT producing OXA-ESBL/NS, but showed limited activity against OXA-ESBL/NS-producing PSA since the MEM resistance mechanism in these isolates is not mediated by β-lactamases.

Wck 5999 (Carbapenem-Wck 4234): *In Vitro* and *In Vivo* Activity of Novel β-Lactam-β-Lactamase Inhibitor (Bl-Bli) against Oxa β-Lactamase-Producing *Klebsiella* (Kp) and *Pseudomonas* (Pa)

Author Block:

H. N. Khande, S. R. Palwe, S. S. Takalkar, K. V. Umarkar, J. S. Satav, P. R. Joshi, S. S. Biniwale, S. S. Bhagwat, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 4234 is a novel BLI with expanded activity against Class D β-lactamases including OXA carbapenamases associated with *Acinetobacter*. KP harbouring OXA 48/181 and PA harbouring OXA 1/2 in conjunction with VEB or GES ESBLs may show resistance towards carbapenems and/or cephalosporins. Herein, we describe the *in vitro* and *in vivo* activity of WCK 4234 in combination with carbapenems.**Method:** BLI activity of WCK 4234 (IC_{50}) was determined against OXA 48/181and OXA 1/2 +VEB β-lactamases using nitrocefin assay. Combination MICs were determined as per CLSI, against KP (n=14) and PA (n=27) strains collected from Indian hospitals. Combination time-kill studies (initial inoculum: 6.6-7.23 $\log_{10}$ CFU/mL) were performed and periodic CFU counts recorded. $ED_{50/90}$, was determined using systemic infection model. Mice were intraperitonealy infected (KP S465 and S468) with 6.30–6.47 $\log_{10}$ CFU/mouse and treatment initiated 2h post-infection (BID, 3h apart for 1 day) and survival was monitored till day 7.**Results:** IC_{50} for WCK 4234 against KP OXA-48, -181 and PA OXA-1/2+VEB was 0.067, 0.09 and 0.043 µM respectively. In OXA KP strains, addition of WCK 4234 (4 µg/mL) lowered the standalone $MIC_{50/90}$ of imipenem (IPM) and meropenem (MEM) from 4/8 and 16/32 µg/mL to ≤0.12/0.25 µg/mL respectively [$MIC_{50/90}$: ceftazidime (CAZ)-avibactam (AVI) - 1/1 µg/mL; IPM-relebactam (REL) - 4/4 µg/mL]. For PA strains, IPM and MEM combined with WCK 4234 (8 µg/mL) provided $MIC_{50/90}$ of 0.5/32 µg/mL, 75% of PA strains were inhibited at 4 and 2 µg/mL, respectively [$MIC_{50/90}$: CAZ-AVI4 - 16/64 µg/mL; IPM-REL4 - 0.5/32 µg/mL]. Against KP S465 and S468, time-kill studies employing WCK 4234 (1 and 2 µg/mL) with either IPM or MEM (1 and 2 µg/mL) showed >2 $\log_{10}$ CFU/mL kill, while standalone IPM (8 µg/mL) failed. In PA Q125, a 1.7 $\log_{10}$ CFU/mL kill was achieved with IPM+WCK 4234 (4+4 µg/mL) while IPM and CAZ-AVI (4+4 µg/mL) failed. ED_{50} for KP S465 and S468: IPM (12.5 mg/kg)-WCK 4234 (6.40 mg/kg) and ED_{90}: IPM (12.5 mg/kg)-WCK 4234 (12.44 mg/kg). Standalone IPM even at higher doses failed to provide protection.**Conclusion**: Carbapenem-WCK 4234 combination provided useful *in vitro* and *in vivo* activity against OXA expressing KP and OXA+VEB expressing PA.

Wck 5999 (Carbapenem-Wck 4234): *In Vitro* and *In Vivo* activity of Novel Broader-Spectrum β-Lactam-β-Lactamase Inhibitor (Bl-Bli) against Indian Oxa Carbapenemase (Oxa-Carb) Expressing *Acinetobacter* (Ab)

Author Block:

H. N. Khande, S. S. Takalkar, K. V. Umarkar, A. M. Kulkarni , P. R. Joshi, S. R. Palwe, S. S. Biniwale, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: OXA-cabapenamases are largely responsible for pan β-lactam resistance in AB. Neither the approved β-lactamase inhibitors (BLIs) nor those under development extend antibacterial coverage to OXA-CARB-expressing AB. Herein, we describe a novel broader-spectrum BLI WCK 4234, that inhibits Class D OXA-CARBs besides Class A and C β-lactamases. **Method:** Inhibitory activity (IC_{50}) of WCK 4234 against diverse OXA-CARBs was determined by employing nitrocefin assay. MICs were determined as per CLSI recommended agar dilution method against 208 OXA-CARB AB strains collected from various Indian tertiary-care centers. Time-kill studies were conducted to assess the cidality of carbapenem-WCK 4234 (WCK 4234 at 4 and 8 µg/mL, initial inoculums: 6.5-6.75 $\log_{10}$ CFU/mL) in AB NCTC 13301 (OXA 23) and 13303 (OXA 26). Viable counts were enumerated by plating aliquots of serially diluted culture. *In vivo,* $ED_{50/90}$ was determined using systemic infection models. Mice were intraperitonially infected with 6.87-7.0 $\log_{10}$ CFU/mouse and treatment (BID for 1 day) was initiated 1h (AB NCTC 13301) or 2h (AB NCTC 13303) post-infection. **Results:** IC_{50} for WCK 4234 against OXA-23, -24, -25, -26 and OXA-27 β-lactamases was 0.70, 0.59, 0.92 and 0.51 µM respectively. $MIC_{50/90}$ of unprotected imipenem (IPM) was 16/64 µg/mL. Addition of 4 and 8 µg/mL of WCK 4234 lowered the $MIC_{50/90}$ of IPM to 2/8 µg/mL and 1/4 µg/mL, respectively. $MIC_{50/90}$ of ceftazidime (CAZ)-avibactam (AVI) was 64/128 µg/mL. Time-kill studies revealed that carbapenem-WCK 4234 (4-8 µg/mL) showed 2 $\log_{10}$ CFU/mL kill, while IPM and CAZ-AVI failed. Efficacy studies showed that ED_{50} was achieved at IPM (50 mg/kg)-WCK 4234 (6.40-23.23 mg/kg) while ED_{90} was achieved at IPM (50 mg/kg)-WCK 4234 (12.44-52.30mg/kg). Standalone IPM even at higher doses failed to provide protection. **Conclusion:** Carbapenem-WCK 4234 combination provided useful therapeutic option for the treatment of OXA-CARB expressing AB.

Publishing Title:

***In Vitro* Antibacterial Activity of WCK 5999: A New Carbapenem/β-Lactamase Inhibitor Combination against ESBL-Phenotype and Carbapenemase-Producing *Enterobacteriaceae* from a Worldwide Surveillance Program (2015)**

Author Block:

M. D. Huband, M. Castanheira, D. J. Farrell, R. K. Flamm, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: WCK 5999 is a new carbapenem/β-lactamase inhibitor combination comprising meropenem (MEM) and the novel broader-spectrum β-lactamase inhibitor, WCK 4234, with enhanced activity against Class D carbapenemases. The *in vitro* antibacterial activity of MEM-WCK 4234 using both fixed 4 (F4) and fixed 8 (F8) µg/mL of WCK 4234 was evaluated against Enterobacteriaceae (ENT) subgroups expressing resistance to β-lactams including ESBL-phenotype, ceftazidime (CAZ) non-susceptible (NS), MEM NS and carbapenem-resistant ENT (CRE).**Methods:** MEM-WCK 4234 (F4 and F8) and comparator compound MIC values were determined using a reference broth microdilution method against ENT subgroups collected during a 2015 worldwide surveillance program.**Results:** MEM-WCK 4234 (F4 and F8) displayed potent activity (MIC_{50}/MIC_{90} values of ≤0.06/≤0.25 µg/mL) against 369 ENT isolates displaying either an ESBL-phenotype, CAZ NS, MEM NS or CRE (Table). The highest MEM-WCK 4234 MIC (F4 and F8) was 0.5 µg/mL compared to >32 µg/mL for MEM alone. Applying CLSI breakpoint interpretive criteria, S rates against ESBL-phenotype *E. coli* (EC) and *Klebsiella pneumoniae* (KPN) ranged 9.2-18.3% for CAZ, 80.0-98.3% for MEM and 41.7-81.7% for piperacillin-tazobactam (P/T). CAZ and P/T S rates against MEM NS KPN and CRE were very low (3.1-4.3%) whereas MEM-WCK 4234 (F4 and F8) combinations retained activity (100% S) with MIC_{90} values of 0.25 and 0.12 µg/mL, respectively.**Conclusions:** WCK 5999 is a potent new antibacterial combination against ENT displaying and ESBL phenotype, CAZ NS, MEM NS and CRE. These data support the continued development of this promising antibacterial combination.

Wck 5999 (Carbapenem-Wck 4234): *In Vitro* Activity against Esbls, Class C, Kpc-Expressing *Enterobacteriaceae* (Ent) Isolates

Author Block:

P. R. Joshi, H. N. Khande, S. R. Palwe, S. S. Biniwale, S. S. Bhagwat, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 4234 is a novel β-lactamase inhibitor (BLI) with expanded activity against ENT ESBLs, Class C, KPCs and Class D β-lactamases including OXA carbapenamses associated with *Acinetobacter*. Herein, we describe the *in vitro* activity of WCK 4234 in combination with carbapenems against diverse MDR ENT.**Methods:** BLI activity of WCK 4234 (IC_{50}) was determined by employing nitrocefin assay. Combination ENT MICs were determined (as per CLSI) against ESBLs (n=135), Class C (n=58) and KPCs (n=23) and ENT outer membrane porin underexpression (OMP)+ESBL (n=6) collected from Indian hospitals. Combination time-kill studies employed initial bacterial count of 6.5-7.0 $\log_{10}$ CFU/mL and periodic CFU was determined.**Results:** WCK 4234 IC_{50} range against ESBLs, Class C and KPC were 0.023-0.10 µM, 0.027-0.033 µM, 0.020-0.054 µM, respectively. For ESBL ENT, $MIC_{50/90}$ for imipenem (IPM) and meropenem (MEM) were 0.12/0.5 and 0.03/0.06 µg/mL respectively that lowered to 0.12/0.25 and 0.015/0.03 µg/mL, respectively upon addition of WCK 4234 (4µg/mL). IPM-relebactam (REL 4 µg/mL) $MIC_{50/90}$ was 0.12/0.25 µg/mL. OMP ENT MIC range for IPM and MEM were 1-4 µg/mL and 2-8µg/mL, respectively that lowered to 0.12-0.25µg/mL, when combined with WCK4234 at 4 µg/mL. IPM-REL MIC range was 0.25-2 µg/mL. For Class C harboring strains, $MIC_{50/90}$ for IPM and MEM were 0.25/1 and 0.06/0.5 µg/mL, respectively. In combination with WCK 4234 (4 µg/mL) $MIC_{50/90}$ were 0.12/0.5 and 0.03/0.25 µg/mL, respectively. IPM-REL showed $MIC_{50/90}$ of 0.12/0.5 µg/mL. For, KPC, $MIC_{50/90}$ for IPM and MEM (32/32 and 32/>32 µg/mL, respectively) lowered to 0.5/0.5 and 0.25/0.25 µg/mL, respectively by WCK 4234. Against KPC *K. pneumoniae* (KP) H521 and KP H 524, time-kill studies employing WCK 4234 (1 and 2 µg/mL) with either IPM or MEM (1 and 2 µg/mL) showed >2 $\log_{10}$ CFU/mL kill, while standalone IPM or MEM (8 µg/mL) failed to do so. Similarly, for KP OMP+ESBL, KP J101, >3 log10 CFU/mL kill was achieved with IPM - WCK 4234 (1+4 µg/mL).**Conclusions:** WCK 4234 activity in combination with IPM and MEM shows promising *in vitro* features against widely prevalent ENT expressing diverse β-lactamases and KPC.

Publishing Title:

Enhanced Activity of Wck 4282 (Cefepime-Tazobactam) Against Kpc-producing Enterobacteriaceae Collected Worldwide When Tested in Physiological Conditions

Author Block:

M. Castanheira, P. R. Rhomberg, B. A. Schaefer, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: KPC-producers are often resistant to several or all available antimicrobials. WCK 4282 (cefepime-tazobactam [high dose]; FEP-TAZ) displayed in vivo efficacy against KPC expressing strains despite elevated FEP-TAZ MICs. In vitro activity of FEP-TAZ was evaluated in physiological conditions against KPC-producers.**Methods**: KPC-producing Enterobacteriaceae (n=191) were susceptibility (S) tested against FEP-TAZ (TAZ at fixed 8 µg/mL) and FEP by CLSI guidelines using Mueller-Hinton broth (MHB) ± 50% human serum or 0.85% sodium chloride (NaCl). *bla*$_{KPC}$ presence was determined by PCR/sequencing.**Results:** FEP-TAZ activity against KPC-producing *K. pneumoniae* (KPN; n=156) was enhanced by at least 2- to 4-fold with the addition of serum ($MIC_{50/90}$, 8/64 µg/mL) or NaCl ($MIC_{50/90}$, 8/64 µg/mL) when compared to results for FEP-TAZ tested under standard conditions ($MIC_{50/90}$, 32/>64 µg/mL). FEP-TAZ inhibited 75.0 and 73.1% of the isolates at ≤16 µg/mL (high-dose FEP-TAZ PK-PD tentative breakpoint; Table) in the presence of added NaCl or serum, respectively. FEP exhibited limited activity against KPC-producing KPN ($MIC_{50/90}$, 32/>64 µg/mL) with only 17.9% of the isolates S at ≤8 µg/mL. FEP-TAZ activity against KPC-producing KPN was similar to that of FEP alone and inhibited 29.5% of these isolates at ≤8 µg/mL when tested under standard conditions. Against non-KPN, the addition of serum ($MIC_{50/90}$, 4/16 µg/mL) or NaCl ($MIC_{50/90}$, 4/32 µg/mL) lowered the MICs for FEP-TAZ when compared to the reference method (n=35; 5 species/complexes) and 88.6-94.3% of these isolates were inhibited by FEP-TAZ at ≤16 µg/mL in the presence of serum or NaCl. The activity of FEP-TAZ (MIC_{50}, 8 µg/mL) and FEP (MIC_{50}, 16 µg/mL) tested in standard conditions was limited against non-KP KPC-producers.**Conclusions:** FEP-TAZ MIC results for all KPC-producing isolates were consistently lower in MHB supplemented with human serum or NaCl (in vivo conditions) and 73.1 to 94.3% of the isolates were inhibited by FEP-TAZ at 16 µg/mL.

Organism (no. tested)/ Antimicrobial agent	No. of isolates at MIC (µg/mL; cumulative %):					
	1	2	4	8	16	32

***In Vitro* Activity of Cefepime Combined with Tazobactam (Wck 4282) Against a Challenge Set of Esbl and Carbapenemase Producing Gram Negative Species**

Author Block:

M. R. Jacobs[1], S. Bajaksouzian[1], K. M. Papp-Wallace[2], R. A. Bonomo[2]; [1]CWRU,UHCMC, Cleveland, OH, [2]Cleveland VAMC, CWRU, Cleveland, OH

Abstract Body:

Background: WCK 4282 is a high dose combination of cefepime (FEP) with tazobactam (TAZO) in Phase I clinical trials. This combination targets a broader spectrum of activity than piperacillin-tazobactam (PIP-TAZO), particularly against PIP-TAZO resistant ESBL-producing Enterobacteriaceae. **Methods:** In vitro susceptibilities of FEP-TAZO (WCK 4282, Wockhardt Research Center, India) and comparator agents including PIP-TAZO, FEP, imipenem (IMI) and meropenem (MER) were tested by CLSI broth microdilution. PIP was tested with TAZO at a fixed concentration of 4 mg/L and FEP with TAZO at fixed concentrations of 4 and 8 mg/L. Isolates tested were from a genetically well-characterized collection of strains that included Enterobacteriaceae and non-fermenters expressing i) class A ESBLs (CTX-M, SHV and TEM types; L2), ii) KPC, OXA 23/24, NDM, VIM and L1 β-lactamases and iii) OMP deletions (Omp35, -36 and OprD). PIP-TAZO resistant ESBL-producing Enterobacteriaceae were specifically selected for inclusion in this study.**Results:** PIP-TAZO and FEP were only active against the NSBL group, with PIP-TAZO only active against 18.9% of the ESBL group. FEP-TAZO (WCK 4282), was active against 73.0% and 81.1% of the ESBL group at TAZO concentration of 4 mg/L and 8 mg/L, respectively, compared to 91.9% for IMI and MER. None of the agents tested showed good activity against carbapenemase producing groups, although FEP-TAZO was active against 45.3-50.9% of KPC strains tested.**Conclusions:** In this study FEP-TAZO (WCK 4282) demonstrated nearly 4-fold greater in vitro activity against many ESBL producing strains of Enterobacteriaceae compared to PIP-TAZO, with improved activity with TAZO at 8 mg/L compared to 4 mg/L.

Wck 4234: Synthesis and Structure-Activity Relationship (Sar) Identifying a Novel β-Lactamase Inhibitor Active against *Acinetobacter* Expressing Oxa-Carbapenemases (Ab-Oxa)

Author Block:

V. J. Patil, R. Tadiparthi, S. S. Birajdar, B. D. Dond, M. U. Shaikh, D. V. Dekhane, M. J. Pawar, S. S. Bhagwat, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background:To date, none of the clinically employed β-lactamase inhibitors are effective against carbapenamases and Class D β-lactamases produced by *Pseudomonas*, *Enterobacteriaceae* and *Acinetobacter*. Thus treatment of these infections poses significant therapeutic challenge in a clinical setting. Here, we present the SAR of a novel β-lactamase inhibitor WCK 4234, that inhibits Class D enzymes, in addition to the Class A, C and KPC. **Methods:** A novel series of DBO test compounds were synthesized by modification of the functional group at C-5 of the 1,6-diazabicyclo octane core. IC_{50} was determined using Nitrocefin as the substrate. Antibacterial synergistic effect of these compounds was evaluated with carbapenem combinations employing CLSI broth micro dilution method. **Results:** Several compounds had good enzyme inhibition (IC_{50}) against Class A and Class C β-lactamases (0.0137->10 µM). Out of these WCK 4234 had the best IC_{50} values (Class A: 0.023-0.10 µM; Class C: 0.027-0.033 µM; KPC: 0.020-0.054 µM). For Class D CHDLs, IC_{50} for WCK 4234 against OXA-23, -24, -25, -26 and OXA-27 β-lactamases were 0.702, 0.591, 0.915 and 0.512 µM respectively. Other C-5 cyano derivatives had poor Class D inhibition (IC_{50} range 1.59->10 µM). AB-OXA (n=197) MICs of imipenem and meropenem were lowered by 4-8 times in combination with WCK 4234 at 4/8 µg/mL indicating good permeation features. **Conclusions:** Of all the DBO compounds synthesized, the cyano DBO derivative WCK 4234 showed promising inhibitory activity for Class A, C, KPC and D β-lactamases. Importantly, WCK 4234 demonstrated activity in whole-cell Acinetobacter MIC tests.

Publishing Title:

Activity of Ceftolozane-Tazobactam (TOL/TAZ) against Drug-Resistant Gram-Negative Pathogens Collected from USA Medical Centers in 2015

Author Block:

M. D. Huband, R. K. Flamm, R. N. Jones, H. S. Sader, D. J. Farrell; JMI Lab., North Liberty, IA

Abstract Body:

Background: TOL/TAZ is an antipseudomonal cephalosporin/β-lactamase inhibitor combination that received USA FDA approval for the treatment of complicated intra-abdominal and complicated urinary tract infections including pyelonephritis in December 2014.**Methods:** Susceptible (S) and multidrug resistant (MDR) *Pseudomonas aeruginosa* (PSA) and Enterobacteriaceae (ENT) isolates collected from medical centers in the USA during 2015 were tested using a reference broth microdilution method against TOL/TAZ (TAZ at fixed 4 µg/mL) and comparator compounds including ceftazidime (CAZ), cefepime (FEP), meropenem (MEM), and piperacillin-tazobactam (P/T). USA-FDA S breakpoints were applied for TOL/TAZ (ENT, ≤2 µg/mL; PSA, ≤4 µg/mL); CLSI breakpoints were applied for comparator compounds.**Results:** Most CAZ non-S (NS), MEM NS, and MDR PSA isolates were S to TOL/TAZ ($MIC_{50/90}$, 1/8 µg/mL; 81.0-88.5% S) whereas S to comparators including CAZ (0.0-57.3% S), FEP (41.4-64.6% S), MEM (0.0-46.8% S) and P/T (10.3-45.8% S) was substantially lower (Table). TOL/TAZ was less active against extensively drug-resistant (XDR) PSA ($MIC_{50/90}$, 2/32 µg/mL; 69.0% S), however, comparator compounds including CAZ, MEM and P/T were inactive (0.0-6.9% S) against XDR PSA. Only colistin (100.0% S) was more active than TOL/TAZ against XDR PSA. TOL/TAZ was also very active against ESBL-phenotype *E. coli* ($MIC_{50/90}$, 0.25/2 µg/mL) with 93.7% S and was more active than CAZ, FEP and P/T (21.4, 23.2, and 88.2% S, respectively). Compared to CAZ (8.6-10.4% S), FEP (15.7-24.4% S), and P/T (38.8-42.9% S), TOL/TAZ ($MIC_{50/90}$, 2/>32 µg/mL; 51.6-54.3% S) was more active against MDR Enterobacteriaceae and ESBL-phenotype *Klebsiella pneumoniae* (KPN).**Conclusions:** TOL/TAZ was highly active against CAZ NS, MEM NS and MDR PSA and ESBL-phenotype isolates collected from patients in USA medical centers during 2015. The potent *in vitro* activity of TOL/TAZ against these drug-resistant isolates support continued development studies with this antibacterial combination.

***In Vitro* Activity of Ceftolozane-Tazobactam against *Pseudomonas aeruginosa* and *Enterobacteriaceae* Isolates Collected from Medical Centers in the USA (2015)**

Author Block:

M. D. Huband, R. K. Flamm, R. N. Jones, H. S. Sader, D. J. Farrell; JMI Lab., North Liberty, IA

Abstract Body:

Background: Ceftolozane-tazobactam (TOL/TAZ) is an antipseudomonal cephalosporin combined with a β-lactamase inhibitor approved for the treatment of complicated intra-abdominal infections (cIAI; in combination with metronidazole) and complicated urinary tract infections (cUTI), including pyelonephritis in the United States (USA).**Methods:** *Pseudomonas aeruginosa* (PSA) and Enterobacteriaceae (ENT) isolates collected from USA medical centers during 2015 were tested using a reference broth microdilution method for susceptibility (S) to TOL/TAZ (TAZ at fixed 4 µg/mL) and comparator compounds including ceftazidime (CAZ), cefepime (FEP), meropenem (MEM), and piperacillin-tazobactam (P/T). USA-FDA breakpoints for S were applied for TOL/TAZ (≤2 µg/mL for ENT; ≤4 µg/mL for PSA); CLSI breakpoints were applied for comparator compounds.**Results:** TOL/TAZ was highly active against contemporary PSA isolates (n=507; 97.6% S) with $MIC_{50/90}$ values of 0.5/1 µg/mL (Table). Against PSA, TOL/TAZ was more active than CAZ, FEP, MEM, and P/T (81.1-88.3% S) and comparable in activity to colistin ($MIC_{50/90}$, ≤0.5/1 µg/mL; 99.8% S) and amikacin ($MIC_{50/90}$, 4/8 µg/mL; 95.3% S). TOL/TAZ was very active against ENT (n=3,800; $MIC_{50/90}$, 0.12/0.5 µg/mL) with 94.9% S and was more active than CAZ, FEP and P/T (87.0-92.6% S). Against *E. coli* (43.6% of ENT), TOL/TAZ was highly active ($MIC_{50/90}$, 0.12/0.25 µg/mL) with 99.1% S. Similarly, against *Klebsiella pneumoniae* (KPN, 22.5% of ENT), TOL/TAZ ($MIC_{50/90}$, 0.25/1 µg/mL; 92.5% S) was more active than CAZ, FEP and P/T (85.0-89.6% S). Slightly reduced S was observed for TOL/TAZ against *Citrobacter* spp. (89.4% S) and *Enterobacter* spp. (85.5% S) compared to FEP (92.5-97.7% S) and MEM (97.3-100.0%).**Conclusions:** TOL/TAZ demonstrated potent *in vitro* activity against PSA and ENT isolates from patients in USA medical centers during 2015. The activity of TOL/TAZ against these contemporary isolates support the continued development of this antibacterial combination.

Antibacterial Activity of Avibactam Combinations Against Recent Carbapenemase-producing *Enterobacteriaceae* Clinical Isolates

Author Block:

Y. Zhang, A. Kashikar, C. Brown, G. Denys, **K. Bush**; Indiana Univ., Bloomington, IN

Abstract Body:

Background: Avibactam is a novel non-beta-lactam beta-lactamase inhibitor recently approved in combination with ceftazidime to treat serious, multidrug-resistant nosocomial infections. In this study avibactam was combined with either ceftazidime (CAZ), ceftaroline (CPT) or aztreonam (ATM) to determine its ability to potentiate their activity against a recent collection of carbapenem-resistant *Enterobacteriaceae* (CRE).**Materials:** CRE isolates collected from central Indiana Health Care Centers from 2010 - 2013 (n=110) were characterized for carbapenemase genes by PCR and sequencing. MICs for avibactam (AVI) combinations, meropenem (MEM) and piperacillin-tazobactam (PTZ) were determined in broth microdilution assays according to CLSI standards, with AVI and tazobactam tested at a fixed 4 μg/ml.**Results:** Serine carbapenemases from 96 *Klebsiella pneumoniae*, 6 *Escherichia coli*, 3 *Serratia marcescens* and 2 *Enterobacter cloacae* isolates included 16 KPC-2- and 91 KPC-3-producing strains. SME-1 was in 3 additional *S. marcescens* isolates. Metallo-beta-lactamases (MBLs) were stably co-produced with KPC-3 in *E. cloacae* (VIM-1, n=2), *E. coli* (VIM-1, n=1) and *K. pneumoniae* (NDM-1, n=1). All isolates were resistant to MEM (MIC >=4 μg/ml); only two isolates (SME-1/*S. marcescens*) had PTZ MICs <128 μg/ml. At least 98% of the isolates were resistant to CAZ, CPT or ATM. The addition of AVI to CAZ and CPT lowered CAZ and CPT MICs to 8 μg/ml for all isolates, except for the 4 MBL producing strains. ATM MICs with AVI were <=8 μg/ml for all isolates, including those with MBLs; 96% (106/110) of all isolates had an ATM MIC <=0.5μg/ml.**Conclusions:** Avibactam together with ceftazidime, ceftaroline or aztreonam lowered MICs of the partner beta-lactams to 4 μg/ml or less for at least 95% of the CRE tested. The added stability of aztreonam to MBL hydrolysis provided a lowering of all ATM MICs to at least 8 μg/ml, indicating the potential utility of these combinations to treat infections caused by carbapenemase-producing bacteria.

Agent	MIC range in μg/ml	MIC_{50} in μg/ml	MIC_{90} in μg/ml
Ceftazidime	1 - >128	>128	>128
Ceftazidime-Avibactam	0.12 - >128	1	2
Ceftaroline	32 - >128	>128	>128

Ceftaroline-Avibactam	<=0.06 - >128	0.5	2
Aztreonam	8 - 128	64	128
Aztreonam-Avibactam	0.06 - 8	0.25	0.5
Meropenem	4- >16	>16	>16
Piperacillin-Tazobactam	<=2 - >128	>128	>128

Coumarin Phosphonates Behave as Inhibitors of the Kpc-2 Carbapenemase

Author Block:

O. Pemberton, Y. Chen; Univ. of South Florida, Tampa, FL

Abstract Body:

Background: Each year in the United States an estimated 2 million people are infected with antibiotic-resistant bacteria, with at least 23,000 people dying as a direct result of those infections. Among all of the bacterial resistance problems, Gram-negative bacterial pathogens pose the greatest threat since they have acquired resistance to many antibiotics, including the beta-lactam antibiotics. The most widespread mode of beta-lactam resistance involves the expression of enzymes called beta-lactamases. Disclosed herein are a series of novel derivatives of coumarin phosphonates, which act as inhibitors of the class A KPC-2 carbapenemase, with the best compound displaying a K_i of 1.5 μM. The complex crystal structure of six compounds in the KPC-2 active site have been solved. **Methods**: The gene encoding KPC-2 was cloned into the pET-GST vector containing an N-terminal hexa-histidine tag. KPC-2 was purified to homogeneity using nickel affinity and gel-filtration chromatography. Steady-state kinetic parameters were determined by using a Biotek Cytation Multi-Mode Reader. Compounds were tested for synergy with the carbapenem antibiotic, imipenem, against BL21 (DE3) *E. coli* expressing KPC-2. MIC values were determined with the Mueller-Hinton broth microdilution method. Crystallization trials were carried out by using Qiagen crystallization kits. After an initial crystallization hit was found, conditions were optimized and crystals were used for compound soaking trials. X-ray data was processed with iMOSFLM, Phenix suite, and WinCoot. **Results**: Steady-state kinetic analysis demonstrated that all the coumarin phosphonate derivatives inhibited KPC-2 with micromolar potency, with the best two compounds possessing a K_i of 1.5 μM and 5.7 μM. The 1.5 μM inhibitor was able to reduce the MIC of imipenem eight-fold in BL21 (DE3) *E. coli* expressing KPC-2. The complex crystal structures demonstrated that the inhibitors form hydrogen bonds with Ser70, Ser130, Thr235, and Thr237. The inhibitors also form a stacking interaction with Trp105. **Conclusions**: The emerging health threat posed by antibiotic resistance is an issue that needs to be addressed. Use of a coumarin phosphonate compound could be useful in potentiating the action of beta-lactam antibiotics in the treatment of multi-drug resistant bacterial infections.

Ceftazidime-Avibactam Antimicrobial Activity When Tested Against Gram-Negative Bacteria Isolated from Intensive Care Unit (ICU) Patients with Pneumonia (2012-2014)

Author Block:

H. S. Sader, M. Castanheira, R. K. Flamm, D. J. Farrell, R. N. Jones; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: Ceftazidime-avibactam (CAZ-AVI) consists of CAZ combined with the novel non-β-lactam β-lactamase (BL) inhibitor AVI, which inhibits extended-spectrum BLs (ESBLs), KPCs, AmpCs and some OXA enzymes. CAZ-AVI is under clinical development for treatment of nosocomial pneumonia.**Methods**: Clinical isolates were consecutively collected from 51 United States (USA) medical centers in 2012-2014 as part of the INFORM Surveillance Program and tested for susceptibility (S) at a central laboratory by reference broth microdilution methods. Results for 1,428 Gram-negative (GN) isolates from ICU patients with pneumonia were evaluated. BL encoding genes were evaluated for all *Klebsiella* spp. (KSP) and *E. coli* (EC) with an ESBL-phenotype (n=98) by microarray-based assay.**Results**: The most frequent GN organisms isolated were *P. aeruginosa* (PSA; 28.5% of GN isolates), followed by KSP (23.8%), *Enterobacter* spp. (EBS; 12.0%) and EC (11.7%). CAZ-AVI was the most active β-lactam tested against PSA (96.1% S) and exhibited good activity against multidrug-resistant (MDR; 82.3% S) and extensively drug-resistant (XDR; 76.3% S) PSA (Table). All Enterobacteriaceae (ENT) strains were S to CAZ-AVI except for one EBS with a CAZ-AVI MIC of 16 μg/mL (99.9% S), which had negative results for all BLs tested. ENT S rates for piperacillin/tazobactam (P/T) and meropenem (MEM) were 84.9 and 96.4%, respectively. MEM exhibited limited activity against ESBL-phenotype KSP (59.2% S) and MDR-ENT (63.5% S), whereas CAZ-AVI was very active against these resistant subsets (98.8-100.0% S). CAZ-AVI, colistin and tigecycline were the only agents active against XDR-ENT and carbapenem-resistant ENT (CRE). *Acinetobacter* spp. showed low S rates for all agents except colistin (94.7% S).**Conclusions**: CAZ-AVI demonstrated potent activity against a large collection of GN isolates from ICU patients with pneumonia. These *in vitro* results support further development of CAZ-AVI for treatment of nosocomial pneumonia in the USA.

Antimicrobial Activity of Ceftazidime-Avibactam and Comparator Agents When Tested against Bacterial Isolates Causing Infection in Cancer Patients (2012-2014)

Author Block:

H. S. Sader, D. J. Farrell, R. K. Flamm, M. Castanheira, R. N. Jones; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: Avibactam (AVI) inhibits classes A (including ESBLs and KPCs), C (AmpC) and some D β-lactamases (BL), restoring ceftazidime (CAZ) activity against Gram-negative (GN) organisms producing these enzymes.**Methods:** A total of 623 Gram-negative (GN) isolates were collected from 52 medical centers over three years (2012-2014) from patients with cancer as part of the International Network for Optimal Resistance Monitoring (INFORM) program in the United States. Isolates were tested for susceptibility (S) against CAZ-AVI (AVI at fixed 4 μg/mL) and comparator agents at a central laboratory by a reference broth microdilution method. BL encoding genes were evaluated for all *E. coli* (EC) and *Klebsiella* spp. (KSP) with an extended-spectrum BL (ESBL) phenotype by microarray-based assay.**Results:** The isolates were predominantly from bloodstream (33.2%) and skin/soft tissue (26.0%), and the most frequent GN organisms were EC (31.5%), KSP (20.9%), *P. aeruginosa* (PSA; 14.1%) and *Enterobacter* spp. (EBS; 12.7%). ESBL-phenotype was observed among 17.3 and 11.2% of EC and KSP, respectively; and 21.5% of EBS were ceftazidime (CAZ)-non-S. All Enterobacteriaceae (ENT; n=486) were S to CAZ-AVI with the highest MIC value at 1 μg/mL. Meropenem (MEM) was also very active against ENT overall (99.6% S); but showed more limited activity against ESBL-phenotype KSP (84.6% S) and multidrug-resistant (MDR) ENT (93.3% S). ESBL-phenotype KSP and MDR-ENT exhibited low S to piperacillin/tazobactam (P/T; 46.2 and 51.7%, respectively), gentamicin (GEN; 46.2 and 26.7%), levofloxacin (LEV; 53.8 and 10.0%) and colistin (83.3 and 86.4%). The most active agents tested against PSA were colistin (100.0% S), amikacin (97.7% S) and CAZ-AVI (96.6% S).**Conclusions:** GN organisms isolated from cancer patients hospitalized in USA medical centers were highly S to CAZ-AVI, including PSA and MDR and/or carbapenem-resistant ENT. The role of CAZ-AVI for treatment of cancer patients should be further evaluated.

Activity of ceftazidime-avibactam tested against clinical isolates of antimicrobial resistant *Pseudomonas aeruginosa* (PSA) isolates from United States (USA) medical centers (2012-2014)

Author Block:

H. S. Sader, D. J. Farrell, R. K. Flamm, R. N. Jones; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: Avibactam (AVI) is a non-β-lactam β-lactamase (BL) inhibitor that inhibits ESBLs, KPCs, AmpCs and some OXA enzymes. Ceftazidime (CAZ)-AVI was approved by the USA-FDA for treatment of intra-abdominal and urinary tract infections in 2015, and is under clinical development for treatment of pneumonia.**Methods**: 5,643 PSA isolates (one per patient) were consecutively collected in 2012-2014 from 74 USA medical centers (37 states from all 9 census regions) by the INFORM Surveillance Program. CAZ-AVI (AVI, fixed 4 μg/mL) and comparators were tested for susceptibility (S) by CLSI broth microdilution methods. The isolates were predominantly from pneumonia (39.8%) and skin/soft tissue (23.7%).**Results**: CAZ-AVI was active against 96.7% of strains at the USA-FDA S breakpoint of ≤8 μg/mL (Table), while S rates for CAZ, cefepime, piperacillin/tazobactam (P/T) and meropenem (MEM), were 83.8, 84.5, 79.9 and 82.3%, respectively. Colistin (COL) and amikacin (AMK) and were active against 99.2 and 97.2% of PSA strains, respectively. High rates of cross-resistance was observed among CAZ, P/T and MEM, whereas CAZ-AVI exhibited good activity against isolates non-S to CAZ (79.6% S), P/T (84.3% S), MEM (84.8%), as well as isolates non-S to CAZ, P/T and MEM (n=610; $MIC_{50/90}$, 8/32 μg/mL; 76.6% S). Multidrug-resistant (MDR) and extensively drug-resistant (XDR) phenotypes were observed in 14.9 and 8.6% of strains, respectively. Among MDR and XDR PSA, 79.8 and 71.5% were CAZ-AVI-S, respectively, while S rates for CAZ, P/T and MEM were ≤21.8% for MDR and ≤9.2% for XDR strains. The most active compounds tested against MDR/XDR strains were COL (98.9/99.0% S), AMK (88.0/83.8% S) and CAZ-AVI (78.9/71.5% S). CAZ-AVI activity remained stable during the study period.**Conclusions**: CAZ-AVI exhibited potent *in vitro* activity and spectrum when tested against a large collection (n=5,643) of recent USA PSA clinical strains, and retained activity against isolates non-S to other anti-PSA β-lactams, as well as MDR and XDR strains.

***In Vitro* Activity of Ceftazidime-Avibactam (CAZ-AVI) and Comparators against Gram-Negative Pathogens Isolated from Patients in Canadian Hospitals in 2009-2015: CANWARD Surveillance Study**

Author Block:

P. Lagacé-Wiens[1], H. Adam[1], A. Denisuik[2], M. Baxter[2], J. Karlowsky[1], A. Walkty[1], D. Hoban[1], G. G. Zhanel[2], Canadian Antimicrobial Resistance Alliance; [1]Diagnostic Services Manitoba, Winnipeg, MB, Canada, [2]Univ. of Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: Avibactam, a β-lactamase inhibitor of Ambler class A, C and some class D enzymes in combination with ceftazidime, is approved for the treatment of complicated urinary tract (cUTI) and intra-abdominal infections (IAI). We determined the in vitro activity of ceftazidime (CAZ) with avibactam (4 μg/mL concentration) and comparators versus Gram-negative pathogens, including extended-spectrum β-lactamase producing (ESBL) and cephalosporin-resistant, non-ESBL-producing *Enterbacteriaceae*, and *Pseudomonas aeruginosa* isolates recovered from October 2009 to December 2015 from patients in medical and surgical wards, intensive care units, clinics, and emergency rooms at 15 Canadian hospitals.**Methods:** Antimicrobial susceptibility testing was performed using broth microdilution panels following CLSI recommendations (M07-A10). Susceptibility was defined in accordance with CLSI, except for CAZ-AVI, where FDA breakpoints were used. Cephalosporin-resistant *Escherichia coli* and *Klebsiella* spp. isolates were genetically characterized for ESBL-production using PCR and sequence analysis.**Results:** The activity of CAZ-AVI and comparators is summarized in the table.

MIC_{90}/% susceptible				
	CAZ-AVI	Ceftazidime	Meropenem	TZP
Escherichia coli (4757)	0.25/100	1/93.8	≤0.03/100	4/97.8

CAZ-AVI: ceftazidime-avibactam, CRO-R: ceftriaxone-resistant; CAZ-R: ceftazidime-resistant; TZP: piperacillin-tazobactam, ERT-R: ertapenem-resistant, ESBL: extended spectrum β-lactamase-producing. ‡63.0% of isolates had MIC ≤ 8 μg/mL *31.1% of isolates had MIC ≤ 8μg/mL				

Conclusions: CAZ-AVI demonstrated potent in vitro activity against clinical isolates of *Enterobacteriaceae*, including those with resistance to oximinocephalosporins by a variety of mechanisms. *P. aeruginosa* were highly susceptible to CAZ-AVI overall, while CAZ, MER and TZP-resistant *P. aeruginosa* were moderately susceptible to CAZ-AVI. Activity against *A. baumannii* was not improved compared to CAZ alone. Activity against *S. maltophilia* was poor but somewhat better than CAZ alone. CAZ-AVI may be useful for the treatment of cUTI and IAI caused by β-lactam-resistant *Enterobacteriaceae* and *P. aeruginosa*.

Efficacy of OP0595, a Novel Serine-β-Lactamase Inhibitor, in a Mouse Pneumonia Model Caused by ESBL-Producing *K. pneumoniae*

Author Block:

N. Kaku, K. Kosai, K. Takeda, Y. Morinaga, T. Miyazaki, K. Izumikawa, H. Mukae, **K. Yanagihara**; Nagasaki Univ., Nagasaki, Japan

Abstract Body:

Background: OP0595 is a novel serine beta-lactamase inhibitor. Since it acts at PBP2 and shows an enhancer effect with beta-lactams, which inhibit PBP3, the combination of OP0595 and beta-lactams such as cefepime (FEP), showed good *in-vitro* antimicrobial activities. In this study, we investigated the antimicrobial effect of the combination of OP0595 and FEP in a pneumonia mouse model. **Methods:** A pneumonia mouse model was generated by the transtracheal-inoculation of ESBL-Kpn at 10^6 CFU/mouse. We treated the mice by intraperitoneal with normal saline (control), 20 mg / kg of OP0595, 100mg / kg of FEP or combination of OP0595 and FEP at an interval of every 12 hours (from 12 hours post-inoculation).**Results:** In the survival study, only combination therapy improved the survival rates, and the survival rate was significantly higher in combination therapy than the others ($P < 0.001$, log-rank test) **(Fig.A)**. The bacterial counts in the lungs had significantly decreased in combination, compared with the others ($P < 0.001$ versus the others) **(Fig.B)**. In the combination therapy, the efficacies in survival rate and bacterial counts were concentration dependent **(Fig.C and D)**. On the basis of the MICs against the ESBL-Kpn and pharmacokinetic analysis, the %T>MIC for 4, 20 or 100 mg/kg of FEP and 20 mg/kg of OP0595 at an interval of every 12 hours were calculated as 0, 3.1, 9.6 and 6.5% in alone, and all 14.1% in combinations.**Conclusions:** The combination of OP0595 and FEP showed good *in-vivo* antimicrobial effect against ESBL-Kpn. Since the %T>MIC for all doses of FEP in combination with OP0595 was the same, OP0595 might act as a β-lactamase-independent β-lactam enhancer to FEP.

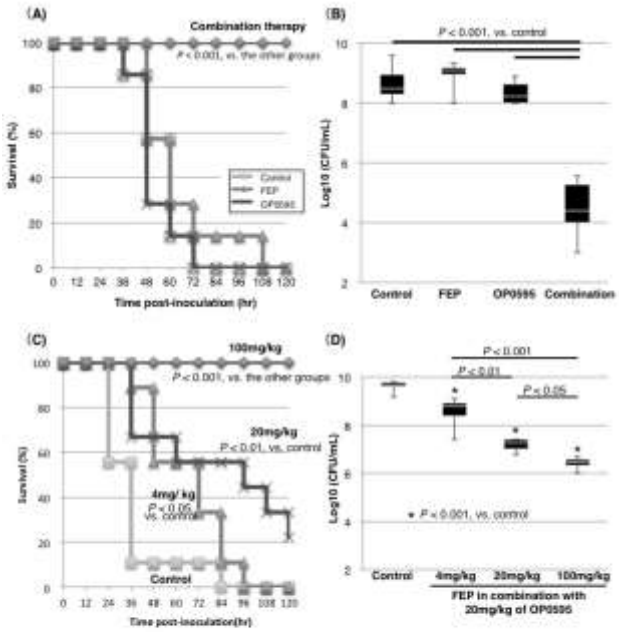

Figure. The survival rate (A and C) and bacterial count in the lungs (B and D).
We treated the mice by intraperitoneal with normal saline (control), 20 mg/kg of OP0595, 100 mg/kg of FEP or combination of OP0595 and FEP (combination) (A and B). We treated the mice with intraperitoneal with normal saline (control) or 4, 20, or 100 mg/kg of FEP in combination with 20 mg/kg of OP0595 (C and D). The survival rate until 120 hours post-inoculation (A and C) and the bacterial count in the lungs at 36 hours post-inoculation were evaluated (B and D). n=6 in each groups (D)

Antimicrobial Susceptibility and Molecular Epidemiology of *Clostridium difficile* Isolates from US Patients with *C. difficile*-Associated Diarrhea (CDAD) from LCD-CDAD-11-06

Author Block:

D. Devaris[1], L. Chesnel[1], S. E. Dale[2], **J. Nary**[2], S. Johnson[3], S. P. Sambol[3], D. M. Citron[4], R. V. Goering[5]; [1]Merck & Co., Inc., Kenilworth, NJ, [2]ACM Med. Lab./ACM Global Central Lab., Rochester, NY, [3]Edward Hines, Jr., Veterans Admin. Hosp., Hines, IL, [4]R.M. Alden Res. Lab., Culver City, CA, [5]Creighton Univ. Sch. of Med., Omaha, NE

Abstract Body:

Background: This study determined susceptibility and epidemiology of *Clostridium difficile* isolates from North America collected from 2012-2015 during the conduct of LCD-CDAD-11-06 (NCT01598311), a phase 3, randomized, double-blind, multi-center trial of surotomycin vs vancomycin in adults with CDAD.**Methods:** *C. difficile* isolates were recovered from baseline fecal samples of microbiological modified intent-to-treat patients from clinical centers in the US (57) and Canada (8). Susceptibility testing was performed by broth microdilution and CLSI-recommended agar dilution methods. Isolates were typed by ribotyping and restriction endonuclease analysis (REA).**Results: Results:** Isolates (N=424) were evaluated from 328 patients in the US and 96 in Canada. In the US fecal samples, 15.9% of strains vs 19.8% of strains from Canadian centers were identified as the epidemic strain BI/NAP1/027 (RT-027). The REA type Y/ribotype 014/020 strain was the most common type found in US patients at 22.0%. Isolates of REA type BK/ribotype 078 were also recovered from US patients. Against RT-027 strains, the *in vitro* activities of surotomycin and vancomycin were similar ($MIC_{50/90}$=0.25/0.25 µg/mL by broth microdilution; $MIC_{50/90}$=1/2 µg/mL by agar dilution). Against non-RT-027 strains, the *in vitro* activity of surotomycin and vancomycin were similar ($MIC_{50/90}$=0.5/2 µg/mL by agar dilution; $MIC_{50/90}$=0.25/0.25 and 0.25/0.5 µg/mL by broth microdilution for surotomycin and vancomycin respectively).**Conclusions:** In this study, the Y/014/020 strain of *C. difficile* was the most prevalent type isolated from US centers. The epidemic BI/NAP1/027 strains represented 15.9% and 19.8% of the US and Canadian isolates, respectively. $MIC_{50/90}$ values and ranges from this study are in agreement with those determined previously from other clinical trials and surveillance studies. From these data, epidemiological cut-off values of 4 µg/mL for agar dilution and 2 µg/mL for broth microdilution can be proposed.

Ridinilazole (Rdz) for *Clostridium difficile* Infection (Cdi) - Further Data from the Codify Phase 2 Clinical Trial

Author Block:

R. J. Vickers[1], M. H. Wilcox[2], D. N. Gerding[3], CoDIFy Study Group; [1]Summit, Abingdon, United Kingdom, [2]Leeds Hosp., Leeds, United Kingdom, [3]Loyola Univ., Chicago, IL

Abstract Body:

Background: CDI is the most common hospital acquired infection in the USA. RDZ is a novel antimicrobial for CDI with a highly targeted spectrum of activity expected to reduce collateral damage to gut microbiota during therapy. Here we report additional safety and efficacy data from the CoDIFy proof-of-concept Phase 2 clinical trial.**Methods:** This multi-centre, double-blind, study randomized 100 patients 1:1 to 10 days RDZ 200 mg BID or vancomycin (VAN) 125 mg QID treatment. Clinical response was assessed 2 days after end of therapy (EOT). Primary endpoint was non-inferiority on sustained clinical response (SCR), defined as clinical response at EOT with an absence of recurrent disease for the next 30 days. The primary analysis population was the modified intent-to-treat (MITT) which included all randomized subjects with a diagnosis confirmed by presence of free toxin in stool.**Results:** The study exceeded its primary endpoint, with RDZ shown to be superior on SCR to VAN with rates of 66.7% and 42.4% respectively (difference in treatment proportions 21.1%; 90% CI 3.1, 39.1). Rates of clinical cure at EOT were 77.8% and 69.7% for RDZ and VAN, respectively (difference in treatment proportions 8.3%; 90% CI -9.3, 25.8). A marked reduction in recurrent CDI for RDZ (14.3%) compared with VAN (34.8%) accounted for superior SCR. When SCR for the MITT was analysed across subgroups at high risk of recurrence, RDZ was favoured over VAN with estimated improvements (90% CI) for patients >75 years of age of 42.7% (9.7, 75.7), for severe disease of 15.9% (-29.8, 61.6) and for prior episodes of CDI of 19.9% (-22.8, 62.5). There were no clinically important differences in overall adverse events (AEs) or serious adverse events (SAEs) between groups. 41 vs 40 AEs and 8 vs 9 SAEs were recorded for RDZ and VAN, respectively. RDZ was associated with reduced gastrointestinal AEs (40% vs 56%). Two deaths on the study were both in the VAN arm. Administration of RDZ resulted in day 5 faecal concentrations markedly above MIC (mean 1298 µg/g) and low systemic exposure (mean day 5 plasma concentrations 0.16 ng/mL).**Conclusions:** RDZ has been shown in an RCT to be highly effective at reducing recurrent CDI which is likely due to its microbiome sparing characteristics. Further clinical development in Phase 3 studies is warranted.

Ridinilazole For *Clostridium difficile* Infection (CDI). Reductions in Calprotectin and Lactoferrin During Therapy

Author Block:

Y. Ke[1], **R. Vickers**[2], Y-X. Li[1]; [1]Medpace Bioanalytical Lab., Cincinnati, OH, [2]Summit PLC, Abingdon, United Kingdom

Abstract Body:

Background: CDI is characterised by inflammation of the intestine due to secretion of toxins by *C. difficile*. Ridinilazole (RDZ) is a novel antimicrobial for CDI that has been shown in a Phase 2 clinical trial to be effective a reducing rates of recurrent CDI when compared with vancomycin (VAN). Here we report data on reductions in the key inflammatory markers calprotectin and lactoferrin monitored in faecal samples collected during the course of therapy in the Phase 2 clinical trial.**Methods:** Subjects were randomised to 10 days of either ridinilazole or vancomycin treatment. Faecal samples were collected at the time of randomisation (prior to initiation of therapy) and at day 5 and day 10. Concentrations of lactoferrin and calprotectin were assessed by validated methods, following FDA and EMA guidelines, using commercially available ELISA kits from ALPCO (Salem, NH, USA) and BioLegend (San Diego, CA, USA) respectively. Only those subjects with a diagnosis of CDI confirmed by the presence of free toxin in stool were considered for this analysis.**Results:** A total of 69 subjects (36 RDZ; 33 VAN) were analysed. Median baseline (BL) faecal concentrations of lactoferrin for subjects receiving RDZ or VAN were 183.95 µg/g and 263.37 µg/g respectively. For calprotectin median BL concentrations were 1948.10 µg/g and 2446.13 µg/g for RDZ and VAN treated subjects respectively. Over the course of therapy, 1.34 and 1.30 log10 reductions in median lactoferrin concentrations were recorded for RDZ and VAN respectively for all subjects. When considering only those subjects with severe CDI, greater reductions in lactoferrin were observed with RDZ therapy with median log10 reductions of 1.93 compared with only a 0.62 recorded for VAN treated subjects. Similar results were observed with calprotectin with 0.89 and 0.92 log10 reductions for all patients receiving either RDZ or VAN, respectively, whereas for those patients with severe CDI 1.70 and 0.22 Log10 reductions with RDZ or VAN were recorded.**Conclusions:** These data indicate that RDZ therapy is associated with more pronounced reductions in key markers of intestinal inflammation for subjects with severe CDI when compared to subjects receiving VAN.

Analysis of *C. difficile* Isolated from Stools of Patients Enrolled in a Phase II Clinical Trial of Ridinilazole (Smt 19969)

Author Block:

D. R. Snydman[1], L. A. McDermott[2], C. M. Thorpe[2], J. Chang[2], J. Wick[2], S. T. Walk[3], R. Vickers[4]; [1]Tufts Med. Ctr. and Tufts Univ. Sch. of Med., Boston, MA, [2]Tufts Med. Ctr., Boston, MA, [3]Montana State Univ., Bozeman, MT, [4]Summit Plc, Abingdon, United Kingdom

Abstract Body:

Background: Ridinilazole is a novel agent being developed for treatment of *C. difficile*-associated diarrhea (CDAD). A phase II randomized trial comparing ridinilazole orally to vancomycin in patients with moderate and some severe CDAD has recently been successfully completed. As part of the clinical trial analysis, stools from patients enrolled in the trial were evaluated for quantity of *C. difficile, C. difficile* ribotype, toxin gene profile and *in-vitro* susceptibility to a panel of antimicrobial agents. **Methods:** Stools from patient enrolled in the phase II clinical trial of patients with CDAD were sent to Tufts Medical Center. Following isolation and confirmation of *C. difficile,* MICs for ridinilazole and a panel of antimicrobial agents were measured by agar dilution using CLSI M11-A8 methods. Toxin gene profiling was performed using the method of Persson et al. and ribotyping was determined by capillary gel electrophoresis.**Results:** Of 100 patients enrolled in the phase 2 trial, 91 had day 1 samples, 90 (98.9%) of whom had isolates of *C. difficile* recovered. One patient had 2 different morphologies of *C. difficile* on day 1; these proved to be 2 different strains for a total of 109 strains evaluated. The median colony count was 1.2×10^4 (range 2.5×10^2 - 7.0×10^6). There were 18 patients with recurrence, all grew *C. difficile*. Ribotypes of patients with recurrence matched initial isolates, except in one instance. All isolates were inhibited by ridinilazole with a median MIC of 0.12 mcg/ml (range 0.06-0.5), including all isolates from patients with recurrence. The median vancomycin MIC was 1 mcg/ml (range 0.5-4 mcg/ml). The most common ribotypes seen in this trial were 014-20 (14), 027 (13), 311 (8), and 002 (7). Toxin gene profiling was able to be performed on 99.1% of isolates. Binary toxin genes (*cdtA/cdtB)* were present in 33% of strains where toxin was detectable.**Conclusions:** Ridinilazole was active against *C. difficile* isolates from CDAD patients enrolled in this clinical trial. Recurrence was not associated with a change in susceptibility. A relatively small proportion of isolates in this trial were ribotype 027.

Resistance Development Studies with Ridinilazole (RDZ) and *Clostridium difficile*

Author Block:

D. Hall[1], C. Pillar[1], R. Vickers[2], **D. Shinabarger**[1]; [1]Micromyx, LLC, Kalamazoo, MI, [2]Summit Therapeutics, Oxford, United Kingdom

Abstract Body:

Background: *C. difficile* infection is a major burden on healthcare resources. RDZ (SMT19969) is a novel antibiotic with good *C. difficile* activity but sparing of the gut microbiota. Resistance development of *C. difficile* to RDZ and comparators was evaluated through spontaneous mutation frequency (FREQ) and serial passage studies.**Methods:** Susceptibility testing of RDZ and comparators was determined by standard agar and broth methods (CLSI M11) against *C. difficile* isolates. FREQ testing was conducted with agar plates containing 4 and 8-fold the MIC of RDZ or vancomycin (VAN) for 2 *C. difficile* isolates. Serial passage studies were conducted with RDZ, fidaxomicin (FDX), VAN, or ciprofloxacin (CIP) using the broth macrodilution method and Brain Heart Infusion broth. Growth from sub-MIC tubes at each passage was used as the inoculum for each subsequent passage. A total of 15 passages were completed with RDZ and the comparator agents.**Results:** The 2 isolates for the FREQ study had initial RDZ agar dilution MIC values of 0.25 μg/mL, and FREQ values are shown in the table below.

Organism	Spontaneous Mutation Frequency			
	Ridinilazole		Vancomycin	
	4X MIC	8X MIC	4X MIC	8X MIC
C. difficile ATCC 700057	7.0×10^{-8}	5.6×10^{-8}	$\leq 7.0 \times 10^{-9}$	$\leq 7.0 \times 10^{-9}$
C. difficile NCTC 13307 (toxin AB)	1.4×10^{-8}	$\leq 7.0 \times 10^{-9}$	$\leq 7.0 \times 10^{-9}$	$\leq 7.0 \times 10^{-9}$

At 4-fold the MIC, RDZ yielded FREQ values of $1.4\text{-}7.0 \times 10^{-8}$, and at 8-fold the MIC the FREQ values ranged from $\leq 7.0 \times 10^{-9}$ to 5.6×10^{-8}. Agar dilution susceptibility testing of RDZ spontaneous mutants revealed that most isolates did not have elevated RDZ MIC values. No spontaneous mutants were obtained with VAN. For serial passage studies, no resistance development occurred after 15 passages with RDZ or FDX for the 2 evaluated isolates, and low level resistance detected with VAN and CIP was generally lost after transfer over drug-free

agar.**Conclusions:** Very few spontaneous mutants were selected in the presence of RDZ, and confirmatory susceptibility testing with mutants revealed a 4-fold increase in the RDZ MIC for a few of the *C. difficile* ATCC 700057 spontaneous mutants only. No resistance development occurred for RDZ after 15 serial passages with 2 *C. difficile* isolates.

***In Vivo* Efficacy of Dual-Action Molecule Tnp-2092 in Hamster and Mouse *Clostridium difficile* Infection Models**

Author Block:

X. XU[1], W. J. WEISS[2], G. T. ROBERTSON[3], F. GUO[4], C. LI[4], J. ZHANG[4], L. JIANG[4], M. YANG[4], D. XU[4], X. WANG[1], Z. MA[1]; [1]TENNOR THERAPEUTICS LTD., SUZHOU, China, [2]Univ. OF NORTH TEXAS HEALTH Sci. CENTER, FORT WORTH, TX, [3]COLORADO STATE Univ., Fort Collins, CO, [4]WuXi AppTec (Shanghai) Co., Ltd, SHANGHAI, China

Abstract Body:

Background: TNP-2092 is a dual-acting molecule in development for the treatment of diseases associated with GI tract infections. TNP-2092 is GI restricted following oral administration and is efficacious in a mouse *H. pylori* infection model. Current studies sought to evaluate the *in vivo* efficacy of TNP-2092 in hamster and mouse *C. difficile* infection models.**Methods:** *In vitro* MICs were determined by the agar dilution method (M11-A6) using a panel of isogenic *C. difficile* strains bearing specific resistance mutations. For the hamster model, animals were pretreated with 10 mg/kg clindamycin on Day -1 and infected with 2-5 x 10^5 CFU *C. difficile* ATCC #43255 by oral gavage on Day 0. Drug treatment (20 mg/kg, PO) started 4 hours after infection and was given once daily for 5 days. Hamsters were monitored for morbidity and mortality during the 5 days of treatment and an additional 16 days for potential relapse. For the mouse model, all animals were administered cefoperazone in drinking water for 10 days followed by a single injection of clindamycin. The mice were then infected with ~5 x 10^6 CFU *C. difficile* ATCC #43255 by oral gavage. Drug treatments began 4 hours later and were given once daily for 7 days by oral gavage. TNP-2092 was given at 6.67, 20 and 60 mg/kg, vancomycin and metronidazole were given at 20 mg/kg doses. The animals were monitored for morbidity and mortality during the 7 days of treatment and an additional 16 days for relapse.**Results:** TNP-2092 treatment protected 100% hamsters from death during both the treatment and relapse period, while vancomycin only partially protected animals from death during the treatment period with all animals ultimately succumbing to infection during relapse. In the mouse model, all 3 doses of TNP-2092 rescued 100% of the infected mice and prevent relapse, while vancomycin only prevented animals from death during the treatment period but failed to provide any protection during the relapse periods.**Conclusions:** TNP-2092 is highly efficacious against lethal *C. difficile* infection in both hamster and mouse infection models.

Publishing Title:

Impact of Surotomycin and Vancomycin Exposure on the Gut Microbiota in Correlation with Clinical Outcomes in the Phase 3 LCD-CDAD-11-06 Clinical Trial

Author Block:

L. Chesnel[1], D. Devaris[1], J. Nary[2], **S. E. Dale**[2]; [1]Merck & Co., Inc., Kenilworth, NJ, [2]ACM Med. Lab./ACM Global Central Lab., Rochester, NY

Abstract Body:

Background: The impact of surotomycin and vancomycin on gut microbiota and correlation with clinical outcomes were analyzed in patients with *Clostridium difficile*-associated diarrhea (CDAD) from LCD-CDAD-11-06 (NCT01598311), a phase 3, randomized, active-controlled, double-blind trial.**Methods:** Stool specimens were recovered from the microbiological intent-to-treat population (N=577) [surotomycin 250 mg/BID (n=285); vancomycin 125 mg/QID (n=292)] at baseline, end of treatment (EOT; Day 10-13), mid-follow-up (Day 24±3), and any recurrence through Day 40-50. Analyses by standard methods included isolation of *C. difficile* and vancomycin-resistant enterococci (VRE), quantitation of *C. difficile* spores and VRE, and quantitative polymerase chain reaction for *Bacteroides fragilis* and *Bacteroides/Prevotella* groups.**Results:** Surotomycin resulted in minimal disruption of *B. fragilis* and *Bacteroides/Prevotella* groups from baseline compared with vancomycin [$p<0.001$ for difference in $\log_{10}$ CFU/mL counts between treatment groups at EOT and Day 24]. Compared with vancomycin, a decrease in VRE count was seen in surotomycin-treated patients [$p<0.001$ for difference in $\log_{10}$ CFU/mL counts between treatment groups at EOT and p=0.004 at Day 24]. *C. difficile* spore counts (mean [standard deviation]) decreased from baseline (4.68 [1.84]/4.66 [1.84] surotomycin/vancomycin) to EOT (0.94 [1.73]/0.85 [1.67]), and then increased by Day 24 to 3.41 [2.60]/3.09 [2.71]. For both treatment groups, the change from baseline to EOT or to Day 24 in $\log_{10}$ CFU/mL counts of *B. fragilis*, *Bacteroides/Prevotella*, *C. difficile* spores, and VRE was not significantly different between patients with recurrence vs those with sustained clinical response.**Conclusions:** Surotomycin treatment resulted in minimal disruption of *B. fragilis* and *Bacteroides/Prevotella* groups and decreased VRE counts compared with vancomycin. For both treatments, change from baseline to EOT and to Day 24 in *Bacteroides/Prevotella*, *C. difficile* spore, and VRE counts was not predictive of clinical outcome. These results highlight differences in the impact of surotomycin, a narrower-spectrum agent than vancomycin, on fecal microbial composition and a lack of correlation with clinical outcomes.

Surotomycin vs. Vancomycin in Adults with *Clostridium difficile*-Associated Diarrhea (CDAD): Primary Clinical Outcomes from Study LCD-CDAD-11-06

Author Block:

T. Louie[1], P. Daley[2], J. E. Lutz[3], U. Stoutenburgh[4], M. Jin[4], A. Adedoyin[4], K. Larson[4], D. Guris[4], L. Chesnel[4], Y. Murata[4]; [1]Univ. of Calgary, Calgary, AB, Canada, [2]Mem. Univ., St. John's, NL, Canada, [3]St. Charles Hlth.System, Bend, OR, [4]Merck & Co., Inc., Kenilworth, NJ

Abstract Body:

Background: Surotomycin has potent *in vitro* activity against *Clostridium difficile* and was studied in LCD-CDAD-11-06 (MK-4261 P006; NCT01598311), a phase 3, randomized, double-blind study of surotomycin vs vancomycin in adults with CDAD.**Methods:** Eligible patients (N=608) were randomized 1:1 to surotomycin 250 mg/BID po or vancomycin 125 mg/QID po for 10 days. Clinical response was defined as resolution of diarrhea at end of therapy (EOT) + 2 days and no need for additional antibiotic treatment after EOT. The primary efficacy endpoint was non-inferiority of surotomycin vs vancomycin based on difference in clinical response rates at EOT in the microbiological MITT population with a 10% non-inferiority margin. Two key secondary endpoints were superiority of surotomycin vs vancomycin clinical response over time (clinical response through EOT and sustained clinical response EOT-Day 40) and superiority of surotomycin vs vancomycin sustained clinical response at end of study (EOS; Day 40-50). Adverse events (AEs) were monitored and patients with cure at EOT were evaluated for CDAD recurrence until EOS.**Results:** Primary efficacy endpoint was met (difference, 1.4% [95% CI: -4.9, 7.6] between cure rates of 83.4%/82.1% with surotomycin/vancomycin). The first key secondary efficacy endpoint was not met (p=0.281). The other key secondary efficacy endpoint was not met (cure rates of 63.3%/59.0% for surotomycin/vancomycin; difference, 4.3% [95% CI: -3.6, 12.2]). Of surotomycin patients, 52.4% experienced ≥1 treatment-emergent AE vs 60.1% of those on vancomycin. Discontinuation of study drug due to AEs was seen in 4.4%/2.3% of the surotomycin/vancomycin groups. Serious AEs (SAEs) and deaths were reported in 11.2% and 3.1% of surotomycin vs 13.0% and 3.7% of vancomycin recipients, respectively. No deaths were deemed treatment related; 1 drug-related SAE occurred in the vancomycin group.**Conclusions:** Surotomycin demonstrated non-inferiority to vancomycin for primary endpoint but neither key secondary superiority endpoints were met. Surotomycin was generally well tolerated.

Publishing Title:

A Randomized Controlled Trial of Oral Vancomycin Followed by Fecal Transplantation versus Tapering Oral Vancomycin Treatment for Recurrent *Clostridium difficile* Infection

Author Block:

S. S. Hota[1], V. Sales[2], G. Tomlinson[1], M-J. Salpeter[1], A. McGeer[3], D. E. Low[3], **S. M. Poutanen**[3]; [1]Univ. Hlth.Network, Univ. of Toronto, Toronto, ON, Canada, [2]Markham-Stouffville Hosp., Markham, ON, Canada, [3]Univ. Hlth.Network, Mount Sinai Hosp., Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background: Recurrent Clostridium difficile infection (RCDI) is a debilitating problem affecting 20-47% of patients with Clostridium difficile infection (CDI). Fecal transplantation (FT) is a promising treatment for RCDI, but its true effectiveness remains unknown. We compared FT with standard of care oral vancomycin taper, in adult patients with RCDI. **Methods:** In a phase 2/3, single center, open-label trial, participants experiencing recurrence of CDI were randomly assigned in a 1:1 ratio to 14 days of oral vancomycin (125 mg orally four times per day) followed by a single FT of 500 mL volume by enema or a six week taper of oral vancomycin. The primary endpoint was recurrence of CDI within 16 weeks. Crossover to the alternate treatment was offered to those with recurrences during follow-up.**Results:** The study was terminated at the interim analysis, after randomization of 30 patients. Baseline characteristics were similar in both randomization groups. Nine of 16 (56.2%) patients who received FT and 5/12 (41.7%) in the vancomycin taper group experienced recurrence of CDI. The Bayesian 95% interval for the change in risk of CDI recurrence with FT ranged from a 2.8% reduction to a 47.3% increase. There was a posterior probability of 22.2% that the FT reduced recurrences at all and only a 2.8% probability that risk was reduced by 20% or more. A futility analysis did not support continuing the study. Adverse events were similar in both groups. Four serious adverse events were reported in three patients. None were deemed related to the study interventions.**Conclusions:** A single FT by enema using fresh donor stools was not significantly different from oral vancomycin taper in reducing RCDI. Further research is needed to explore optimal donor selection, FT preparation and administration, including number of administrations.

Publishing Title:

Recurrent *Clostridium difficile* infection (rCDI) and colonization in the 12 months following administration of Bezlotoxumab (BEZ) alone and in combination with Actoxumab (ACT)

Author Block:

E. Goldstein[1], D. Citron[1], D. Gerding[2], M. Wilcox[3], R. Tipping[4], M. Dorr[4], L. Gabryelski[4], K. Eves[4], N. Kartsonis[4], A. Pedley[4]; [1]RM Alden Res Lab, Santa Monica, CA, [2]Hines VA Hosp, Hines, VA, [3]Univ of Leeds, Leeds, United Kingdom, [4]Merck, Kenilworth, NJ

Abstract Body:

Background: MODIFY II was a global, randomized, double-blind, placebo-controlled trial of ACT & BEZ, monoclonal antibodies which neutralize *C. difficile* toxins A & B, respectively, in adults receiving standard of care antibiotics for primary or rCDI. The trial showed that a single 10 mg/kg IV dose of ACT+BEZ (14.9%) or BEZ alone (15.7%) is superior to placebo (PBO, 25.7%) in prevention of rCDI through 12 weeks (both $p \leq 0.0003$). This abstract summarizes the results from the subset of ~300 subjects enrolled in an extension sub-study & followed for up to 12 months. **Methods:** Loose stool counts & sampling for toxigenic *C. difficile* testing were carried out for subjects with a new diarrheal episode. Also, stool samples were collected at Month 6, 9 & 12 visits to assess for *C. difficile* colonization using culture with toxin testing. **Results:** Only 3 subjects experienced rCDI during the extension phase of the study (ACT+BEZ: n=2; PBO: n=1) among those who resolved their initial episode & had no rCDI during the 12 weeks of the main study. *C. difficile* colonization rates among subjects who provided a stool sample were similar across treatment groups at each follow-up time point & ranged between 16.3% & 32.8%. **Conclusion:** In this extension cohort, rCDI rates increased only marginally when follow up time was extended from 12 weeks to 12 months. *C. difficile* colonization rates were not different in antibody versus in PBO recipients. These findings suggest that the efficacy of ACT+BEZ & BEZ seen in the main study is due to prevention of CDI recurrence rather than a delay in onset of a recurrent CDI episode.

Bezlotoxumab (Bzo) Decreases Recurrence and is Associated with a Reduction in 30-day Cdi-associated Readmissions in Hospitalized Patients with *Clostridium difficile* Infection (Cdi)

Author Block:

Y. Golan[1], E. Dubberke[2], M. Hanson[3], J. Liao[3], A. Pedley[3], M. Dorr[3], S. Marcella[3], V. Prabhu[3]; [1]Tufts, Boston, MA, [2]Washington Univ. Sch. of Med., St. Louis, MO, [3]Merck, Kenilworth, NJ

Abstract Body:

Background: MODIFY I & II demonstrated that BZO and standard of care antibiotics (SOC) prevent rCDI significantly better than placebo (PBO) + SOC when given to patients with initial or rCDI. In a *post hoc* analysis we used pooled data from the MODIFY trials to estimate 30-day all-cause and CDI-associated hospital readmission rates in hospitalized patients at high risk of rCDI. **Methods:** rCDI was defined as a new episode of diarrhea and positive stool test for toxigenic C *difficile* after resolution of baseline CDI episode. All-cause 30-day readmission was defined as % of patients hospitalized at the time of medication infusion that had a readmission within 30-days of discharge. Readmissions with a CDI-related discharge diagnosis were classified as CDI associated readmissions. Confidence intervals (CI) were estimated using Miettinen and Nurminen's method. **Results:** At baseline, 68% of patients were in a healthcare facility. The % of patients with 30-day all-cause and CDI-associated readmission & the difference between treatment arms with 95% CI are shown in the table for inpatients and by risk group. The % of inpatients with rCDI was lower with BZO + SOC [73/530 (13.8)] vs placebo (PBO) + SOC [120/520 (23.1); difference (95% CI): -9.3%, -14.0,-4.6)], consistent with the overall study population. Treatment with BZO + SOC vs PBO + SOC resulted in fewer 30-day CDI associated hospital readmissions for inpatients and for all high-risk groups assessed. **Conclusion:** Among inpatients, including those at high risk for rCDI, BZO + SOC was associated with a reduction in rCDI and 30-day CDI-associated hospital readmissions vs PBO + SOC.

	BZO + SOC, n/N (%)	PBO + SOC, n/N (%)	Difference (95% CI)
30-day all-cause readmissions	123/530 (23.2)	140/520 (26.9)	-3.7% (-9.0, 1.5)
30-day CDI-associated readmissions	21/530 (4.0)	50/520 (9.6)	-5.7% (-8.8, -2.7)
Age ≥ 65 years	11/298 (3.7)	37/308 (12.0)	-8.3% (-12.8, -4.2)
CDI prior 6 months	8/127 (6.3)	18/122 (14.8)	-8.5% (-16.6, -0.9)
Immunocompromised	5/131 (3.8)	9/112 (8.0)	-4.2% (-11.2, 1.8)
Severe CDI	2/113 (1.8)	12/116 (10.3)	-8.6% (-15.7, -2.7)
027 ribotype	7/67 (10.4)	14/81 (17.3)	-6.8% (-18.2, 4.9)

Inactivation of Vegetative Bacteria During Production of Ser-109, a Microbiome-Based Therapeutic for *Clostridium difficile* Infection

Author Block:

S. A. ALMOMANI, J. E. BUTTON, B. M. SCHUSTER, J. G. AUNINS, M-J. LOMBARDO, **G. J. MCKENZIE**; SERES THERAPEUTICS, CAMBRIDGE, MA

Abstract Body:

Background: Fecal microbiota transplant (FMT) from healthy screened stool donors has been shown to be effective in preventing *Clostridium difficile* infection (CDI) in patients with multiply recurrent disease. FMT is minimally processed, so potential transmission of infectious agents remains a concern. Screened donors may be asymptomatic carriers or be colonized with pathogens below the limit of detection of standard assays. An alternative treatment for recurrent CDI with improved safety is needed. SER-109 is a purified ecology of bacterial spores, which was shown to be highly efficacious in the treatment of recurrent CDI in a Phase 1/2b study. SER-109 is derived from stool of healthy screened donors, but production includes processing steps such as treatment with ethanol, a well-known bactericide, parasiticide, and virucide that does not affect bacterial spores. We present spike recovery studies demonstrating that a model of the SER-109 manufacturing process kills vegetative cells.**Methods:** Model Gram-positive (*Listeria innocua, Enterococcus faecalis* and *Staphylococcus aureus*) and Gram-negative (*Salmonella enterica*) bacteria were spiked into SER-109 process intermediates to simulate contamination. Ethanol was then added to simulate process inactivation. Titers of the spiked bacteria were determined by plating on selective media.To assess whether non-spore-forming organisms were in SER-109, bacteria in SER-109 lots were cultured by standard anaerobic culture methods and 10,000 colonies were randomly picked and identified by Sanger 16S rDNA sequencing.**Results:** Ethanol treatment reduced the viable titers of spiked vegetative bacteria to below the limit of detection in less than a minute. Extrapolation of linear inactivation kinetics to process duration demonstrates a very high level of inactivation. Characterization of more than 10,000 cultivatable bacteria in SER-109 after ethanol treatment revealed only spore-forming bacteria from the phylum Firmicutes.**Conclusions:** The SER-109 manufacturing process leads to a purified fraction of bacterial spores. Ethanol processing is lethal to vegetative bacterial cells and thus reduces the risk of pathogen transmission to a level that cannot be achieved through donor screening alone.

Differences in Characteristics and Outcomes among Veterans with *Clostridium difficile* Infection (Cdi) by Treatment

Author Block:

H. Morrill, J. Morton, Y. Wang, K. LaPlante, A. Caffrey; Providence VAMC, Providence, RI

Abstract Body:

Background: Clinical characteristics and outcomes by treatment among Veterans with first episode CDI are largely unknown. **Methods:** This was a retrospective study in a national cohort of adult Veterans with a first CDI episode between 2010-2014, defined as a positive stool sample for *C. diff* toxin(s) or an ICD-9 code for CDI (008.45), and receipt of ≥2 days of CDI treatment (IV or PO metronidazole [MTZ], PO or PR vancomycin [VAN|, or fidaxomicin [FID]) and no CDI episodes in prior year. Recurrence was a CDI episode within 30 days of the end of treatment. CDI admission/re-admission were defined as admission (for outpts) /re-admission (for inpts) to an acute care facility and a primary CDI diagnosis. Differences between patients treated with MTZ vs. VAN, MTZ+VAN, and FID alone or in combination with VAN +/- MTZ (FID/+) were assessed using Fisher's exact or χ^2 tests and Wilcoxon Rank Sum test.**Results:** The table below includes characteristics and crude outcomes by treatment. Data presented as n (%) or median (IQR) (*p<0.05).

	MTZ	**VAN**	**MTZ+VAN**	**FID/+**
	43,904 (81.1)	4368 (8.1)	5779 (10.7)	93 (0.2)
Median Age (IQR)	65 (58-76)	69 (63-81)*	68 (62-80)*	72 (65-82)*
Gender, male	40,958 (93.3)	4139 (94.8)*	5541 (95.9)*	89 (95.7)
White Race	32,546 (74.1)	3330 (76.2)*	4221 (73.0)	81 (87.1)*
Inpatient treatment	12,232 (27.9)	1913 (43.8)*	4320 (74.8)*	61 (65.6)*
Comorbidities				
Solid Organ Cancer	2856 (6.5)	461 (10.6)*	901 (15.6)*	19 (20.4)*
COPD	2989 (6.8)	455 (10.4)*	918 (15.9)*	11 (11.8)
CKD	3216 (7.3)	601 (13.8)*	1046 (18.1)*	23 (24.7)*
DM	3602 (8.2)	644 (14.7)*	933 (16.1)*	20 (21.5)*
30-Day CDI Recurrence	6175 (14.1)	920 (21.1)*	1534 (26.5)*	15 (16.1)

30-Day All Cause Mortality	3783 (8.6)	488 (11.2)*	1194 (20.7)*	15 (16.1)*
30-Day CDI Readmission	869/10,799 (8.1)	164/1645 (10.0)*	370/4022 (9.2)*	<5/59
30-Day CDI Hospital Admission	447/32,653 (1.4)	73/2658 (2.8)*	57/1657 (3.4)*	<5/33*

Conclusions: Patients that received VAN, MTZ+VAN, or FID/+ were sicker, older and had higher mortality rates compared to those that received MTZ. Higher recurrence rates were observed in those that received VAN and MTZ+VAN compared to MTZ. Comparative effectiveness studies are needed to identify optimal CDI treatment.

Publishing Title:

Tapering Courses of Oral Vancomycin Induce Persistent Disruption of the Microbiota That Provide Colonization Resistance to *Clostridium difficile* and Vancomycin-Resistant Enterococci in Mice

Author Block:

M. E. Tomas[1], T. S. C. Mana[2], M. A. Retuerto[2], B. M. Wilson[1], P. K. Mukherjee[2], M. A. Ghannoum[2], C. J. Donskey[1]; [1]Cleveland VA Med. Ctr., Cleveland, OH, [2]Case Western Reserve Univ., Cleveland, OH

Abstract Body:

Background: Vancomycin taper regimens are recommended for the treatment of recurrent *Clostridium difficile* infections. One rationale for tapering and pulsing of the dose at the end of therapy is to reduce vancomycin selective pressure on the normal intestinal microbiota. However, it is not known if the indigenous microbiota that provide colonization resistance against *C. difficile* is re-populated during tapering courses of vancomycin.**Methods:** Mice were treated orally with fidaxomicin (30 mg/kg/d) for 10 days, vancomycin (37.5 mg/kg/d) for 10 days, vancomycin taper for 39 days (37.5 mg/kg/d for 10 days, 18.75 mg/kg/d for 7 days, 9.38 mg/kg/d for 7 days, 9.38 mg/kg/d every other day for 3 doses, and 9.38 mg/kg/d every three days for 3 doses), or saline. To assess recovery of colonization resistance, subsets of mice were challenged with 10^4 colony-forming units (CFU) of an epidemic NAP1/027 *C. difficile* strain and vancomycin resistant Enterococci (VRE) at multiple time points during and after completion of the antibiotic courses. 16S rRNA sequencing was used to analyze the fecal microbiota.**Results:** Vancomycin taper-treated mice developed disruption of colonization resistance that persisted 18 days after discontinuation of treatment, whereas mice treated with a 10 day course of vancomycin exhibited recovery of colonization resistance by 15 days after discontinuation of treatment. Fidaxomicin and saline-treated mice maintained intact colonization resistance to *C. difficile* and VRE. Firmicutes were markedly suppressed during and after completion of the vancomycin-taper, whereas Firmicutes recovered to pre-treatment levels within 2 weeks in mice receiving the 10 day course of vancomycin and remained intact in fidaxomicin-treated mice.**Conclusions:** In mice treated with 39-day tapering course of vancomycin, disruption of the indigenous microbiota responsible for colonization resistance to *C. difficile* and VRE persisted up to 2 weeks after completion of therapy. In contrast, colonization resistance recovered within 2 weeks after completion of a 10 day course of vancomycin and was not altered by fidaxomicin.

Publishing Title:

Impact of Oral Fidaxomicin Administration on the Intestinal Microbiota and Susceptibility to *C. difficile* Infection

Author Block:

N. Ajami[1], C. Buffie[2], E. Pamer[2], M. Wong[3], J. Petrosino[1], **L. Chesnel[4]**; [1]Diversigen, Houston, TX, [2]Sloan-Kettering, New York, NY, [3]Alkek, Houston, TX, [4]Merck, Kenilworth, NJ

Abstract Body:

Background: Antibiotic (ABX) administration disrupts the intestinal microbiota, increasing susceptibility to pathogens such as *Clostridium difficile*. We used a mouse model of *C. difficile* infection (CDI) to determine susceptibility to CDI following P.O. administration of fidaxomicin (FDX) or vancomycin (VAN) and characterized the impact of drug exposure on the intestinal microbiota. **Methods:** Samples were collected over 24 days from mice administered VAN (5.625 mg/ml), or FDX (30 mg/ml) by oral gavage once daily for 3 days. At 1,3,6,10,14, and 20 days after the administration of the third antibiotic dose, mice were challenged with *C. difficile* strain VPI 10463 by oral gavage of 1,000 spores. Fecal and intestinal samples were collected and subjected to 16S rDNA sequencing (v4v5, Illumina MiSeq). **Results:** One mouse remained susceptible to CDI 6 days after exposure to FDX. Mice remained susceptible to CDI 3, 6, and 10 days after exposure to VAN. All mice were resistant to CDI after day 10. Fecal bacterial diversity was similar for all treatment groups before ABX administration and decreased significantly 3 days after. Treatment with FDX resulted in a reduced loss of bacterial community evenness as evidenced by the Shannon Diversity Index scores. Although treatment with FDX resulted in a shift in the bacterial community structure, the loss of bacterial community was lower and recovery was faster compared to VAN treatment. The relative abundance of Enterobacteriaceae species was 9.04% compared to 70.26% in the vancomycin group across all intestinal sites 1 day after cessation. Four days after cessation of ABX, the FDX group had 25% of the initial relative abundance of Clostridiales species compared to only 10% in the VAN treated group. Recovery was marked by a lack of expansion of *Enterococcus* spp., and rapid expansion of species of Erysipelotrichaceae, Lactobacillus spp., Bifidiobacterium spp., and Turicibacter spp. across all sites. **Conclusion:** Both ABX treatments resulted in loss of bacterial diversity and a shift in the bacterial community structure and composition. All FDX exposed mice (except for 1) remained resistant to CDI post exposure, which correlated with reduced disruption and rapid recovery of the intestinal microbiome.

Publishing Title:

***Clostridium difficile* Infection Recurrence Using Vancomycin vs. Fidaxomicin in High Risk Patients**

Author Block:

K. Beaulac, J. Wick, S. Doron; Tufts Med. Ctr., Boston, MA

Abstract Body:

Background: *Clostridium difficile* infection (CDI) is a common healthcare-acquired infection with high rates of recurrence. A novel antimicrobial, fidaxomicin (F), has been associated with a lower rate of recurrence in clinical trials compared with vancomycin (V). Our institutional protocol recommends the use of fidaxomicin in patients at high risk for recurrent CDI (rCDI), which we define as age >70, creatinine clearance (CrCl) <60 mL/min, or history of CDI in the past year. We aimed to validate the clinical trial findings in a real-life cohort of patients at high risk for rCDI. **Methods:** A prospective observational study was performed from 2012-2015. Patients were included in the analysis if CDI positive, received V or F as an inpatient for at least 2 days, and considered high risk of rCDI per our protocol. The primary outcome was 30 day (30D) rCDI, but demographic data, length of stay, readmission, and mortality were compared as well. Patients were excluded if they were lost to follow up before 30D, except for the 12 month endpoint in which patients were excluded if lost before 12 months.**Results:** Of 126 patients enrolled, 58 received F as their predominant therapy, and 68 received V. There were 7 excluded in each arm for loss to follow up before 30D. Five patients experienced 30D rCDI, 4/51 F (7.8%) and 1/61 V (1.6%) (p=0.11). Fourteen patients developed rCDI within 12 months, 11/33 F (33.3%) and 3/26 V (11.5%) (p=0.034). Patients in both arms had an average of 1.6 of the 3 risk factors (p=0.46), but F patients were more likely to have a history of CDI (p=0.006) and a higher Charlson Comorbidity Index (5.2 vs. 4.2, p=0.048). In patients with history of CDI, 30D rCDI occurred in 4/28 F and 1/18 V patients (p=0.35). There were 13 instances of 30D readmission in each arm (p=0.60), with 30D mortality occurring in 9F and 4V patients (p=0.68).**Conclusions:** We were not able to demonstrate the reduction in recurrence with F seen in clinical trials. Our observed rate of rCDI was lower than expected, potentially resulting in inadequate power. Furthermore, the observational nature of the study assigned choice of therapy to the clinician, thus potential unmeasured factors led to decision to use F in otherwise higher risk patients. With history of CDI being the strongest known predictor of recurrence, the heterogeneity of this risk factor in the two arms potentially confounds the rCDI rate.

Vancomycin-Resistant *Enterococcus* (VRE) Colonization and *C. difficile* Epidemiology: Results From the Phase 3b Deflect-1 Study

Author Block:

L. Chesnel[1], D. Devaris[1], D. Citron[2], S. Sambol[3], D. Hecht[3], P. Sears[1]; [1]Merck, Kenilworth, NJ, [2]Rm Aldan Res, Culver City, CA, [3]Hines VA Hosp, Hines, IL

Abstract Body:

BACKGROUND: This multicenter study used a randomized, placebo-controlled, double-blind design to evaluate the safety and efficacy of fidaxomicin (FDX) vs. placebo (PLC) as *Clostridium difficile*-associated diarrhea (CDAD) prophylaxis in individuals undergoing hematopoietic stem cell transplantation (HSCT). • *C. difficile* susceptibility, typing and VRE colonization were analyzed and compared across both arms. **METHODS:** Stool samples collected at Screening and End of Treatment/Early Termination (EOT/ET) for all subjects were submitted to the central microbiology laboratory and tested for colonization by VRE. • At any Unscheduled Visit (USV) where CDAD was suspected, a stool sample was collected. An aliquot was assayed locally for the presence of toxigenic *C. difficile*. For positive samples, an aliquot was shipped to the central microbiology laboratory for isolation and culture, restriction endonuclease analysis (REA), antibiotic susceptibility testing. **RESULTS:** *C. difficile* was isolated after baseline from 44 (7.3%) subjects in the mITT population, 16 subjects in the FDX arm and 28 subjects in the PLC arm. The most common REA group was non-specific REA (16 subjects), followed by Y group (10 subjects). • For all strains tested, rifaximin had the lowest MIC_{50}, MIC_{90}, and geometric mean, followed by FDX. Overall, the types and susceptibilities of isolates were similar in both treatment arms. • At Screening, 13.2% and 12.3% of subjects in the FDX and PLC arms were colonized with VRE. At follow-up (EOT/ET or USV), the incidence of VRE colonization was significantly lower in the FDX arm (15.6%) vs. the PLC arm (26.4%; p=0.0058). The proportion of subjects negative at Screening but positive at EOT/ET or USV was 2-fold higher in the PLC arm (17.7%) as compared to the FDX arm (8.4%; p=0.0090). **CONCLUSION:** All C. difficile strains were susceptible to FDX in both treatment groups with minimum inhibitory concentration distribution within the wild type range. • No changes in susceptibility were observed upon the duration of FDX exposure. • The incidence of VRE colonization was significantly lower in the FDX arm (15.6%) than in the PLC arm (26.4%) at follow-up (p=0.0058). • The proportion of subjects who developed VRE posttransplant was 2-fold higher in the PLC arm (17.7%) versus the FDX arm (8.4%; p=0.0090).

Publishing Title:

Fidaxomicin for the Management of *Clostridium difficile* Infection Non-Responsive to Oral Vancomycin Based Therapy or Recurrent/Relapsed Disease

Author Block:

N. N. Pettit, K. Mullane, Z. Han, J. Pisano; Univ. of Chicago Med., Chicago, IL

Abstract Body:

Background: *Clostridium difficile* infection (CDI) is among the most common healthcare associated infections. Optimal management of CDI non-responsive to first line therapy or those with relapsed or recurrent infection presents a clinical challenge. Fidaxomicin (FDX) is a treatment option for managing severe or recurrent CDI. At our hospital, FDX is commonly reserved for patients failing to respond to oral vancomycin (POVAN) or in the setting of relapsed/recurrent (R/R) CDI. The efficacy of FDX in the setting of persistent or R/R disease is not well established.**Methods:** All adult inpatients receiving FDX for CDI non-responsive to POVAN or R/R CDI between 1/1/2012-1/31/2015 were included. Patients were evaluated to determine incidence of relapse at <=8weeks or recurrence at >8weeks following FDX, all-cause 30-day mortality, and length of stay (LOS). Also assessed were potential risk factors for R/R following FDX.**Results:** 27 patients received FDX for the included indications, of which 6 (22%) patients had R/R (n=3 relapse, n=3 recurrence) following FDX therapy. Average LOS was 34 and 23 days in the R/R versus non-R/R group. No patients died 30 days following FDX. Risk factors assessed are shown in table 1.

TABLE 1: Risk Factors for R/R following FDX salvage therapy			
Risk Factor	R/R (n=6)	Non-R/R (n=21)	p-value
Age >65	1 (16.7)	10 (46.7)	0.2
Hematologic malignancy	2 (33.3)	6 (28.5)	0.5
WBC >15,000	1 (16.7)	6 (28.5)	0.5
SCr >1.5x baseline	2 (33.3)	4 (20)	0.4
Albumin <3.5	6 (100)	14 (70)	0.1
Concomitant PPI	5 (83.3)	10 (50)	0.1
Fluoroquinolone (FQ) w/in 24 hrs	1 (16.7)	1 (5)	0.25
Concomitant cephalosporin	3 (50)	8 (40)	0.5
History of 1 or more recurrences	1 (16.7)	2 (10)	0.4

IgG <800	4 (66.7)	10 (50)	0.094
IVIG	3 (50)	3 (15)	0.1
FDX followed by taper	2 (33.3)	10 (50)	0.4
Change to FDX after poor POVAN response	6 (100)	13 (65)	0.09

Risk factors meeting a priori of <0.20 on univariate analysis were included in multivariate regression, no statistically significant association identified.			

Conclusions: FDX is a reasonable option for CDI non-responsive to POVAN or for R/R CDI, with only 22% of patients with R/R disease following FDX for the included indications. None of the risk factors assessed were significantly associated with R/R, however the small sample size precludes definitive conclusions. A larger proportion of patients in the R/R group had recent FQ exposure, received concomitant cephalosporins, and had markers of more severe disease at baseline and a history of 1 more recurrences.

Transcriptomic Profiling of *Escherichia coli* Following Exposure to Smp24 and Smp43, Alpha-Helical Antimicrobial Peptides from the Egyptian Scorpion, *Scorpio maurus palmatus*

Author Block:

M. M. Tawfik[1], P. R. Heath[2], M. A. Abdel-Rahman[3], P. Strong[1], K. Miller[1]; [1]Biomolecular Sci. Res. Ctr., Sheffield, United Kingdom, [2]Sheffield Inst. for Translational NeuroSci., Sheffield, United Kingdom, [3]Suez Canal Univ., Ismailia, Egypt

Abstract Body:

Background: Scorpion venoms consist of diverse mixtures of peptides and proteins with varying activities and offer an attractive source of novel therapeutics. Smp24 (24 aa) and Smp43 (43 aa) are antimicrobial peptides (AMPs) that were identified from the venom gland of the scorpion *Scorpio maurus palmatus*. The main objective of this study was to analyse the transcriptomic response of *E.coli* following exposure to Smp peptides.**Methods:** Bacteria were cultured overnight at 37°C in MH broth, MICs were determined by serial microdilution. Using DNA micoarray, we examined the transcriptomic responses of *E. coli* to sub-inhibitory doses of Smp24 and Smp43 peptides following 5 hrs incubation. Knockout strains for differentially regulated genes were screened to assess susceptibility to Smp peptides.**Results:** Smp peptides showed activity against Gram-positive and Gram-negative bacteria with MICs ranging from 4 - 128 µg/ml. Genes were identified by microarray where there was a greater than 2-fold change ($p<0.05$) in expression compared with cells in the absence of peptides. 72 genes were down-regulated by Smp24 and 79 genes were down-regulated by Smp43. Of these, 14 genes were down-regulated in common and were associated with bacterial respiration. 52 genes were up-regulated by Smp24 alone; these genes were predominantly related to cation transport, particularly iron transport. 3 unrelated genes were specifically up-regulated by Smp43. No genes were up-regulated by both Smp24 and Smp43. 10 mutants in the knockout library increased resistance to Smp24; these genes were associated with iron transport and binding. 2 mutants increased resistance to Smp43 but these mutants differed from those affected by Smp24. 5 mutants decreased resistance to Smp24 and 7 mutants decreased resistance to Smp43. Of these, the resistance of 1 gene (fdnG, formate dehydrogenase) was decreased in common.**Conclusions:** These peptides offer a promising starting point for the development of new antimicrobial agents and transcriptomic analysis can help identify metabolic processes affected by AMPs which may be beneficial in understanding their mechanism of action.

In Vitro* Evaluation of Dual-Action Molecule Tnp-2092: Studies of the Mode of Action in Gastrointestinal Pathogen *Helicobacter pylori

Author Block:

G. T. ROBERTSON[1], J. Ding[2], Z. MA[2]; [1]COLORADO STATE Univ., Fort Collins, CO, [2]TENNOR THERAPEUTICS LTD., SUZHOU, China

Abstract Body:

Background: TNP-2092 is a dual-acting molecule in development for the treatment of diseases associated with GI tract infections. It is a potent inhibitor of RNA polymerase, DNA gyrase and topoisomerase IV and exhibits a low propensity for resistance development in *S. aureus*. In the present study, the mode of action of TNP-2092 was further assessed in *H. pylori* by testing against a panel of isogenic strains with defined resistance mutations in each of its proposed cellular targets. **Methods**: TNP-2092 was tested against a panel of 14 isogenic strains derived from *H. pylori* ATCC #700392 bearing defined resistance mutations. MICs were measured on Mueller Hinton agar with 5% aged sheep blood in accordance with CLSI guideline M7-A9. All assays were conducted in a microaerophilic environment at 35-37°C for 72 h. **Results**: The MIC for TNP-2092 ranged 0.25-0.5 g/ml against *H. pylori* ATCC #700392, similar to rifampin (0.25 g/ml) and levofloxacin (0.5 g/ml). The MIC was not altered in strains bearing only *rpoB* mutations, as compared to 64 to >256-fold increase in MIC for rifampin. The MIC for TNP-2092 increased 2 to 16-fold in strains bearing *gyrA* mutations, as compared to 8 to >128-fold increase in MIC for levofloxacin. TNP-2092 showed a further 2-fold increase in MIC against a strain bearing both *rpoB* and *gyrA* mutations, relative to an otherwise isogenic strain bearing the *gyrA* allele alone. **Conclusions**: The activity of TNP-2092 against *H. pylori* is derived primarily from its quinolizinone functionality, but it also retains significant secondary antimicrobial activity attributed to the rifamycin pharmacophore.

***In Vivo* Efficacy Of Dual-Action Molecule Tnp-2092 in Mouse *H. pylori* Infection Model: Dose Relationship and Impact of Proton Pump Inhibitor**

Author Block:

M. E. PULSE[1], W. J. WEISS[1], P. NGUYEN[1], Z. MA[2]; [1]Univ. OF NORTH TEXAS HEALTH Sci. CENTER, FORT WORTH, TX, [2]TENNOR THERAPEUTICS LTD., SUZHOU, China

Abstract Body:

Background: TNP-2092 is a dual-action molecule in development for the treatment of digestive diseases associated with GI tract infections. Previous studies indicated that TNP-2092 is highly active against *H. pylori* clinical isolates, including multidrug resistant strains. It is efficacious as a monotherapy in a mouse *H. pylori* infection model. TNP-2092 has high and prolonged exposure in the gastric mucosal layer following oral administration. Current studies further evaluate the dose relationships of TNP-2092 and impact of a proton pump inhibitor in the mouse *H. pylori* infection model.**Methods:** C57/BL6 mice were infected by *H. pylori* SS1 (CagA+, VacA+) and treatment initiated 7 days later. Mice were euthanized and their stomachs isolated, homogenized, serially diluted and plated for colony counts under microaerophilic conditions at 37°C. In the first experiment, TNP-2092 was administered orally at 5, 15 and 45 mg/kg, BID for 7 days. In the second experiment, TNP-2092 was administered orally or subcutaneously, with or without omeprazole, once or twice per day and continued for 7 or 14 days.**Results:** In the first experiment, administration of TNP-2092 at 45 mg/kg reduced stomach bacterial titers to 2.56 $\log_{10}$ CFU after 7 days of treatment. The 15 mg/kg, 5 mg/kg and vehicle control groups resulted in 4.67, 4.85 and 5.05 $\log_{10}$ CFU stomach titers respectively. In the second experiment, TNP-2092 (45 mg/kg, PO) alone reduced bacterial titers to 4.27 and 4.01 $\log_{10}$ CFU after 7 and 14 days of treatment as compared to 6.51 and 6.49 $\log_{10}$ CFU for the vehicle control group respectively. The bacterial titers for TNP-2092 when administered together with 1 mg/kg omeprazole at 7 and 14 days were 4.48 and 3.51 $\log_{10}$ CFU. TNP-2092 administered subcutaneously at 45 mg/kg did not show efficacy as compared to the untreated controls on Day 7.**Conclusions:** The effective dose for TNP-2092 in mouse *H. pylori* infection model was 45 mg/kg. Oral administration was more efficacious than subcutaneous administration and twice per day dosing was more efficacious than once per day administration. However, extension of treatment duration from 7 to 14 days and addition of omeprazole did not significantly improve overall efficacy.

***In Vivo* Efficacy of Dual-Action Molecule Tnp-2092 in Mouse *H. pylori* infection Model as Compared to Triple Therapies and Distribution within the Gastric Mucosal Layer**

Author Block:

W. J. WEISS[1], M. E. PULSE[1], P. NGUYEN[1], Z. MA[2]; [1]Univ. OF NORTH TEXAS HEALTH Sci. CENTER, FORT WORTH, TX, [2]TENNOR THERAPEUTICS LTD., SUZHOU, China

Abstract Body:

Background: TNP-2092 is a dual-action molecule in development for the treatment of diseases associated with GI tract infections. Previous studies indicated that TNP-2092 is highly active against *H. pylori* clinical isolates, including multidrug resistant strains. TNP-2092 is locally active in the GI tract after oral administration. Current studies sought to evaluate the *in vivo* efficacy of TNP-2092 in a mouse *H. pylori* infection model as compared to PrevPac (omeprazole + clarithromycin + amoxicillin) and Helidac (Bismuth salicylate + metronidazole + tetracycline) and study its distribution into gastric mucosal layer.**Methods:** C57/BL6 mice were infected by *H. pylori* SS1 (CagA+, VacA+) and treated with TNP-2092 and comparators orally, BID for 7 days. Mice were euthanized and their stomachs isolated, homogenized, serially diluted and plated for colony counts after incubation under microaerophilic conditions at 37°C. For PK studies, mice were euthanized at selected time points on Days 1 and 7 for collection of blood and stomach mucosal samples.**Results:** Low plasma exposure was observed for TNP-2092 with C_{max} of 1.2-1.5 ug/mL and $AUC_{0\text{-}inf}$ of 2.8-3.4 ug•hr/mL for Day 1 and Day 7. Exposure in the gastric mucin was high and prolonged with peak levels of 82.9-85.5 ug/g and exposures of 466.4-540.5 ug•hr/g for Days 1 and 7. At 30 mg/kg, TNP-2092 treatment resulted in stomach bacterial titers of 3.41 $\log_{10}$ CFU at 24 hours after the last dose. PrevPac exhibited comparable efficacy with bacterial titers of 3.47 $\log_{10}$ CFU. Helidac was less active with 4.42 $\log_{10}$ CFU. Neither rifampin nor rifalazil demonstrated efficacy. At 45 mg/kg, TNP-2092 reduced stomach bacterial titers to below the detection limit ($< 2.35 \log_{10}$ CFU).**Conclusions:** TNP-2092 exhibited high exposures in the gastric mucosal layer with drug levels in excess of its MIC against *H. pylori* 24-36 hours after oral administration at 45 mg/kg. This high exposure resulted in the reduction of the *H. pylori* bacterial titers to below the limit of detection after 7 days of treatment. TNP-2092 as a monotherapy appeared to be equally efficacious as PrevPac and superior to Helidac in mouse *H. pylori* infection model.

Sch. of Med., SHANGHAI, China, [5]WuXi App Tec (Shanghai) Co., Ltd, SHANGHAI, China

Abstract Body:

Background: *H. pylori* colonizes gastric mucosal layer and causes chronic gastritis, peptic ulcers, MALT lymphoma and gastric cancer. In China, *H. pylori* infects ~58% of adults and is associated with ~300,000 gastric cancer deaths per year. The eradication rate for standard triple therapy is declining due to development of antibiotic resistance, particularly to clarithromycin. Bismuth-containing quadruple therapy is now recommended as the first-line treatment in China. TNP-2092 has demonstrated potent activity against *H. pylori* in *vitro* and in *vivo*. The current studies report the antibacterial activity of TNP-2092 against *H. pylori* clinical isolates collected from three major hospitals in China. **Methods:** 239 *H. pylori* isolates were collected, including100 from primary patients admitted to The First Affiliated Hospital of Nanchang University, 78 from retreated patients admitted to Peking University First Hospital and 61 from Renji Hospital of Shanghai Jiao Tong University. MICs were measured using two-fold serial agar dilution method according to CLSI and EUCAST guidelines. *H. pylori* ATCC #43504 was used as QA strain. **Results:** See table below. **Conclusions:** TNP-2092 exhibited appreciably lower MIC_{50} and MIC_{90} values relative to comparator agents against both susceptible and drug-resistant *H. pylori* clinical isolates from China.

Dual-Action Molecule Tnp-2092: *In Vivo* Pharmacokinetics, Excretion and Metabolic Profiles Following Intravenous and Oral Administration in Rats and Dogs

Author Block:

M. WU[1], G. QIN[1], Q. CUI[1], Y. ZHU[1], T. ZHANG[2], **Z. MA**[2]; [1]WuXi AppTec Co., Ltd, SHANGHAI, China, [2]TENNOR THERAPEUTICS LTD., SUZHOU, China

Abstract Body:

Background: TNP-2092 is a dual-acting molecule in development for the treatment of diseases associated with gastrointestinal tract infections. TNP-2092 is chemically and metabolically stable in liver microsomes and human simulated gastric juice. Current studies sought to investigate the *in vivo* pharmacokinetics, excretion and metabolic profiles of TNP-2092 following intravenous and oral administrations in rats and dogs.**Methods:** Male SD rats were administered with TNP-2092 by single intravenous bolus at 25 mg/kg and oral gavage at 100 mg/kg. Blood samples were collected for up to 24 hours, and feces, urine and bile samples were collected for up to 72 hours post dosing. Male beagle dogs were dosed with TNP-2092 by single intravenous bolus at 5 mg/kg and oral gavage at 30 mg/kg. Blood samples were collected for up to 24 hours and the feces were collected for up to 72 hours post dosing. Concentrations of TNP-2092 in plasma, urine, feces and bile samples were analyzed by using LC-MS/MS.**Results:** TNP-2092 showed low bioavailability of 1.81% in rats after single oral administration. The majority of the dose (86.7%) was recovered in feces as unabsorbed parent with low levels excretion in bile (1.22%) and in urine (0.143%). Four metabolites were identified in samples from rats as M1: dehydrogenation followed by glucuronidation; M2: glucuronidation; M3: dehydrogenation; M4: deacetylation followed by S-glutathione conjugation. M1, M2 and M3 were observed as metabolites in rat plasma and bile following oral administration. Only M3 was identified in feces and no metabolite was detected in urine samples. Similarly, TNP-2092 showed a low bioavailability of 0.315% after a single oral administration in dogs and 93.5% of dose was recovered in feces after 72 hours. Three metabolites were found in samples from dogs as M2, M3 and M5 (oxygenation). M2 was the only metabolite in plasma and no metabolites were detected in feces.**Conclusions:** TNP-2092 is a locally active drug in gastrointestinal tract. It is mainly excreted through feces as unchanged form after oral administration in rats and dogs and no linker cleavage products have been detected.

Dual-Action Molecule Tnp-2092: Caco-2 Cell Permeability, Stability and Metabolism in Liver Microsomes and Human Simulated Gastric Fluid

Author Block:

M. WU[1], G. QIN[1], S. CHEN[1], Y. ZHOU[1], T. ZHANG[2], **Z. MA**[2]; [1]WuXi AppTec Co., Ltd, SHANGHAI, China, [2]TENNOR THERAPEUTICS LTD., SUZHOU, China

Abstract Body:

Background: TNP-2092 is a dual-acting molecule in development for the treatment of diseases associated with gastrointestinal tract infections. Current studies evaluate its Caco-2 cell permeability, and its stability and metabolism in mouse, rat, dog, monkey and human liver microsomes and in human simulated gastric fluid pertaining to oral drug delivery.**Methods:** Caco-2 cell monolayer assay was performed according to an established method. Metabolic stability and metabolism of TNP-2092 in CD-1 mouse, SD rat, beagle dog, cynomolgus monkey and human liver microsomes were assessed by incubating with microsomes at 37°C for 0, 5, 10, 20, 30 and 60 min in the absence and presence of the NADPH regeneration system and analyzed by LC-MS/MS. Stability and metabolism in human simulated gastric fluid were performed by incubating TNP-2092 (10 μM) in human simulated gastric fluid for 4 hours. Potential metabolites were identified by LC-MS/MS.**Results:** The P_{app} (A-B) and P_{app} (B-A) values were 0.05×10^{-6} cm/s and 0.48×10^{-6} cm/s respectively for TNP-2092 at 10 μM. The P_{app} (B-A) value decreased to 0.03×10^{-6} cm/s in the presence of a P-gp inhibitor. After incubation with mouse, rat, dog, monkey and human liver microsomes for 60 min, there were 98.2%, 83.5%, 79.0%, 98.4% and 89.4% of TNP-2092 remaining respectively. No detectable metabolites of TNP-2092 were found. After incubating with human simulated gastric juice, only a dehydrogenation product of TNP-2092 was observed which could be a result of air oxidation. No linker cleavage products or other breakdown products were detected.**Conclusions:** TNP-2092 showed low permeability across the Caco-2 cell monolayer and might be a substrate of active transport mediated by P-gp. TNP-2092 was stable in mouse, rat, dog, monkey and human liver microsomes with or without NADPH cofactor. TNP-2092 was stable in human simulated gastric fluid and no linker cleavage products could be detected.

In Vitro* Activity of FAB001, a Novel FabI Inhibitor against Antibiotic-Resistant *Neisseria gonorrhoeae

Author Block:

C. Mouze[1], S. Magnet[2], S. Hawser[2], I. Morrissey[2]; [1]FAB Pharma, Paris, France, [2]IHMA Europe, Epalinges, Switzerland

Abstract Body:

Background: FAB001 (formerly MUT056399), a novel antibacterial fatty acid biosynthesis inhibitor targeting FabI enzyme, is under clinical development by FAB Pharma for the treatment of severe human infections. A Phase I trial has already been conducted. *In vivo* results to date may have important clinical implications as FAB001 has the potential to treat *Staphylococcus aureus* infections and *Acinetobacter baumannii* infections in combination with carbapenems. The objective of this study was to investigate the activity of FAB001 against other Gram negative bacteria, such as *Neisseria gonorrhoeae*.**Methods:** A total of 76 recent antibiotic-resistant *N. gonorrhoeae* isolates with different resistance phenotypes and from various body locations (urethra, vagina, rectum, urine, wound) were tested to determine FAB001 MIC by CLSI agar dilution method.**Results:** Results are presented in the Table below. FAB001 exhibited good activity against all *N. gonorrhoeae* strains (N=76) with narrow MIC distribution and overall MIC range of ≤0.03 µg/mL to 0.5 µg/mL. MIC_{50} and MIC_{90} of FAB001 were 0.12 µg/mL and 0.25 µg/mL respectively. The activity of FAB001 was not influenced by resistance to other antimicrobials agents.**Conclusions:** FAB001 demonstrated promising *in vitro* activity against antibiotic-resistant *Neisseria gonorrhoeae.* Further studies are merited.

***In Vitro* Activity of Pexiganan (Px) and Ten Comparator Antimicrobials Against Anaerobic Bacteria Recovered from Skin and Skin Structure Infections (SSSI)**

Author Block:

D. M. Citron, K. L. Tyrrell, E. J. C. Goldstein; R.M. Alden Res. Lab., Culver City, CA

Abstract Body:

Background: Pexiganan, a 22-amino acid synthetic cationic analogue of peptide magainin II, acts by selectively damaging bacterial cell membranes. PX is in Ph3 clinical development as a topical cream (0.8%) for treatment of mild infections of diabetic foot ulcer and has potential for other skin and skin structure infections. The aim of this study was to evaluate the MICs of recent anaerobic isolates associated with SSSI. **Methods:** Most of the strains were recovered during the past 3 years, although some of the unusual species were older. About 20% were from patients in Europe and Canada. PX was tested using Brucella broth supplemented with vitamin K and hemin, with and without 5% lysed horse blood (CLSI M11-A8). Lysed horse blood has the potential for increased binding of pexiganan. Agar is not suitable for testing PX due to interference by the calcium concentration in agar. Other antimicrobials including penicillin (PCN), amoxicillin-clavulanate (A-C), piperacillin-tazobactam (P-T), meropenem (MR), clindamycin (CM), doxycycline (DX), moxifloxacin (MX), metronidazole (MT), linezolid (LN) and vancomycin (VA) were tested by the agar dilution method (CLSI M11-A8). **Results:** For Gram-negative species, the no. of isolates and MIC90%s were as follows: *B. fragilis* (103), 16 µg/ml; other *Bacteroides fragilis* group spp. (67), 4 µg/ml; *Prevotella* and *Fusobacterium* spp., (82), 32 µg/ml; and *Porphyromonas* spp., (40), 64 µg/ml. For Gram-positive species the MIC 90%s were as follows: *P. acnes*, (20), 4 µg/ml; *E. lenta* and *P. anaerobius*, (20), 32 µg/ml; other Gram-positive rods and cocci, (129), 4 µg/ml; *Clostridium perfringens*, (10), 128 µg/ml; and other clostridia, (19), 256 µg/ml. None of the higher PX MICs was related to resistance in any of the other antimicrobial agents. Some of the fastidious anaerobes failed to grow in Brucella broth without lysed horse blood, thus the PX MICs reported here were all from the blood containing broth. **Conclusions:** PX showed a high level of activity against this diverse group of organisms. The concentration of PX in the cream is 8,000 µg/ml, more than 30 times the highest MIC obtained for a few of the clostridia and 500 times greater than 90% of *B. fragilis* isolates. PX shows great potential for treating SSSI involving anaerobes.

Sequence Optimization and Computational Design of Synthetic Antibiofilm Peptides

Author Block:

E. F. Haney, Y. Brito-Sánchez, M. J. Trimble, S. C. Mansour, A. Cherkasov, R. E. W. Hancock; Univ. of British Columbia, Vancouver, BC, Canada

Abstract Body:

Biofilms are aggregates of bacterial cells that are resistant to conventional antibiotics and are associated with many bacterial diseases and chronic infections. Specifically targeting the cells within a biofilm represents an attractive drug target and our group recently recognized that short synthetic peptides possessed potent antibiofilm activity (*PLoS Pathogens* 2014. 10(5):e1004152). While many of these antibiofilm peptides share characteristics with the well-studied antimicrobial peptides (such as positive charge and amphipathicity), the sequence requirements that govern their antibiofilm potency remain unclear. Using our most active peptide, 1018 (VRLIVAVRIWRR-NH_2), as a sequence template, a substitution library of 96 single amino acid substitution variants was SPOT-synthesized on cellulose membranes and their antibiofilm activity was assessed against biofilms formed by methicillin resistant *Staphylococcus aureus* (MRSA). The data from this *in vitro* screen was then used to establish, for the first time, quantitative structure activity relationship (QSAR) models that identified molecular descriptors of antibiofilm peptides and accurately predicted (up to 90%) the activity of antibiofilm peptides. These accurate QSAR models were subsequently used to predict the activity of 100,000 virtual peptides *in silico*. A subset of these virtual peptides were SPOT-synthesized and screened against MRSA biofilms to evaluate their activity and to further assess the quality of the QSAR models. The results revealed that the QSAR models could correctly predict ~85% of the optimized antibiofilm peptides, demonstrating the robustness of the initial models. The most active peptides were then chemically synthesized to high purity and their activity against MRSA biofilms was assessed and found to be largely comparable to 1018. Importantly, one peptide exhibited up to an 8-fold increase in antibiofilm potency compared to 1018 and eradicated MRSA biofilms grown in flow cells at a peptide concentration as low as 0.125 µM. This optimized antibiofilm sequence demonstrates that this methodology could be used to design novel antibiofilm peptides for therapeutic applications to treat biofilm associated infections.

Identification of *Staphylococcus pseudintermedius* Sortase A Inhibitors

Author Block:

M. Balachandran, J. Baudry, D. Bemis, S. Kania; Univ. of Tennessee, Knoxville, TN

Abstract Body:

Background: Conventional antibiotic-based therapies against *S.pseudintermedius* infections have failed in recent years due to the increased prevalence of methicillin resistance and multidrug resistance. Therefore, alternate strategies for treatment of infection have to be explored. Anti-infective therapy based on sortase inhibition holds potential to address this shortcoming. Sortase A (srtA) is a transpeptidase commonly produced by Gram-positive bacteria. It has specificity for proteins that harbor the LPXTG motif and cleaves between the threonine (T) and glycine (G) residues. These proteins are subsequently incorporated into the peptidoglycan cell wall and displayed on the surface. They include numerous virulence factors and proteins that may overcome the host immune response. The objectives of the present study were (a) to clone and express the *srtA* gene from *S.pseudintermedius* in *E.coli* and (b) to use the recombinant protein to screen for potential inhibitors against sortase A.**Methods and Result:** A *srt A* gene from *S.pseudintermedius* optimized for *E.coli* codon usage was synthesized, inserted into an expression vector and expressed successfully in *E.coli*. The size and purity of the protein were verified by SDS-PAGE and Western Blot. A FRET-based assay using a synthetic substrate, Abz-LPETG-K(Dnp)-NH_2, showed that the protein was functional and had a higher specific activity than commercially obtained *S.aureus* sortase A. Using molecular dynamic simulations, a 3-D model of sortase A was created to screen a library of compounds from the National Cancer Institute (NCI) for potential inhibitors. From the top twenty most active inhibitors, ten were selected and tested for their ability to inhibit sortase *in-vitro*. Four of these compounds showed ~50% inhibition of sortase A in the FRET-based functional assay. The effect of these compounds in an *in-vivo* model is yet to be investigated.**Conclusion:** Recent advancements in computational biology have made it possible for structure-based molecular discovery of novel compounds that could serve as potential inhibitors of sortase A. Therefore, these results indicate the possibility of sortase A inhibition as a potential therapeutic strategy in the treatment of staphylococcal infection in both humans and animals.

Investigation of Antibacterial and Antifungal Activity of New Keton and Ketoxime Derivatives Containing Benzofuran, Naphthofuran or Cyclobutane Ring

Author Block:

H. Yigit, E. Demiray, M. Koca; Adiyaman Univ., Adiyaman, Turkey

Abstract Body:

In this study new ketone and benzofurane, naphthofurane or cyclobutane ring containing ketoxime derivatives were investigated for Gram (+) and Gram (-) antibacterial and antifungal activities for 4 *Candida* specieses. Minimum Inhibition Concentration (MIC) and Minimum Bactericidal Concentration (MBC) of the compounds were determined and time kill studies were carried out for the active compounds by using the CLSI methods. Compounds 4,, 21, 41 and 45 were active against some of the bacteria while compound 18 was active on some of the bacteria as well as the yeasts tested in this study. The results from the MBC and time kill studies suggested that compounds number 18 and 21 are bacteriocidal. MIC and MBC results for the *Candida* specieses were the same indicating sidal activity. MIC values of compound 18 were as follow: *Staphylococcus aureus* ATCC 29213 32-64 µg/mL, Methicillin Resistant *Staphylococcus aureus* (MRSA) 16-32 µg/mL, *Enterococcus faecalis* ATCC 29212 32-64 µg/mL, Vancomycin Resistant *Enterococcus faecalis* (VRE) 16-32 µg/mL. The MIC values of compound 18 for yeasts were: *Candida krusei* ATCC 6258 32 µg/mL, *Candida albicans* ATCC 10231 64 µg/mL, *Candida glabrata* ATCC 90030 128 µg/mL and *Candida parapsilosis* ATCC 22019 128 µg/mL. MIC values for compound 21 were: *Enterococcus faecalis* ATCC 29212 32-64 µg/mL and VRE 32-64 µg/mL. The results showed that some of the compounds containing benzofurane, naphthofurane or cyclobutane ring have anti-bacterial and/or antifungal activity. Interestingly, compounds like 18 and 21 demontsrated both anti-fungal and anti-bacterial activity. The antibacterial activity of compounds 18 and 21 included MRSA and VRE.

Cell Membrane Interactions with Antimicrobial Alginate Oligog Cf-5/20

Author Block:

M. F. Pritchard[1], K. Beck[1], P. C. Griffiths[2], L. C. Powell[1], S. Khan[1], E. Onsøyen[3], P. D. Rye[3], K. E. Hill[1], D. W. Thomas[1], **E. L. Ferguson**[1]; [1]Cardiff Univ., Cardiff, United Kingdom, [2]Univ. of Greenwich, Gillingham, United Kingdom, [3]AlgiPharma AS, Sandvika, Norway

Abstract Body:

Background: Cystic Fibrosis is a chronic, autosomal-recessive disease, characterized by chronic pseudomonal lung infection and formation of antibiotic-resistant biofilms. We have shown that a low molecular weight alginate oligosaccharide therapeutic, OligoG CF-5/20, potentiates the activity of conventional antibiotics against a range of Gram-negative, multi-drug resistant pathogens including *Pseudomonas aeruginosa*. This study sought to determine whether this potentiation was the result of direct interaction with, and modulation of, the Gram-negative lipopolysaccharide (LPS) membrane. **Methods:** Cell membrane permeabilization was assessed by measuring the internalization of nitrocefin, propidium iodide and 1-N-phenylnaphthylamine (NPN) dye by *P. aeruginosa* strains and release of carboxyfluorescein from single lamellar liposomes in the presence of OligoG (0-20 mg/mL). A chromogenic endotoxin assay was used to measure the gel-clot reaction of *Limulus* amebocyte lysate (LAL) in the presence of LPS, following pre-incubation with OligoG. LPS from *P. aeruginosa* (10 mg/mL) was incubated with OligoG (0-20 mg/mL) at various pHs and NaCl concentrations and measured by electrophoretic light scattering (ELS), small-angle neutron scattering (SANS; ILL, Grenoble) and circular dichroism (CD) spectroscopy.**Results:** OligoG did not alter the surface charge of pseudomonal LPS, nor did it neutralize the biological activity or induce aggregation of LPS *in vitro*. Antibiotic potentiation by OligoG (of up to 512-fold) was independent of any significant membrane perturbation, observed in antimicrobial peptide (RTA3 or polymyxins) controls. Whilst OligoG induced subtle structural changes in LPS solution conformation at higher salt concentrations (0.1 > 0.01 > 0.001 M NaCl), these effects were pH-independent. Likewise, the CD spectra for LPS remained unaltered in the presence of OligoG. The effects seen with OligoG contrasted with the distinct conformational changes induced by colistin, which has high affinity for LPS.**Conclusions:** These data demonstrate that the novel potentiation of antimicrobial activity by OligoG does not simply reflect permeabilization of the cell membrane or structural changes to LPS.

MIC Reproducibility of Iron Depleted Cation Adjusted-Mueller Hinton Broth (ID-CAMHB) for Microdilution Testing of S-649266, a Novel Siderophore Cephalosporin

Author Block:

M. Tsuji[1], M. Hackel[2], R. Echols[3], D. Sahm[2], Y. Yamano[1]; [1]Shionogi & Co., Ltd., OSAKA, Japan, [2]IHMA Inc, Schaumburg, IL, [3]Shionogi Inc, Florham Park, NJ

Abstract Body:

Background: S-649266, a novel parenteral catechol-substituted siderophore cephalosporin, is active against carbapenem-resistant Gram-negative bacteria. Accurate *in vitro* testing of S-649266 by broth microdilution requires the use of iron-depleted conditions to mimic the condition in mammalian hosts. Previous MIC testing of S-649266 has used apo-transferrin containing medium and Chelex-treated Isosensitest broth (ISB) to suppress the trailing phenomenon which was observed in *Acinetobacter baumannii*. In this study, we evaluated MIC reproducibility using iron depleted Mueller Hinton Broth (ID-CAMHB) as an alternative medium for the *in vitro* microbiological assessment tests to establish the MICs for S-649266. **Methods**: Broth microdilution testing was done according to CLSI guidelines except that CAMHB was made iron deficient by pretreatment with Chelex-resin (Bio-Rad Laboratories) with subsequent replenishment of Ca, Mg and Zn. ID-CAMHB did not significantly affect the growth control. MIC endpoints were defined as the first drug well in which growth is significantly reduced (i.e. a button of < 1 mm or light/faint turbidity) relative to growth control. MIC reproducibility was determined against 20 clinical isolates (3 *Escherichia coli* including KPC and NDM strains), 4 *Pseudomonas aeruginosa* including VIM, OprD-deficient strains, 3 *Klebsiella pneumoniae* including KPC and NDM strains, 10 *A. baumannii* including OXA-23 and -24 strains. Reproducibility of S-649266 was calculated as the ratio of total number of results that fell within 1 or 2 wells of the mode results divided by total number of results. **Results**: Trailing phenomenon was observed for *A. baumannii* using ID-CAMHB although not observed in apo-transferrin containing or Chelex treated ISB. However, by using the established guidelines for reading MICs, ID-CAMHB was considered to be the appropriate medium for the MIC determination of S-649266. For the 5 of 20 test strains showing trailing phenomenon, it was possible to assign a reproducible MIC value to 471/500 (94.2%) of the isolates. **Conclusions:** Based on the good reproducibility of *in vitro* MICs obtained in ID-CAMHB, ID-CAMHB is the effective and reliable broth medium for assessing the *in vitro* activity of S-649266.

Publishing Title:

Skin Deep - Novel Thiazole Compounds Exhibit Potent Antibacterial Activity *In Vitro* and *In Vivo* in a Methicillin-Resistant *Staphylococcus aureus* (MRSA) Skin Infection Mouse Model

Author Block:

H. Mohammad, M. Cushman, M. N. Seleem; Purdue Unversity, West Lafayette, IN

Abstract Body:

Bacterial resistance to antibiotics is a significant public health challenge that is currently affecting every geographic region of the world. One of the most problematic bacterial pathogens worldwide, methicillin-resistant *Staphylococcus aureus* (MRSA) is a significant source of skin and wound infections in humans. Many first-line antibiotics, such as mupirocin, and drugs of last resort, such as vancomycin, are losing their effectiveness as treatment options. This highlights the urgent need for identification and development of novel antibacterial agents to address this public health crisis. The present study demonstrates the ability of five thiazole compounds, synthesized by our interdisciplinary research group, to effectively and rapidly inhibit the growth of clinically-relevant strains of MRSA responsible for skin infections (at concentrations as low as 1.3 μg/mL). Interestingly, utilizing the checkerboard assay, the three most potent compounds *in vitro* exhibited a synergistic relationship when combined with mupirocin (at subinhibitory concentrations) against MRSA. Additionally, the MTS assay revealed four compounds are not toxic to human keratinocytes at concentrations up to 20 μg/mL. When tested in a murine model of MRSA skin infection, four compounds mimicked the effect of mupirocin in significantly reducing the bacterial load present in infected wounds. A preliminary mechanism of action study (using a target overexpression experiment with *Bacillus subtilis*) indicates these thiazole compounds may disrupt a pathway involved in cell wall synthesis in bacteria. Collectively, the results demonstrate these thiazole compounds warrant further investigation as a novel treatment option (alone and in combination with mupirocin) for drug-resistant staphylococcal skin infections.

Phase 2 Study of Relebactam (Rel) + Imipenem/Cilastatin (Imi) vs Imi Alone in Subjects with Complicated Urinary Tract Infection (Cuti)

Author Block:

M. D. Sims[1], V. Mariyanovski[2], P. McLeroth[3], W. Akers[3], Y-C. Lee[3], M. Brown[4], J. Du[4], A. Pedley[4], N. Kartsonis[4], A. Paschke[4]; [1]Beaumont Hlth., Royal Oak, MI, [2]Univ. Hosp. N. I. Pirogov, Sofia, Bulgaria, [3]Covance Inc, Princeton, NJ, [4]Merck Sharp & Dohme Corp., North Wales, PA

Abstract Body:

Background: REL (MK-7655) is a novel Class A/C ß-lactamase inhibitor intended for use in combination with IMI for the treatment of Gram-negative bacterial infections. REL restores imipenem activity against resistant Enterobacteriaceae and *Pseudomonas* strains.**Methods:** In this multicenter double-blind study, subjects ≥18 years of age with cUTI or acute pyelonephritis were randomized (1:1:1) to IMI + REL 250 mg, IMI + REL 125 mg, or IMI + placebo, each given IV every 6 hours for 4-14 days. Efficacy was evaluated at discontinuation of IV therapy (DCIV), early follow-up (EFU), and late follow-up (LFU). The primary endpoint was the proportion of microbiologically evaluable (ME) subjects with a favorable microbiological response (MR) at DCIV, assessed by non-inferiority testing with a 15% margin.**Results:** Of 302 randomized subjects, 298 were treated and 230 (76%) were ME at DCIV (52% female, mean age 56 years; 51.7% with cUTI, 48.3% with pyelonephritis). 25 subjects (11% of the ME population) had imipenem-resistant Gram-negative infections at baseline. Efficacy and safety outcomes were similar across treatment groups, as shown below (see table). Both doses of REL + IMI were non-inferior to IMI alone: the favorable MR rate at DCIV was 95.5% for IMI + REL 250 mg, 98.6% for IMI + REL 125 mg, and 98.7% for IMI + placebo.**Conclusions:** In subjects with cUTI, both doses of REL + IMI were at least as effective as IMI alone, with respect to MR at DCIV, and were generally well tolerated.

Proportion of subjects with favorable microbiological response (ME population[†])

Minimum Inhibitory Concentration (MIC) of New Heteroarotinoids Drugs for *Mycobacterium tuberculosis* (MTB)

Author Block:

S. N. M. Hanif[1], D. Benbrook[2], L. Garcia-Contreras[2]; [1]Bastyr Univ., San Diego, CA, [2]Oklahoma Hlth.Sci. Ctr., Oklahoma City, OK

Abstract Body:

Background: New drug entities are desperately needed to improve tuberculosis (TB) treatment and the threat of drug resistant strains. Evaluation of new drug candidates require accurate drug susceptibility testing (DST) for MTB. Heteroarotinoid compounds that have demonstrated efficacy against cancer share same structural characteristics with some existing anti-TB compounds. In this study, we performed DST of MTB to these compounds using two different methods. **Methods:** Middlebrook 7H11 medium supplemented with OADC was used to prepare DST plates with different concentrations of drugs SA, SB, SC or isoxyl (a known anti-TB drug used as control). 100 µl of MTB ($1x10^5$) were inoculated on the plates. Plates were incubated (37^oC, 5% CO_2) for 3 weeks. Colonies were counted visually. For Alamar Blue test, drugs were incubated with Middlebrook 7H9 (OADC) and MTB ($1x10^5$) for 8 days and MIC determined visually by color change from blue to pink after 24h of incubation with Alamar Blue. **Results:** Tested concentrations of 1, 2.5, 3, 5, 7.5, 10, 20 and 30 µg/ml for all drugs in agar diffusion test showed that MIC for SC, Isoxyl, SB and SA were 1, 5, 5, 10 µg/ml, respectively. Whereas, Alamar Blue assay resulted in MIC of 1.25, 5, 1.25, 5 µg/ml for SC, Isoxyl, SB and SA, respectively. The slight difference in the MIC obtained with Alamar Blue assay could be because of different in the media as both Middlebrook 7H9 and 7H11 media are different in their composition. **Conclusions:** Heteroarotinoids exhibit promising anti-TB activity with similar or greater efficacy compared to isoxyl. Particularly, SA could be a leading candidate since formal toxicological studies show no adverse effect to this drug. The Alamar Blue assay showed similar results to the agar plate method, thus it could be reliable for DST and save testing time.

Study of Anti-Bacterial Activity of Baicalin on Mycobacterium tuberculosis

Author Block:

H-L. Eng[1], J-Y. Chen[2], Y-F. Wang[1], T-M. Lin[3]; [1]Kaohsiung Chang Gung Mem. Hosp. and Chang Gung Univ. Coll. of Med.,, Kaohsiung., Taiwan, [2]Kaohsiung Med. Univ. Hosp., Kaohsiung., Taiwan, [3]E-DA Hosp./I-Shou Univ., Kaohsiung., Taiwan

Abstract Body:

Tuberculosis (TB) is a major worldwide health problem in part due the emergence of drug resistant strains that are threatening and impairing the control of this disease. Baicalin is a flavonoid compound extracted from Scutellaria roots that has been reported to possess antibacterial, anti-inflammatory, and antiviral activities. However, the antimycobacterial effect of baicalin is still unknown. In this study, the efficacy of baicalin on *mycobacterium tuberculosis* (*MTB*) was investigated *in vitro*. The bacteriostatic action of baicalin on *MTB* was detected by Bactec MGIT 960 automated drug susceptibility testing system. We established the standard growth curves of reference strain of *MTB*, H37Rv (ATCC27294) with time to detection (TTD) from MGIT 960 system. MIC50 was calculated from TTD of MGIT 960 system with the following concentrations: 0.625, 1.25 and 2.0 mM of baicalin. The minimum inhibitory concentration (MIC) of baicalin on H37Rv was 2.0 mM, and MIC50 was 0.6 mM, accompanied with minimal cytotoxity against THP-1 cells. The therapeutic dose was showed within an acceptable range. Of the total 36 clinical isolated *MTB* strains, the MIC of baicalin on 8 strains (8/10) of drug sensitive, 2 strains (2/8) of multiple-drug resistant(MDR), 1 strain (1/10) of INH resistant and 6 strains (6/8) of streptomycin resistant were < 2.0 mM. In comparison to the reference strain, the MIC50 of baicalin was higher (>0.6 mM) in 3 strains (30%) of drug sensitive, 7 strains (87.5%) of MDR, 10 strains (100%) of INH resistant and 1 strain (12.5%) of streptomycin resistant *MTB.* In conclusion, we demonstrated the anti-mycobacterial effect of baicalin on clinical *MTB isolates in vitro,* with minimal cytotoxicity of baicalin toward THP-1 cells. However, the MIC was significantly higher in INH resistant strains.

A Diversity Oriented Synthesis Compound Selectively Inhibits *M. tuberculosis* Tryptophan Synthase

Author Block:

S. Wellington[1], P. P. Nag[1], S. Johnston[1], S. L. Schreiber[2], D. T. Hung[3]; [1]Broad Inst., Cambridge, MA, [2]Harvard Univ., Cambridge, MA, [3]Harvard Med. Sch., Boston, MA

Abstract Body:

Mycobacterium tuberculosis (Mtb) has now surpassed HIV as the leading cause of deaths due to an infectious agent. Though the current regimen of antibiotics is effective against drug-sensitive strains of Mtb, it is also slow, requiring 6-9 months of treatment. The lengthy treatment time often results in patient non-compliance, fueling the development of extensive drug resistance. This rise in resistance necessitates the development of new therapeutics with novel mechanisms for which there will not be cross-resistance to current therapies.Standard screening methods are failing to identify these types of compounds. In a unique approach, whole-cell screening of new small molecules generated through diversity oriented synthesis has allowed us to identify new types of inhibitors. This research explores the mechanisms of action of these compounds.One such compound, BRD-4592, is stereoselective and non-toxic to human cells and to mice, yet is bactericidal and effective against clinical isolates of Mtb. Resistance to BRD-4592 can arise due to mutations in tryptophan synthase and work with recombinant protein demonstrates that BRD-4592 binds tryptophan synthase and inhibits enzyme activity through a completely novel mechanism. No inhibitors of Mtb tryptophan synthase have been previously described, and recent work in the field has demonstrated that host immune responses deprive bacteria of tryptophan making tryptophan synthesis essential *in vivo.* BRD-4592 is a promising therapeutic candidate and we ultimately aim to fully characterize mode of inhibition as well as *in vivo* efficacy.

Elucidating the Mechanism of Action of Cb81, a Novel Anti-mycobacterial Agent

Author Block:

J. S. Aneke, L. A. Weiss, C. L. Stallings; Washington Univ. in St. Louis, St. Louis, MO

Abstract Body:

Each year, an estimated 9.6 million people become infected with *Mycobacterium tuberculosis* (*Mtb*). With the rising number of multidrug resistant strains, this presents a large public health threat. To combat this threat, there is a need to introduce new antibiotics into the drug pipeline. CB81 was identified in a screen for compounds that inhibit the growth of *Mycobacterium smegmatis*, a non-pathogenic model organism for *Mtb*, in culture. When we tested CB81 for activity in other bacteria, we found that CB81 has no effect on other Gram positive or Gram negative bacteria, but is specifically a potent killer of mycobacteria, with a minimum inhibitory concentration (MIC) between 100 and 500 nM in *Mycobacterium tuberculosis*. To gain insight into the mechanism of action of CB81 in *M. tuberculosis*, we are performing a detailed analysis of the effects of the drug on the bacteria. We have shown that in liquid culture, CB81 is bactericidal in *M. tuberculosis*. CB81 also inhibits biofilm formation, a physiological process that recapitulates some aspects of chronic infection, like drug tolerance and reduced replication, which may suggest that CB81 affects these pathways. Experiments are underway to determine the changes in expression profiles, metabolism, and lipid content that result from treatment of *M. tuberculosis* with CB81. Additionally, we are seeking to discover the target(s) of CB81 by generating resistant mutants. Finally, we show that a closely related compound, CB82 (MIC in *M. tuberculosis* between 1 and 10 uM), is non-toxic in mouse bone marrow-derived macrophages and inhibits replication of *M. tuberculosis* in macrophages at 50 uM. Future experiments include measuring the survival of drug sensitive and multidrug resistant *Mtb* during infection of murine macrophages and the effect on the efficacy of other standard of care antibiotics during macrophage infection. We have identified a novel and potent mycobacterium-specific antibiotic that kills *Mtb* at sub-micromolar concentrations, and is non-toxic in macrophages. CB81 presents the field with a promising new therapeutic to add to the pipeline of drugs available to treat *M. tuberculosis* infections.

Sch. - Rutgers, Newark, NJ, [5]Univ. of Illinois at Chicago, Chicago, IL

Abstract Body:

Background: Recently, we have disclosed the *in vitro* profiling of various imidazo[2,1-*b*]thiazole-5-carboxamides that target QcrB and potently inhibit growth of both *Mycobacterium tuberculosis* (*Mtb*) and *Mycobacterium avium complex* (MAC). Herein we report the *in vivo* safety and lung tissue distribution of HT-03 being developed for the treatment of *Mtb* as well as MAC. **Methods:** *Synthesis* - Synthesis followed our previously published methods. HT-03 was purified and characterized by mp, NMR and LC/HRMS.*In vitro activity vs. Mtb* - H37Rv was evaluated in both GAS and 7H12 media with metabolic activity measured using a Microplate Alamar Blue Assay. Activity against non-replicating *Mtb* was evaluated with a luminescence readout using the low oxygen recovery assay. MIC determined in 7H9/ADC/Tween to lab adapted, hypersensitive and *qcrB* mutant strains.*In vitro activity vs.* MAC - 11 strains of *M. avium* were exposed to compounds for 3 days and metabolic activity and bacteriostatic/bactericidal activity was measured by the colorimetric resazurin assay and colony forming units, respectively.*In vivo* tolerability - 6 to 8 week old female Balb/c mice were dosed by oral gavage with 250 mg/kg and 500 mg/kg of HT-03 in DMSO. Animals were dosed once daily 6 days a week for two weeks at 250 mg/kg and 6 days a week for one week at 500 mg/kg.**Results:** HT-03 (MW 533, clogP 5.4) had MICs of 2 ng/mL against H37Rv-*Mtb* and MIC against MAC (clinical isolates from AIDS patients) serotypes from 31 to >100 ng/mL. HT-03 at steady state dosing of 100 mg/kg had a lung to plasma concentration ratio of 1.6 (8 hr) and 6.5 (12 hr) with drug levels above the MIC in the lung. HT-03 was well tolerated in mice with no deaths, weight loss or signs of distress observed.**Conclusion:** Novel imidazo[2,1-*b*]thiazole-5-carboxamide, HT-03, is potent inhibitor of growth of both *Mtb* and MAC strains. It has good *in vivo* safety, tolerability, pharmacokinetics and appropriate tissue distribution to warrant further development and evaluation within *Mtb* and MAC infection models.

A Whole Cell Screen Targeting a Novel Methylthioadenosine Nucleosidase (Rv1422) of *Mycobacterium tuberculosis*

Author Block:

J. Zeng[1], K. Hartland[2], K. Coser[2], B. P. Selbach[3], J. Bittker[2], K. Rhee[3], R. Husson[1]; [1]Boston Children's Hosp., Harvard Med. Sch., Boston, MA, [2]Broad Inst. of Harvard and Massachusetts Inst. of Technology, Cambridge, MA, [3]Weill Cornell Med. Coll., New York, NY

Abstract Body:

There is an urgent need for new drugs to treat tuberculosis (TB), both to combat the increasing number of drug-resistant strains of *Mycobacterium tuberculosis* (Mtb) and to shorten the duration of treatment required to cure drug-susceptible TB. Genes that are required for virulence or growth during infection constitute a potentially rich, but un-mined, source of highly attractive drug targets. The *M. tuberculosis* gene Rv1422 encodes a protein of unknown function we previously showed to be essential for optimal *M. tuberculosis* growth on several carbon sources including cholesterol. Cholesterol is a critical carbon source for this pathogen during infection, particularly for intracellular bacteria within macrophages. This gene is also required for *M. tuberculosis* virulence and persistence in a mouse model of infection. We previously determined that a strain of *M. smegmatis* in which the Rv1422 homologue (MSMEG3080) has been deleted is hypersusceptible to β-lactam antibiotics, and that the *M. tuberculosis* Rv1422 gene fully complements this susceptibility phenotype. Based on these findings, we used the microplate alamarBlue assay (MABA) to perform a whole cell screen in the *M. smegmatis* MSMEG 3080 deletion strain complemented by Mtb Rv1422 to identify inhibitors of the *M. tuberculosis* Rv1422 protein. In a screen of ~10,000 compounds, we found 177 compounds that inhibit growth at 30 uM and showed an IC50 at least 2-fold greater in the presence versus the absence of cefotaxime. In recent work, we have shown that the Rv1422 protein catalyzes the glycosidic bond cleavage of 5'-methylthioadenosine. Using recombinant Rv1422 protein we have developed an *in vitro* microplate enzyme assay to measure the 5'-methylthioadenosine nucleosidase activity of Rv1422. We will use this assay to identify the compounds from the screen that directly inhibit Rv1422. In the future, we will further validate and optimize inhibitors of Rv1422, which will be valuable as probes to determine the role of Rv1422 in the Mtb cell and potentially as leads for the development of novel anti-TB drugs.

Type and Frequency of Mutations in *kat*G and *rpo*B Genes in Multidrug-Resistant Strains of *Mycobacterium tuberculosis* Complex

Author Block:

M. Munir; PMRC TB Res. Ctr., Lahore, Pakistan

Abstract Body:

Background: Tuberculosis remains a major cause of morbidity and mortality in several parts of world. Use of polymerase chain reaction amplification and ***Mycobacterium tuberculosis*** DNA sequencing analysis detects mutations in different genes and is a predictive of drug resistance with the potential to provide rapid detection of isoniazid, rifampicin and or multi drug resistant strains of *Mycobacterium tuberculosis*. Genetic basis and mutations in *kat*G and *rpo*B genes are responsible for isoniazid and rifampicin resistance respectively in most of the cases of ***Mycobacterium tuberculosis***. However these mutations are geographically distributed and different mutations confer different degree of drug resistance.**Objectives:** To determine the type and site of mutation in ***kat*G** and ***rpo*B** genes in confirmed MDR-TB isolates and to find the frequency of various mutations with respect to the site of mutation.**Methodology:** The study was carried out in Pakistan Medical research Council TB Research Centre and Department of Chest Medicine, Mayo Hospital Lahore. 100 AFB Smear positive specimens of MDR TB suspects and Rifampicin resistant on GeneXpert were collected. Drug susceptibility of isoniazid and rifampicin was carried out by standard drug proportion method. DNA isolation of ***Mycobacterium tuberculosis*** was done by boiling the bacterium at 80C° for 20 minutes and supernatant was used as template for sequencing, PCR Single Strand Conformation Polymorphism Analysis and restriction fragment polymorphism.**Results:** A total of 100 smear positive, rifampicin resistant on GeneXpert were included; consist of 53% females and 47% males with male to female ratio of 1:1.13 in the present study. Most of the study subjects (87%) lie in the age ≤45 years of age, 84% having low socio-economic status and 30/47 (63.8%) males were addicts. Mutations in ***rpo*B** Gene were found to be 98% of rifampicin resistant cases and in ***kat*G** 76.7% of isoniazid resistant cases. Most of the mutations (60%) in ***rpo*B** Gene were observed on codon 531 while all the mutations in ***kat*G** Gene were observed on codon 315. No novel mutation was found in the present study.**Conclusion:** Mutation pattern of ***rpo*B** gene that confers rifampicin resistance is different to a little extent from other national and international studies while pattern is same for ***kat*G** gene that confers isoniazid resistance. No novel mutation was observed in present study.

Efflux Pump Gene Expression in Brazilian Clinical Isolates of *Mycobacterium tuberculosis*

Author Block:

L. B. Marino, C. Q. F. Leite, **F. R. Pavan, FRP**; São Paulo State Univ., Araraquara, Brazil

Abstract Body:

Background: Absence of mutations within the genes encoding drug targets in some drug resistant strains of *Mycobacterium tuberculosis* suggests possible involvement of alternative mechanisms such as overexpression of efflux pumps. In this study five putative multidrug efflux pumps genes expression were evaluated in 13 clinical isolates and H_{37}Rv (ATCC 27294) after treatment with rifampicin in four times, 0, 24 h, 48 h and 72 h: three members of Major Facilitator Superfamily (*Rv1258c, Rv1410c* and *Rv2459*) and two members of ATP-binding cassette Superfamily (*Rv1217c* and *Rv1218c*). **Methods:** MIC determination: The rifampicin MIC was determined by REMA technique. RT-qPCR: To evaluate the efflux pump expression profiles the isolates were grown in 7H9 medium until OD_{600nm}=0.6. Rifampicin was added in the concentration of 1/4 of the MIC. Samples for RNA extraction were collected in times of 0h, 24h, 48h and 72h after the treatment. RNA was extracted using RNeasy Mini Kit (QIAGEN) and cDNA was synthesized with High Capacity cDNA Reverse Transcription Kit (Applied Biosystems®). The reactions were run in Applied Biosystems 7500 Real-Time PCR System and the results interpreted in Biogazelle qbase+ software by ΔΔCt method, using *groEL2* and *sigA* as reference genes. **Results:** The treatment with rifampicin for 24 h was not enough to allow the expression of the genes studied. We observed 72 h as the best time for analysis of efflux pumps overexpression. 11 out 13 isolates were classified as MDR with MIC rangin from 2 to 125 μg/mL and 2 susceptible strains showed overexpression in all efflux pumps with similar results (±3 times fold) different than H_{37}Rv with down regulation. Two MDR isolates showed high overexpression in all genes highlighting the *Rv1258c* gene with an increase of 16 fold expression. Interestingly, we observed two MDR isolates with down regulation of expression in all genes overall the time-points. **Conclusions:** Likewise the literature our results showed overexpression in all efflux pumps and the *Rv1258c* was the most overexpressed between the strains. We have not seen any correlation between the MIC and the overexpressed genes. However, the results strengthen the role of efflux pumps in determining antimicrobial resistance for Brazilian clinical isolates of *M. tuberculosis.*

Characterization of "*Mycobacterium* Gyrase Inhibitors" (MGIs): A Novel Class of Gyrase Poisons

Author Block:

E. G. Gibson[1], T. Blower[2], M. Cacho[3], J. Berger[4], N. Osheroff[1]; [1]Vanderbilt Univ., Nashville, TN, [2]Durham Univ., Durham, United Kingdom, [3]GSK, Madrid, Spain, [4]Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract Body:

Tuberculosis is a leading cause of mortality worldwide. The current standard treatment is the RIPE regimen: rifampin, isoniazid, pyrazinamide, and ethambutol. Because resistance is developing against these drugs and the second-line treatment, fluoroquinolones (FQs), there is an urgent need for the development of novel antitubercular drugs to combat resistance. Therefore, we characterized a new class of "*Mycobacterium* Gyrase Inhibitors" (MGIs) that display activity against *Mycobacterium tuberculosis* (Mtb).[1] Three MGIs obtained from GlaxoSmithKline: GSK000, GSK325, and GSK126, displayed activity against Mtb gyrase, with GSK000 being the most efficacious. In marked contrast to FQs (which induce double-stranded DNA breaks), MGIs induce gyrase-mediated single-stranded DNA breaks, even at high drug concentrations or long cleavage time courses. While increasing single-stranded cleavage, MGIs appear to suppress double-strand DNA breaks. Like FQs, MGIs act by inhibiting religation of cleaved DNA. GSK000 displays a strong preference for Mtb gyrase over *Bacillus anthracis* topoisomerase IV or gyrase and *Escherichia coli* topoisomerase IV, suggesting specificity for Mtb. Finally, MGIs retain activity against common FQ resistant mutant gyrase enzymes (GyrA A90V, D94H, and D94G) and displayed no significant activity against recombinant human topoisomerase IIα. Our results suggest that MGIs are a novel class of gyrase poisons that have potential as antitubercular drugs.

Pravastatin Therapy Augments Bactericidal Activity of the First-line Tuberculosis Regimen *In Vivo*

Author Block:

N. K. Dutta[1], N. Bruiners[2], M. L. Pinn[1], M. D. Zimmerman[2], L. Klinkenberg[1], V. Dartois[2], M. L. Gennaro[2], P. C. Karakousis[1]; [1]Johns Hopkins Univ. Sch. of Med., Baltimore, MD, [2]Publ. Hlth.Res. Inst., New Jersey Med. Sch., Newark, NJ

Abstract Body:

Mycobacterium tuberculosis (Mtb) is known to subvert immune responses to establish infection and cause disease. Thus, host-directed therapy (HDT), as adjunctive treatment to traditional antitubercular regimens, is an attractive strategy. Statins are a class of drugs used to lower cholesterol levels by inhibiting the 3-hydroxy-3-methylglutaryl coenzyme A reductase, a crucial enzyme in the cholesterol biosynthesis pathway. Recently, we reported that simvastatin, when added to the first-line antitubercular regimen, shortens the duration of tuberculosis treatment in mice. Here, we conducted a preclinical animal study aimed at comparing the bactericidal activities of the standard TB regimen (rifampin, isoniazid, pyrazinamide and ethambutol; RHZE) with or without escalating doses of pravastatin against chronic TB in BALB/c mice. Antibiotics were given five times weekly for 8 weeks (continuous phase) beginning 6 weeks after infection. To better understand the in vivo outcomes, we also studied single-dose and steady-state pharmacokinetics of the drug in uninfected mice, as well as its efficacy in macrophages. Pravastatin at 180 mg/kg once daily was well tolerated for up to 8 weeks of treatment. Treatment with RHZE plus pravastatin at doses ranging from 30 to 180 mg/kg demonstrated a dose-dependent increase in bactericidal activity, reducing lung bacillary counts by 0.2-0.6 $\log_{10}$, 0.3-0.6 $\log_{10}$ and 0.3-0.8 $\log_{10}$ compared to RHZE alone at weeks 2, 4 and 8, respectively. After 8 weeks of treatment, the degree of lung inflammation correlated with the bactericidal activity of each drug regimen. Also, there was a distinct pravastatin dose-dependent effect observed between 5 μM and 50 μM against Mtb in THP-1 cells. The pharmacokinetics of pravastatin was dose proportional from 15 to 60mg/kg, and the drug is very soluble. Results of the current study raise the possibility of a potentially important class effect against TB. The goal of future studies will be to elucidate the mechanism(s) by which pravastatin exerts its antimycobacterial effect and to determine its contribution to the sterilizing activity of combination regimens against drug-susceptible and drug-resistant TB.

Cd271+ Bone Marrow Mesenchymal Stem Cell Type Is a Targetable Hypoxic Niche for Dormant *Mycobacterium tuberculosis*

Author Block:

J. Garhyan[1], S. Gayan[2], S. Sandhya[2], J. Talkudar[2], R. Bhatnagar[1], B. Das[3]; [1]Jawaharlal Nehru Univ., New Delhi, India, [2]Kavikkrisna Lab., Guwahati, India, [3]The Forsyth Inst., Cambridge, MA

Abstract Body:

Background: The protective niche that shelters dormant *Mycobacterium tuberculosis* (Mtb) is not yet clearly known, hampering our efforts to eradicate latent Mtb infection. We have successfully isolated viable Mtb from the hypoxic CD271+/CD133+ bone marrow mesenchymal stem cells (CD271+ BM-MSCs) of subjects treated for pulmonary tuberculosis (1,2). We then characterized the CD271+ BM-MSC hypoxic niche of dormant Mtb-H37Rv in the Cornell model of Mtb dormancy in mice (2). Our studies identify a novel stem cell niche that shelters dormant Mtb. Here, we investigate the potential targeting of the dormant Mtb stem cell niche by hypoxia-activated agents including tirapazamine (TPZ), a ROS inducing hypoxia-activated agent and ursolic acid, an inhibitor of HIF-1α (3). **Method:** GFP labeled Mtb-H37Rv and streptomycin dependent mutant strain of 18b (m18b), an unique strain of non-replicating dormant Mtb (1) were used for the study. The CD271+ BM-MSCs were infected with these two Mtb strains in vitro/in vivo and then treated with TPZ or Ursolic acid to study potential ROS-induced apoptosis of the Mtb harboring stem cell population. **Results:** In vitro, the TPZ treatment led to increased ROS production, p53 expression, and apoptosis of the Mtb infected CD271+ BM-MSCs, which could be reversed by treating the BM-MSCs with pifithrin α treatment (10 μM for 3 days), a small molecular inhibitor of p53. We found similar results with Ursolic acid (15 μM for 3 days) treatment. The uninfected CD271+ BM-MSCs did not undergo apoptosis following treatment with TPZ or Ursolic acid. In vivo, TPZ treated group showed complete loss of CD271+ BM-MSCs in the Mtb-m18b treated mice and the TPZ effect was reduced by pifithrin-α treatment. We found similar results from ursolic acid group. **Conclusion:** Our work suggest that the dormant Mtb stem cell niche could be targeted by hypoxia-mimetic agents like TPZ and HIF-1α inhibitors like the naturally occurring agent, ursolic acid. Moreover, we speculate that HIF-1α could be working upstream of p53 for survival of Mtb in the host bm niche which could further researched as therapeutic intervention for dormant Mtb in stem cell niche.

Analysis of *Mycobacterium smegmatis* Glutamate Racemase Mutants Suggests a New Pathway of D-Glutamate Biosynthesis

Author Block:

G. Rathnaiah, F. Barnawi, D. K. Zinniel, R. G. Barletta; Univ. of Nebraska, Lincoln, NE

Abstract Body:

Glutamate racemase (MurI) is the main enzyme for D-glutamate biosynthesis in eubacteria and a potential target for drug design. Unfortunately, there are contradictory reports on the essentiality of *murI* in *Mycobacterium*. For example, a recent study indicated that *M. smegmatis murI* is essential in the absence of D-glutamate. However, the corresponding *murI* mutants displayed unusually abundant growth in high osmolarity media without D-glutamate.To reexamine the issue of *murI* essentiality, we generated new *M. smegmatis murI* allelic exchange deletion mutants in low osmolarity Middlebrook 7H9 media (MADC) with 2% sucrose. We confirmed the deletion by PCR, Southern blotting and RT-qPCR analyses; and characterized the mutant strains by growth curves, drug-susceptibility assays and negative staining electron microscopy.These mutants were able to grow on the low osmolality MADC without D-glutamate, though with a significant lag time of about 48 hours as compared to the wild type. However after passage on the same media without D-glutamate, the mutant strain grew without this lag time. Moreover, complementation of the mutant strains restored wild type properties. In contrast to the previous study mentioned above, mutants and the wild type grew very poorly in high osmolarity conditions (MADC with 5% sodium chloride). Furthermore, in low osmolality MADC in the presence or absence of D-glutamate, both wild type and mutant strains displayed similar morphologies when analyzed by electron microscopy. The *murI* mutants were hypersusceptible to D-cycloserine (MIC $\leq$ 3.0 vs. 75.0 μg/ml for the wild type and complemented strains; $P < 0.05$).The viability of *murI* mutants in the absence of D-glutamate in media with low osmolarity indicates that the inactivation of *murI* does not impose an auxotrophic requirement for D-glutamate in *M. smegmatis*. Thus, *murI* is not an essential gene in the absence of D-glutamate. Moreover, these results suggest the existence of a redundant pathway for the biosynthesis of D-glutamate, one of the key amino acids involved in peptidoglycan crosslinking. Understanding this mechanism would be of utmost importance to design new peptidoglycan synthesis inhibitors that could be developed as antimicrobial agents against pathogenic mycobacteria.

Potential Involvement of RuvAB in the Resistance of Mycobacteria to Ethacridine

Author Block:

P. K. Garcia[1], R. Perera[2], Y-C. Tse-Dinh[1]; [1]Florida Intl. Univ., Miami, FL, [2]Sanford-Burnham Med. Res. Inst., Orlando, FL

Abstract Body:

Topoisomerases are essential enzymes for solving all topological problems that are related to the physical structure of the double helix of the DNA. These enzymes are required for the processes of DNA replication, transcription and influence virulence gene expression in many pathogenic bacteria. Topoisomerases generate transient protein-DNA complexes on DNA strand (covalent intermediate). Type I topoisomerase cleaves one DNA strand, while type II topoisomerases cleaves both DNA strands. The transient formation of these covalent intermediates is critical and also dangerous for the cell. Stabilization of any covalent intermediate would induce SOS response and may cause cell death. Bacteria do not possess any enzyme capable of directly hydrolyzing the tyrosyl-DNA phosphodiester bond in the covalent intermediate; instead these complexes are processed by mechanisms of DSB (Double Strand Break) repair. The RuvABC and RecG proteins play significant role in DSB repair mechanisms by resolving the Holliday junctions following DSB formation in the later stages of homologous recombination. In this study whole cell phenotypic profiling coupled with the whole genome sequencing (WGS) of spontaneous resistant mutants was employed in the identification of cellular targets in the growth inhibition of *Mycobacterium smegmatis* by ethacridine. The WGS revealed mutations in *ruvB* gene, which could be a potential target of ethacridine. Alternatively, RuvB may be involved in the ethacridine resistance mechanism because of its role in the processing of topoisomerase covalent intermediate.

Oral Encochleated Amikacin Demonstrates Reduced Toxicity Compared to Intravenous Amikacin

Author Block:

R. Lu[1], J. C. Craft[1], C. Lambros[2], R. Doppalapudi[3], L. Iyer[3], J. C. Mirsalis[3], E. C. Tramont[4], **R. J. Mannino**[1]; [1]Matinas BioPharma, Inc., Bedminster, NJ, [2]NIH/NIAID, Rockville, MD, [3]SRI Intl., Menlo Park, CA, [4]NIH, Bethesda, MD

Abstract Body:

Background: Amikacin (AMK) is a broad spectrum aminoglycoside commonly administered parenterally. Treatment with AMK is frequently associated with oto- and nephrotoxicity, therefore, careful monitoring of blood levels is required. To overcome issues associated with administration and toxicity of AMK, a lipid-crystal, nano-particle forumulation (CAMK) has been developed for oral delivery. Previously CAMK has been shown to be efficacious in mouse models of disseminated and pulmonary *Mycobacterium avium*.**Methods:** Rats were administered 50 mg/kg/day or 200 mg/kg/day oral dose of CAMK in 0.66 M NaCl, in 1mM bile salts, or in 2 mM bile salts for 7-days. Free AMK was administered at 200 mg/kg/day oral and at 50 mg/kg/day intravenously (iv). Rats were euthanized on Day 8. Parameters that were evaluated include mortality/morbidity, clinical observations, body weights, plasma drug levels, toxicokinetic analysis, clinical pathology, necropsy observations, organ weights, and histopathology.**Results:** All animals survived to scheduled sacrifice. Across dose groups oral CAMK provided 100-fold lower plasma levels of AMK than the iv dose. There was a trend toward a lower exposure on Day 7 versus Day 1 in several dose groups. The amikacin prescribing information states that the C_{max} of amikacin should not exceed 35 µg/mL. The C_{max} of all CAMK formulations did not exceed 2 µg/mL (2000 ng/mL) but in the *Mycobacterium avium* lung and disseminated model 100 mg/kg doses showed efficacy. The various changes seen in all treatment groups were of minimal toxicologic significance.**Conclusions:** CAMK in three different vehicle formulations was well-tolerated at 50 and 200 mg/kg for 7 days. Based on changes in organ weights, the NOAEL is considered to be less than 50 mg/kg for CAMK in NaCl and 200 mg/kg for CAMK in 1 mM and 2 mM bile salts. This compares favorably with the published NOAEL for free AMK in rats which is 100 mg/kg.

Magnitude of Gene Mutations Conferring Drug Resistant in *Mycobacterium tuberculosis* Strains in Southwest Ethiopia

Author Block:

M. Tadesse; Jimma Univ., Jimma, Ethiopia

Abstract Body:

The nature and frequency of mutations in rifampicin (RIF) and isoniazid (INH) resistance *M. tuberculosis* isolates vary considerably according to the geographic locations. However, information regarding specific mutational patterns in Ethiopia remains limited. Mutations associated with RIF and INH resistance were studied by GenoType MTBDRplus line probe assay in 112 *M. tuberculosis* isolates. Culture (MGIT960) and identification tests were performed at Mycobacteriology Research Center of Jimma University, Ethiopia. Mutations conferring resistance to INH, RIF and MDR were detected in 36.6% (41/112), 30.4% (34/112) and 27.7% (31/112) of *M. tuberculosis* isolates respectively. The retreatment category 'treatment failure' is associated with a high rate of mutations associated with drug resistance (p-value <0.05). Among 34 rifampicin resistant isolates, 82.4% (28/34) had *rpoB* gene mutations at codon 531, 2.9% (1/34) at codon 526 and 5 had mutations only at wild type probes. The later isolates were depicted as unknown. Of 41 INH resistant strains, 87.8% (36/41) had mutations in the *katG* gene at Ser315Thr1 and 9.8% (4/41) of strains had mutation in the *inhA* gene at C15T. One INH resistant strain had mutation only at *KatG* wild type probe. Mutations in *inhA* promoter region were strongly associated with INH monoresistance. Monoresistance to INH (10 isolates) was frequently observed as compared to RIF monoresistance (3 isolates). High rate of drug resistance, including MDR, was commonly observed among failure cases. The most frequent gene mutations associated with the resistance to INH and RIF were observed in the codon 315 of the *katG* gene and codon 531 of the *rpoB* gene, respectively. Further studies on mutations in different geographic regions using DNA sequencing techniques are warranted to improve the kit by including more specific mutation probes in the kit.

Inhibition of *Mycobacterium tuberculosis C*holesterol Catabolism Through Camp Production

Author Block:

K. L. Brown[1], I. Casabon[1], L. Ballell-Pages[2], L. D. Eltis[1]; [1]Univ. of British Columbia, Vancouver, BC, Canada, [2]Tres Cantos Open Lab Fndn., Madrid, Spain

Abstract Body:

Mycobacterium tuberculosis, the causative agent of TB, now outranks HIV as the world's leading cause of mortality from an infectious disease with 1.5 million deaths in 2014 alone. The rise of antibiotic resistant strains has led to an urgent need for novel therapeutics for the treatment of TB. The ability of *M. tuberculosis* to catabolize host-derived cholesterol during infection has emerged as a promising target for the development of new antimycobacterial agents as it has been shown repeatedly to be essential for pathogenesis. In a screen designed to identify compounds that inhibit growth of *M. tuberculosis* both intracellularly and *in vitro* with cholesterol as a sole carbon source, an intriguing candidate that inhibits growth on cholesterol with an IC_{50} of 0.2 μM was identified. The compound acts indirectly to inhibit cholesterol catabolism through stimulation of cAMP production by interaction with the adenylate cyclase Rv1625c. Treatment of *M. tuberculosis* with our compound resulted in a ~50x increase in intracellular [cAMP]. Using LC-MS, we found that the compound also leads to a decrease in the ratio of acetyl-CoA to propionyl-CoA from 4:1 to 1:1, indicating that the compound has profound effects on downstream central metabolism when *M. tuberculosis* is grown on cholesterol as a sole carbon source. Growth on cholesterol in the presence of the compound can be rescued with the addition of vitamin B12, enabling *M. tuberculosis* to shunt excess propionyl-CoA through the vitamin B12-dependent methylmalonyl pathway. These data suggest that the mode of action involves excess propionyl-CoA accumulation, which is toxic to *M. tuberculosis* and other microorganisms. This toxicity was shown to be mediated by stimulation of Rv1625c activity, as the effect is not observed in an Rv1625c transposon mutant. Treatment of *Rhodococcus jostii* RHA1 expressing full length but not truncated Rv1625c results in compound-dependent production of cAMP, indicating the compound likely interacts with the transmembrane domain of the protein. Rv1625c is a promising drug target and the downstream effects of the compound-mediated cAMP production are yielding intriguing insights into the metabolic regulation of *M. tuberculosis.*

Pharmacokinetic Parameters of Daptomycin According to Renal Function in Japanese Patients with Skin and Soft Tissue Infections: Subset Analysis of a Phase III Study

Author Block:

T. Ueda[1], Y. Takesue[1], H. Mikamo[2], S. Kusachi[3], K. Takahashi[4], N. Aikawa[5]; [1]Hyogo Coll. of Med., Hyogo, Japan, [2]Aichi Med. Univ., Aichi, Japan, [3]Toho Univ. Med. Ctr. Ohashi Hosp., Tokyo, Japan, [4]MSD K.K, Tokyo, Japan, [5]Sch. of Med., Keio Univ., Tokyo, Japan

Abstract Body:

Background: The clinical outcomes of a phase III study of patients with skin and soft tissue infections (SSTI) that were treated with 4 mg/kg of daptomycin were reported by Aikawa et al. (2013). Using data for a subgroup of the study population, we investigated the pharmacokinetic (PK) parameters of daptomycin according to renal function. **Methods**:We analyzed the PK parameters of 82 patients with creatinine clearance (CL_{CR}) rates of ≥30 ml/min in whom SSTI caused by Gram-positive cocci were treated with 4 mg/kg/day daptomycin. Blood samples (5 time points) were collected at 4 days after the initiation of treatment. The PK parameters were calculated for three renal function groups (CL_{CR} values: ≥80, 40-80, 30-40 ml/min). **Results**: There were significant correlations between renal function and the PK parameters including the clearance and half-life of daptomycin (Table, [a]: Significantly different from the >80 ml/min group, Scheffe adjusted p-value <0.05). Although the patients with CL_{CR} rates of 40-80 or 30-40 mL/min exhibited significantly higher minimum daptomycin concentrations (C_{min}) than those with CL_{CR} rates of ≥80 ml/min, both of these groups exhibited clinically low C_{min} values (7.81 and 7.49 μg•hr/mL, respectively). The $AUC_{0\text{-}24}$ was 407.0 μg•hr/mL in the patients with CL_{CR} rates of 40-80 ml/min and 323.0 μg•hr/mL in those with CL_{CR} rates of ≥80 ml/min. **Conclusions**:The PK values of each CL_{CR} group were similar to the values reported for phase II/III subjects by Dvorchik B et al. (2004). Renal function contributed to interindividual variations in daptomycin clearance in patients with SSTI who were administered 4 mg/kg/day daptomycin. In addition, we confirmed that dosage adjustment was not required in patients with CL_{CR} rates of 30-80 ml/min.

Summary of pharmacokinetic parameters sorted by estimated CLCR and obtained by Bayesian estimation

	Value for each CL_{CR} group: median (range)		
PK parameter	≥80 ml/min (n=38)	40-80 ml/min (n=37)	30-40 ml/min (n=7)
CL (L/hr)	0.75 (0.45-3.28)	0.53 (0.27-0.95)a	0.47 (0.26-0.78)a
V1 (L)	5.24 (3.42-14.00)	4.81 (2.06-11.30)	5.27 (3.25-15.00)
Vss (L)	9.84 (6.10-19.30)	8.97 (4.60-14.10)	9.05 (6.23-18.60)

T1/2 (hr)	9.16 (4.54-12.80)	11.90 (6.28-18.20)a	14.95 (10.80-20.10)a
Cmin (µg/mL)	4.75 (0.31-14.00)	7.81 (1.29-19.50)a	7.49 (5.37-17.70)a
Cmax (µg/mL)	45.65 (18.30-72.10)	45.30 (12.80-66.50)	40.80 (17.80-67.40)
AUC0-24 (µg•hr/mL)	323.0 (85.5-696.0)	407.0 (124.0-769.0)	368.0 (256.0-737.0)

Pharmacokinetics of Meropenem During Initial Severe Sepsis

Author Block:

K. Trerayapiwat, S. Jaruratanasirikul; Prince of Songkla Univ., Faculty of Med., Hat Yai, Songkla, Thailand

Abstract Body:

Background: Pathophysiological alterations during severe sepsis can affect pharmacokinetics (PK), resulting in the therapeutic success of antimicrobial agents. The objective of this study was to determine the PK of meropenem during the initial period of severe sepsis. **Methods:** The study was conducted during the first 8 h of life-threatening severe sepsis in 12 patients. The severity of the critically illness of the patients were assessed by the Acute Physiology and Chronic Health Evaluation (APACHE) II scores and the Sepsis-related Organ Failure Assessment (SOFA) score. The PK studies were performed during the 1st dose of 1 g every 8 h of a 1-h infusion of meropenem and compared to PK parameters of a 3-h infusion of a single 1-g dose of meropenem in healthy volunteers from pervious study.**Results:** The mean PK parameters of meropenem in this patient population compared to healthy volunteers are shown in Table.

PK Parameter	Patients with severe sepsis	Healthy Volunteers	*p* value
C_{max} (mg/L)	46.24 ± 17.69	24.95 ± 6.85	< 0.01
C_{min} (mg/L)	6.47 ± 6.95	0.47 ± 0.23	< 0.01
$AUC_{0-\infty}$ (mg*h/L)	195.10 ± 163.62	80.06 ± 21.86	< 0.05
$t_{1/2}$ (h)	4.19 ± 4.04	0.61 ± 0.14	< 0.01
k_e (h^{-1})	0.30 ± 0.18	1.21 ± 0.38	< 0.01
V (L)	28.77 ± 16.18	11.72 ± 2.22	< 0.05
CL (L/h)	9.02 ± 7.45	14.46 ± 5.88	0.08

Conclusions: 1) The PK parameters in the patients with severe sepsis exhibited a high range of variability, and 2) the *V* and $t_{1/2}$ of meropenem were greater, but the CL lower, in the patients with severe sepsis than in the healthy volunteers.

Dosage Modification of Linezolid in Patients Undergoing Continuous Venovenous Hemodiafiltration

Author Block:

T. Ueda[1], Y. Takesue[1], K. Nakajima[1], T. Ide[1], S. Nishi[1], H. Kohama[1], K. Ikawa[2], N. Morikawa[2]; [1]Hyogo Coll. of Med., Hyogo, Japan, [2]Hiroshima Univ., Hiroshima, Japan

Abstract Body:

Background: Linezolid (LZD) dosage adjustment is not recommended for patients undergoing continuous venovenous hemodiafiltration (CVVHDF). We reported that LZD clearance (CL) was decreased in patients that underwent low-flow-rate CVVHDF, which is popular in Japan (Ide T et al., ICAAC 2011). We propose a revised LZD regimen for such patients and investigate the pharmacokinetics (PK) of this protocol.**Methods:** Patients on CVVHDF received 600 mg LZD intravenously once a day (with/without a 600 mg loading dose twice daily for the first 2 days). Blood samples were collected at 0, 1, 1.5, 2, 3, and 5h after the infusion on days 5-8 of therapy. The maximum and minimum concentrations (C_{max}, C_{min}), $T_{1/2}$, concentration time curve (AUC_{0-24}), CL, and volume distribution (Vd) were evaluated. Thrombocytopenia was defined as a $\geq 10 \times 10^4$ cells/mm³ decrease or ≥30% reduction in the platelet count from the baseline.**Results:** Nine patients were included. No. 8 and 9 did not receive the twice-daily loading dose. The mean blood, dialysate, and filtration flow rates were 83.3±10.0 mL/min, 13.3±5.3 mL/hr, and 16.2±4.1 mL/min, respectively. Thus, the CVVHDF was performed at a low flow rate. The patients exhibited slower LZD CL than patients with normal renal function (Stalker D. J et al., LZD CL: 7.4 L/h). The target C_{min} value (≤7 μg/mL; Pea F et al.; chosen to prevent adverse effects) was only achieved in 5 patients (55.6%), but the target AUC_{0-24} value (≥200 μg h/mL; Rayner CR, et al.; chosen to increase clinical efficacy) was achieved in 8 patients (88.9%). Of the 4 patients without leukemia, No. 1, 5, and 7, who exhibited higher C_{min} values than patient 6, developed thrombocytopenia. Clinical success was achieved in No. 3, 7, and 8, and no correlation with AUC was seen.**Conclusions:** Although the target AUC value was achieved during the daily administration of 600 mg LZD, significant LZD accumulation was observed in patients that underwent low-flow-rate CVVHDF. Even lower doses might be required in this setting.

Table: The PK of LZD during the daily administration of 600 mg LZD

Intraperitoneal Penetration of Piperacillin-Tazobactam in Patients Undergoing Abdominal Surgery

Author Block:

H. Ohge, N. Murao, K. Ikawa, Y. Watadani, S. Uegami, N. Shigemoto, N. Shimada, T. Kajihara, R. Yano, N. Morikawa, T. Sueda; Hiroshima Univ., Hiroshima, Japan

Abstract Body:

Background: While piperacillin-tazobactam (PIPC/TAZ) is widely used for the treatment of intra-abdominal infections, limited data on intraperitoneal penetration are available. This study was conducted to define the pharmacokinetics and pharmacodynamics of PIPC/TAZ in the peritoneal cavity.**Methods:** PIPC/TAZ (4.0-0.5 g) was intravenously administered to 10 abdominal surgery patients with inflammatory bowel disease. Plasma, peritoneal fluid, and peritoneum samples were obtained at the end of the infusion (0.5 h) and 1.5, 2.5, 3.5, and 4.5 h post dosing. Drug concentration data were analyzed non-compartmentally and were fit to a multi-compartment model to estimate the amount of time the drug concentration exceeded the minimum inhibitory concentration (T > MIC).**Results:** The mean maximum PIPC and TAZ concentrations were 192.7 and 23.6 mg/L in peritoneal fluid and 131.3 and 14.9 mg/kg in the peritoneum, respectively. The mean area under the PIPC concentration-time curve from 0 to infinity (AUC) and the ratio to plasma were 498.1 mg•h/L and 0.75 for peritoneal fluid and 327.6 mg•h/kg and 0.49 for the peritoneum. The mean PIPC/TAZ ratio was 8.1 in the two sites (**Table**). Using the mean pharmacokinetic model parameters, site-specific pharmacodynamic-derived breakpoints (the highest MIC at which T > MIC for PIPC in both peritoneal fluid and the peritoneum was >50%) were 16 mg/L for dosing both 4.5 g every 8 h and 3.375 g every 6 h (13.5 g/day) and 32 mg/L for dosing 4.5 g every 6 h (18 g/day).**Conclusions:** PIPC-TAZ penetrated well into the peritoneal cavity, maintaining the drug combination ratio of 8:1. Dosages of 13.5 g/day and 18 g/day achieved the bactericidal T > MIC target in the sites with MICs of 16 and 32 mg/L, respectively.

Mean ± SD (n = 10)	Peritoneal fluid AUC (mg•h/L)	Peritoneum AUC (mg•h/kg)	Peritoneal fluid/ plasma ratio	Peritoneum/ plasma ratio
PIPC (4 g)	498.1 ± 161.4	327.6 ± 84.0	0.75 ± 0.21	0.49 ± 0.12
TAZ (0.5 g)	61.4 ± 19.1	41.2 ± 12.4	0.79 ± 0.19	0.53 ± 0.14
PIPC/TAZ ratio	8.1 ± 0.6	8.1 ± 0.8

Population Pharmacokinetics (Poppk) of Cefazolin (Cfz) in Serum and Adipose Tissue (At) from Obese Women Undergoing Cesarean Section

Author Block:

M. Grupper[1], J. L. Kuti[1], M. L. Swank[2], L. Maggio[3], D. P. Nicolau[1]; [1]Ctr. for Anti-Infective Res. & Dev., Hartford Hosp., Hartford, CT, [2]Miller Children's & Women's Hosp., Long Beach, CA, [3]Univ. of South Florida, Tampa, FL

Abstract Body:

Background: CFZ is often used as antibiotic prophylaxis for cesarean delivery. The optimal dosing regimen for obese women is unknown. We determined the variability of CFZ AT exposure in this population and evaluated 1, 2, and 3 gram (g) doses.**Methods:** PopPK analyses were performed using the non-parametric adaptive grid algorithm within Pmetrics for R to co-model serum and AT concentrations from patients enrolled in 2 previous pharmacokinetic studies. Patients received CFZ as a 5 min infusion followed by 1-3 serum and AT samples collected during surgery. AT penetration was calculated as the $AUC_{0\text{-}8AT}$ over the free $AUC_{0\text{-}8serum}$. Serum protein binding was assumed to be 85%. A 5000 patient Monte Carlo simulation was conducted for 1, 2 and 3g doses to calculate probability of target attainment (PTA) for AT concentrations remaining above the minimum inhibitory concentration (MIC_{90}, 1 mcg/mL) of methicillin susceptible *Staphylococcus aureus* (MSSA) at 2 and 4 h after the dose. **Results:** 68 patients (mean body weight (BW): 102 kg; range: 54-152 kg; mean body mass index (BMI): 38.5 kg/m^2; range: 24.3-55.8 kg/m^2) provided 102 serum and 136 AT samples for inclusion. The mean±SD time interval from CFZ administration to fascia closure was 76.5±21 min (max: 146 min). A 2 compartment model, with one of the compartments representing AT concentration, fit the data best. BW and BMI covariates were explored, and although significant, did not improve the model. The final model resulted in the following parameter values: clearance = 7.4±5.3 L/h, volume of central compartment = 11.7±9.3 L, and AT volume of distribution = 80.6±54.6 L. The mean±SD (median) penetration ratios into AT were 1.1±3.1 (0.73). At 2 h after the dose, PTA for the 1, 2, and 3 g doses was 80.6, 89.6, and 92.6%, respectively. At 4 h, PTA for the 1, 2, and 3 g doses was 57.3, 71.8, and 77.5%, respectively. **Conclusion:** Considering the surgery duration (~1-2 h) for most patients undergoing cesarean delivery, these data suggest that a CFZ 2 g dose will provide AT concentrations above the MIC of MSSA for the majority of obese females up to 150 kg. A second dose may be considered if surgery extends beyond 2 h.

Population Pharmacokinetics (Poppk) and Safety of Ceftolozane/Tazobactam (C/T) in Adult Cystic Fibrosis (Cf) Patients Admitted with Acute Pulmonary Exacerbation (Ape)

Author Block:

M. L. Monogue[1], R. S. Pettit[2], J. J. Cies[3], M. Muhlebach[4], D. P. Nicolau[1], J. L. Kuti[1]; [1]Ctr. for Anti-Infect. Res. & Dev., Hartford Hosp., Hartford, CT, [2]Riley Hosp. for Children, Indianapolis, IN, [3]St. Christopher's Hosp. for Children, Philadelphia, PA, [4]UNC, Chapel Hill, NC

Abstract Body:

Background: C/T has potent activity against *Pseudomonas aeruginosa*, a pathogen associated with CF APE. Due to the rapid elimination of many antibiotics, CF patients frequently have altered PK. Herein, we describe the PopPK and safety of C/T in CF patients admitted with an APE.**Methods:** In this multicenter, open-label PK study, adult CF patients admitted with APE received 3g of C/T q8h. After 4-6 doses, blood was collected at 6 time-points for measuring ceftolozane and tazobactam concentrations by HPLC. PopPK was performed by Non-Parametric Adaptive Grid in Pmetrics for R. A 5,000 patient Monte Carlo simulation was performed to determine the probability of target attainment (PTA) for a 3g q8h (1 h infusion) regimen across a range of MICs using a ceftolozane target of 39% free time above the MIC, assuming 20% protein binding.**Results:** 11 adults (3 male, 8 female) with mean (range) age, weight, and height of 21 (18-30) years, 51.3 (41.6-58.7) kg, and 159.6 (149.7-175.3) cm, respectively, were included. Ceftolozane and tazobactam concentration data were best described by 2-compartment models. Final parameter estimates for ceftolozane were: Clearance (CL) = 4.5±1.0 L/h, Volume of Central Compartment (Vc) = 6.9±2.9 L, and intercompartment transfer constants (Kcp) = 1.5±2.5 h^{-1} and (Kpc) = 0.8±1.2 h^{-1}. Final PopPK parameters for tazobactam were: CL = 19.7±5.0 L/h, Vc = 13.0±8.6 L, Kcp = 1.3±1.3 h^{-1}, and Kpc = 1.7±2.7 h^{-1}. The R^2, bias, and imprecision for the final individual predicted versus observed concentrations were 0.99, -0.13, and 1.75, respectively, for ceftolozane and 0.99, -0.09, and 1.01, respectively, for tazobactam. PTA for a 3g q8h regimen was 99.8, 99.7, 99.6 and 92.3% at MICs of 4, 8, 16, and 32 µg/mL, respectively. No clinically significant adverse events were observed.**Conclusions:** In these 11 CF patients with APE, C/T 3g q8h was well tolerated, PopPK estimates were in accordance with published data in healthy volunteers and non-CF patients, and this regimen achieved target PD exposure at MICs up to 32 µg/ml. These observations support additional studies of C/T for *Pseudomonas aeruginosa* APE in CF patients.

Pharmacokinetics of Daptomycin (Dap) in Patients Undergoing Continuous Veno-Venous Hemodiafiltration (Cvvhdf)

Author Block:

T. Ide[1], S. Nishi[1], Y. Takesue[1], K. Ikawa[2], N. Morikawa[2]; [1]Hyogo Coll. of Med., Nishinomiya City, Hyogo, Japan, [2]Hiroshima Univ., Hiroshima City, Japan

Abstract Body:

Background: Eight mg/kg DAP every 48 h is recommended for critically ill patients on CVVHDF[1)] . Investigating effects of flow rate on DAP withdrawal during CVVHDF is essential for adjusting therapeutic dosage. **Methods:** DAP 6 mg/kg was administered intravenously every 48 h to CVVHDF patients. Blood and filtrate samples were collected at 0, 1, 1.5, 2, 5, 12, 24, and 48 h after infusion. All collected samples were analyzed using HPLC and pharmacokinetics evaluated. Patient characteristics and CVVHDF parameters including blood, dialysate, and filtration flow rates were recorded.**Results:** Seven patients were included in the study. Mean blood, dialysate, and filtration flow rates were 85.7 ± 9.8 mL/min, 7.7 ± 1.6 mL/min, and 7.7 ± 1.6 mL/min, respectively, confirming that CVVHDF was performed under low-flow setting. The types of infection were was bacteremia (3), intraabdominal infections (2), necrotizing fasciitis (1), and pyogenic spondylitis (1). The types of pathogen were methicillin-resistant *Staphylococcus aureus* (3), *Enterococcus faecium* (3), and empiric therapy (1). Maximum concentration was 50.5 ± 15.9 mg/L; trough serum concentration (C_{min}), 20.0 ± 16.5 mg/L; elimination half-life (T-1/2), 34.8 ± 26.0 h; area under concentration-time curve (AUC), 1060 ± 659 mg h/L; volume of distribution, 18.9 ± 10.5 L; clearance (CL), 7.63 ± 4.57 mL/min; and fraction unbound, 7.2 ± 2.6 %. Sieving coefficient and CL of dialyzer were 0.09 ± 0.04 and 1.34 ± 0.44 mL/min, respectively. No patient met the creatine phosphokinase (CPK) elevation criteria. The clinical response rate was 71.4% (5/7 patients).**Conclusions:** DAP, > 666 to 1061 mg h/L of AUC/MIC was required to obtain clinical success[2)], and C_{min} cutoff point of 24.3 g/mL was associated with CPK elevation[3)]. Because the MIC of DAP in almost all isolates was <1 μg/mL[2),4)], an adequate AUC was obtained in our study. However, because of the low-flow rate setting in our study, T-1/2 was relatively higher than in a previous report[5)], and resulted in higher C_{min}. Although target AUC was achieved, 6 mg/kg DAP every 48 h increased the risk of accumulation in patients on CVVHDF in a low-flow setting.

Publishing Title:

Ampicillin (AMP) Pharmacokinetics (PK) in Neonates Receiving Extra-Corporal Life Support (ECLS)

Author Block:

J. Cies[1], W. Moore, II[1], M. Young[2], V. Bains[2], D. Carella[2], A. Enache[3], A. Chopra[4]; [1]The Ctr. for Pediatric Pharmacotherapy, Pottstown, PA, [2]St. Christopher's Hosp. for Children, Philadelphia, PA, [3]Atlantic Diagnotic Lab., Ben Salen, PA, [4]NYU Langone Med. Ctr., New York, NY

Abstract Body:

Background: Many factors can affect PK in the neonatal ICU including sepsis and ECLS. Currently, no AMP PK data exists for children on ECLS with the current ECLS equipment. The purpose of this study was to describe AMP PK in neonates with a contemporary ECLS operation, including the Quadrox-ID Pediatric (HMOD 30000) diffusion membrane.**Methods:** This was a PK study of hospitalized neonates receiving IV AMP 100 mg/kg/dose q8 hr infused over 0.5 hr for suspected sepsis/meningitis between January-December 2015. Each patient contributed at least 2 blood samples over the dosing interval for AMP concentration determination. AMP concentrations were determined by liquid chromatography/tandem mass spectroscopy. AMP concentrations were modeled using Pmetrics, a nonparametric pharmacometric modeling and simulation package for R. Multiple compartmental and covariate (body weight) models were explored. The % of the dosing interval with free drug concentrations above the MIC (*f*T>MIC) was calculated using an MIC of 8 and 16 mcg/mL. Bactericidal exposure was defined as ≥ 50% *f*T>MIC. The probability of target attainment (PTA) > 90% for each MIC was defined as optimal.**Results:** 4 neonates contributed 9 AMP concentrations. The median gestational age was 37.5 weeks (range 36-39 weeks). Mean ± SD birth weight was 3.14 ± 0.3 kg. AMP concentration data best fit a 2-compartment model using weight as a covariate for clearance (CL) and volume of the central compartment (Vc). Population estimates for CL, Vc, and intercompartment transfer constants were 0.74 ± 0.52 mL/min/kg, 0.05 ± 0.03 L/kg, 2 ± 0.16 h^{-1} and 3.2 ± 2 h^{-1}, respectively. R^2, bias, and precision for the individual predicted versus observed fit were 0.6, -1.74 and 1.05 µg/mL, respectively. The mean ± SD k_e was 0.4 ± 0.17 hr^{-1}. The mean ± SD $t_{1/2}$ was 1.94 ± 0.83 hrs. At the MICs of 8 and 16 mcg/mL, the PTA for 100 mg/kg/dose q8 hr was 100%.**Conclusions:** These are the first AMP PK data in neonates with a contemporary ECLS circuit utilizing the Quadrox-ID Pediatric (HMOD 30000) diffusion membrane demonstrating higher CL values with a smaller Vd.

Gentamicin Pharmacokinetics in Neonates with Hypoxic Ischemic Encephalopathy in the Setting of Controlled Hypothermia

Author Block:

T. Habib[1], O. Menkiti[1], V. Bains[1], M. Young[1], W. Moore, II[2], A. Chopra[3], **J. Cies**[2]; [1]St. Christopher's Hosp. for Children, Philadelphia, PA, [2]The Ctr. for Pediatric Pharmacotherapy, Pottstown, PA, [3]NYU Langone Med. Ctr., New York, NY

Abstract Body:

Background: Perinatal asphyxia and subsequent therapeutic controlled hypothermia (CH) are independently known to alter renal function but the combined effect on the pharmacokinetics (PK) of commonly used medications is unknown. We aimed to evaluate the combined effect of moderate to severe hypoxic ischemic encephalopathy (HIE) and CH on gentamicin (G) pharmacokinetics (PK).**Methods:**This was a PK study of hospitalized neonates with moderate to severe HIE undergoing CH receiving IV G 4-5 mg/kg q36 infused over 0.5 hr for suspected meningitis between Sept-Dec 2015. Each patient contributed at least 5 (range 5-9) scavenged blood samples over multiple dosing intervals for G concentration determination. G concentrations were determined by liquid chromatography/tandem mass spectroscopy. G concentrations were modeled using Pmetrics, a nonparametric pharmacometric modeling and simulation package for R. Multiple compartmental and covariate (body weight) models were explored.**Results:**5 neonates contributed 29 G samples. The median gestational age was 39 weeks (range 36-41 weeks). Mean ± SD birth weight was 3.2 ± 0.62 kg. G concentration data best fit a 2-compartment model using weight as a covariate for clearance (CL) and volume of the central compartment (Vc). Population estimates for CL, Vc, and intercompartment transfer constants were 0.69 ± 0.21 mL/min/kg, 0.11 ± 0.01 L/kg, 0.62 ± 1.3 h^{-1} and 0.72 ± 1.48 h^{-1}, respectively. R^2, bias, and precision for the individual predicted versus observed fit were 0.97, -0.82 and 2.32 µg/mL, respectively. The mean ± SD $t_{1/2}$ was 13.8 ± 8 hrs as compared to a reported $t_{1/2}$ range of 3-11 hrs in term newborns. The mean ± SD Vd was 0.24 ± 0.1 L/kg as compared to a reported Vd of 0.45 ± 0.1 L/kg in term newborns.**Conclusions:**These data suggest that CH does have an impact on the PK of G in neonates with HIE undergoing CH, most notably a smaller volume of distribution with a similar CL estimate.

Publishing Title:

Tissue Concentrations Of Vancomycin During Posterior Spinal Fusions In Neuromuscular Scoliosis

Author Block:

S. M. Brown; Washington Univ. Sch. of Med., St. Louis, MO

Abstract Body:

Due to the rate of surgical site infections (SSI) in posterior spinal fusions (PSF) in neuromuscular (NM) scoliosis and the prevalence of multi-drug resistant organisms, vancomycin is part of standard antibiotic prophylaxis. This prospective study of 17 consecutively enrolled patients who underwent definitive PSF for NM scoliosis received vancomycin infusion pre-operatively evaluated tissue penetrance of vancomycin in the neuromuscular scoliosis population. Serum vancomycin concentrations were obtained immediately after infusion, at surgical incision, and then at 1 hour, 2 hours, and 4 hours post incision. Perispinal muscle tissue samples were obtained at incision, 1 hour, 2 hours, and 4 hours post incision and analyzed by a validated liquid chromatography-tandem mass spectrometry (LC-MS/MS) method. The study consisted of 10 males and 7 females with a mean age of 15y1.5m (10-20y). Mean infusion amount was 15.03 mg/kg. Median vancomycin concentrations were 19.8 (µg/ml) after infusion, 15.1 at incision, 10.5 at 1 hour, 9.6 at 2 hours, and 6.7 at 4 hours post infusion. Median muscle concentrations were 0.6 (µg/ml) at incision, 0.7 at 1 hour, 0.4 at 2 hours, and 0.5 at 4 hours post infusion. Hence, median serum concentrations were demonstrated to reach MIC at incision and at all time points during surgery, but median muscle concentrations never reached MIC at any time point. No patients had any cardiac or kidney disease, and all patients had normal kidney function based on laboratory values. Using accepted guidelines for the administration of intravenous vancomycin, serum vancomycin concentrations reached MIC at all time points tested during PSF for NM scoliosis. However, at no time point tested did muscle concentrations reach MIC.

Comparison of Ceftazidime-Avibactam (CAZ-AVI) Exposure and PK/PD Target Attainment (TA) Across Patient Subgroups

Author Block:

S. Das[1], J. G. Wright[2], **T. Riccobene**[3], M. Macpherson[2], T. J. Carrothers[3], M. Lovern[4];
[1]AstraZeneca, Macclesfield, United Kingdom, [2]Wright Dose, Altrincham, United Kingdom, [3]Allergan, Jersey City, NJ, [4]Quantitative Solutions, Raleigh, NC

Abstract Body:

Background: Factors such as rate of creatinine clearance (CrCL), obesity, age or severity of inflammation could potentially impact CAZ and AVI pharmacokinetics (PK). Using population PK (popPK) models, individual patient exposures of Phase 3 patients with complicated intra-abdominal or urinary tract infections (cIAI or cUTI) were estimated. The impact of various covariates on CAZ and AVI exposures and PK/PD TA was explored in relevant patient subgroups.**Methods:** Data from ~1350 patients with cIAI or cUTI from Phase 3 studies were used along with Phase 1 and 2 study data to develop full covariate CAZ and AVI popPK models. Most patients received CAZ-AVI 2000-500 mg as a 2 h IV infusion q8h. These models were used to generate individual predictions for Phase 3 patients of CAZ and AVI area under the plasma concentration-time curve at steady state during the dosing interval (AUC_{SS}), maximum plasma concentration at steady state (C_{maxSS}) and TA (targets: CAZ 50% fT>CAZ-AVI MIC of 8 mg/L; AVI 50% fT>C_T of 1.0 mg/L). Exposures and TA were summarized across subgroup categories: CrCL (>150 vs. 80-150 mL/min); BMI (>39.9 vs. <39.9 kg/m^2); and age (>65 vs. <65 y). More severe systemic inflammation at baseline was also assessed by comparing exposure: in the presence or absence of SIRS, bacteremia, and fever; APACHE II score >10 or ≤10; and white blood cell count (WBC) ≤12,000/mm^3 or >12,000/mm^3.**Results:** High estimated CrCL (>150 mL/min), obesity and older age were associated with modest decreases in AUC_{SS} for both CAZ and AVI compared with patients with CrCL 80-150 mL/min normal renal clearance, lower BMI and younger age; however, PK/PD TA remained >95% across all patient categories. Presence of SIRS, bacteremia, fever, APACHE II score >10 or high WBC (>12,000/mm^3) at baseline had no significant impact on CAZ or AVI exposure and TA was >95% in all subgroups.**Conclusions:** CAZ-AVI 2000-500 mg by 2 h infusion q8h provides robust PK/PD TA for MICs ≤8 mg/L in patients with high CrCL (>150 mL/min), obesity, or aged over 65. Systemic inflammation did not impact CAZ or AVI exposure, demonstrating the dose is sufficient in patients with more severe disease.

Clinical Pharmacokinetics of Levornidazole in Elderly Subjects and Dosing Regimen Evaluation

Author Block:

B. Guo, G. He, X. Wu, J. Yu, G. Cao, Y. Li, Y. Fan, Y. Chen, Y. Shi, Y. Zhang, J. Zhang; Inst. of Antibiotics, Huashan Hosp., Fudan Univ., Shanghai, China

Abstract Body:

Background: Levornidazole, the levo isomer of ornidazole, is a third-generation nitroimidazole derivative newly developed after metronidazole, tinidazole and ornidazole. Levornidazole was approved by the China Food and Drug Administration in 2009. The objective of this study was to investigate the pharmacokinetic (PK) profile of levornidazole and metabolites in healthy Chinese elderly subjects, and to evaluate the dose regimens for the elderly patients.**Methods:** An open-label, non-randomized, parallel control design, single-dose study was conducted at Huashan Hospital, Fudan University, Shanghai, China. Levornidazole was intravenous administered at 500 mg in 100 mL of sodium chloride injection to 12 healthy Chinese elderly or young subjects. The PK profiles of levornidazole and its five metabolites (M1, M2, M4, M6 and M16) and drug disposition in the elderly subjects were evaluated and compared with the young group. WinNonlin software was used to simulate the PK profiles of levornidazole in the elderly population following the dosing regimens of 500 mg twice daily and 750 mg once a day for 7 days. The cumulative fraction of response (CFR) of levornidazole against *Bacteroides fragilis* and other *Bacteroides spp* and the probability of target attainment (PTA) for various MIC levels were estimated using Monte Carlo simulation.**Results:** The C_{max}, AUC_{0-24} and $AUC_{0-\infty}$ of levornidazole were 11.98 μg/mL, 131.36 μg·h/mL and 173.61 μg·h/mL in the elderly group. The $T_{1/2}$, CL_t and $MRT_{0-\infty}$ of the elderly subjects were 12.21 h, 2.91 L/h and 16.46 h. The metabolic ratios of M1, M2, M4, M6 and M16 in the elderly groups were 2.14%, 0.08%, 2.91%, 0.03% and17.70%, respectively. The recoveries in urine of levornidazole, M1, M2, M4, M6 and M16 over 96 hours for the elderly subjects were 10.21%, 0.92%, approximate 0%, 2.69%, 0.54% and 41.98%. The PK parameters of levornidazole and urinary recoveries of all compounds did not show statistical difference between two groups ($p > 0.05$). For both dose regimens, the CFR was >90% against *Bacteroides fragilis* and other *Bacteroides* when the PK/PD target of AUC_{0-24}/MIC =157.6 and C_{max}/MIC=14.1 were used, and PTA was greater than 90% when MIC not greater than 1μg/mL.**Conclusion:** Both regimens may achieve satisfactory clinical and microbiological efficacies against *Bacteroides spp* in the elderly.

A Pilot Study of Immune Activation and Rifampin Absorption in Hiv-infected Patients

Author Block:

C. Vinnard[1], I. Manley[1], B. Scott[1], M. Bernui[1], S. Varghese[1], J. Adams[2], M. Kutzler[1]; [1]Drexel Univ. Coll. of Med., Philadelphia, PA, [2]Brown Univ., Providence, PA

Abstract Body:

Background: Rifampicin malabsorption is frequently observed in tuberculosis (TB) patients co-infected with HIV, but cannot be predicted by patient factors such as CD4+ T cell count, HIV viral load, or the presence of diarrhea. We sought to describe the relationship between HIV-associated immune activation, measures of gut absorptive capacity and permeability, and rifampin PK parameters, in a pilot study of HIV-infected patients who were naïve to antiretroviral therapy (ART).**Methods:** We conducted an intensive pharmacokinetic (PK) study of single-dose rifampin among 6 HIV-infected patients naïve to antiretroviral therapy (ART). Blood samples were obtained for measurement of HIV-associated immune activation, enterocyte damage, and microbial translocation. We conducted the D-xylose assay to measure overall intestinal absorptive capacity, and the lactulose/mannitol assay to measure intestinal permeability.**Results:** The median rifampin AUC(0-8) was 42.8 mg•hr/L (range 21.2 to 57.6), with a median Cmax of 10.1 mg/L (range 5.3 to 12.5). We observed delayed rifampin absorption, defined as a time to maximum concentration (Tmax) greater than 2 hours, in 2 of 6 participants. Neither of the participants with delayed rifampin absorption demonstrated low intestinal absorptive capacity by D-xylose testing, or increased intestinal permeability by the lactulose/mannitol ratio. There was a trend towards increased serum concentrations of sCD14, a marker of monocyte activation in response to LPS, among participants with delayed rifampin absorption (median 1925 ng/mL) compared to participants with rapid absorption (median 1225 ng/mL, p=0.06).**Conclusions**: Delayed rifampin absorption may be associated with elevated markers of bacterial translocation among ART-naïve HIV-infected individuals. The limited sample size precluded the conduct of compartmental PK analysis using non-linear mixed effects models, and therefore we were unable to evaluate the individual measures of immune activation as covariate effects on the coefficient of absorption. These pilot data will inform the design of future studies to test the hypothesis that measures of HIV-associated immune activation can predict delayed rifampin absorption at the time of initiation of anti-TB therapies.

Population Pharmacokinetics (Pk) and Pharmacodynamics (Pd) of Teicoplanin (Teic) in Neonates

Author Block:

V. Ramos-Martín[1], M. Neely[2], P. McGowan[3], S. Siner[4], K. Padmore[4], E. Scott[4], M. Peak[4], M. W. Beresford[1], M. A. Turner[1], S. Paulus[4], W. W. Hope[1]; [1]Univ. of Liverpool, Liverpool, United Kingdom, [2]Univ. of Southern California, Los Angeles, CA, [3]Liverpool Women´s Hosp., Liverpool, United Kingdom, [4]Alder Hey Children´s Hosp., Liverpool, United Kingdom

Abstract Body:

TEIC is frequently administered to neonates to treat Gm (+) infections. Little is known about the PK profile of TEIC in neonates and there is uncertainty about the optimal regimens to achieve desired target concentrations. The aim of the study was to determine the population PK of TEIC in neonates, evaluate currently recommended regimens and explore exposure-effect relationships.An open label PK study was conducted. Neonates from 26-44 weeks post-menstrual age were recruited (n=18). Patients received a loading dose (16 mg/kg) followed by 8 mg/kg q24h. Serum was collected at 1, 3, 6 and 24 h, and at steady state. A standard 2-compartment PK model was developed, followed by models that incorporated weight (wt). Wt was allowed to affect clearance using linear and allometric scaling terms. CRP serial concentrations were also collected as a PD input. Monte Carlo simulations were performed using Pmetrics. The AUCs at steady state and the proportion of patients achieving the recommended drug exposures in terms of Cmin (>15 mg/L) were determined.A total of 96 PK samples and 106 CRP serial concentrations were available for analysis. The PK allometric model best accounted for the observed data and was chosen for further analysis. The PK parameters medians were: Clearance=0.435*(wt /70)$^{0.75}$ (L/h), Volume 0.765 (L), Kcp 1.3 (h^{-1}), Kpc 0.629 (h^{-1}). The fit of the PK-PD data was acceptable. The time-course of CRP was well described using the Bayesian posterior median estimates for each patient. All patients except three were able to suppress CRP levels after the 5th dose of therapy. The simulated median AUC $_{96\text{-}120}$ was 297.8 mg*h/L, median Cmin at 120 h was 12.8 mg/L. The percentage of patients with Cmin >15 mg/L was 38.1 %TEIC population PK is highly variable in neonates. Wt (allometric relationship) is the best descriptor of PK variability (clearance) in the population. AUC drug exposures were comparable to exposures in adults (400 mg/day) and effective in terms of suppressing CRP levels in this study. However, only a low percentage of neonates were able to achieve Cmin >15 mg/L. The routine use of TDM and improved knowledge on the PD relationships between target exposures and response is required.

Immune Activation and Isoniazid Metabolism in Hiv-associated Tuberculosis

Author Block:

C. Vinnard[1], S. Ravimohan[2], N. Tamuhla[3], V. Ivaturi[4], J. Pasipanodya[5], S. Kant[5], D. Weissman[2], G. P. Bisson[2]; [1]Drexel Univ. Coll. of Med., Philadelphia, PA, [2]Univ. of Pennsylvania, Philadelphia, PA, [3]Botswana-Upenn Partnership, Gaborone, Botswana, [4]Univ. of Maryland, Baltimore, Baltimore, MD, [5]Baylor Inst. for Immunology Res., Dallas, TX

Abstract Body:

Background: Adverse drug events frequently complicate the course of anti-tuberculosis (TB) therapy in HIV-infected patients. Certain cytokines that are elevated in HIV and TB can regulate expression of enzymes involved in metabolism of isoniazid, raising the possibility that host immune status affects risk of drug toxicity. Furthermore, HIV-infected individuals with rapid acetylator NAT2 genotypes often demonstrate slow acetylation phenotypes. We hypothesized that levels of systemic immune activation in adults with HIV/TB would be associated with variability in the clearance of isoniazid.**Methods:** We conducted a prospective cohort study of isoniazid pharmacokinetics (PK) in HIV/TB patients in Gaborone, Botswana. Because antiretroviral therapy (ART) can alter levels of immune activation in HIV/TB, we performed an intensively sampled PK visit before ART initiation. Immune activation parameters included CD38 and HLA-DR co-expression on CD8+ T cells, IL-6, and CRP. Population PK modeling was performed to determine whether levels of HIV-associated immune activation contributed to between subject variability in isoniazid clearance (CL).**Results:** We enrolled 40 HIV/TB patients into the PK study, after a median of 20 days of anti-TB therapy (range 7-65 days). No patients were receiving ART at the time of the PK visit. The isoniazid concentration data were best fitted with a 2-compartment model with first-order elimination, BSV on the central volume (V) and clearance (CL), and a combined additive/proportional residual error model NAT2 genotype (slow/intermediate/rapid) was a strong predictor of isoniazid CL (reduction of objective function value from 261 to 249). No additional covariate relationships were identified by the stepwise selection process.**Discussion:** Immune activation did not contribute to variability in isoniazid metabolism prior to initiation of ART. Future efforts will determine the covariate effect of immune activation on intra-occasional variability in isoniazid metabolism before and after ART initiation.

Safety and Efficacy of High Dose (Hi-D) Polymyxin B (Pb) Regimens Against Extensively Drug Resistant (Xdr) Gram Negative Bacteria (Gnb) in Critically Ill Patients: A Clinical Study

Author Block:

Y. Cai, J. Teo, T-P. Lim, W. Lee, A-L. Kwa; Singapore Gen. Hosp., Sg, Singapore

Abstract Body:

Background: Recent simulation studies suggested that higher doses (30000U/kg/day) of PB may be beneficial, but its clinical efficacy & safety have yet to be described. This study described the safety and efficacy of Hi-D PB regimens in critically-ill patients. **Methods:** An observational cohort study was done from Jan 2013 - Dec 2014 in a tertiary Singapore hospital. All critically ill patients prescribed ≥48h Hi-D PB (≥30000U/kg/day TBW) were included. Demographics, comorbidities, infection-related details, & antibiotic use & doses were collected. Outcomes measured were 30-day all-cause mortality, clinical cure, bacteriological clearance & presence of acute kidney injury (AKI). Daily serum creatinine (SCr) was trended. A multivariable regression model was used to determine predictors of AKI . **Results:** 45 patients were included. Mean (s.d.) APACHEII score was 19 (8) at time of Hi-D PB initiation; majority was ICU patients (69%). Hi-D PB was culture-directed in 36 (80%) patients. The most common indication for Hi-D PB was pneumonia (24%) & soft tissue infection (24%). 22 (49%) patients also had positive blood cultures. Pathogens were *A. baumannii*, *P. aeruginosa* & Enterobacteriaceae in 24 (53%), 11 (24%) & 10 (22%) patients respectively - 38 (84%) were extensively drug-resistant, but all were fully susceptible to PB (MIC range: 0.25 - 2mg/L). 43 (96%) patients received Hi-D PB as part of a 2- or 3-antibiotic combination regimen. Median (range) daily Hi-PB dose was 31310 (28170 - 40704) U/kg, & median cumulative Hi-D PB dose was 20 (4 - 127) MU. Clinical cure & 30-day mortality was observed in 35 (76%) & 11 (24%) patients respectively. In the 22 patients with positive blood culture, bacteriologic clearance was seen in 21 (95%) patients. 19 (42%) patients developed AKI during Hi-D PB; of these, AKI resolved fully in 10 (53%) patients. Peak SCr in AKI patients occurred at a median of 12 (2 - 40) days. In the multivariable regression model, only total cumulative PB was associated with AKI (OR 1.04, 95% C.I. 1.00 - 1.08). **Conclusion:** We observed favorable mortality rates & bacteriologic clearance in Hi-D PB patients. PB-induced AKI appeared to be related to total cumulative PB dose as opposed to high daily doses. Clinicians should balance the risk of AKI against the benefits of adequate PB dose.

Publishing Title:

Nafithromycin (WCK 4873) Concentrations in Plasma, Epithelial Lining Fluid, and Alveolar Macrophages of Healthy Subjects

Author Block:

R. Chugh[1], A. Bhatia[1], M. Gupta[1], N. Sharma[1], M. Gotfried[2], K. Rodvold[3]; [1]Wockhardt, Mumbai, India, [2]Pulmonary Associates, PA, Phoenix, AZ, [3]Univ. of Illinois at Chicago, Chicago, IL

Abstract Body:

Nafithromycin is a novel oral antibacterial agent belonging to the ketolide class with potent in vitro antimicrobial activity against typical and atypical pathogens commonly associated with community-acquired lower respiratory tract infections. The primary objective of this study was to determine and compare plasma, epithelial lining fluid (ELF), and alveolar macrophages (AM) concentrations of nafithromycin in healthy adult male and female subjects. Nafithromycin concentrations in plasma, ELF, and AM of 37 subjects were measured by LC-MS/MS following repeat oral dosing of nafithromycin (800 mg once daily for 3 days). Noncompartmental pharmacokinetic (PK) parameters were determined from serial total plasma concentrations collected over a 24-hour interval following the first and third oral doses. Each subject underwent one standardized bronchoscopy with bronchoalveolar lavage (BAL) at 3, 6, 9, 12, 24 or 48 hours after the third dose of nafithromycin. Mean (± SD) PK parameters after the first dose included maximum concentration (Cmax) of 1.02 ± 0.31 µg/mL, time to Cmax (tmax) of 3.97 ± 1.30 h, clearance (CL/F) of 67.3 ± 21.3 L/h, and elimination half-life (t½) of 7.7 ± 1.1 h. Plasma PK parameters after the third dose were Cmax of 1.39 ± 0.36 µg/mL, tmax of 3.69 ± 1.28 h, CL/F of 52.4 ± 18.5 L/h, and t½ of 9.1 ± 1.7 h. Nafithromycin concentrations (Table) and AUC0-24 values of nafithromycin based on mean or median plasma concentrations at BAL sampling times were 16.2 µg•h/mL. For ELF, the respective AUC0-24 values were 224.1 and 176.3 µg•h/mL, whereas AUC0-24 values for AM were 8538 and 5894 µg•hr/mL. Penetration ratios based on ELF to plasma AUC0-24 values were 13.8 and 10.9, whereas ratios of AM to plasma were 527 and 364, respectively. The in vitro antibacterial activity and the sustained ELF and AM concentrations for 48 hours after the third dose suggest that nafithromycin has the potential to be a useful agent for the treatment of lower respiratory tract infections.

Nafithromycin concentrations (mean ± SD) at time of bronchoscopy and BAL

Sampling Time	Plasma (µg/mL)	ELF (µg/mL)	AM (µg/mL)
3-hour	1.105 + 0.140	18.48 + 12.31	290.2 + 179.0
6-hour	0.966 + 0.439	15.29 + 14.53	375.4 + 218.2
9-hour	0.922 + 0.286	8.37 + 4.38	401.1 + 420.3

12-hour	0.817 + 0.261	9.67 + 6.20	729.4 + 739.0
24-hour	0.239 + 0.055	4.13 + 1.38	120.9 + 66.2
48-hour	0.060 + 0.029	1.62 + 0.86	22.4 + 10.4

Pharmacokinetic-Pharmacodynamic (PK-PD) Target Attainment (TA) Analyses to Support WCK 4873 Dose Selection for the Treatment of Community-Acquired Bacterial Pneumonia (CABP)

Author Block:

J. C. Bader[1], E. A. Lakota[1], C. M. Rubino[1], M. V. Patel[2], S. S. Bhagwat[2], P. G. Ambrose[1], S. M. Bhavnani[1]; [1]ICPD, Latham, NY, [2]Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

WCK 4873 is a novel oral (PO) lactone ketolide, active against multi-drug resistant *S. pneumoniae* (SP). PK-PD TA analyses were performed to provide WCK 4873 dose selection support for a Phase 2 CABP clinical trial. Analyses utilized a Phase 1 population PK (PPK) model, non-clinical PK-PD targets from a neutropenic murine-lung infection model, and WCK 4873 MIC data for SP. The PPK model was a 4-compartment model (2 absorptive, 2 distributive) with parallel linear and non-linear clearance. Epithelial lining fluid (ELF) PK was described using a 2-compartment model. Using PK parameter estimates, ELF and free-drug plasma (*f*) concentration-time profiles were simulated for 2000 patients administered WCK 4873 600 mg PO q24h x 5 d or 800 mg PO q24h x 3 d. Average $AUC_{0\text{-}24}$ over Days 1-3 was calculated. The median and second highest ELF AUC:MIC ratio (833 and 1553, respectively) and *f*AUC:MIC ratio (6.99 and 14.1, respectively) targets associated with 1-$\log_{10}$ CFU reduction from baseline for SP *ermB*$^+$ were evaluated. Percent probabilities of PK-PD TA (%PTA) by MIC and over SP MIC distributions were determined. Using median targets, %PTA by MIC for both dosing regimens were $\geq$99.6% at the MIC_{90} of 0.06 mg/L for SP isolates collected worldwide (see Figure). Sensitivity analyses based on the second highest targets showed %PTA of $\geq$81.0% and $\geq$97.1% for the 600 and 800 mg regimens, respectively, at this MIC. Using the worldwide MIC distribution for all SP and all 4 targets, overall %PTA were $\geq$94.0 % for both dosing regimens. Results of these PK-PD TA analyses provide WCK 4873 dose selection support for the treatment of patients with CABP, including patients with SP *ermB*$^+$.

Publishing Title:

Population Pharmacokinetic (PPK) Model Describing the Disposition of WCK 4873 in the Plasma and Epithelial Lining Fluid (ELF) of Healthy Subjects

Author Block:

E. A. Lakota[1], J. C. Bader[1], S. M. Bhavnani[1], K. A. Rodvold[2], M. V. Patel[3], S. S. Bhagwat[3], P. G. Ambrose[1], C. M. Rubino[1]; [1]ICPD, Latham, NY, [2]Univ. of Ill, Chicago, IL, [3]Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

WCK 4873 is a novel oral (PO) lactone ketolide currently in clinical development. WCK 4873 is active against pathogens commonly associated with community-acquired bacterial pneumonia (CABP), including multi-drug resistant *S. pneumoniae*. Data from 3 Phase 1 studies were used to develop a PPK model to describe the time course of WCK 4873. The PPK model was developed in NONMEN 7.1.2 using 2800 plasma and 37 ELF concentrations from 117 and 37 healthy subjects, respectively. Subjects received WCK 4873 as single (100 to 1200 mg) or multiple (600 to 1000 mg) PO doses. Various structural PK models were evaluated. A covariate analysis was conducted to assess the impact of food and various patient demographic features on WCK 4873 PK. A 4-compartment model (2 absorptive, 2 distributive) with parallel linear and non-linear clearance best described the plasma WCK 4873 PK data. Bi-phasic absorption was accomplished using separate processes: one with a lag time and zero-order absorption and one with a time delay, using 4 transit compartments. The mean (%CV) of the linear clearance component was 34.8 L/hr (45.6%). The nonlinear clearance component had a maximum elimination rate of 14.8 mg/hr (4.97%) with a concentration at which clearance is half-maximal of 253 mcg/L. The effect of food was significant; bioavailability was reduced by 12.6% in the fasted state. The ELF data was described using a 2-compartment model for the lung. Bi-directional rate constants (%CV) between ELF central compartment and plasma were 0.0436 (23.7%) and 0.228 hr^{-1}, respectively. The PPK model provided acceptable fits to the plasma and ELF data (r^2=0.941 and 0.350 for observed vs fitted concentrations, respectively). Goodness-of-fit diagnostics indicated an unbiased fit to the data. From Day 1 to 5, the mean (%CV) accumulation was 42.1% (17.7%). Mean (%CV) Day 3 ELF and total- and free-drug plasma $AUC_{0\text{-}24}$ for a 800 mg PO daily regimen were 213 (24.1%), 15, and 2.96 (23.7%) mg·h/L, respectively. Using Day 3 $AUC_{0\text{-}24}$, mean (%CV) ELF:total and ELF:free penetration ratios were 14.4 and 73.0 (16.0%), respectively. A PPK model was successfully developed to describe WCK 4873 PK. This model will be useful to support dose selection for future CABP clinical trials.

Publishing Title:

Population Pharmacokinetics (PPK) of Omadacycline (OMC) Following Intravenous (IV) or Oral Administration and Evaluation of Phase 3 Sparse PK Sampling Strategies

Author Block:

S. A. VanWart[1], A. Manley[2], S. M. Bhavnani[1], K. Tanaka[2], E. Loh[2], E. Tzanis[2], P. G. Ambrose[1]; [1]ICPD, Latham, NY, [2]Paratek Pharmaceuticals, Inc., Boston, MA

Abstract Body:

OMC is a first in class aminomethylcycline antibiotic currently being developed to treat acute bacterial skin and skin structure infections and community-acquired bacterial pneumonia. A population PK model for OMC developed using Phase 1 data was used to evaluate potential Phase 3 sparse PK sampling strategies. A 3-compartment model with zero-order IV input, or first-order oral absorption with transit compartments, best described plasma PK data from 281 subjects. Clearance (CL) was a function of creatinine clearance; bioavailability (F) was estimated based upon the timing of a meal relative to dosing. Using this model, PK data were simulated for 2000 patients administered 100 mg IV q12h on Day 1 followed by 100 mg q24h thereafter. Patients were randomly switched to 300 mg oral OMC q24h between Days 4 and 7. Maximum a-posteriori (MAP) Bayesian estimation was performed in NONMEM for various PK datasets with 2 samples each on Days 1 and 7. Absolute prediction error percent (|PE%|) for the Bayesian PK estimates relative to the true values were calculated for CL, steady-state volume of distribution, F, and the maximum concentrations after IV and oral dosing. The median |PE%| for each parameter within each sparse PK sampling scheme was calculated. The simulated patient data, with circles depicting suggested PK sampling times, are shown in Figure 1 using an interactive R-Shiny app. Based on a composite ranking of |PE%| across parameters, PK samples should be collected 3 to 5 h and at 12 h after first IV dose on Day 1, and pre-dose and 1 to 3 h after oral dosing on Day 7. A population PK model for OMC developed using Phase 1 data was used to recommend a Phase 3 sparse PK sampling strategy.

Evaluation of the *In Vitro* Activity Profile of Omadacycline against *Haemophilus influenzae*

Author Block:

B. D. VanScoy[1], H. Conde[1], K. Tanaka[2], S. M. Bhavnani[1], J. N. Steenbergen[2], P. G. Ambrose[1]; [1]ICPD, Latham, NY, [2]Paratek Pharmaceuticals, Inc., Boston, MA

Abstract Body:

Background: Omadacycline is a novel aminomethylcycline in Phase 3 clinical development for use against multiple bacterial pathogens, including *H. influenzae.* In order to evaluate the *in vitro* activity of omadacycline, a series of foundation studies were undertaken. **Methods:** *In vitro* studies were performed using a panel of 5 *H. influenzae* clinical isolates. The studies included evaluating the MIC, the resistance mutation frequency, static time-kill activity and the post-antibiotic effect of omadacycline. All studies were performed using the Clinical Laboratory Standards Institute and European Committee on Antimicrobial Susceptibility Testing guidelines for broth and agar methodologies using their respective growth mediums (Haemophilus Test Medium and Mueller Hinton broth medium supplemented with 5% defibrinated horse blood, plus 20 mg/L β-nicotinamide adenine dinucleotide MH-F). **Results:** The MIC values for omadacycline ranged from 0.5 to 2 mg/L using broth and agar dilution methodologies. No isolates were recovered from the omadacycline drug-containing agar plates utilized in the mutation frequency studies at concentrations of 3 times the baseline MIC, using an average inoculum of 6.2×10^9 CFU/mL. These results demonstrated omadacycline's resistance mutation frequency to be below detection for the 5 clinical isolates. The results of the static time-kill studies showed that concentrations of 1 to 2 times the omadacycline MIC achieved a ≥ 3 Log_{10} CFU reduction from baseline. The median (min, max) duration of the post-antibiotic effect for omadacycline was 2.95 (1 to 4) hrs when examined against four clinical *H. influenzae* isolates from the original panel. **Conclusion:** Bactericidal *in vitro* activity for *H. influenzae* was observed at omadacycline concentrations either matching or twice the MIC value for each individual isolate. This bactericidal activity along with low resistance mutation frequency demonstrate potent activity of omadacycline against *H. influenzae* and warrant further *H. influenzae* studies.

Antibacterial Efficacy of Eravacycline (Erv) *In Vivo* Against Gram-positive and Gram-negative Organisms

Author Block:

M. L. Monogue[1], A. K. Thabit[1], Y. Hamada[2], D. P. Nicolau[1]; [1]Ctr. for Anti-Infect. Res. & Dev., Hartford Hosp., Hartford, CT, [2]Aichi Med. Univ. Hosp. Sch. of Med., Aichi, Japan

Abstract Body:

Background: Members of the tetracycline class are frequently classified as bacteriostatic; conversely, recent findings have demonstrated an improved bacterial killing profile, often achieving bactericidal activity, when given for periods of > 24 hours. The objective of this study was to elucidate the bacterial killing effect of ERV, a novel fluorocycline, in the setting of humanized exposures over a 72-hour treatment period. **Methods:** Antibacterial efficacy was studied against two methicillin-resistant *Staphylococcus aureus* (MRSA) (ERV MICs = 0.03 and 0.25 μg/ml) and three Enterobacteriaceae isolates (ERV MICs = 0.125-0.25 μg/ml) in an immunocompetent murine thigh infection model. The humanized doses of ERV (2.5 mg/kg IV q12h), in addition to comparator antibiotics (linezolid, tigecycline, vancomycin, meropenem), were administered starting two hours after infection. Efficacy was measured as the change in $\log_{10}$CFU at 24h, 48h, and 72h compared with 0h controls.**Results:** Progressively enhanced activity of ERV was noted over the 72-hour study period against the tested isolates. The bacterial density was reduced by > 3 $\log_{10}$CFU at 72 hours against the MRSA isolates (Table) and one *E. coli* isolate, and > 1 $\log_{10}$CFU against *C. freundii* and the second *E. coli* isolate. Overall, bacterial killing by ERV was similar to the comparator antibiotics, although more variability in bacterial killing was observed for all antibacterial agents against the Gram-negative isolates.**Conclusions:** ERV has shown strain- and species-specific bactericidality *in vitro*. These studies demonstrate that the drug exhibits a cumulative dose response and may achieve bactericidal activity *in vivo* after 72 hours of therapy against MRSA and Enterobacteriaceae. Therefore, an analysis of the pharmacodynamic profile beyond 24 hours should be considered when assessing the clinical efficacy of this novel agent.

Group	Time of Collection	$\log_{10}$ CFU		Change in $\log_{10}$ CFU	
		Mean	SD	Mean	SD
S. aureus 426	0h	6.98	0.20	-	-

Post-Antibiotic Effect of Omadacycline against Target Pathogens

Author Block:

R. Hinshaw, L. Stapert, D. Shinabarger, **C. Pillar**; Micromyx, Kalamazoo, MI

Abstract Body:

Background: Omadacycline (OMC) is a new once daily oral and IV aminomethylcycline under phase 3 development for the treatment of serious community-acquired skin and respiratory infections. To better understand the pharmacodynamic properties during dosing, it is important to evaluate the post-antibiotic effect (PAE). In this study, the PAE of OMC, tigecycline (TIG), and linezolid (LZD) was evaluated against target pathogens.**Methods:** MICs of OMC, TIG, and LZD were determined in accordance with CLSI M7 against clinical isolates of *S. aureus* (n=2; 1 MRSA), *E. faecalis* (n=1), *E. faecium* (n=1; VRE), *S. pneumoniae* (n=2; 1 PRSP), and *E. coli* (n=1). PAE was evaluated after initial exposure of log-phase bacteria to 5X the MIC of OMC,TIG, or LZD for 1 hr alongside an unexposed control. Post-exposure, the drug was removed via centrifugation and washing and the bacteria were incubated in fresh drug free media for 10 hr. Viable bacteria were enumerated at 2 h intervals post-exposure. PAE was calculated as the time it took for bacteria to grow 1-log after initial exposure and drug washout relative to unexposed controls.**Results:** The PAE (hr) of OMC, TIG, and LZD after exposure to 5X the MIC is shown in the table below.

Test Agent	***S. aureus* MSSA/MRSA**	***E. faecalis* VSE**	***E. faecium* VRE**	***E. coli***	***S. pneumoniae* PSSP/PRSP**
OMC	2.6/2.2	2.0	2.1	1.4	3.3/2.3
TIG	3.9/2.5	3.8	4.4	1.4	3.3/3.6
LZD	1.3/1.0	1.2	1.7	not tested	2.2/1.5

Similar initial exposure concentrations (µg/mL) were used for OMC (1.25 - 5) and TIG (0.6 - 2.5) across isolates except for *S. pneumoniae* (0.15 - 0.3 for OMC and TIG). Initial exposure for LZD was higher (5 - 20 µg/mL). OMC PAEs varied between 1.4 hr (*E. coli*) and 3.3 hr (*S. pneumoniae*). TIG PAEs were similar to OMC PAEs with the exception of enterococci where the TIG PAE was slightly longer (3.8 - 4.4 hr) compared to OMC (2.0 - 2.1 hr). OMC and TIG PAEs were longer than LZD (PAEs between 1.0 and 2.2 hr) for all organisms tested.**Conclusions:** Overall, the PAE of OMC was similar to that of TIG with the exception of the evaluated enterococci where slightly longer PAEs were observed with TIG relative to OMC. Both OMC and TIG exhibited prolonged PAE relative to LZD. These PAE data demonstrate some prolonged

activity of OMC and TIG which may provide a benefit in the treatment of serious community-acquired bacterial infections.

Nafithromycin Phase 1 Multiple Ascending Dose Study in Healthy Subjects

Author Block:

R. Chugh[1], M. Gupta[1], P. Iwanowski[2], A. Bhatia[1]; [1]Wockhardt, Mumbai, India, [2]Wockhardt, Warsaw, Poland

Abstract Body:

Background: Nafithromycin (WCK 4873) is a novel antibacterial agent belonging to the ketolide class with potent *in vitro* antimicrobial activity against typical and atypical pathogens commonly associated with community-acquired lower respiratory tract infections. This study was conducted to determine the safety, tolerability and pharmacokinetics (PK) of multiple ascending doses of nafithromycin in healthy subjects. **Methods:** 30 healthy subjects were enrolled in 3 cohorts (8 subjects on nafithromycin and 2 on placebo in each cohort) in a double-blind manner. Concentrations of nafithromycin in plasma, urine, feces, and polymorphonuclear white blood cells (PMN WBCs) were measured following multiple oral doses of 600 mg, 800 mg, and 1000 mg nafithromycin OD for 7 days.**Results:** C_{max} and AUC_{0-24} values were approximately 1.2 to 1.6 fold and 1.4 to 2 fold higher on Day 7 compared to the respective C_{max} and AUC_{0-24} values on Day 1 (Table 1). After single and multiple dosing with nafithromycin, the mean $t_{1/2}$ was between 9.16 and 14.4 h and tended to increase with increasing dose. On average, steady-state was achieved after Day 3 of nafithromycin administration. The mean recovery of nafithromycin via urine over 24-hours interval was higher (between 16.3 and 22.4%) than the mean recovery of nafithromycin via feces (between 3.2 and 9.4%). High intracellular accumulation of nafithromycin was observed in PMN WBCs with a maximum accumulation ratio ranging between 120.3 and 138.6 on Day 1 and between 142.3 and 366.6 on Day 7 across the dose range tested. All treatment-emergent adverse events were mild except one (diarrhoea) of moderate severity with 1000 mg, and resolved at follow-up. There were no deaths, serious adverse events or clinically significant findings in laboratory, 12-lead ECG, and physical examination.**Conclusions:** Nafithromycin demonstrated non-linear PK with a 2-fold maximum accumulation, and was safe and well tolerated following 7 days of dosing with 600, 800, and 1000 mg.**Table 1. Nafithromycin - AUC_{0-24} and C_{max} on Day 1 and Day 7**

Nafithromycin	**C_{max} (ng/mL)**		**AUC_{0-24} (h.ng/mL)**	
	Day 1	**Day 7**	**Day 1**	**Day 7**

Nafithromycin Single Ascending Dose (SAD) and Food Effect (FE) Study in Healthy Subjects

Author Block:

A. Bhatia[1], R. Chugh[1], M. Gupta[1], P. Iwanowski[2]; [1]Wockhardt, Mumbai, India, [2]Wockhardt, Warsaw, Poland

Abstract Body:

Background: Nafithromycin (WCK 4873) is a novel antibacterial agent belonging to the ketolide class with potent *in vitro* antimicrobial activity against typical and atypical pathogens commonly associated with community-acquired lower respiratory tract infections. The primary objective of this study was to determine safety, tolerability, and pharmacokinetics of SAD of nafithromycin, and the effect of food on nafithromycin in healthy adult subjects. **Methods:** Subjects in the SAD part (4 cohorts) were administered a single oral dose of 100, 200, 600 or 1200 mg of nafithromycin (8 subjects in each cohort) or placebo (2 subjects in each cohort) in a double-blind manner. Subjects in the 2 FE cohorts were administered a single oral dose of 400 mg or 800 mg nafithromycin (12 subjects each) or placebo (2 subjects each) in a double-blind cross-over method (fed and fasted state). Analysis of plasma, urine and feces samples were performed for nafithromycin using validated methods. **Results:** Median t_{max} was reached at 1 to 4 h post-dose in the SAD part. Mean maximum concentrations (C_{max}) and exposures based on $AUC_{0\text{-}inf}$ increased with increasing dose and ranged from 99.4 to 1742 ng/mL and 662 to 22,925 h.ng/mL, respectively (Table 1). The half-life ($t_{1/2}$) ranged from 5.15 to 8.95 h. For the food effect cohorts, fed state $AUC_{0\text{-}t}$ and C_{max} were approximately 1.2 to 1.3 higher than in the fasted state (Table 1). All treatment-emergent adverse events (TEAEs) were mild, except for one event of vomiting of moderate intensity, and resolved without sequelae. There were no severe or serious AEs (SAEs) or deaths reported during the study. There were no clinically significant findings in laboratory values, vital signs, 12-lead ECG, and physical examination. **Conclusions:** Plasma exposure to nafithromycin appeared to increase more than doseproportional over the 100 to 1200 mg single dose range and was only mildly affected by food. Overall, single oral treatment with nafithromycin up to a dose level of 1200 mg was safe and well-tolerated by healthy adult subjects.**Table 1. Plasma PK parameters of nafithromycin**

The Effect of Gepotidacin (Gsk2140944), a Novel Triazaacenaphthylene Bacterial Topoisomerase Inhibitor, on Cardiac Repolarization Parameters

Author Block:

M. Hossain[1], **C. Tiffany**[2], M. McDonald[2], E. Dumont[2]; [1]GlaxoSmithKline, King of Prussia, PA, [2]GlaxoSmithKline, Collegeville, PA

Abstract Body:

Background: Gepotidacin (GEP) is a novel triazaacenaphthylene antibiotic, which inhibits bacterial DNA replication and has *in vitro* activity against susceptible and drug-resistant pathogens associated with a range of conventional and biothreat infections. **Methods:** 4-period, randomized, active- and placebo-controlled, double-blinded, crossover study in 55 healthy male and female subjects. Single doses of gepotidacin 1000 mg and 1800 mg were infused over 2 hours; placebo, and oral moxifloxacin 400 mg were administered using double-dummy methods. PK (blood and urine) and PD (12-lead Holter ECG) sampling, and safety assessments were performed at specified intervals. **Results:** The infusion of gepotidacin caused an increase from baseline in HR (ΔHR). The placebo corrected ΔHR (ΔΔHR) was elevated with a largest effect observed at 2 hours (end of infusion) of 6.5 bpm and 10.4 bpm after 1000 mg and 1800 mg, respectively. QTcF was selected as the primary endpoint based on the ability to remove the HR dependence of the QT interval. The ΔΔQTcF was observed at the end of the infusion with a largest value of 12.1 msec (90% CI: 9.5 to 14.8) after 1000 mg and 22.2 msec (90% CI: 19.6 to 24.9) after 1800 mg. The ΔΔQTcF fell after the end of the infusion. For moxifloxacin, the largest mean ΔΔQTcF was observed at 3 hours (12.7 msec) with the lower bound of the 90% CI above 5 msec at all prespecified time points (2, 3, and 4 hours) confirming assay sensitivity. Exposure response analysis using a linear model with an intercept demonstrated a statistically significant positive relationship between gepotidacin plasma levels and ΔΔQTcF(slope 1.45 msec per µg/mL). There were no severe AEs, SAEs, or deaths reported during this study. **Conclusions:** Infusion of gepotidacin at a dose of 1000 mg and 1800 mg caused a mild increase in HR (6 to10 bpm) and QT prolongation measured as ΔΔQTcF of 12 msec to 22 msec. QT prolongation was quickly reversed over 2 hours after the end of the infusion. Gepotidacin did not have a clinically relevant effect on cardiac conduction (PR and QRS intervals).

Activity of S-649266 Siderophore Cephalosporin and Comparators against *Pseudomonas aeruginosa* in Murine Thigh Infection Model

Author Block:

I. Ghazi[1], M. Tsuji[2], D. P. Nicolau[1]; [1]Hartford Hosp., Hartford, CT, [2]Shionogi, Osaka, Japan

Abstract Body:

Background: S-649266 is a siderophore cephalosporin that has demonstrated activity against Gram-negative bacteria as well as stability against serine- and metallo-carbapenemases in animal models. The objectives of this work were to demonstrate the efficacy of S-649266 as compared to two other siderophore based compounds against *P. aeruginosa* and to explore the pharmacodynamic (PD) profile of this novel compound using the neutropenic murine thigh infection model.**Methods: :** Six clinical *P. aeruginosa* isolates (1403, JJ4-36, JJ11-54, JJ8-16, AZ32-13 and JJ5-35) were tested *in vivo*. MICs were determined by broth microdilution in triplicate and modal MIC reported. Groups of 3 mice were inoculated and 2 hours later were treated with ascending doses of S-649266 12.5, 25, 50, 100, 200, 300, 400 and 500 mg/kg/day divided q8h or humanized doses of siderophores MB1 and AZ3167 as determined in previous studies. After 24 hours, the animals were sacrificed for bacterial enumeration and determination of the change in bacterial density ($\log_{10}$ CFU) relative to the starting inoculum (0h). Analysis of PD driver of efficacy was carried out using the inhibitory sigmoid E_{max} model.**Results:** The *P. aeruginosa* MIC ranges for three siderophores S-649266, AZ3167 and MB1 were: 0.063-0.5, 0.063-0.5 and ≤0.031-1 mg/L, respectively. In controls mean ± SD bacterial density at 0h was 5.5 ± 0.4 which increased to 8.5 ± 0.5 $\log_{10}$CFU at 24h. CFU reductions exceeding 1 log were observed for all *P. aeruginosa* after the administration of S-649266 at doses ≥ 100mg/kg/day. As previously reported, the current study confirmed that a humanized exposure of MB1 was effective against 1403 but not against JJ4-36, JJ11-54, JJ8-16, AZ32-13 and JJ5-35. Similar to historical data AZ3176 displayed no efficacy against JJ4-36. The pharmacodynamic analysis revealed that the magnitudes of *f*T>MIC, *f*C_{max}/MIC and *f*AUC/MIC were inversely proportional to observed CFU counts.**Conclusions:** Unlike the previously reported lack of efficacy with siderophores MB1 and AZ3175 against the *P. aeruginosa* studied, S-649266 displayed sustained antibacterial effects for all isolates over the treatment period. Enhanced bacterial kill was observed over the dose range studied and as previously observed % *f*T>MIC was well correlated to the efficacy of S-649266.

Publishing Title:

Application of Pharmacokinetic-Pharmacodynamic (Pk-Pd) Models for Brilacidin (Bri) Dose Selection Support for Patients with Acute Bacterial Skin and Skin Structure Infections (ABSSSI)

Author Block:

S. M. Bhavnani[1], J. P. Hammel[1], A. Forrest[1], S. A. VanWart[1], P. Sager[2], K. J. Tack[3], R. W. Scott[4], D. M. Jorgensen[3], P. G. Ambrose[1]; [1]ICPD, Latham, NY, [2]Stanford Univ., Palo Alto, CA, [3]Cellceutix Corp., Beverly, MA, [4]Fox Chase Chemical Diversity Ctr., Doylestown, PA

Abstract Body:

Introduction: BRI is a synthetic molecule of a novel class of agents that demonstrates potent antimicrobial activity against Gram-positive organisms, including MRSA. BRI is being developed for the treatment of patients with ABSSSI. Using population PK and PK-PD models for efficacy and safety developed using data from two Phase 2 studies of BRI-treated patients with ABSSSI and Monte Carlo simulation (MCS), BRI dosing regimens were evaluated. **Methods:** MCS was used to generate 5000 patients with distributions for covariates of PK based on data included in the previous PK analysis population. MCS was carried out using the BRI population PK model. Individual post-hoc parameter estimates were used to generate plasma BRI concentration-time profiles for simulated patients following 8 BRI dosing regimens, 4 of which were single doses (0.4, 0.6, 0.8 and 1 mg/kg) and 4 of which were 3-day dosing regimens. These included 0.4 mg/kg on Day 1, followed by 0.2 mg/kg on Days 2 and 3; 0.5 mg/kg on Day 1, followed by 0.2 mg/kg on Days 2 and 3; 0.5 mg/kg on Day 1, followed by 0.3 mg/kg on Days 2 and 3; and 0.6 mg/kg on Day 1, followed by 0.3 mg/kg on Days 2 and 3. Daily AUCs were calculated. Using parameter estimates from PK-PD models for clinical response at test of cure (TOC) and systolic blood pressure (SBP) and appropriate distributions or assumptions for independent variables retained in multivariable models, average predicted % probabilities of these endpoints were determined for each BRI dosing regimen. **Results:** Across BRI dosing regimens, % probabilities of clinical success averaged over a BRI MIC distribution for *S. aureus* ranged from 86.4 to 93.1%. During Days 1-7, the % of simulated patients with sustained SBP ≥160 and ≥180 mmHg over 24 h ranged from 1.44 to 4.06% and 0.02 to 0.10%, respectively. A single 0.6 mg/kg dose best balanced safety and efficacy considerations, with % probabilities of 89.2, 1.7, and 0.02% for these endpoints, respectively. **Conclusions:** Application of PK-PD relationships for efficacy and safety to simulated data allowed for benefit/risk discrimination among the BRI dosing regimens assessed for patients with ABSSSI.

***in Vitro* Protein Binding With Omadacycline, A First In Class Aminomethylcycline Antibiotic**

Author Block:

S. J. Villano, E. Tzanis, S. K. Tanaka; Paratek Pharmaceuticals, King of Prussia, PA

Abstract Body:

Background: Omadacycline is a first in class aminomethylcycline antibiotic that is undergoing clinical development as once daily oral or intravenous monotherapy for acute bacterial skin and skin structure infections and community-acquired bacterial pneumonia. Omadacycline protein binding was investigated during *in vitro* studies in monkey, mouse, rat, and human plasma. **Methods:** *In vitro* protein binding of omadacycline was determined using human plasma and in mouse (CD-1), rat (HanWistar), and monkey (Cynomolgus) using defrosted plasma pools. Binding was determined at nominal omadacycline concentrations of 10, 100, 1000, and 10000 ng/mL. For human binding studies, plasma was obtained from the blood of three healthy male volunteers. Plasma was defrosted from storage at -20°C before use, and pools of human plasma were used for all studies. Plasma from mouse, rat, and monkey was supplied by Harlan Laboratories Ltd. (Netherlands), Milan Analytica AG (Rheinfelden, Switzerland) and Centre de Primatologie ULP (France), respectively. Protein binding was measured using an ultrafiltration method. Plasma bound and unbound concentrations of omadacycline were determined by a LC-MS/MS method with a lower limit of quantification = 5.0 ng/mL.**Results:** Omadacycline was weakly bound to plasma proteins in human plasma as well as in monkey, mouse, and rat plasma. Over the concentration range of 10-10000 ng/mL, no apparent concentration dependent effect of omadacycline on plasma protein binding was observed. The mean ± SD unbound protein fraction in human plasma was 78.7 ± 9.7%. In animals, the mean unbound plasma protein fractions were rat (73.9 ± 12.1%), monkey (78.8 ± 7.3%), and mouse (84.7 ± 5.3%). The low human plasma protein binding of omadacycline (21%) contrasts markedly with other tetracyclines, which exhibit high concentration dependent protein binding (approximately 80%).**Conclusions:** In contrast to other tetracycline-derived antibiotics, omadacycline has markedly low human plasma protein binding (21%), with no concentration-dependent binding. These data may be relevant to the clinical effectiveness of omadacycline since the free, unbound fraction of the drug typically is most closely correlated with antimicrobial activity.

Publishing Title:

Effect Of Food On The Bioavailability Of Omadacycline In Healthy Volunteers

Author Block:

E. Tzanis, A. Manley, S. J. Villano, S. K. Tanaka, S. Chitra, E. Loh; Paratek Pharmaceuticals, King of Prussia, PA

Abstract Body:

Background: Omadacycline is a first-in-class aminomethylcycline antibiotic that is being studied in Phase 3 studies as an oral and intravenous monotherapy for skin infections and community-acquired pneumonia. This study evaluated the effect of food consumption on the oral bioavailability of a single 300 mg dose. **Methods:** This was a phase 1, randomized, open-label 4-period, crossover study. Healthy subjects were randomized to 1 of 4 treatment sequences: A) standard 6-hour fast, B) standard, high fat, non-dairy meal 4 hours before dosing, C) standard, high fat, non-dairy meal 2 hours before dosing, and D) standard, high fat meal containing dairy 2 hours before dosing, separated by a 5 day washout period. Patients received a single 300 mg oral dose of omadacycline during each treatment sequence. Blood samples for pharmacokinetic (PK) analysis were collected at frequent intervals for 24 hours after each dose, and safety assessments included adverse events, clinical laboratory tests, vital signs, and electrocardiogram (ECG). A linear mixed-effect model with treatment condition, sequence, and period as fixed effects and subject nested within sequence as a random effect was fitted to the natural log-transformed PK parameters for estimation of effects and 90% confidence intervals (CIs) for the fed states compared with the fasted state.**Results:** Thirty-one subjects were included in the PK analysis. Fasted $AUC_{0\text{-}inf}$, $AUC_{0\text{-}t}$, and $AUC_{0\text{-}24}$ were 10158, 7206, and 7205 ng*h/mL, respectively and C_{max} was 641 ng/mL Compared with a fasted dose, bioavailability was reduced by 15% to 17% for a nondairy meal 4 hours before dosing, 40% to 42% reduction for a nondairy meal 2 hours before dosing, and 59% to 63% reduction for a dairy meal 2 hours before dosing. The effect of food was more pronounced when a high-fat meal was consumed closer to dosing and when dairy was included in the meal. Across all treatment sequences, mean $T_{1/2}$ ranged from 13.5 to 13.8 hours, and median T_{max} ranged from 2.5 to 2.9 hours. No treatment-related adverse events or clinically relevant changes in laboratory values, ECG or vital signs occurred.**Conclusions:** A single oral dose of omadacycline was well tolerated. Administration of a 300 mg dose within 2 to 4 hours of food reduced the bioavailability compared with the fasted state. Once daily oral omadacycline should be administered at least 6 hours following a meal.

Publishing Title:

Pyranopyridine Efflux Pump Inhibitors (Epi) with Improved Adme Properties Maintain Potent Epi Activity

Author Block:

S. M. Kwasny, Z. Aron, J. D. Williams, T. L. Bowlin, **T. J. Opperman**; Microbiotix, Inc., Worcester, MA

Abstract Body:

Background: The RND family of efflux pumps plays an important role in Multi-Drug Resistance (MDR) in Gram-negative pathogens, making efflux pump inhibitors (EPIs) potentially useful weapons in the fight against MDR. We have developed a novel family of pyranopyridine EPIs that exhibit potent EPI activity against AcrB, the archetypal RND efflux pump. Using co-crystal structures of pyranopyridine analogs bound to the hydrophobic trap of AcrB, we are designing analogs with improved drug-like properties that maintain potency. Here, we present the biological activities of the most potent pyranopyridine analogs. **Methods:** Pyranopyridine analogs were designed and synthesized using published methods. Checkerboard MIC assays were used to measure the MPC4 (Minimum Potentiation Concentration that decreases the MIC of an antibiotic 4-fold). Killing curve assays measured potentiation of bactericidality, and the rate of accumulation of H33342 was used to estimate efflux activity. The cationic dye 3,3'-dipropylthiadicarbocyanine Iodide was used to measure the effect of compounds on membrane potential.**Results:** Analogs that carry substitutions on the phenyl and morpholino moieties exhibited improved drug-like properties while maintaining potency. In particular, compounds with dimethyl morpholinyl and urea containing substituents on the phenyl group (e.g. MBX3795, MBX3796, and MBX3797) were most active in killing curve and checkerboard MIC assays, with MPC4 values 0.1-0.4 µM against a strain of *Escherichia coli* that overexpresses AcrAB-TolC. In addition, MBX3795, MBX3796, and MBX3797 exhibited submicromolar MPC4s vs. pathogenic Enterobacteriaceae, but were not active vs. *Pseudomonas aeruginosa*. The antibiotic potentiation activity of these compounds was correlated with inhibition of efflux pumps, but not with membrane activity.**Conclusion:** Pyranopyridine analogs with improved ADME and PK properties maintain potent EPI activity against pathogens of the Enterobacteriaceae, paving the way for *in vivo* proof of concept experiments.

Publishing Title:

A Phase 1, Open-label Study of the Effect of Delafloxacin (Dlx) on the Pharmacokinetics (Pk) of a Single Oral Dose of Midazolam (Mid)

Author Block:

L. Lawrence[1], M. Quintas[1], R. Hoover[1], R. Wood-Horrall[2], M. Benedict[2], S. Paulson[3], R. Criste[4], S. Cammarata[1]; [1]Melinta Therapeutics, New Haven, CT, [2]PPD, Inc., Austin, TX, [3]Pharma Start, LLC, Northbrook, IL, [4]PPD, Inc., Richmond, VA

Abstract Body:

DLX is an anionic fluoroquinolone with activity against methicillin-resistant *Staphyloccocus aureus* and susceptible gram-negative bacteria currently in Phase 3 development. This Phase 1 study was performed to determine the impact of DLX treatment on the sensitive CYP substrate MID.Twenty-two male and female subjects were enrolled in this single sequence, single group study. A single 5 mg oral dose of MID was given to fasted subjects on Days 1 and 8. Subjects received oral DLX (450 mg) twice daily on Days 3 - 8. Plasma samples were analyzed for DLX, MID, and 1-hydroxymidazolam (1OH-MID) concentrations with validated LCMS/MS methods. Analysis of variance was performed on the ln-transformed AUC_{0-t}, $AUC_{0\infty}$, and C_{max} of MID and 1OH-MID to estimate the ratio of geometric least squares (LS) means between treatments and their 90% confidence interval (CI).Co-administration of DLX with MID did not alter the PK of MID as the 90% CI of geometric mean ratios of C_{max} (ng/mL) and AUC (h•ng/mL) values were within 80 to 125% acceptance criteria. The 1-OH-MID AUC values were also not affected by co-administration, whereas 1-OH-MID C_{max} values were slightly increased. The statistical analyses of plasma noncompartmental PK parameters of MID and 1OH-MID (MID/1-OH + DLX vs. MID alone) are presented:

Parameter	**Substrate**	**Ratio (%) of Geometric LS Means**	**90% CI of the Ratio (%)**
AUC_{0-t}	MID	89.4	(83.2, 96.1)
$AUC_{0-\infty}$		89.4	(83.2, 96.0)
C_{max}		93.6	(83.7, 104.6)
AUC_{0-t}	1OH-MID	106.6	(98.8, 114.9)
$AUC_{0-\infty}$		105.7	(97.7, 114.3)
C_{max}		116.1	(101.7, 132.4)

DLX reached steady state by Day 7 after 4 days of dosing. A similar C_{max} was observed on Days 3 and 7, and terminal elimination half-life was 2.5 and 2.9 hours, respectively. Five subjects

(22.7%) reported at least 1 mild treatment-emergent adverse event (TEAE), and no deaths, serious AEs or TEAEs leading to study discontinuation were reported. All TEAEs resolved by study end.DLX did not affect the C_{max} and $AUC_{0-\infty}$ of MID/1OH-MID, and minimal effect was indicated for 1OH-MID C_{max}. DLX was shown to have no clinically significant interaction with CYP3A substrate MID in a Phase 1 study.

Optimization of Pyranopyridine Efflux Pump Inhibitor (Epi) Adme Properties

Author Block:

Z. Aron[1], S. M. Kwasny[1], H. Sjuts[2], S. Cardinale[1], J. D. Williams[1], T. L. Bowlin[1], K. M. Pos[2], T. J. Opperman[1]; [1]Microbiotix, Inc., Worcester, MA, [2]Goethe Univ. Frankfurt, Frankfurt, Germany

Abstract Body:

Background: The RND family of efflux pumps plays an important role in Multi-Drug Resistance (MDR) in Gram-negative pathogens. Recently, we reported analogs of MBX 2319 as being potent pyranopyridine efflux pump inhibitors (EPIs) that target the major RND pumps of Enterobacteriaceae. Co-crystal structures of these materials reveal them bound to the hydrophobic trap of the *Escherichia coli* RND pump AcrB. Here, we detail our use of structure-based drug design and SAR analysis to improve the ADME properties of our molecules providing access to EPIs with improved pharmacokinetic profiles.**Methods:** Pyranopyridine analogs were synthesized using published methods. Potency was determined through checkerboard MIC assays that measure the Minimum Potentiation Concentration which decreases the MIC of levofloxacin or piperacillin four fold (MPC4). *In vitro* ADMET assays (cytotoxicity, solubility, human liver microsome stability, and CYP3A4 inhibition) were used to estimate pharmacokinetic properties of analogs. Pharmacokinetic parameters from *In vivo* assays were calculated using WinNonLin. Co-crystal structures of pyranopyridine analogs bound to the periplasmic domain of AcrB were generated in the laboratory of Martin Pos.**Results:** Optimization efforts leveraged existing SAR and structural analyses of pyranopyridines bound to AcrB to improve ADME properties and maintain potency, improving the solubility, stability and ligand efficiencies of lead compounds. This work identified “hot spots” of metabolic activity such as the C4’ amide of MBX3132 that could be modified to improve stability. Additionally, the placement of basic amines and alcohols in water-filled pockets identified in the crystal structure allowed for improved solubility profiles. Further co-crystal structures of new analogs further aided these efforts. Based on this work, Compounds MBX3132, MBX3795, MBX3796 and MBX3797 were profiled for PK in mouse, revealing excellent overall profiles (AUCs ranging from 10,000-40,000, CL<1000 mL/hr/kg with 10 mg/kg IV), paving the way for *in vivo* proof of concept experiments.**Conclusion:** Structural alterations of the pyranopyridine scaffold improved potency, metabolic stability, and solubility allowing the identification of materials with excellent PK profiles.

Publishing Title:

The Assessment of SPR741 for Nephrotoxicity in Cynomolgus Monkeys and Sprague-Dawley Rats

Author Block:

S. Coleman[1], M. Bleavins[2], T. Lister[1], M. Vaara[3], T. J. Parr, Jr[1]; [1]Spero Therapeutics, Cambridge, MA, [2]White Crow Innovation, LLC, Dexter, MI, [3]Northern Antibiotics, Espoo, Finland

Abstract Body:

Background: SPR741 is a polymyxin derivative devoid of direct antibacterial activity that is currently being investigated as a partner in combination with antibiotics for the treatment of multi-drug resistant Gram-negative infections. Antibiotic polymyxins have been shown to exhibit kidney toxicity and as such, we investigated the nephrotoxicity of SPR741 in monkeys and rats to determine the impact on nephrotoxicity. **Methods:** SPR741 was administered to female cynomolgus monkeys as a one-hour infusion three times per day for seven days at dose levels of 12, 30, and 60 mg/kg/day. SPR741 was also administered to male Sprague-Dawley rats as a one-hour infusion three times per day for seven days at dose levels of 5, 15, and 30 mg/kg/day. Control animals received the vehicle (sterile saline) only for both studies while Polymyxin B (PMB) was a positive control in each study. Blood samples were taken for toxicokinetic analysis on study days 1 and 7 in monkeys while only taken on study day 7 in rats while in both studies blood was taken for serum chemistry. All animals were euthanized on study day 8 and kidneys were processed to slides stained with hematoxylin and eosin, and read by a board certified veterinary pathologist. **Results:** In monkeys, SPR741 was not associated with nephrotoxicity at any dose level as determined by histopathology while PMB demonstrated the anticipated nephrotoxicity. The exposure of SPR741 in monkeys at the highest dose tested of 60 mg/kg/day was an $AUC_{0\text{-}24}$ of 163 ug*hr/mL and a C_{max} of 66 ug/mL. In rats, SPR741 was associated with minimal nephrotoxicity at 30 mg/kg/day demonstrated by pathology of a low degree of nephrotoxicity accompanied with slight increases (1.7X) in serum creatinine. PMB did not produce nephrotoxicity in rats. In rats, the exposure of SPR741 at the NOAEL of 15 mg/kg/day was an $AUC_{0\text{-}24}$ of 54 ug*hr/mL and a C_{max} of 7 ug/mL. **Conclusions:** SPR741 demonstrated a no observed adverse effect level (NOAEL) of greater than 60 mg/kg/day (the highest dose tested) following seven days of repeated three times daily one hour infusions in cynomolgus monkeys whereas in rats the NOAEL was 15 mg/kg/day following seven days of repeated three times daily one hour infusions.

A Single-centre, Double-blind, Placebo-controlled Study in Healthy Men to Assess the Safety and Tolerability of Single and Repeated Ascending Doses of mgb-Bp-3, a New Class of Antibacterial Agent

Author Block:

M. Ravic, MD, PhD[1], D. Firmin, PhD[1], I. Hunter, PhD[2], C. Suckling, PhD[2], F. van den Berg[3], O. Sahgal[3]; [1]MGB Biopharma Ltd, Glasgow, United Kingdom, [2]Univ. of Strathclyde, Glasgow, United Kingdom, [3]Hammersmith Med.s Res. Ltd, London, United Kingdom

Abstract Body:

Background: MGB-BP-3 (MGB) binds selectively to the bacterial DNA minor groove and has strong bactericidal *in vitro* and *in vivo* activity against *Clostridium difficile*. Completion of a full non-clinical package, including formal GLP toxicology and safety pharmacology, allowed progression to a Phase I human study, to assess the safety, tolerability and PK profile of single (Part A) and multiple (Part B) ascending oral doses of MGB.**Methods:** Part A was a randomised, double-blind, placebo-controlled, cross-over, single ascending-dose trial in 16 healthy men. Subjects were enrolled in 2 groups of 8 (Groups 1-2). Each subject received a single oral dose of MGB in each of 3 study sessions; Group 1 - 250mg, 500mg, 750mg; Group 2 - 1000mg, 1500mg, 2000mg; 6 volunteers received matching placebo in 1 study session. Part B was a randomised, double-blind, placebo-controlled, sequential-group, repeated ascending-dose trial in 24 healthy men. Subjects were enrolled in 3 groups of 8 (Groups 3-5). Each subject had 1 study session, receiving twice-daily oral doses of MGB, or matching placebo, for 9 days (Days 1-9) and a single dose on the morning of Day 10. Doses were 2X250mg, 2X500mg and 2X1000mg. Primary safety and tolerability variables, and secondary variables were assessed throughout.**Results:** No serious adverse events were reported during Parts A or B at any dose level tested. Adverse events were mild to moderate and primary safety variables (including vital signs, cardiac monitoring, lab safety tests, medical examinations and FOB) were all within acceptable limits. Plasma PK assessment showed no absorption after oral administration. Details of intestinal permeability, urine and faecal PK and faecal flora analysis will be presented.**Conclusion:** Orally-administered MGB was tolerated well in healthy volunteers at all dose levels tested in this Phase I clinical trial, with no dose limiting toxicity or serious adverse events. The safe dose was 2000mg MGB, administered orally at 1000mg twice a day over 10 days. MGB is suitable for progression into Phase II clinical trials to assess efficacy in patients with *C. difficile* infection.

Aminoglycoside (Ag) Activity Against *Enterobacter* spp., and Correlation with the Presence of Aminoglycoside Modifying Enzymes (Ames), *Klebsiella pneumoniae* Carbapenemases (Kpcs) and Extended-spectrum-Beta-Lactamases (Esbls)

Author Block:

G. Haidar, S. Cheng, T. M. Churilla, B. M. Churilla, A. Alkroud, R. K. Shields, Y. Doi, C. J. Clancy, M. H. Nguyen; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: KPC-producing *Enterobacter* spp. are emerging. Gentamicin (GEN) is active against the majority of carbapenem-resistant *K. pneumoniae*. The activity of GEN and other AGs against KPC-producing *Enterobacter* is not known. **Methods:** We compared the *in vitro* susceptibility of KPC-producing (KPC+) and non-producing (KPC-) *Enterobacter* isolates to aminoglycosides (GEN, tobramycin TOB, amikacin AMK). We determined the presence of KPC, ESBL and AME genes by PCR. **Results:**21 KPC+ (12 *E. aerogenes* (EA) and 9 *E. cloacae* (EC)) and 44 KPC- isolates (12 EA and 32 EC) were compared. 71% (15) and 7% (3) of KPC+ and KPC- isolates were resistant to GEN, respectively ($p<0.0001$). Corresponding rates were 67% (14) and 9% (4) for TOB ($p<0.0001$), and 9% (2) and 0% for AMK ($p=0.10$). AMEs were more common among KPC+ (95%) than KPC- isolates (20%, $p<0.0001$), as were ESBLs (41% vs. 30%, $p<.0001$). Likewise, mean and median numbers of AMEs were higher for KPC+ (4 and 5) than KPC- isolates (0.4 and 0). The most common AME genes among KPC+ isolates were: *aac(6')-Ib* (62%), *aadA2* (62%), *aac(6')-II* (57%) and *aadA1* (57%). The presence of either *aac(6')-Ib* or *aac(6')-II* was associated with resistance to all 3 AGs. The presence of any one of *aac(3)-II* and *-IV*, *aadA1* and *aadA2* was associated with resistance to GEN and TOB but not AMK. The presence of *aph(3')-Ia* was associated with GEN resistance. GEN, TOB and AMK MICs were significantly increased as the number of β lactamases (either KPC or ESBL) increased (<0.001). There was a direct correlation between presence of KPC and presence of *aac(6')-Ib* and *aph(3')-Ia*, and between presence of ESBL and *aac(6')-II* and *aph(3')-Ib* (all $p<0.01$). **Conclusion:**A significant majority of KPC+ *Enterobacter* spp. were resistant to GEN and TOB. Associations between presence of AME, KPC and ESBL genes suggest that they may be acquired on the same plasmids. The high prevalence of KPC+ isolates with *aac(6')-Ib*, known to confer resistance to GEN, TOB and AMK, suggests that these AG are unlikely to have a significant role in the treatment of KPC+ *Enterobacter* infections.

Publishing Title:

A Conjugative A*cinetobacter baumannii* Plasmid Carrying the *sul2* Sulfonamide Resistance Gene

Author Block:

M. Hamidian, S. J. Ambrose, R. M. Hall; Univ. of Sydney, Sydney, Australia

Abstract Body:

Background: Two globally disseminated clones of *Acinetobacter baumannii*, GC1 and GC2, are responsible for the majority of resistance to multiple antibiotics. We previously showed that the GC1 reference strain, A297 (RUH875) isolated in the Netherlands in 1984, is resistant to multiple antibiotics including tobramycin, gentamicin, kanamycin, neomycin, tetracycline, sulfonamides, trimethoprim and streptomycin. Resistance genes *aadB* in the 6-kb plasmid pRAY*, and *aphA1b*, *tetA*(A), *bla*$_{TEM}$, *catA1*, *sul1* and *dfrA5* in the AbaR21 resistance island in the chromosome accounted for most of the phenotype. However, *strAB* and *sul2* genes, which are rarely seen in GC1 isolates, were also found and shown to be linked. The objective of this study was to determine the context of the region containing *sul2* and *strAB*.**Methods:** A297 was sequenced using Illumina HiSeq and reads were used to generate a de novo assembly. Standalone BLAST was used to identify contigs that carry resistance genes. PCR followed by sequencing was used to join the contigs. Conjugation experiments were also conducted.**Results:** The *sul2* and *strAB* genes were found in pA297-3, a 200 kb plasmid that included a set of genes encoding conjugative transfer functions. However, no *rep* gene was in pA297-3. pA297-3 is conjugative and transferred streptomycin and sulfonamide resistance to a sensitive recipient. The *sul2* gene was part of ISAba1-*sul2*-CR2-*strAB* within a transposon structure named Tn*6172*. Tn*6172* was found to be identical to the right hand side of ABGRI1-2 resistance island found in the chromosome of GC2s. Exploring GenBank also revealed that pAB3, a 148 kb plasmid in the ATCC17978 strain, contains a transposon similar to Tn*6172*, named Tn*6174*. Tn*6174* was flanked by an orf region followed by a copy of Tn*6021*. Detailed analyses revealed that the structure found in pAB3, including orf region and Tn*6174*, forms an ancestral structure for the ABGRI1 group of islands.**Conclusions:** pA297-3, which caries Tn*6172* explains the presence of *sul2* in the A297 genome. Tn*6172* appears to be derived from of Tn*6174*. Tn*6174* together with its adjacent region is an ancestral form of the ABGRI1-2, the main resistance island found in the most globally widespread clone of *A. baumannii*, GC2. This novel finding highlights the role of plasmids in evolution and crafting complex genomic resistance islands in *A. baumannii*.

Detection of Extended-Spectrum β-Lactamase from Carbapenem-resistant *Acinetobacter baumannii* from Philadelphia Tertiary-Care Hospital

Author Block:

K. M. Raible[1], B. Sen[1], C. Emery[2], K. Krevolin[3], T. Bias[3], N. Law[1], G. Ehrlich[1], S. Joshi[1]; [1]Drexel Univ., Philadelphia, PA, [2]Drexel Coll. of Med., Philadelphia, PA, [3]Hahnemann Univ. Hosp., Philadelphia, PA

Abstract Body:

Background: *Acinetobacter baumannii* is the third most common Gram-negative bacillus isolated from patients in intensive care units associated with ventilator-associated pneumonia and is considered major nosocomial pathogen. Currently, treating these infections is difficult due to pathogen's innate resistances, and its high propensity to acquire exogenous resistance genes through horizontal gene transfer. Carbapenem resistance genes in *A. baumannii* require special attention in this regard. In the present study, we tested for the four major β-lactamase classes, as well as mobile gene elements in clinical isolates of carbapenem-resistant *Acinetobacter baumannii* (CRAB) from Hahnemann University Hospital in Philadelphia, PA.**Methods:** Carbapenem minimum inhibitory concentration results were obtained for each CRAB isolate (n=28) using VITEK$^{@}$2 and the results were confirmed by broth microdilution. Detection of β-lactamase genes and mobile elements were performed using PCR-based assays. The PCR assays were validated using Clinical Laboratory Standards Institute (CLSI)- recommended quality control (QC) strains, and the results were verified by Sanger sequencing.**Results: :** PCR-based detections established the presence of both innate and exogenous β -lactamase genes (particularly Classes A, C, and D) in all CRAB isolates. In addition, the presence of mobile elements (integron-cassettes, integrase genes, and insertion sequence (IS) elements) were also present in all isolates.**Conclusions:** IS-elements upstream of innate A. baumannii β -lactamase genes were found in all 28 CRAB isolates leading to increased expression of these genes. Insertion type correlated with resistance phenotype. The presence of plasmid-borne β -lactamase genes (OXA-23 and OXA-40) as well as integron cassettes in the CRAB isolates suggests the acquisition of these genes through multiple recombinatory events. Further sequencing studies are currently being performed to gain a better understanding of the local distribution and phenotypic impact of these resistance genes, and possibly provide a mechanism of how these resistance genes spread.

Selenium Increases the Sensitivity of Multidrug-Resistant *Acinetobacter baumannii* to Antibiotics through Synergistic Interactions

Author Block:

M. Surendran Nair, Y. Liu, K. Venkitanarayanan; Univ. of Connecticut, Storrs, CT

Abstract Body:

Background: Multidrug resistant (MDR) *Acinetobacter baumannii* is a nosocomial pathogen causing a wide spectrum of clinical conditions in humans. *A. baumannii* is equipped with a multitude of antibiotic resistance mechanisms, rendering them resistant to most of the antibiotics. Thus, it is critical to devise novel approaches for controlling *A. baumannii* infections. This study investigated the efficacy of Selenium (Se), a dietary essential mineral, in increasing *A. baumannii*'s sensitivity to three classes of antibiotics, namely beta-lactams (Ampicillin), tetracyclines (Tetracycline) and quinolones (Ciprofloxacin). Additionally, the synergistic interactions of Se with the antibiotics were determined using checkerboard assay.**Methods:** Two MDR *A.baumannii* isolates (~5 log CFU/ml) were separately inoculated into Muller Hinton broth supplemented with or without the sub-inhibitory concentration (SIC, highest concentration not inhibiting growth) of Se (5.6 mM) along with or without ampicillin, tetracycline or ciprofloxacin at their respective break point concentration. Bacterial growth was determined at 600 nm following incubation at 37°C for 24 h. The interactions of Se with the three antibiotics was investigated using microdilution checkerboard assay. Moreover, E-test was used to measure the reduction in the MIC of antibiotics when *A. baumannii* was exposed to the antibiotics with Se. The entire study was repeated twice with duplicate samples.**Results and Conclusion:** Se increased *A.baumannii*'s sensitivity to ampicillin, tetracycline and ciprofloxacin ($P \leq 0.05$) as evident from the decreased bacterial population in samples containing Se and antibiotic compared to those with antibiotics alone. Furthermore, the combination of Se with ampicillin produced a synergistic interaction ($FIC_{index} = \leq 0.5$), whereas with tetracycline and ciprofloxacin produced a synergistic ($FIC_{index} = \leq 0.5$) or additive ($0.5 \leq FIC_{index} \leq 1.10$) interaction was observed. The E test results showed a two-fold reduction in the MIC of the antibiotics when combined with Se. The results suggest that Se could potentially be used to enhance *A. baumannii*'s antibiotic sensitivity, thereby making the pathogen susceptible to the drugs.

Antibiotic Resistance Determinants in the Cystic Fibrosis Pathogen *Achromobacter xylosoxidans*

Author Block:

A. K. Lee; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Cystic fibrosis (CF) is an autosomal, recessive disease caused by a mutation in the Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) causing an increase in mucus viscosity. This creates an ideal environment for microbial colonization resulting in the establishment of a diverse microbial community. Recently, *Achromobacter xylosoxidans*, an opportunistic pathogen often associated with nosocomial infections, has been implicated in later disease states in CF patients. It has proved resistant to a broad range of antibiotics, transmissible between patients, and shows robust biofilm formation as well as other virulence factors, increasing its importance as a pathogen and creating difficulties in identifying effective therapeutic strategies. Despite its relevance in disease, little is known regarding mechanisms involved in pathogenicity, including antibiotic resistance. In this study, we used transposon mutagenesis to identify genes contributing to antibiotic resistance in a transmissible, multidrug-resistant, clinical isolate of *A. xylosoxidans*. In the presence of the minimum inhibitory concentration of four antibiotics (ampicillin, gentamicin, chloramphenicol, and ciprofloxacin), we screened approximately 10,000 mutants, representing 90 percent of the *A. xylosoxidans* genome, for drug resistance determinants. Genes we identified included efflux pumps, transcriptional regulators, and hypothetical proteins. One particular gene of interest was a HTH-type transcriptional regulator, *dmlR*. This gene confers resistance to ciprofloxacin, gentamicin and chloramphenicol. DmlR, in addition to other determinants were further screened for their involvement in resistance to 10 antibiotics commonly used in CF treatment, revealing several other genes involved in multidrug resistance. With this information, we can tailor future studies toward characterizing the role of these genetic determinants in antibiotic resistance, which will potentially inform the design of novel therapeutic strategies.

Investigations into the *hipa7* High Persister Mutation in Clinical *Burkholderia cenocepacia* Isolates

Author Block:

S. E. Nicolau, Y. Shan, K. Lewis; Northeastern Univ., Boston, MA

Abstract Body:

Background: *Burkholderia cenocepacia* is a difficult pathogen to treat because it possesses an abundance of virulence factors, multiple resistance mechanisms and often infects compromised hosts. Moreover, this pathogen often presents as a reoccurring infection and is associated with increased mortality in cystic fibrosis (CF) patients. Historically, beta-proteobacteria, like *Burkholderia* species, do not possess the *hipA* gene, a previously identified persister gene. Persisters are phenotypic variants of a population that go dormant, allowing them to survive antibiotic treatment. However, for some reason that remains unclear at the present time, human pathogenic isolates of *Burkholderia* appear to contain this gene. The purpose of this experiment was to evaluate the presence of the *hipA7* allele, a high persister mutation in *E. coli* that has been linked to reoccurring clinical urinary tract infections, in clinical isolates of *Burkholderia cenocepacia*. **Methods:** In this study, colony polymerase chain reaction (PCR) was done on 30 clinical isolates of *B. cenocepacia* using predesigned primers upstream and downstream of the *hipA* gene. *E. coli* MG1655 was run simultaneously as a positive control. Success of the PCR was confirmed by gel electrophoresis. PCR products were then purified and samples were sequenced by GENEWIZ (South Plainfield, NJ).**Results:** The *E. coli* MG1655 control presented on the gel with a band size representative of the *hipA* gene, confirming the viability and specificity of the PCR protocol utilized. Of the 30 *B. cenocepacia* clinical isolates screened, none contained the *hipA7* allele. In the absence of this specific high persister mutation, P77S, I91T, A107S, P155L, L168P, N394D and A403S were found to be common mutations among many of the clinical isolates.**Conclusions:** In this study we were unable to locate the presence of the *hipA7* high persister mutation in the 30 clinical isolates of *B. cenocepacia* screened. While these data suggest that the *hipA7* allele may not be present in this organism, many of these isolates contained mutations in their amino acid sequence, which could translate into currently unidentified high persister alleles.

Complex Regulation of the *Burkholderia pseudomallei bpeef-oprc* Multidrug-Resistance Operon

Author Block:

K. A. Rhodes[1], N. L. Podnecky[2], H. P. Schweizer[1]; [1]Univ. of Florida, Gainesville, FL, [2]The Arctic Univ. of Norway, Tromso, Norway

Abstract Body:

Background: *Burkholderia pseudomallei* is an emerging pathogen and the etiologic agent of melioidosis. *B. pseudomallei* infections are difficult to treat because of the bacterium's intrinsic and acquired antibiotic resistance. Efflux mediated by members of the resistance nodulation cell division (RND) family of efflux pumps is the dominant resistance mechanism. Of the three RND pumps characterized in some detail, the BpeEF-OprC pump encoded by the *llpE-bpeE-bpeF-oprC* efflux operon located on chromosome 2 represents the clinically most relevant efflux pump. Genetic evidence indicates that efflux operon expression is governed by the product of the *bpeT* gene, located upstream of and transcribed divergently from the efflux operon. BpeT is a LysR-type transcriptional regulator and mutations to the carboxy-terminal domain cause constitutive operon expression. Pump expression results in multidrug resistance, including clinically used trimethoprim and in some instances trimethoprim-sulfamethoxazole [SXT]). **Methods:** Genetic, biochemical and molecular methods were used to study molecular mechanisms governing BpeEF-OprC efflux pump expression. To avoid dual use of research concerns, resistance and recombinant experiments were performed using a select agent excluded *B. pseudomallei* strain. **Results:** BpeT overexpression activates transcription of the efflux operon. Purified BpeT binds to the 187-nucleotide *bpeT-llpE* intergenic region. Genome sequence analysis of a SXT resistant mutant identified *bpeS*, on chromosome 1 whose product shares >60% amino acid homology to BpeT. Mutations affecting the BpeS carboxy-terminal domain and its presumptive DNA binding domain, but not BpeS overexpression, cause high-level *llpE-bpeE-bpeF-oprC* operon expression. Purified BpeS also binds to the *bpeT-llpE* intergenic region. While BpeT and BpeS are both involved in regulation of BpeEF-OprC expression, their impact on drug resistance is curiously not the same. **Conclusions:** Our data show that expression of BpeEF-OprC is complex, and further studies are needed to understand the interplay of regulatory factors causing increased pump expression and subsequent decreased antimicrobial susceptibility in *B. pseudomallei*.

Fluoroquinolone Resistance (FQR) Mechanisms in Extended-Spectrum β-Lactamase Producing *Enterobacteriaceae* (ENT) Isolates from Children

Author Block:

L. K. Logan[1], S. H. Marshall[2], A. M. Hujer[2], T. N. Domitrovic[2], S. D. Rudin[2], F. A. Scaggs[1], X. Xheng[3], N. K. Qureshi[4], A. Karadkhele[1], M. K. Hayden[1], R. A. Bonomo[2]; [1]Rush Univ. Med. Ctr., Chicago, IL, [2]Cleveland VA Med. Ctr., Cleveland, OH, [3]Northwestern Univ. Feinberg Sch. of Med., Chicago, IL, [4]Loyola Univ. Med. Ctr., Maywood, IL

Abstract Body:

Background: Fluoroquinolones are not commonly prescribed in children, yet the increasing incidence of MDR GNR infections in this population is escalating to a threatening level. Our long term goal is to define the molecular epidemiology of MDR GNRs in children, in order to devise more effective treatment and prevention strategies. Here we report our findings regarding FQR *Ent* in children. **Methods:** A retrospective cohort study of clinical GNR isolates obtained from children ages 0-21 years hospitalized from 2011-14 at three Chicago hospitals was performed. Plasmid-mediated FQR (PMFQR) and mutations in the quinolone resistance-determining regions (QRDR) of *gyrA* and *parC* in isolates were investigated. Rep-PCR determined genetic relatedness. DNA microarray (Check-Points CT101/103XL) was used to detect β-lactamase genes (*bla*). Multilocus sequence typing (MLST), PCR and DNA sequencing were also performed. **Results:** Of 169 ESBL-producing *Ent* isolates, 85 (50%) were FQR of which 82 were analyzed (96.4%). The median age of patients was 4.8 years. All patients were deemed to have infection by these isolates. The predominant FQR organism was *E. coli* 65/82 (79%), and the predominant *bla* genotype associated with FQR in *Ent* was $bla_{\text{CTX-M-1}}$ group in 51/82 cases (62%). Within ESBL *E. coli*, FQR was commonly associated with phylogenetic group B2 and ST43/ST131 containing $bla_{\text{CTX-M-1}}$ group in 47/63 cases (75%). PMFQR was found in 56/82 (62%) isolates, of which *aac 6'1b-cr* (Y102R and/or D179Y), *oqx A/B*, *qnr A/B/D/S*, and *qepA* gene mutations were found in 51%, 10%, 10%, and 9%, respectively. PMFQR was found with *gyrA* and/or *parC* mutations in 84% of cases. Several isolates contained >1 *bla*/PMFQR gene. **Conclusions:** This report defines the emerging molecular epidemiology of FQR in ESBL-producing *Ent* in this population of hospitalized children in Chicago. PMFQR and QRDR mutations are the primary mechanisms. Knowledge of these genotypes among children without direct clinical exposure to FQs raises the concern that in this population, transmission is readily occurring by multiple means.

Compassionate Use Ceftazidime/Avibactam (Cazavi) for Carbapenem-Resistant (Cr) Gram-Negative Rod (Gnr) Infections

Author Block:

J. C. Gallagher[1], J. McKinnell[2], CAZAVI Compassionate Use Research Group; [1]Temple Univ. Sch. of Pharmacy, Philadelphia, PA, [2]David Geffen Sch. of Med., Los Angeles, CA

Abstract Body:

Background: CAZAVI is a novel agent with activity against MDR GNRs, including carbapenem-resistant Enterobacteriaceae (CRE). We collected the experience of US clinicians who used CAZAVI during a compassionate use program available before its FDA approval for CR-GNR infections.**Methods:** Clinicians of record who requested and were granted approval for compassionate use CAZAVI were contacted and asked to contribute blinded data on their patient cases into a central database. Patients were included if they had received CAZAVI and had sufficient data to determine outcomes. CRE was defined as isolates resistant to all carbapenems by CLSI standards. Outcomes included in-hospital mortality and microbiological and clinical success. Microbiological success required a negative culture at the end of therapy. Clinical success was judged by improved symptoms and defervesence.**Results:**

Characteristic	**Results (N=15)**
Male gender (n,%))	7 (47%)
Age, median (range)	61 (31-92)
Length of stay, median (range)	72 (26-585)
Charlson Comorbidity Index, median (range)	3 (1-12)
Pitt Bacteremia Score, median (range)	3 (1-8)
ICU residence, n (%)	12 (80%)
Organ transplant, n (%)	5 (33%)
Acute renal failure, n (%)	7 (47%)
Ventilator requirement, n (%)	9 (60%)
Septic shock, n (%)	8 (53%)
Hepatic disease, n (%)	11 (73%)
Organism, n *K. pneumoniae*	12 1

E. coli *E. aerogenes* *P. aeruginosa*	1 1
Infection(s), n Bacteremia Intra-abdominal Pneumonia Urinary tract	10 7 2 1
Isolates susceptible to CAZAVI, n/N (%)	8/10 (80%)
Days of CAZAVI use, median (range)	24 (3-50)
In-hospital mortality, n (%)	10 (67%)
Microbiologic success, n (%)	13 (87%)
Clinical success, n/N (%)	5/11 (45%) 4 indeterminate outcomes

All patients received therapy with alternate antibiotics prior to CAZAVI. While receiving CAZAVI, one patient had a hypersensitivity reaction and 2 had transient LFT elevations.**Conclusion:** In this seriously ill population with CR-GNR infections and delayed receipt of CAZAVI, high rates of microbiological success coupled with moderate clinical success were seen.

Susceptibility and Mechanisms of Resistance to Carbapenems Among Us Gram-negative Bacilli (Gnb)

Author Block:

R. M. Echols[1], B. N. Kreiswirth[2], D. Sahm[3], M. Ariyasu[4]; [1]Shionogi, Inc., Easton, CT, [2]NJMS Rutgers Univ,, Newark, NJ, [3]IHMA, Inc., Schaumburg, IL, [4]Shionogi, Ltd,, Osaka, Japan

Abstract Body:

Introduction: Strains of GNB (n = 3843) obtained from a systematic surveillance at 50 clinical laboratories in the US and Puerto Rico were evaluated for susceptibility to imipenem (IMP), meropenem (MER), doripenem (DOR) based on CLSI and FDA breakpoints; a subset of DOR non-susceptible isolates (41 *Enterobacteriaceae*, 20 *P. aeruginosa*, 20 *Acinetobacter* spp.) were analyzed for their underlying resistance mechanisms.**Methods***: In vitro* activity of the carbapenems was determined centrally (Eurofins, Chantilly, Va) according to CLSI guidelines for broth microdilution. Real-time PCR was used to detect mobile β-lactamase targets, including genes for carbapenemases (KPC, NDM, IMP,VIM, OXA-48, OXA-23, OXA-40, OXA-51, and OXA-58), ESBLs (CTX-M-1, CTX-M-2, CTX-M-9, and CTX-M-8/25) and AmpC (CMY1/MOX, ACT/MIR, CMY2/LAT/CEF,DHA, FOX, and ACC). Chromosomally encoded *ampC* gene, SHV and TEM genes and *K. pneumoniae* sequence type were determined. Porin genes for *K. pneumoniae* (*ompK35, ompK36*), *E. coli* (*ompF, ompC, ompR*), *A. baumannii* (*oprD, carO*) and *P. aeruginosa oprD* were determined. Gene expression of efflux pumps in *P. aeruginosa* was compared to the reference strain PAO1.**Results**: DOR was the most active carbapenem *vs P. aeruginosa* (N=1175). 8.1% isolates were multi-drug resistant (MDR). 50-53% of *Acinetobacte*r spp (N=335) were susceptible to DOR, MER or IMP. 41 (1.75%) Enterobacteriaceae (N=2333) were non-susceptible to DOR and all contained KPC. 89% KPC *K. pneumoniae* were ST258. Among 20 DOR-non-susceptible *P. aeruginosa*, only 7 contained KPC while 13 different *oprD* porin mutants were identified. OXA-51 was present in 95% *Acinetobacter* isolates and strains harboring only OXA-51 showed DOR MIC of 2 μg/ml. All 10 *Acinetobacter* strains with doripenem MIC >32 μg/ml contained either OXA-23 or OXA-40 in combination with OXA-51.**Conclusion**: This study contains a robust collection of phenotypic and genetic profiles of key Gram-negative pathogens. While KPCs among *K. pneumoniae* are directly correlated with higher doripenem MICs, the overall picture is that multidrug resistance is the result of several complex factors (i.e. enzymes, porins, and efflux) that combine to create carbapenem resistance phenotypes, especially among *P. aeruginosa* and *Acinetobacter* spp.

A Bottom-Up Approach for Rationalising Molecule Permeation in Gram-Negative Bacteria

Author Block:

M. Ceccarelli[1], S. Acosta Gutierrez[1], I. Bodrenko[1], G. Malloci[1], M. A. Scorciapino[2], J. Wang[3], H. Bajaj[4], M. Winterhalter[4]; [1]Dept. of Physics, Univ. of Cagliari, Monserrato, Italy, [2]Dept. of BioMed. Sci., Univ. of Cagliari, Monserrato, Italy, [3]Nanion, Munich, Germany, [4]Jacobs Univ., Bremen, Germany

Abstract Body:

Background: The demand of new drugs for combating multidrug-resistant bacteria appears more urgent for Gram-negative bacteria: the presence of the outer membrane, which hinders the access of molecules to internal targets, renders the development of anti-infectives more challenging. Today neither a robust screening method for permeation nor defined physical/chemical rules governing permeation through the outer membrane are available.As part of the IMI-ND4BB platform, a Public-Private Partnership funded by the EU and EFPIA, we are applying a bottom-up approach to investigate the problem of molecule permeation through the outer membrane. We started from high-resolution crystal structures of simple porins, followed by monitoring their expression in the bacteria in different growth conditions. With this information we defined a priority list of proteins and selected antibiotics and inhibitors from different families to rationally explore the chemical space. We then combined molecular modeling with molecular dynamics enhanced sampling techniques to characterize electrostatic of porins and simulate the permeation of antibiotics through porins, identifying the key molecular parameters.We focused initially on Enterobacteriaceae, where OmpF/OmpC orthologs constitute the main influx routes for polar antibiotics. The results were analyzed with a simple Hamiltonian model, showing how (i) the minimal projection area and (ii) the molecular dipole moment represent key parameters to modulate permeation through simple porins. Other parameters such as size/shape fluctuations, which correlate with rotatable bonds, were also considered. Cell-free electrophysiology at single molecule level on reconstituted porins was used to confirm our data whenever possible.Without a strong and accurate experimental method to assess the flux of antibiotics through porins, our Hamiltonian model, based on steric hindrance and electrostatic of pore/antibiotic complex, represents a useful tool to explore the chemical space for searching new scaffolds and/or optimize at the molecular level existing molecule for an enhanced permeation through bacterial porins.

Understanding Epistasic Interactions in Evolving Antibiotic Resistant Populations

Author Block:

R. A. Hickman, M. O. A. Sommer; Novo Nordisk Fndn. Ctr. for Biosustainability, Hørsholm, Denmark

Abstract Body:

Background: Bacterial evolution of antibiotic resistance is significant public health problem contributing to treatment failures for an increasing number of infections. We have previously used amplicon sequencing to screen mutagenic genomic hot-spots at various time points from five drug adaption 14-day *E. coli* evolution experiments done in triplicate. The drugs used were amikacin, chloramphenicol, ciprofloxacin, amikacin + chloramphenicol and chloramphenicol + ciprofloxacin, we were interested in these drugs as they are all clinically relevant, and the last two combinations the first exhibits collateral sensitivity (amikacin + chloramphenicol), whilst the second exhibits collateral resistance (chloramphenicol + ciprofloxacin). We identified mutations that where closely correlated (positively or negatively) with other mutations. In this study we explore these potential epistasic interactions and use recombineering to introduce representative sets of resistance conferring mutations and explore their fitness effects and population dynamics.**Method:** To recreate all the mutants we used PMA7 based recombineering in *E. coli*. Once all mutants were created doubling times were measured to assess fitness and antibiotic IC90s to assess selective advantage compare to their ancestral wild type. Then competition experiments were performed with strains transformed with plasmids inducing fluorescent proteins to simulate population dynamics previously seen.**Results:** Our results indicate that antibiotic resistance development is more complex than previously reported in the literature. We found that double mutants that were positively correlated had a fitness cost but a significant selective advantage, whilst this selective advantage did not occur with the negatively correlated mutations.**Conclusion:** These results demonstrate that epistasic interactions exist amongst resistance mutations and likely play a role in shaping the evolutionary trajectory leading to resistance.

Identification of a Novel Meropenem-intermediate Resistance Factor Using a Genomic Dna Library of *Bacteroides fragilis* gai92214 Strain

Author Block:

T. Goto[1], Y. Morita[2], M. Hayashi[1], K. Tanaka[1]; [1]Gifu Univ., Gifu city, Gifu, Japan, [2]Aichi Gakuin Univ., Nagoya city, Aichi, Japan

Abstract Body:

Background: *Bacteroides fragilis*, an anaerobic opportunistic pathogen, is resistant to a broader range of antimicrobials. Approximately 2% of *B. fragilis* clinical isolates are resistant to carbapenems. We previously reported a highly carbapenem-resistant isolate, GAI92082 strain, in which carbapenemase (CfiA) gene was encoded by a plasmid (pBFUK1). As carbamenem-intermediate resistant *B. fragilis* isolates are also problems in chemotherapy recently, we aimed to identify a novel resistance factor using *B. fragilis* GAI92214 strain (*cfiA* gene negative) conferred meropenem (MP)-intermediate resistance (MP MIC, 16 µg/ml). **Methods:** We constructed a genomic DNA library of the GAI92214 strain. Briefly, we purified 3-5 kb DNA fraction from sheared GAI92214 genomic DNA and ligated it into a high copy vector, pHSG398. Resulting recombinant plasmids were electroporated into *Escherichia coli* KAM3 Δ*tolC* strain, hypersusceptible to antimicrobials. We performed screening a novel MP resistance factor from forty thousand clones, using LB agar plates contained 0.04 µg/ml MP. **Results:** One of forty thousand clones showed slightly higher resistance (MP MIC, 0.06 µg/ml) than the host strain, KAM3 Δ*tolC*. The partial sequence of 'major facilitator superfamily (MFS) transporter' was revealed by sequencing of insert DNA in recombinant plasmid purified from this resistant clone. We sequenced the complete sequence of this transporter, its promoter and terminator regions (named as MFS whole region). This complete MFS transporter contained 12 transmembrane regions. The MFS whole region was ligated into the pHSG398 and transformed into the KAM3 Δ*tolC*. Resulting recombinant clone showed MP resistance (MIC, 0.06 µg/ml) slightly higher than the KAM3 Δ*tolC*. **Conclusions:** Identified MFS transporter may contribute slightly to MP resistance in the GAI92214 strain. Not only gene expression analyses of this MFS transporter in the GAI92214 strain is necessary, but also other genomic approaches will be needed to identify other factors (e.g., other pumps, mutation of porins) contributed greatly to MP intermediate resistance in the GAI92214 strain.

A Novel Ndm-1 Gene Carrying *Acinetobacter baumannii* from University Hospital in a Resource Starved Country, Nepal

Author Block:

S. Shrestha[1], B. Pokhrel[1], B. Rijal[1], J. Sherchand[1], T. Tada[2], T. Kirikae[2]; [1]Inst. of Med., Kathmandu, Nepal, [2]Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan

Abstract Body:

Background: In recent years, the emergence of multidrug-resistant *Acinetobacter baumannii* associated with hospital-acquired infections has been increasingly reported worldwide and in particular emergence of $bla_{\text{NDM-1}}$ has created the most concern. The aim of this study was to investigate the prevalence of NDM-1 carrying *Acinetobacter baumannii* species from nosocomial infection in a university hospital in Nepal. **Methods:** A total of 246 *Acinetobacter* species isolates obtained from different patients were screened for MDR *A. baumannii* during December 2013 to December 2014. Identification of the MDR *A. baumannii* strains at the species level was confirmed by 16S rRNA sequencing. Minimum inhibitory concentrations (MICs) were determined using the guidelines of the Clinical and Laboratory Standards Institute (CLSI). Carbapenem-resistant isolates were further screened for metallo-β-lactamase (MBL) production by a combination disc method using imipenem and ethylene-diamine -tetraacetic acid (EDTA). Among 122 MDR *A. baumannii*, 52 isolates were tested for the presence of $bla_{\text{NDM-1}}$ by PCR and confirmed by sequencing. **Results:** Among 246 *Acinetobacter* species collected, 122 were MDR *A. baumannii* with the majority resistant to aminoglycosides, carbapenems, and fluoroquinolones but not to colistin and tigecycline. We found a high prevalence of $bla_{\text{NDM-1}}$ among *A. baumannii* clinical isolates with 18/52 (34.6.%) isolates being $bla_{\text{NDM-1}}$ positive. **Conclusion:**This is the first report describing multidrug-resistant *A. baumannii* strains harboring $bla_{\text{NDM-1}}$ isolated from hospital-acquired infection in Nepal. Further investigations to find the origin of this gene and its mechanism of spread is urgently needed.

Macrolide Efflux Genetic Assembly (Mega) Element in Haemophilus Parainfluenzae

Author Block:

A. Endimiani[1], A. Lupo[1], D. Wüthrich[2], A. Allemann[1], M. Hilty[1]; [1]Inst. for Infectious Diseases, Bern, Switzerland, [2]Univ. of Bern, Bern, Switzerland

Abstract Body:

Background: Two identical extensively drug-resistant (XDR) *Haemophilus parainfluenzae* isolates non-susceptible to β-lactams, macrolides, quinolones, tetracycline, and chloramphenicol were recently described.**Methods:** In the efforts to analyze how the resistance genes of these pathogens were organized, one isolate (AE-2096513) underwent Illumina HiSeq 200 whole genome sequencing (WGS). Sanger sequencing was additionally performed to bridge the contigs.**Results:** We describe for the first time the tet(M)-Macrolide Efflux Genetic Assembly (MEGA) element in a *H. parainfluenzae* isolate. Furthermore, it was revealed that the tet(M)-MEGA element was inserted 2bp downstream of RF-3 (ORF19190) at position 1'989'391 compared to *H. parainfluenzae* T3T1. Inspecting the ends of the element revealed that there were no inverted repeats. In AE-2096513, tet(M) together with MEGA were in a "non-Tn916" context because Tn916 typically contains the ORF8 to 23 that were absent in our element.**Conclusions:** *H. parainfluenzae* is normally isolated from the pharynx, where there are also streptococci and pneumococci. A genetic exchange between these two bacterial species was therefore likely. Our finding may serve as a paradigmatic example of microbial acquisition of mobile genetic elements carrying resistant genes against clinically implemented antibiotics.

Structure-Guided Drug Design for the Antibiotic Resistance Enzyme OXA-48

Author Block:

B. A. Lund, S. Ahkter, Y. Guttormsen, T. Christopeit, A. Bayer, H-K. S. Leiros; UiT - The Arcitc Univ. of Norway, Tromsø, Norway

Abstract Body:

Background: Antibiotic resistance shakes the foundation of modern healthcare. While there are several mechanisms, some of the worst problems are caused by antibiotic resistance enzymes such as the class D β-lactamase OXA-48. These enzymes catalyze the hydrolysis of antibiotics, making the bacteria resistant to penicillins and carbapenems. Avibactam is currently the only approved drug on the market that is effective in inhibiting the class D β-lactamases, and there is a need for more compounds in the pipeline to have a backup when resistance arises. **Methods:** The project focuses on designing inhibitors towards these enzymes based on the structural information we have from X-ray crystallographic structures, in order to prolong the lifetime of the current antibiotics with combination therapies. We have performed a surface plasmon resonance (SPR) screen with 490 fragments to find inhibitor scaffolds for OXA-48, and validated the hits using a biochemical assay. **Results:** Several interesting starting points for further optimization have been identified in this manner. By systematically varying the substitutions on the scaffolds we have identified the key interactions of these compounds, and the binding mode for several compounds by X-ray crystallography. The compounds bind non-covalently and reversibly, and with good ligand efficiency (Above 0.3 kcal/mol per heavy atom). We were also able to use two alternate conformations from a structure to design and synthesize a merged compound with improved inhibitory potency.

Conclusions: Our most potent compound has a K_D of 50 µM and an IC_{50} of 18 µM, and the compounds represent a novel inhibitory scaffold for an important drug target involved in antibiotic resistance.

Discovery of Novel Antibacterials Targeting the MEP Pathway Using the Crystal Structure of *F. tularensis* lspD

Author Block:

S. M. Noble[1], A. Tsang[1], N. Pattabiraman[2], C. Johny[3], A. Haymond[3], R. Couch[3]; [1]Walter Reed Army Inst. of Res., Silver Spring, MD, [2]MolBox, Silver Spring, MD, [3]George Mason Univ., Fairfax, VA

Abstract Body:

Francisella tularensis is classified as a category A agent by the US Centers for Disease Control and Prevention due to its ease of transmission, low infectious dose and significant potential to cause severe illness and death. Due to the prevalence of antimicrobial resistance and the feasibility by which resistance can be engineered into bacteria such as *F. tularensis* and *Y. pestis*, continued development of novel antibiotics is needed. The methylerythritol phosphate (MEP) pathway presents a series of enzymes that may be exploited for antibacterial development. The MEP pathway is utilized by bacteria, apicomplexan protozoa, and plants for biosynthesis of isoprenoids, which are vital for cellular processes such as electron transport, cell wall biosynthesis, and signal transduction. All isoprenoids are derived from either the MEP pathway or the mevalonic acid (MVA) pathway. Since humans acquire isoprenoids through the non-homologous MVA pathway, enzymes within the MEP pathway provide attractive targets for antimicrobial development. We hypothesize that inhibitors of the MEP pathway in *F. tularensis* will serve as effective antibiotics by blocking isoprene biosynthesis. Our objective is to determine crystal structures of MEP pathway enzymes to facilitate development of inhibitors effective against *F. tularensis* and other pathogenic bacteria. We have expressed, purified, crystallized and determined the 2.4 Å crystal structure of *F. tularensis* IspD (*Ft*IspD). The *Ft*IspD structure was then used for *in silico* screening of the PubChem compound database. Of 100 compounds identified from *in silico* screening, 36 were evaluated for enzyme inhibition. Two compounds exhibited IC_{50}'s of 2.47 μM and 1.58 μM and inhibited growth of *F. tularensis* in liquid culture. One of these compounds also inhibited growth of *Y. pestis*. In conclusion, using structure-based drug design methods, an inhibitor was identified that demonstrated antimicrobial activity against *F. tularensis* and *Y. pestis*. We are in the process of determining structures of *Ft*IspD bound to the two compounds with the lowest IC_{50}s for rational design and further improvement of antimicrobial activity.

Structure-Function Analysis of the *P. aeruginosa* Type III Secretion Needle

Author Block:

N. O. Bowlin[1], B. J. Berube[2], J. D. Williams[1], J. Mecsas[3], A. R. Hauser[2], T. L. Bowlin[1], D. T. Moir[1]; [1]Microbiotix, Inc., Worcester, MA, [2]Northwestern Univ., Chicago, IL, [3]Tufts Univ., Boston, MA

Abstract Body:

Background: The type III secretion system (T3SS) is a clinically important virulence mechanism in *Pseudomonas aeruginosa* (*Paer*) that secretes and translocates protein effector toxins into human cells. We previously identified a highly stereoselective phenoxyacetamide (PhA) inhibitor of *Paer* T3SS and demonstrated that mutations selected for resistance to PhA mapped to the needle protein gene, *pscF* (Bowlin et al., 2014). To better understanding the T3SS needle protein and its interaction with PhA, we initiated a structure-function analysis of *Paer* PscF. **Methods:** Random *pscF* mutants were generated by error-prone PCR, fused to the chaperone genes *pscE* and *pscG*, expressed from the *lac* promoter on pUCP24, introduced into Δ*pscF* or wild-type (WT) *Paer* cells, and assayed for T3SS secretion +/-PhA, +/-IPTG, +/-EGTA. Mutant and wild-type *pscF* alleles were combined in the same strain for dominance studies by expressing the second allele from the *ara* promoter and integrating it into the chromosome of Δ*pscF* cells with miniTn7. **Results:** Alleles of *pscF* with 80 non chain-terminating mutations in 54 different residues of the 84 residue PscF protein were identified. About 50% of the mutations eliminated secretion, 34% had no detectable effect on secretion, and nearly 19% resulted in secretion that was weakly or strongly PhA-resistant. Mutations conferring strong PhA resistance mapped to 8 distinct residues in the C-terminal 25% of PscF, and the side chains face the needle lumen, according to a *Paer* needle model based on the NMR/EM structure of the assembled Salmonella needle protein PrgI. None of the mutants was resistant to 3 other published T3SS inhibitors. Three mutant *pscF* alleles (D14V, D76N, and Q83H) caused constitutive T3SS expression. PhA resistance appeared to be co-dominant with the WT allele, revealing a continuous increase in PhA IC_{50} as the proportion of mutant allele expression was increased. In contrast, the constitutive expression phenotype was recessive to the WT allele. **Conclusions:** *Paer* T3SS resistance to PhA arises predominately from mutations in the C-terminal quarter of PscF. PscF subunits appear to play a role in T3SS regulation based on the constitutive expression phenotype of three *pscF* mutants.

Identification of Small Molecule Inhibitors of the Type II Secretion System in *Acinetobacter baumannii*

Author Block:

U. B. Waack, L. Simmons, H. L. T. Mobley, M. Sandkvist; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Multi-drug resistant (MDR) bacterial infections pose a major health threat. The increasing frequency of antibiotic resistance in many bacteria, including the nosocomial pathogen *Acinetobacter baumannii*, highlights the need for new therapeutic targets and treatment approaches. The Type II Secretion (T2S) system and its secreted substrates may be one such target as inactivation of the T2S system in *A. baumannii* results in reduced fitness in a murine model of bacteremia. Similarly, deletion of the genes coding for the T2S substrates, lipase (LipA) and metalloprotease (CpaA), results in reduction of *in vivo* colonization. In this study, we have designed and employed a high throughput (HT) screen for the identification of inhibitors of the *A. baumannii* T2S system. A HT lipase assay was developed to detect the functionality of the T2S system using the activity of LipA as a reporter. To eliminate false positives, counter screens were also developed. These counter screens were designed to remove compounds that interfere with bacterial growth, LipA expression or LipA activity. The lipase secretion assay and counter screens were evaluated in a pilot screen in which we tested 6400 compounds of known biological function. Following validation in the proof-of-concept pilot study, we screened 140,000 compounds for inhibition of the *A. baumannii* T2S system. One hundred thirty-three compounds that tested positive for the lipase secretion assay, but negative for the counter screens, were retested over a range of concentrations. Seventy-three of these compounds had an $IC_{50} \leq 30$ μM and inhibited lipase secretion by ≥ 35% at the highest dose tested. Fifty-four compounds were commercially available for reorder and will be retested. Following confirmation of activity, positive compounds will be analyzed for their ability to inhibit secretion of CpaA, another T2S substrate from *A. baumannii*. After verifying that the remaining T2S inhibitors have no adverse effect on the integrity of the cell envelope, they will be subjected to structure activity relationship and pharmacokinetic analysis. The ultimate goal is to identify compounds that may be used as chemical probes for studies of T2S or as therapeutics that, either alone or in tandem with other therapies, can treat MDR *A. baumannii* infections.

Validation of a High-Thoughput Screening Assay for Identification of Adjunctive and Directly Acting Antimicrobials Targeting Carbapenem-Resistant *Enterobacteriaceae*

Author Block:

K. Smith, J. E. Kirby; Beth Israel Deaconcess Med. Ctr., Boston, MA

Abstract Body:

Carbapenem resistant Enterobacteriaceae (CRE) are classified as an urgent threat by the CDC and new strategies for treatment are needed. We hypothesized that some known bioactive compounds will restore efficacy of carbapenems (termed antimicrobial adjunctives) or directly inhibit CRE. In this study, we developed, validated, and performed a high-throughput screen to simultaneously identify both of these antimicrobial types.Briefly, a representative CRE strain, *Klebsiella pneumoniae* BIDMC12A, was inoculated into 384-well plates containing test compounds in the presence (screen) or absence (counterscreen) of meropenem. Inocula and media corresponded to standards for in vitro susceptibility testing. Output was optical density with hits selected by z-score. Compounds inhibitory solely in the screen were considered potential adjunctives while those inhibitory in the screen and counterscreen were considered direct antimicrobials. Throughout screening, Z' scores routinely exceeded 0.6.Primary screening of 11,698 known bioactive compounds at the Institute of Chemistry and Cell Biology (Harvard Medical School) revealed 14 adjunctives and 79 direct antimicrobials, 74 of which were subject to abbreviated synergy testing in secondary analysis. Compounds showing positive results in secondary analysis were subject to dose-response and high-resolution synergy assays. Triclosan, a fatty acid synthesis inhibitor, was synergistic with meropenem (Fractional inhibitory concentration = 0.48). NH125 (MIC = 4 µg/ml), diphenyleneiondonium chloride (MIC = 8 µg/ml), and azidothymidine (AZT, MIC = 4 µg/ml) acted as direct antimicrobials. AZT, a nucleoside analog antiviral, was selected for a spectrum of activity assay due to its known low toxicity in humans. Using a panel of 103 clinical Enterobacteriaceae isolates, half of which were CRE, AZT showed an MIC_{50} of 2 µg/ml suggesting potential for clinical efficacy based on known human pharmacokinetic-pharmacodynamic parameters.Taken together, our data demonstrate proof of concept for our high-throughput screen and secondary analyses to identify compounds with direct antimicrobial activity or meropenem synergy. We are currently continuing our screen to identify novel and as yet uncharacterized inhibitors of CRE.

Development and Application of Bioluminescent Reporter Screens for the Discovery of Isoprenoid Biosynthesis Inhibitors in *P. aeruginosa*

Author Block:

D. M. Mills[1], J. D. Williams[1], D. C. Crick[2], T. L. Bowlin[1], D. T. Moir[1]; [1]Microbiotix, Inc., Worcester, MA, [2]Colorado State Univ., Ft. Collins, CO

Abstract Body:

Background: Isoprenoids are essential for cell viability due to their role in electron transport and cell wall biosynthesis. Many Gram-negative nonfermenters, including *Pseudomonas aeruginosa (Paer)*, utilize an alternate isoprenoid synthesis pathway, the 2-C-methyl-D-erythritol 4-phosphate (MEP) pathway, which is quite distinct from that found in humans, the mevalonate (MVA) pathway. To identify new inhibitors of this pathway as potential antibacterials, we developed and applied cellular reporter screens. **Methods:** A Δ*ispC* (aka *dxr*) *Paer* efflux-deficient strain with a deletion of the gene encoding the first step in the MEP pathway was constructed by complementation with a *lac*-regulated *ispC* copy on a plasmid. Growth of the regulated Δ*ispC* strain is directly proportional to the amount of added IPTG. To identify promoters that respond to reduction in *ispC* levels, the Δ*ispC* strain was grown in limiting IPTG, and RNA was isolated and subjected to RNASeq transcriptional profiling. **Results:** Profiles revealed that transcription of MEP genes does not respond to depletion of the first enzymatic step. Therefore, we selected responsive promoters apparently unrelated to the MEP pathway. To reduce identification of compounds with non-specific responses, we selected two promoters -- one (PA1317) that responded by up-regulation and one (PA2126) by down-regulation to *ispC* depletion. Promoter regions from the respective genes were inserted into a miniTn7 vector upstream of *luxCDABE* and integrated into efflux-deficient *Paer* cells. Application of both reporter strain assays to >150,000 compounds followed by secondary validation assays resulted in the discovery of 10 apparent MEP pathway inhibitors. All 10 have drug-like scaffolds and failed to stimulate reporter strains designed to detect inhibitors of other targets. Furthermore, they inhibit the growth of the *Paer* efflux-deficient Δ*ispC*/pUCP24-P*lac*-*ispC* strain inversely proportional to the concentration of IPTG provided. Inhibitors exhibited low or undetectable cytotoxicity (HeLa CC_{50} >100 μM), and did not inhibit the growth of *S. aureus* cells, which utilize the MVA pathway. **Conclusions:** This research resulted in the discovery of several novel scaffolds with characteristics of selective MEP pathway inhibitors.

Combating Antibiotic Resistant Bacteria (Carb) Program Leads to Novel Screening and Drug Development Efforts

Author Block:

D. V. Zurawski, R. J. Sciotti, Y. Si, M. H. Khraiwesh, R. K. Kim, C. E. Bane, R. A. Heitkamp, P. E. Waterman, L. T. Read, S. D. Tyner; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

In 2014 the President initiated a National Strategy for Combating Antibiotic Resistant Bacteria (CARB). This initiative tasked the Walter Reed Army Institute of Research (WRAIR) with the delivery of a novel Gram negative antibiotic drug candidate. Two research divisions at the WRAIR collaborated to construct a drug development pipeline that encompassed: initial compound screening with medicinal chemistry input, followed by typical ADME analysis and subsequent safety and efficacy testing in animal models of infection. The primary in vitro screen employed a novel approach using clinically relevant multidrug-resistant (MDR) Gram negative isolates against a proprietary compound library of about 10,000 compounds from WRAIR's 500,000 compound library. The isolates tested were previously characterized imipenem-resistant *Acinetobacter baumannii* (AB5711) and *Klebsiella pneumoniae* (KP4640). Both strains are clinical isolates from wound infections, harbor multiple carbapenemases and develop robust biofilms in vitro. Compounds were screened in CAMHB, and each isolate was grown in the presence or absence of imipenem (IMP). From the primary screen, 208 (about 2%) were found to inhibit growth with: 133 positives w/IMP against AB5711; 40 positives w/IMP against KP4640; 51 positives w/o IMP against AB5711; and 18 positives w/o IMP against KP4640. We then employed a novel secondary screen against these hits utilizing a more physiologically relevant minimal medium against positives from the primary screen. This secondary screen yielded further potential drug candidates, representing an additional down selection from our original library. Now, we will determine the MIC for these candidate compounds against a broad range of Gram positive and Gram negative bacteria. In addition, we will perform a diversity set screen against a representative panel of currently circulating MDR clinical isolates if that species appears susceptible. This screening approach, utilizing clinically relevant isolates in physiologically relevant media, with and without the current antibiotic standard of care, can identify novel small molecules that are potential antibiotics as well as antibiotic adjuvants.

Discovery of Novel Inhibitors of Multi-drug Resistant *Acinetobacter baumannii*

Author Block:

I. Soojhawon[1], N. Pattabiraman[2], A. Tsang[1], A. Roth[1], E. Kang[1], S. Noble[1]; [1]Walter Reed Army Inst. of Res., Silver Spring, MD, [2]MolBox LLC, Silver Spring, MD

Abstract Body:

Background: The rapid emergence of multidrug resistant *Acinetobacter baumannii* strains significantly reduces the efficacy of currently available antibiotics in the treatment of nosocomial infections. To combat antimicrobial resistance, novel drugs with new mechanisms of actions are urgently needed. Promising drug targets in Gram-negative bacteria include the outer membrane proteins (OMPs), especially the outer membrane protein W (OmpW). OmpW is a key transport channel and functions in the maintenance of homeostasis during cellular stress. Previous research studies have shown that *E. coli* colicin S4, a naturally occurring antimicrobial protein, exploits OmpW for its entry into the cell, and deletion of the OmpW gene from *E. coli* decreased the minimum inhibitory concentrations (MICs) for a range of antibiotics. Our overall objective is to use a structure-based approach to develop novel inhibitors of *A. baumannii* OmpW2.**Methods:** Computational modeling was utilized to generate a homology model of one of the isoforms of *A. baumannii* OmpW (OmpW2) based on the x-ray crystal structure of *E. coli* OmpW. Molecular docking studies were performed using the homology model to determine the binding pockets in the protein. Using a 3D stereo-electronic pharmacophore, *in silico* screening of the PubChem chemical library was performed for potential *A. baumannii* inhibitors. The antimicrobial activities of the identified compounds were then evaluated on the growth of a panel of *A. baumannii* strains by determining the MICs according to CLSI guidelines.**Results:** Fifty compounds were identified from the *in silico* screen and evaluated for antimicrobial activities. Three lead inhibitors designated as WRAIR_D5, WRAIR_D6 and WRAIR_D12 inhibited the growth of the *A. baumannii* strains with MICs ranging between 1 to 32 μg/ml.**Conclusions:** These results provide the preliminary information to refine the pharmacophore, perform further structure based drug screening and synthesize optimized derivatives of the leads. We conclude that this structure-based drug screening strategy offers promising inhibitors of *A. baumannii*, and that further studies are warranted to validate OmpW2 as a novel drug target.

Developing an Antimicrobial Screening Approach Using a T7 Phage Library

Author Block:

W. R. Rodriguez Polanco, C. Rios-Velazquez; Univ. of Puerto Rico at Mayaguez, Mayaguez, PR

Abstract Body:

The use of antibiotics is essential to treat microbial infections, patients that need surgery, chemotherapy or are immunocompromised need to be treated with antibiotics, but their misuse is causing the development of antibiotic resistant strains (ARS). Since the ARS spreading surpass the generation of new antibiotics, it is imperative to find novel antimicrobial agents, capable of inhibiting the antibiotic resistant pathogens. Also, due to the difficulty to find new antimicrobial agents by conventional screening, novel techniques and technologies needs to be developed. The main focus of this research is to test a novel antimicrobial screening strategy to detect antimicrobial agents using combinatorial chemistry. A bacterial bioprospect from our laboratory collection, previously isolated from Guánica Dry Forest in Puerto Rico and capable of inhibits *Staphylococcus aureus*, was used as a candidate to generate a combinatorial chemistry Phage Display Library (PDL). After extracting the bioprospect genomic DNA by a direct method, a genomic library was generated using T7 Select 10-3 cloning kit (Novagen). Three different screening types were done to the generated library. The first one was a plaque assay for inhibition, where a *Escherichia coli* lawn with individual T7-Bioprospect PDL plaques were exposed to the target, by pouring top agar inoculated with *Staphylococcus aureus* over the plaques. The second screening combined the T7-Bioprospect PDL with *E. coli* and *S. aureus* in the same top agar solution. A third screening was done by selecting and amplifying individual phage plaques in a 96 well plate, follow by transferring two micro-litters aliquot from each amplification on a Petri plate with *Staphylococcus aureus* lawn. In all the screening methods, the presence of a clear zone on the target was scored as a positive result. Preliminary tests have been done and no candidate has been found yet. A bioprospect T7 Phage display library was generated with approximately 9×10^9 plaque forming units. After screening approximately 10,000 clones (0.00001%) of the combinatorial library no visible inhibition zones have been detected. There is a possibility that the size and expression of the displayed peptides is affecting the antimicrobial activity. While more library screening and optimization processes are is in progress, this is a promising strategy to find molecules with antibiosis activity.

Phage Display Selected Peptides as Potential Anti-Adhesives Molecules in Paracoccidioidomycosis Therapy

Author Block:

H. C. de Oliveira[1], J. Michaloski[2], J. F. Silva[1], L. Scorzoni[1], A. C. A. de Paula e Silva[1], C. M. Marcos[1], P. A. Assato[1], A. M. Fusco-Almeida[1], R. J. Giordano[2], M. J. S. Mendes-Giannini, 14801902[1]; [1]Faculdade de Ciências Farmacêutica de Araraquara - FCFAr UNESP, Araraquara, Brazil, [2]Univ.e de São Paulo, USP, São Paulo, Brazil

Abstract Body:

Paracoccidioides brasiliensis and *P. lutzii* are dimorphic fungi, etiologic agents of paracoccidioidomycosis (PCM). Fungi of *Paracoccidioides* genus have mechanisms that enable them to adhere and invade host tissues and adhesion is one of the most important steps in the *Paracoccidioides* infection, being responsible for differences in virulence of isolates of these fungi. Regarding the importance of the adhesion to the establishment of the infection, this study focused in a preliminary development of a new therapeutic strategy to avoid the adhesion of *Paracoccidioides*, inhibiting infection and preventing the development of this systemic mycosis. This disease is an important public health issue in Latin America, mainly in Brazil, country with most endemic areas for this disease. We used two phage display libraries with the aim to select peptides that strongly bind to *Paracoccidiodes* cell wall and avoid the adhesion to host cells and extracellular matrix (ECM) components: laminin, fibronectin and types I and IV collagen. With this approach we identify four peptides that inhibits *in vitro* up to 64% of the adhesion to pneumocytes and up to 57% the adhesion to the different ECM components. With these results, we decided to evaluate, in a preliminary way, if these selected peptides can protect the alternative animal model *Galleria mellonella* of *Paracoccidioides* infection. For this, we treated *G. mellonella* larvae with the different peptides for three hours prior to infection with *P. brasiliensis* and *P. lutzii* and them we observed the survivor of these larvae. The results shows us that all tested peptides increasing up to 64% the survivor of larvae infected with *P. brasiliensis* and up to 60% when infected with *P. lutzii*. These data, besides preliminary, open us new horizons in therapeutic strategies to face PCM. The important role of the adhesion in *Paracoccidioides* infection show us that an anti-adhesive therapy could be an important strategy and the selected peptides have potential as prototypes to be explored in the PCM therapy.

Eravacycline *In Vitro* Antibacterial Activity against 110 Carbapenemase-Producing *Enterobacteriaceae* Clinical Isolates

Author Block:

Y. Zhang, X. Lin, K. Bush; Indiana Univ., Bloomington, IN

Abstract Body:

Background: Carbapenem-resistant *Enterobacteriaceae* (CRE) are among the most urgent threats in the antibiotic resistance spectrum and have been increasing in central Indiana Health Care Centers since 2009. Our laboratory has characterized Indiana CRE isolates that produce both serine and metallo-carbapenemases resulting in resistance to most beta-lactam antibiotics. Eravacycline (ERV) is a novel synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity, being developed for the treatment of serious infections, including those caused by multidrug-resistant pathogens. In this study we compare its activity to other agents used to treat enteric infections.**Materials:** CRE isolates from 2010 - 2013 (n=110) were characterized for carbapenemase genes by PCR and sequencing. MICs for ERV, tetracycline, tigecycline, amikacin, imipenem, ceftazidime, cefotaxime and levofloxacin were determined in broth microdilution assays according to CLSI standards.**Results:** Among the CRE isolates were 96 *Klebsiella pneumoniae* with the serine carbapenemases KPC-2 (n=15) or KPC-3 (n=81); 6 *Escherichia coli* isolates with KPC-2 (n=1) or KPC-3 (n=5); 6 *Serratia marcescens* isolates with SME-1 (n=3) or KPC-3 (n=3); and 2 *Enterobacter cloacae* isolates with both KPC-3 and a VIM-1-type metallo-beta-lactamase (MBL). Other MBL-producing isolates included 5 KPC-3-producing *K. pneumoniae* isolates with VIM-1 (n=4) or NDM-1 (n=1). The isolates were highly resistant to all beta-lactams tested and to levofloxacin and were intermediate to tetracycline and amikacin, based on MIC_{50}/MIC_{90} values. MIC_{50}/MIC_{90} values for ERV were 1 / 2 μg/ml compared to 2 / 2 μg/ml for tigecycline. ERV MICs were often 2-fold lower than for tigecycline, with only 4% of tigecycline MICs <2 μg/ml compared to 64% of the ERV MICs.**Conclusions:** Eravacycline demonstrated the lowest cumulative MICs against this panel of recent carbapenem-resistant *Enterobacteriaceae* with MIC_{50}/MIC_{90} values of 1 and 2 μg/ml. Thus, eravacycline may have the potential to treat infections caused by CRE.

Agent	MIC range μg/ml	MIC_{50} in μg/ml	MIC_{90} in μg/ml
Eravacycline	0.5-4	1	2
Tetracycline	4 - >64	8 (I)	8 (I)
Tigecycline	1 - 4	2 (S)	2 (S)

Amikacin	2 - >64	32 (I)	32 (I)
Imipenem	4 - >64	8 (R)	32 (R)
Ceftazidime	1 - >32	>32 (R)	>32 (R)
Cefotaxime	1 - >8	>8 (R)	>8 (R)

In Vitro* Intracellular Activity of Omadacycline against *Legionella pneumophila

Author Block:

J. Dubois[1], M. Dubois[1], J-F. Martel[1], S. K. Tanaka[2]; [1]M360, Sherbrooke, QC, Canada, [2]Paratek Pharmaceuticals, Boston, MA

Abstract Body:

Background: Omadacycline (OMC) is the first once-daily, oral and IV aminomethylcycline in late stage clinical development for serious community-acquired bacterial pneumonia (CABP) and acute bacterial skin and skin structure infection (ABSSI). *In vitro* bacterial activity and intracellular activities using human monocytes against a variety of *L. pneumophila* serogroup one (1) were investigated.**Methods:** The intracellular activity of **OMC** was compared with that of doxycycline (DO), moxifloxacin (MO) and azithromycin (AZ) against a total of three (3) erythromycin-resistant and two (2) erythromycin-susceptible strains of *L. pneumophila* serogroup 1. The minimal extracellular concentration inhibiting the intracellular multiplication of *L. pneumophila* (MIEC) was determined by exposing human monocytes, U937 cell line, with intracellular *Legionella* to antibiotic at the 1X, 1/2X, 1/4X, 1/8X or 1/16X the extracellular MIC of each strain during 4 days exposure. Counts of CFU/mL were performed daily in triplicate using the Buffer Yeast Extract agar with charcoal.**Results:** All tested strains of *L. pneumophila* (5/5 strains) had a MIC of 0.25 mg/L to **OMC.** A mean reduction of ≥50% of *L. pneumophila* grown in human monocytes at Day 3 or Day 5 of **OMC** exposure, was achieved at a MIEC of 0.06 mg/L or at MIEC/MIC ratio of 0.24 (1/4XMIC). An intracellular activity at Day 3 or at Day 5 of **OMC** exposure with a reduction (≥50%) of *L. pneumophila* grown in macrophages and with a MIEC/MIC ratio of 0.12 (1/8XMIC) was observed with only 1 erythromycin-resistant strains of *L. pneumophila*. In this study, the MIEC/MIC ratio of **OMC** (0.24 or 1/4XMIC) was lower than the MIEC/MIC ratio of doxycycline (0.5 or 1/2XMIC), moxifloxacin (0.5 or 1/2XMIC), and azithromycin (1 or 1XMIC).**Conclusions:** These data, demonstrating robust bacterial activity and human monocyte penetration, highlight the potential utility of **OMC** as an effective oral and IV antibiotic for the treatment of CABP caused by *L. pneumophila*.

***In Vitro* Activity of Omadacycline against *E. coli* Biofilms**

Author Block:

D. Diehl[1], **N. Bionda**[1], N. C. Cady[1], A. D. Strickland[1], S. K. Tanaka[2]; [1]iFyber, Ithaca, NY, [2]Paratek Pharmaceuticals, King of Prussia, PA

Abstract Body:

The goal of the current study was to investigate the anti-biofilm properties of omadacycline (OMC), a first-in-class compound of a new class of aminomethylcycline antibiotics. OMC exhibits potent bacteriostatic activity against both Gram-negative and Gram-positive bacteria and is currently in Phase III clinical trials for multiple indications. Microbial biofilms are defined by a dense extracellular polymeric substance that can act as a physical barrier to the external environment, and results in a subpopulation of metabolically quiescent microbes, which can lead to a remarkable tolerance to antibiotics that normally kill planktonic bacteria. Given that OMC exhibits activity against a broad spectrum of organisms and has potential utility against organisms that produce biofilms, the current study aimed to establish the baseline anti-biofilm properties of OMC. Focusing on *Escherichia coli* (ATCC 25922), which is a common cause of community-acquired infections, doses of OMC above and below the minimum inhibitory concentration (MIC) for planktonic cells were assessed for biofilm prevention and/or induction, and against established biofilms using the MBEC™ 96 well plate high throughput screening device. In experiments using sub-MIC and supra-MIC doses of OMC applied to early-phase and established biofilms in the presence of planktonic bacteria, sub-MIC doses (e.g., 0.74 µg/mL) do not appear to induce further biofilm propagation above the levels observed in the absence of OMC. Further, biofilm prevention/induction assays indicate that OMC strongly inhibits biofilm formation at all doses above the MIC. At sub-MIC doses (e.g., 0.74 µg/mL), mean biofilm formation is reduced by approximately 3 to 4 log units compared to controls, in high and low inoculum conditions, respectively. In contrast to other translation inhibitors, sub-MIC doses of OMC not only failed to induce biofilm formation above the level of controls, several doses below the MIC appear to have an inhibitory effect on biofilm formation.

Antibacterial Activity of Kbp-7072 Against Clinical Isolates of Drug-resistant Bacteria

Author Block:

Y. Wang, Q. Liu, **B. Zhang**; KBP BioSci.s, Princeton, NJ

Abstract Body:

The purpose of this study was to investigate the activity of KBP-7072, a novel broad spectrum aminomethylcycline, against Gram positive (GP) and Gram negative (GN) multidrug resistant isolates. The *in vitro* activity of KBP-7072 against multidrug resistant GP and GN strains collected from Chinese hospitals was compared with that of tigecycline. GP strains included at least 12 isolates each of Methicillin-resistant *S. aureus*, MRSE, *E. faecium*, *E. faecalis*, and *S. pneumoniae*. GN strains included at least 12 isolates of ESBLs *E. coli*, ESBLs *K. pneumoniae*, *Acinetobacter,* and *P. aeruginosa*. Susceptibility testing was performed according to the M7-A9 and M7-A11 CLSI-recommended agar dilution methods. The bacteria freshly grown in MHA and BHIA plates containing sterile fiber sheep blood were suspended in 0.9% sodium chloride for injection to 0.5 McFarland standard absorbance and were further diluted 10x. The testing bacterial suspension was then inoculated onto MHA and BHIA plates with sterile fiber sheep blood and test articles by multipoint microplanter at 10^4 CFU per point. Test plates were incubated at 35°C for 16 -20 hrs or with 5% CO_2 for 20 to 24 hrs as specified by CLSI M07-A9 and M07-A11. The range of MIC in GP bacteria was 0.015-2 μg/mL for KBP-7072 vs 0.015 to 2 μg/mL for tigecycline. The MIC_{90} values of KBP-7072 and tigecycline were 0.5 vs 2 μg/mL (MRSA), 1 vs 2 μg/mL (MRSE), 0.125 vs 0.25 μg/mL (*E. faecium)*, 0.25 vs 0.5 μg/mL (*E. faecalis)*, and 0. 5 vs 1 μg/mL (PRSP), respectively. The range of MIC in GN bacteria (excluding *P. aeruginosa*) was 0.06 to 16 μg/mL for KBP-7072 vs 0.125 to 16 μg/mL for tigecycline. The MIC_{90} values of KBP-7072 and tigecycline were 2 vs 2 μg/mL (ESBLs *E. coli*), 4 vs 2 μg/mL (ESBLs *K. pneumoniae*), 1 vs 4 μg/mL (*A. baumannii*), and 1 vs 2 μg/mL (*A. lwoffi*). After a single step culture, KBP-7072 showed better or equal resistance frequency compared to tigecycline ranging from 2.40×10^{-8} to 1.05×10^{-6} in 13 clinical isolates. At 2-fold and 4-fold MICs, the resistance frequency of KBP-7072 was comparable to tigecycline. KBP-7072 demonstrates excellent *in vitro* activity against clinical bacterial isolates and strains including multi-drug resistant GP and GN bacteria. KBP-7072 showed better or equal resistance frequency compared to tigecycline in 13 clinical isolates after a single step culture, as well as at 2-fold and 4-fold MICs.

***In Vitro* Activity of Plazomicin aAgainst 110 Carbapenemase-Producing *Enterobacteriaceae* Clinical Isolates**

Author Block:

Y. Zhang, **A. Kashikar**, X. Lin, K. Bush; Indiana Univ., Bloomington, IN

Abstract Body:

Background: Carbapenem-resistant *Enterobacteriaceae* (CRE) represent one of the most stringent challenges to our current antibacterial armamentarium. Our laboratory has been monitoring the presence of CRE in central Indiana Health Care Centers since 2009. These multidrug-resistant isolates with serine and metallo-carbapenemases are not susceptible to most beta-lactam antibiotics. In this study, we tested plazomicin, a new aminoglycoside, for its antibacterial activity against Indiana CRE isolates in comparison to meropenem or piperacillin-tazobactam.**Materials: I**nitial carbapenem MICs for 110 CRE isolates were determined using a Vitek 2. Carbapenemases were characterized by PCR and sequencing. MICs for imipenem, amikacin and plazomicin were determined in broth microdilution assays according to CLSI.**Results:** The CRE isolates included 96 *Klebsiella pneumoniae* isolates producing KPC-2 (n=15) or KPC-3 (n=81) serine carbapenemases, 6 *Escherichia coli* isolates with KPC-2 (n=1) or KPC-3 (n=5), 2 *Enterobacter cloacae* isolates producing both KPC-3 and a VIM-1-type metallo-beta-lactamase, and 6 *Serratia marcescens* isolates producing SME-1 (n=3) or KPC-3 (n=3). VIM-1 was also in 4 *K. pneumoniae* isolates with KPC-3; NDM-1 was in one *K. pneumoniae* with a KPC-3 enzyme. The isolates were highly resistant to carbapenems with MIC_{90} values >4 μg/ml. Amikacin MIC_{50} / MIC_{90} values were in the intermediate range. Plazomicin had the lowest MICs of all the agents, with MIC_{50}/MIC_{90} values 0f 0.5 / 1 μg/ml. The only isolates with plazomicin MICs >4 μg/ml were 1) a *S. marcescens* with SME-1 (MIC 8 μg/ml); and 2) a *K. pneumoniae* isolate with NDM-1 (plazomicin MIC 256 μg/ml, amikacin MIC >64 μg/ml), presumably due to production of a ribosomal methylase.**Conclusions:** Plazomicin was the most potent agent tested against this panel of recent carbapenem-resistant *Enterobacteriaceae* with an MIC_{90} of 1 μg/ml. These data suggest that plazomicin may provide useful activity against CRE that produce serine carbapenemases.

Agent	MIC in μg/ml		
	MIC range	MIC_{50}	MIC_{90}
Imipenem	0.5 - $\geq$ 8	$\geq$ 8	$\geq$ 8
Meropenem	0.5 - $\geq$ 8	$\geq$ 8	$\geq$ 8

Amikacin	2 - >64	32	32
Plazomicin	0.25 - 256	0.5	1

Aminospectinomycins Display Efficacy in Murine Gonorrheal Infections

Author Block:

M. M. Butler[1], S. L. Waidyarachchi[2], R. E. Lee[2], A. E. Jerse[3], K. L. Connolly[3], T. L. Bowlin[1]; [1]Microbiotix, Inc., Worcester, MA, [2]St. Jude Children's Res. Hosp., Memphis, TN, [3]Uniformed Services Univ., Bethesda, MD

Abstract Body:

Background: Bacterial sexually transmitted infections are widespread and common, with an estimated 1.4 million reported cases annually in the US. *Neisseria gonorrhoeae* (*Ng)* causes gonorrhea, a very common, but often asymptomatic, STD that can be urogenital, anorectal or pharyngeal in nature. If left untreated, gonorrhea can cause pelvic inflammatory disease in women, leading to infertility or may disseminate, causing joint and skin symptoms. The recommended treatment for gonorrhea is ceftriaxone (CTX) plus azithromycin, both as a single dose. Antibiotic resistance to all existing cures has developed in gonorrheal infections. The need for new antibiotics is great and the pipeline for new drugs is alarmingly small. The aminospectinomycins (AmSPCs), a new class of semisynthetic analogs of the antibiotic, spectinomycin (SPC), have increased potency against *Ng*. We recently reported *in vitro* potency against resistant isolates.**Methods:** The *in vivo* efficacy of lead AmSPC compounds was evaluated by pretreating estradiol-treated mice with streptomycin (STR) and trimethoprim to suppress overgrowth of commensal flora that occurs under estradiol treatment. On day 0, mice were inoculated with approximately 10^4 CFU of *Ng* strain H041 (STR^R-CTX^R); treatment with 1950, 2324 and SPC by the SC route or positive control, gentamicin (GEN), by the IP route was initiated on day 2 and continued once daily for 5 days. Daily vaginal swabs were tested for the presence of *Ng* during the treatment regimen and for an additional 3 days.**Results:** The percentage of mice in each group that was colonized with *Ng* prior to and after treatment was calculated. 100% of mice given Lee 1950, SPC, or GEN and 90% of mice given 2324 cleared infection by the study endpoint. The effect of test and control compounds on *Ng* colonization was measured by counting CFU recovered in vaginal swabs. The colonization load of *Ng* was significantly reduced after treatment with 1950, 2324, SPC and GEN compared to the vehicle control; colony counts dropped to below the limit of detection.**Conclusions:** In summary, data produced by this study support AmSPCs as a promising series for treating gonorrhea, including infections caused by CTX^R *Ng*. These compounds as well as SPC were comparable to GEN in this model.

Comparative Antimicrobial Activity of Mul-1867, a Novel Antimicrobial Compound and Amikacin, against New Clinically Important Airway Pathogens in Cystic Fibrosis *S.maltophilia, A.xylosoxidans, M.abscessus*

Author Block:

G. Tetz[1], M. Cynamon[2], V. Tetz[1]; [1]TGV-Therapeutics, New York, NY, [2]VA Med. Ctr., Syracuse, NY

Abstract Body:

Background: As a result of treatment of "classic" bacterial infections in cystic fibrosis (CF), there are now increasing problems with innately resistant new airway pathogens such as *S.maltophilia, A.xylosoxidans, M.abscessus*. These bacteria are are associated with higher morbidity among CF patients and display high resistance to antimicrobials. The aim of the present study was to compare selected antimicrobials against these planktonic and sessile pathogens. **Methods:** We used clinical isolates of *S.maltophilia* and *A.xylosoxidans* from cystic fibrosis patients and a clinical isolate of *M.abscessus.* Two antimicrobial agents were tested: novel broad spectrum antimicrobial Mul-1867 ($C_{426}H_{852}N_{204}$ * 60 HCl) and amikacin as representative aminoglycosides that are commonly used to treat CF patients. The anti-biofilm activity against 48-h-old S.*maltophilia* and *A.xylosoxidans* biofilms was evaluated as minimum biofilm eliminating concentration that completely eradicated mature biofilms (MBEC100). Biofilms were exposed for 24 h containing antibacterial at 1 - 128× the MIC. All assays were repeated in triplicate. **Results:** Mul-1867 exhibited a high level of antimicrobial activity against all strains with the MIC values 0.125 mg/L against *S.maltophilia*, 0.25 mg/L against *A.xylosoxidans* and 2.0 mg/L against *M.abscessus*. Amikacin was less active than Mul-1867; the MIC for *S.maltophilia* was 128 mg/L, for *A.xylosoxidans* was 25 mg/L, and for *M.*abscessus 8.0 mg/L. Mul-1867 showed MBEC100 values of 2× and 4× the MIC, respectively, against *S.maltophilia* and *A.xylosoxidans*. Amikacin displayed lower antibiofilm activity against *S.maltophilia* and *A.xylosoxidans* with $MBEC_{100}$ values of 128× and 64× the MIC, respectively. **Conclusions:** In the current study, we found that a novel drug candidate, Mul-1867, exhibits a high level of antimicrobial activity against *S.maltophilia, A.xylosoxidans* and *M.abscessus*. We revealed that Mul-1867 was more active than amikacin against selected clinical isolates, displayed lower MICs and possessed low MBEC100/MIC. The efficacy of Mul-1867 raises the possibility that it may serve as a locally acting antimicobial compound in CF patients.

Me1100, a New Formulation of Arbekacin for Inhalation: The Antimicrobial Activity of Arbekacin in Comparison with Other Aminoglycosides Against Aminoglycoside Modifying Enzymes Producing Strains

Author Block:

N. Baba, T. Takata, T. Sugano, Y. Takayama, N. Senju, E. Murase, Y. Tsutsumi, T. Ida, K. Kondo; Meiji Seika Pharma Co., Ltd., Tokyo, Japan

Abstract Body:

Background: ME1100, arbekacin (ABK), is a semi-synthetic aminoglycoside derived from Kanamycin B, designed to be stable to various aminoglycoside modifying enzymes (AMEs). ABK shows strong antibacterial activity against both Gram-positive and Gram-negative bacteria and possesses a possibility to be a drug for HABP/VABP treatment. We determined MICs and MBCs of ABK against AMEs producing MRSA and *P. aeruginasa* (Pa) and compared the values with those of other aminoglycosides.**Methods:** The MICs and MBCs for aminoglycosides were determined by using standard techniques in accordance with CLSI guidelines.**Results:** For MRSA, the geometric mean (GM) MICs and GM-MBCs of ABK against 3 strains without AMEs genes were 0.6 μg/mL and 2.5 μg/mL, respectively, and they were lower than those of amikacin (AMK). The GM-MICs and GM-MBCs of ABK against 9 strains with *aac(6')/aph(2")* gene were 1.5 μg/mL and 4.3 μg/mL, respectively, and they were considerably lower than those of other aminoglycosides. The GM-MICs and GM-MBCs of ABK against 9 strains with *ant (4')-Ia* gene were 0.5 μg/mL and 2.2 μg/mL, respectively, and they were considerably lower than those of AMK and TOB. Furthermore, the GM-MICs and GM-MBCs of arbekacin against 8 strains with both *aac(6')/aph(2")* and *ant (4')-Ia* genes were 1.8 μg/mL and 7.3 μg/mL, respectively, and they were considerably lower than those of other aminoglycosides. For Pa, the GM-MICs and GM-MBCs of ABK against 13 strains without AMEs genes were 2.1 μg/mL and 7.6 μg/mL, respectively, and they were almost similar to those of other aminoglycosides. On the other hand, the GM-MICs and GM-MBCs of ABK against 9 strains with *aac(6')-Ib* gene were 34.6 μg/mL and 101.6 μg/mL, respectively and those of ABK against 12 strains with *aac(6')-Iae* gene were 20.2 μg/mL and 42.7 μg/mL, respectively. These values were not so low, but were considered superior activity among aminoglycosides tested.**Conclusions:** Since ABK is stable to AMEs such as AAC(6'), APH(2") and ANT(4'), ABK showed excellent antibacterial and antibactericidal activities against AME-producing MRSA and Pa among aminoglycosides tested.

In Vitro* Dynamic Pharmacokinetic-Pharmacodynamic (Pk-Pd) Modeling of Arbekacin Inhalation Solution (Me1100) Against *K. pneumoniae

Author Block:

N. Sato, K. Matsumoto, S. Ouchi, N. Baba, Y. Nagira, Y. Tsutsumi, K. Kondo; Meiji Seika Pharma Co., Ltd., Tokyo, Japan

Abstract Body:

Background: Arbekacin (ABK) is an aminoglycoside antibiotic that has been approved for an injectable formulation in Japan. Currently, arbekacin inhalational solution (ME1100) is under development for treatment of ventilator-associated bacterial pneumonia (VABP). We investigated the PK-PD properties of ME1100 against *K. pneumonia* strains using dynamic PK-PD model and evaluated the predictability of the fluctuation of the number of bacteria in the *in vitro* chemostat model by the *in vitro* dynamic PK-PD model.**Methods:** The time-kill study and the *in vitro* chemostat model study were conducted against three *K. pneumonia* strains for 24 hours. The dynamic PK-PD model was established to investigate the PK-PD relationship of ME1100 against the *K. pneumonia* strains. This model hypothesizes two populations (the sensitive and the low sensitive populations) for the bacteria, which differ in growing ability and sensitivity to ABK. The PD parameters, which represent the properties of the two populations of bacteria, were obtained by analysing the time-kill study data with the dynamic PK-PD model. The computer simulation of the fluctuations in $\log_{10}$ CFU was conducted using the PD parameters from the time-kill study and the mimicked ABK concentrations in human ELF. And then, the correlation of the time-dependent fluctuations in $\log_{10}$ CFU between the observed data from the *in vitro* chemostat model and the predicted values based on the dynamic PK-PD model were statistically evaluated.**Results:** The time-kill study data were analyzed with the dynamic PK-PD model and the 12 PD parameters were obtained. The fittings of the observed Log_{10} CFU and the predicted Log_{10} CFU were good. The fluctuations in $\log_{10}$ CFU, which was predicted using the PD parameters and the mimicked ABK concentrations in human ELF, were compared with the *in vitro* chemostat model study data. The 90 percentile confidence intervals of the residues between the predicted and the observed $\log_{10}$ CFU were about -2~3.**Conclusions:** These analyses suggest that our dynamic PK-PD model can predict *in vitro* chemostat model results based on the *in vitro* time-kill data and the mimicked PK profile.

Aminospectinomycins: Novel Therapeutics for Biothreat Pathogens

Author Block:

S. L. Waidyarachchi[1], M. M. Butler[1], R. Panchal[2], D. Lane[2], T. Bowlin[1], R. E. Lee[3]; [1]Microbiotix, Inc, Worcester, MA, [2]US Army Med. Res. Inst. of Infectious Diseases, Frederick, MD, [3]St.Jude Children's Res. Hosp., Memphis, TN

Abstract Body:

Background: The dramatic rise in the prevalence of antibiotic resistance requires the discovery and development of new antibiotics. There is also a clear need to identify novel therapeutic agents for biodefense purposes that can prevent and treat multiple types of respiratory tract infections. In this regard, we have re-visited the synthetic modification of the low molecular weight aminocyclitol **antibiotic** spectinomycin (SPC) producing a series of aminospectinomycins (AmSPCs). The AmSPCs show excellent efficacy for treatment of otherwise lethal *S. pneumoniae* pneumonia in mice. Herein, we report the exploration of AmSPCs as agents to treat pulmonary infections from biothreat bacterial pathogens. **Methods:** Guided by computational design, compounds were synthesized in 5 steps from SPC and potency evaluated against a broad panel of Gram positive and negative bacterial including the most prominent bacterial biothreat pathogens. *In vivo* efficacy trials were performed with a mouse models of *Burkholderia .mallei and Franciscella tularensis* infection. Target inhibition of protein synthesis was studied at the ribosomal level in a cell free *M. smegmatis* mycobacterium translation assay. Mammalian cytotoxicity was assessed *in vitro* against HepG2 cell line.**Results:** From the AmSPCs synthesized, a clear structure activity relationship was established. Analogs with substituted benzyl moieties displayed the best activities. The most active compound, **1950**, showed substantially improved potency against *B. mallei* (MIC_{90} 12.5 ug/ml), *B. suis* (MIC_{90} 3.1 ug/ml), *F. tularensis* (MIC_{90} 100 ug/ml) and showed limited activity against *Y. pestis* (MIC_{50} 50 ug/ml) and *B. anthracis Ames* (MIC_{50} 50ug/ml). Compounds appeared to be mostly ineffective against *Burkholderia pseudomallei* (MIC_{50} >200 ug/ml). Lead **1950** was active against a panel of drug resistant *B. mallei, B. suis and F. tularensis* clinical isolates *in vitro,* and cleared mice of *B. mallei* infection at a dose of 50 mg/kg BID.**Conclusion:** In summary, amSPCs represent a new chemotype with many suitable properties for further development to treat infections caused by biothreat bacterial pathogens.

Publishing Title:

Aminospectinomycins Are Potent Inhibitors of Mdr Pathogens That Cause Pneumonia and Otitis Media

Author Block:

M. M. Butler[1], S. L. Waidyarachchi[2], R. E. Lee[2], J. W. Rosch[2], T. L. Bowlin[1]; [1]Microbiotix, Inc., Worcester, MA, [2]St. Jude Children's Res. Hosp., Memphis, TN

Abstract Body:

Background: *Streptococcus pneumoniae* (*Sp*) is the leading cause of bacterial pneumonia and meningitis in the United States. It also is a major cause of bloodstream infections, otitis media (OM) and sinus infections. *Sp* has developed resistance to drugs in the penicillin and erythromycin groups, as well as to other, less commonly used antibiotics. As described in CDC's *2013 Antibiotic Resistance Threats in the United States*, multi-drug-resistant (MDR) *Sp* is classified as a "serious" threat, with 1.2 million resistant infections per year, along with 22,000 deaths from *Sp* disease overall. Other bacterial causes of pneumonia and OM include MDR *Haemophilus influenzae* (*Hi*) and *Moraxella catarrhalis (Mc)*. Adding to the growing resistance problem, the number of new antibiotics approved has steadily decreased in the past three decades, leaving fewer options to treat MDR bacteria. The aminospectinomycins (AmSPCs), a new class of semisynthetic analogs of the antibiotic, spectinomycin (SPC), have demonstrated improved potency against *Sp, Hi and Mc*. Herein, we report the exploration of AmSPCs as agents to treat pulmonary and ear infections from these MDR bacterial pathogens.**Methods:** The *in vitro* potency of the lead AmSPC compound 1950 was determined against groups of 20-30 isolates of each species using the broth dilution method. Most of the isolates were resistant to at least two antibiotic families. Additionally, the efficacy of 1950 was tested in murine models of *Sp*-associated pneumonia, sepsis, meningitis and OM using luminescent strain BHN97x; assessments included survival rates, colony counts and luminescence.**Results:** Compound 1950 demonstrated good potency, with Minimal Inhibitory Concentrations for *Sp*, *Hi* and *Mc* ranging from 1-16 µg/mL across 90 MDR isolates. Additionally, 1950 was fully protective in mice against lethal *Sp* pneumonia, sepsis, meningitis and OM when dosed at levels of 5-25 mg/kg, dropping bacterial counts to below detectable limits. 1950 had comparable or better potency than the comparator ampicillin and was superior to SPC. Furthermore, 1950 displayed good efficacy in a murine co-infection model with *Hi* and with the influenza virus.**Conclusions:** In summary, these studies support the AmSPCs as a promising new series for treating MDR bacterial pneumonia and OM.

***In Vivo* Efficacy of Combinations of Novel Antimicrobial Peptide Spr741 and Rifampicin in Short-Duration Murine Thigh Infection Models of Gram-Negative Bacterial Infection**

Author Block:

P. Warn[1], P. Thommes[1], S. Vaddi[1], D. Corbett[1], D. Coles[1], L. Vaccaro[1], S. Standring[1], T. Lister[2], T. R. Parr, Jr[2]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: There is an acute shortage of effective antimicrobial agents to treat multi-drug-resistant Gram-negative infection. An attractive approach to addressing the dearth of treatment options is potentiation of antimicrobial agents to either increase the spectrum of activity or enhance activity. In these studies we assessed the efficacy of combinations of a novel antimicrobial cationic peptide (SPR741) with rifampicin (Rif) in murine models of thigh muscle infection.**Methods:** Male ICR mice were rendered neutropenic using 2 doses of cyclophosphamide on days -4 & -1. Mice were infected by IM injection into the lateral thigh muscle on day 0 with either *E. coli* (ATCC 25922 and IR60 [Bla_{NDM-1}), *Klebsiella pneumoniae* (Kp114 [Bla_{KPC}] or ATCC BAA 2146 [Bla_{NDM-1}]) or *Acinetobacter baumannii* (ATCC BAA 747). Treatment was initiated 1h post infection with SPR741 administered at 1, 3.5 and 7h post infection and Rif administered at 1 and 5h post infection). SPR741 was administered at 10, 20 and 40mg/kg/dose, the doses of Rif were based on preliminary dose response experiments (range 0.376-64mg/kg/dose). Mice were euthanized 9h post infection and the thigh muscle quantitatively cultured.**Results:** SPR741 and Rif were well tolerated and all animals continued to the study end. All isolates demonstrated robust *in vivo* growth of 1.55-3.4Log_{10}cfu/g thigh tissue between pre-treatment and harvest samples. Monotherapy with SPR741 at 40mg/kg/dose or Rif (at the doses used) had little effect on the burdens and did not achieve stasis against any isolate. In contrast in all models combinations with ≤20mg/kg/dose SPR741 with Rif led to highly significant reductions in burden below stasis (2.2, 3.7, 4.7, 1.6 and 2.9Log_{10}cfu/g below stasis for ATCC 25922, IR60, Kp114, ATCC BAA 2146 and ATCC BAA 747 respectively).**Conclusions:** The combination of SPR741 with Rif was highly effective at reducing the thigh burden of mice infected with *E. coli, K. pneumonia* and *A. baumannii* including strains expressing Bla_{KPC} and Bla_{NDM-1}. These studies support continued development of novel antimicrobial cationic peptide for the treatment of multi-drug-resistant Gram-negative infections.

The Efficacy of Arbekacin Inhalation (Me1100) as Adjunctive Therapy to Iv Antibiotics in Murine Pneumonia Models

Author Block:

N. Baba, E. Murase, S. Sakakibara, Y. Takayama, T. Takata, S. Ouchi, T. Ida, K. Kondo; Meiji Seika Pharma Co., Ltd., Tokyo, Japan

Abstract Body:

Background: ME1100, arbekacin inhalation solution, has been designated as a Qualified Infectious Drug Product (QIDP) for the adjunctive treatment of mechanically ventilated patients with bacterial pneumonia. *S. aureus* including MRSA and *P. aeruginosa* (Pa) are the most prevalent bacteria in VABP, and the two species account for about 50% in total. We compared the efficacy of ME1100 and vancomycin (VCM) or meropenem (MEM) combination therapy with that of each antibiotic in a murine pneumonia model of MRSA or aminoglycosides resistant Pa.**Methods:** Immunosuppressed mice were nasally inoculated with MRSA or Pa. At 2 hours post-infection, ME1100 was administered by a nebulizer (eFlow®) in conjunction with/without subcutaneous administration of VCM or MEM to mice. Viable cell counts in lungs were measured at 18 hours after infection.**Results:** ME1100 alone or in combination with VCM or MEM demonstrated potent *in vivo* activity. In MRSA, the viable cell counts (Log CFU/lung ± S. D.) of control group was 6.42 ± 0.89, and those of treatment groups with ME1100 (30 mg/mL for 5 min) alone, VCM (10 mg/kg) alone and their combination were 3.49 ± 1.04, 3.95 ± 0.90 and 2.51 ± 0.35 (n=6 or 7), respectively. In Pa, the viable cell counts of control group was 6.92 ± 0.51, and those of treatment groups with ME1100 (30 mg/mL for 5 min) alone, MEM (10 mg/kg) alone and their combination were 5.31 ± 0.65, 4.51 ± 1.86 and 2.08 ± 0.26 (n=3 or 4), respectively.**Conclusions:** The therapeutic effects of inhaled ME1100 in combination with VCM or MEM were superior to those of VCM alone or MEM alone. These data support the potential utility of ME1100 as adjunctive therapy to best available therapy for severe pneumonia due to drug-resistant bacteria.

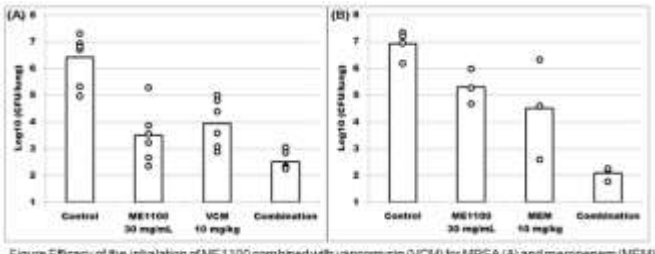

Figure Efficacy of the inhalation of ME1100 combined with vancomycin (VCM) for MRSA (A) and meropenem (MEM) for *P. aeruginosa* (B) in murine pneumonia models.

Tp-271 is Efficacious in a *Francisella tularensis* Cynomolgus Monkey Treatment Model

Author Block:

T. H. Grossman[1], L. N. Henning[2], M. Gooldy[3], A. K. Radcliff[3], V. H. Tam[4], J. A. Sutcliffe[1]; [1]Tetraphase Pharmaceuticals, Watertown, MA, [2]Battelle, Columbus, OH, [3]CUBRC, Inc., Buffalo, NY, [4]Univ. of Houston Coll. of Pharmacy, Houston, TX

Abstract Body:

Background: *Francisella tularensis* (*Ft*) is a biothreat that can be weaponized for use in an aerosolized mass attack. This study evaluated the therapeutic efficacy of TP-271, a fully synthetic tetracycline with potent broad spectrum antibacterial activity, against inhalation tularemia in cynomolgus monkeys. **Methods:** Cynomolgus monkeys received an average aerosolized dose of 1144 colony forming units of *Ft* (SCHU S4; NR-10492) using a head-only inhalation exposure chamber. Treatment was initiated within 6 hours of a confirmed fever (fever persisting for at least 2 hours). Animals were administered 3 mg/kg/day TP-271, 1 mg/kg/day TP-271, or saline (vehicle control) by a 90 min IV infusion for 21 days (QD), followed by 14 days of post-treatment monitoring. Animals were monitored for changes in body temperature and activity (by telemetry), body weight, clinical pathology, and blood culture, quantitative PCR (qPCR), and bacterial tissue assessment. Gross necropsies were conducted on all animals and target tissues were evaluated microscopically from all animals found dead or euthanized *in extremis* to confirm *Ft* infection. **Results:** All infected animals treated with TP-271 survived to the end of the study, whereas none of the vehicle control animals (0/8) survived inhalational exposure to *Ft*. All of the vehicle control animals were bacteremic before death, had quantifiable levels of *Ft* in all tissues assessed (lung, liver, spleen, mediastinal lymph node), and microscopic findings consistent with tularemia. In contrast, TP-271-treated animals did not have a positive blood culture or quantifiable qPCR result at any time point during the study and *Ft* was detected only in the mediastinal lymph node for 19% (3/16) of the TP-271-treated animals. The TP-271 mean $AUC_{0\text{-}24}$ on Day 1/Day 21 of dosing was 10.41/27.48 µg·hr/mL and 1.95/7.75 µg·hr/mL for the 3 mg/kg and 1 mg/kg doses, respectively, for males and females combined. **Conclusions:** TP-271 was efficacious when administered therapeutically to cynomolgus monkeys after aerosol exposure to *Ft*. Further studies with TP-271 are warranted to confirm efficacy and evaluate the utility of TP-271 for treatment of respiratory infections caused by other biothreat pathogens.

Publishing Title:

Effect of Kbp-7072 on Bacterial Activity and Survival in a *S. pneumoniae*-induced Murine Pneumonia Model

Author Block:

Q. Liu, Y. Wang, **B. Zhang**; KBP BioSci.s, Princeton, NJ

Abstract Body:

KBP-7072 is a novel aminomethylcycline with broad-spectrum activity against Gram+ and Gram- multidrug resistant bacterial isolates and strains. *In vivo* antibacterial activity was assessed in a *S. pneumoniae*-induced murine pneumonia model. 6-8 week old female CD-1 mice, 23 - 27 g, were randomized to treatment groups based on body weight. KBP-7072 was dosed at 5, 15, or 45 mg/kg, po, qd; 2.5 or 7.5 mg/kg, po, bid; linezolid 7.5 mg/kg, po, bid; and vehicle 0.2 mL, po, qd. 15 mice were assigned to each dose group. After randomization, animals were rendered neutropenic with 150 mg/kg of cyclophosphamide ip at Day 4 and Day 1 prior to infection, then anesthetized with 6.5% pentobarbital sodium at a dose of 65 mg/kg ip. Each animal was inoculated with 50 µL of a log phase culture of *S. pneumoniae* 6962spn-310 placed on the tip of the nares. KBP-7072 and antibiotics were started 18 hours post inoculation and continued for 3 days. Animals were euthanized at 0 (control group), 24, 48, and 72 hours post final dose. The lungs were harvested, homogenized in saline, and serial dilutions of the homogenates were cultured overnight on an MH agar plate. Bacterial CFUs were counted and presented as $\log_{10}$CFU/lung. Respiratory infection occurred in all inoculated mice. Treatment with KBP-7072 resulted in a significant dose-dependent decrease in CFUs at all doses and time points tested. At 72 hours post dose, KBP-7072 45 mg/kg qd, or 2.5 mg/kg and 7.5 mg/kg bid, resulted in no detectable bacteria in the lung. Linezolid 7.5 mg/kg bid showed no inhibition of bacteria growth, and linezolid 15 mg/kg bid resulted in 33.9% inhibition of number of bacteria in lung vs vehicle ($p<0.01$). KBP-7072, 5 and 15 mg/kg, resulted in a 133% and 166% dose-dependent increase respectively ($p<0.0001$), and linezolid 7.5 mg/kg resulted in a 66% increase ($p<0.0001$) compared to vehicle in median survival at Day 3. At Day 10, the survival rate in the KBP-7072 45 mg/kg group was 93.3% and median survival was not reached. The survival rate and median survival of all KBP-7072-treated groups were significantly higher than observed in the linezolid group ($p<0.0001$). These results demonstrate that KBP-7072 has greater antibacterial activity compared to linezolid and significantly increased the survival rate and prolonged median survival of treated animals compared to linezolid in a *S. pneumoniae*-induced murine pneumonia model in a dose-dependent manner.

Abstract Body:

KBP-7072 is a novel aminomethylcycline with broad-spectrum activity against Gram+ and Gram- multidrug resistant bacterial isolates and strains. *In vivo* antibacterial activity was assessed in a *K. pneumoniae*-induced murine pneumonia model. 6-8 week old female CD-1 mice, 23 - 27 g, were randomized to treatment groups (15 per group) based on body weight. KBP-7072 was dosed at 150, 300, and 600 mg/kg, po, qd; minocycline 300 mg/kg, po, qd; and vehicle 0.2 mL, po, qd. After randomization, animals were rendered neutropenic with 150 mg/kg of cyclophosphamide ip at Day -4 and Day -1, then anesthetized with 6.5% pentobarbital sodium at a dose of 65 mg/kg ip. Each animal was inoculated with 50 µL of a log phase culture of *K. pneumoniae* 5615kpn-493 placed on the tip of the nares. KBP-7072 and antibiotics were started 3 hours post inoculation and continued for 3 days. Animals were euthanized at 0 (control group), 24, 48, and 72 hours post final dose. The lungs were harvested, homogenized in saline, and serial dilutions of the homogenates were cultured overnight on an MH agar plate. Bacterial CFUs are presented as $\log_{10}$CFU/lung. Respiratory infection occurred in all inoculated mice. Treatment with KBP-7072 resulted in a significant dose-dependent decrease in CFUs at all doses and most time points tested. At 72 hours post dose, KBP-7072 150, 300, or 600 mg/kg qd, or 75 mg/kg and 150 mg/kg bid, resulted in 17.5%, 21.6%, 47.4%, 23.7% and 47.4% inhibition, respectively, vs vehicle ($p<0.05$ to 0.001). Minocycline resulted in no significant inhibition of bacteria growth. Treatment with KBP-7072 resulted in a dose-dependent increase in survival rate. At doses of 150 and 300 mg/kg, KBP-7072 resulted in a median survival of 3 days, a 50% increase compared to median Day 2 survival in vehicle-treated animals ($p=0.0001$). At day 10, the survival rate in the KBP-7072 600 mg/kg group was 73.3% and the median survival was not reached, vs vehicle ($p<0.0001$). Minocycline 300 mg/kg resulted in no increase in median survival. The survival rate and median survival in all KBP-7072-treated groups were significantly higher than for minocycline ($p=0.0001$). These results demonstrate that KBP-7072 has greater antibacterial activity compared to minocycline and significantly increased the survival rate and prolonged median survival of treated animals in a *K. pneumoniae*-induced murine pneumonia model in a dose-dependent manner.

Eravacycline is Active against MDR, Cephalosporin- and Carbapenem-Resistant *Enterobacteriaceae* and *Acinetobacter baumannii*

Author Block:

T. H. Grossman[1], I. Morrissey[2], **J. A. Sutcliffe**[1]; [1]Tetraphase Pharmaceuticals, Watertown, MA, [2]HMA Europe Sàrl, Epalinges, Switzerland

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity being developed for the treatment of serious infections, including those caused by MDR pathogens. ERV was tested *in vitro* against Gram-negative pathogens of concern, including 3rd/4th generation cephalosporin-resistant (CEPH-R) and carbapenem-resistant (CP-R) *Enterobacteriaceae*, and CP-R and MDR *Acinetobacter baumannii*. **Methods:** MIC assays were performed as per CLSI methodology and data for ERV was analyzed across multiple non-clinical and recent surveillance studies using a composite database housed at International Health Management Associates (IHMA). The IHMA Surveillance Data Link Network (SDLN) webtool was used to analyze isolates by resistance phenotypes, including MDR (resistant to ≥3 antibiotic classes), as per 2015 CLSI criteria. A subset of cephalosporin and/or carbapenem resistant isolates were screened using published PCR conditions for narrow- and extended-spectrum β-lactamases and carbapenemases.**Results:** For most pathogens, ERV $MIC_{50/90}$ values increased ≤2-fold across resistant subclasses, indicating that ERV had *in vitro* potency against enterobacterial pathogens which are resistant to other antibacterials, including 3rd/4th generation cephalosporins and carbapenems, and MDR organisms (Table). ERV had an overall $MIC_{50/90}$ of 0.5/2 µg/mL for a subset of 416 molecularly characterized CP-R *Enterobacteriaceae* which included 255 isolates positive for bla_{KPC} and 106 isolates positive for bla_{IMP}, bla_{VIM}, or bla_{NDM} metallo-β-lactamase genes. The $MIC_{50/90}$ was 1/2 µg/mL for a subset of 220 CEPH-R, CP-R *Enterobacteriaceae*. The ERV $MIC_{50/90}$ for CP-R *A. baumannii* containing bla_{OXA} (n=94) was 0.5/1 µg/mL, and MIC values for strains with bla_{NDM} (n=5) and bla_{KPC} (n=1) were 0.12-0.25 µg/mL and 0.5 µg/mL, respectively.**Conclusions:** ERV is active against difficult-to-treat CEPH-R, CP-R and MDR Gram-negative pathogens.

Organism	**Phenotype[a] (# isolates)**	**ERV MIC_{50}/MIC_{90}/ Range[b]**
Enterobacteriaceae	**All (12,292)**	**0.25/1/ ≤0.015-16**

Publishing Title:

Omadacycline (PTK0796) Spectrum of Activity from 2003-2015

Author Block:

M. M. Traczewski; Clinical Microbiol. Inst., Wilsonville, OR

Abstract Body:

Background: Omadacycline (OMC) is the first aminomethylcycline antibiotic under development for use as a once daily oral and IV treatment in skin and soft tissue and respiratory infections. Omadacycline is currently in Phase 3 clinical development for acute bacterial skin and skin structure infections. This study compares spectrum of activity studies of OMC performed in 2003, 2007 and 2015. **Materials and Methods:** All three studies used the Clinical and Laboratory Standards Institute (CLSI) frozen broth microdilution (BMD) methods described in the M7 and M45 documents current at the time of testing. MIC panels were prepared using fresh broth (<12 hrs old) and frozen at -70^{o} C until use. Clinical isolates used for each of these studies were < 3 years old at the time of testing for >80% of the total isolates tested in each study. **Results:** $MIC_{50/90s}$ and range of MICs are listed in Table 1.**Conclusions:** The activity of OMC has remained stable from 2003 through 2015. OMC had good activity against *Enterococcus faecium*, *Enterococcus faecalis*, *Staphlyococcus aureus*, β-hemolyctic streptococci, *Streptococcus pneumoniae* and *Moraxella catarahhalis* with MIC_{50s} ranging from 0.06 to 0.25 μg/ml and MIC_{90s} from 0.06 to 0.25. Haemophilus influenzae had slightly higher MIC_{50s} which ranged from 0.5 to 1 μg/ml and MIC_{90s} from 1 to 2. OMC MIC_{50s} vs. *Escherichia coli* ranged from 1 to 2 μg/ml and MIC_{90s} from 2-4 μg/ml. *Klebsiella pneumonae* MIC_{50s} were 2 μg/ml and MIC_{90s} were 8 μg/ml.

Table 1. Spectrum of Activity of Omadacycline from 2003 to 2015

Activity of Eravacycline and Comparators against 6,338 Pathogens Isolated from Canadian Hospitals: Canward 2014 and 2015

Author Block:

G. G. ZHANEL[1], H. Adam[2], M. Baxter[1], B. Weshnoweski[2], R. Vashisht[1], S. Biju[1], A. Golden[1], A. Denisuik[1], A. Walkty[2], P. Lagace-Wiens[2], J. A. Karlowsky[2], D. J. Hoban[2]; [1]Univ. of Manitoba, Winnipeg, MB, Canada, [2]Diagnostic Services Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity being developed for the treatment of serious infections, including those caused by multidrug-resistant (MDR) pathogens. The activity of this synthetic fluorocycline was compared to a variety of comparators including meropenem (MER) and piperacillin-tazobactam (PTZ) against Gram-negative and Gram-positive pathogens causing infections in Canadian hospitals.**Methods:** From January 2014-December 2015, inclusive, 13 sentinel hospitals submitted pathogens from patients attending hospital clinics, emergency rooms, medical and surgical wards, and intensive care units as part of an ongoing national surveillance program in Canadian hospitals. 6,338 total isolates were collected for 2014 and 2015. Susceptibility testing was performed using CLSI broth microdilution methods.**Results:**The activity (µg/ml) of ERV, MER and PTZ against select pathogens is described below:

Organism (# isolates)	ERV MIC_{50}/MIC_{90}	MER MIC_{50}/MIC_{90}	PTZ MIC_{50}/MIC_{90}
S. agalactiae (115)	0.03/0.06	≤0.06/≤0.06	≤1/≤1

Aminoglycoside Potentiation for the Treatment of Catheter-Associated Urinary Tract Infections

Author Block:

M. Koeva[1], D. Sweeney[2], D. L. Shinabarger[2], **D. Joseph-McCarthy**[1]; [1]EnBiotix, Inc., Cambridge, MA, [2]Micromyx, LLC, Kalamazoo, MI

Abstract Body:

Background: Bacterial persisters are a quasi-dormant sub-population of cells that are tolerant to antibiotic treatment. EBX-002 is a combination of the aminoglycoside amikacin with a bacterial metabolite as a potentiator. This product is being developed with the goal of reducing recurrent infections in the treatment of catheter-associated urinary tract infections (CAUTIs).**Methods:** MICs were determined by standard broth microdilution methods (CLSI M7). *E. coli* cultures in planktonic stationary phase were used to select for bacterial persisters. Experiments were conducted with and without a pre-selection step utilizing the fluoroquinolone ofloxacin. Using the time-kill method (CLSI M26), a panel of 10 *E. coli* UTI amikacin-sensitive clinical isolates were evaluated, varying the concentration of amikacin and metabolite. Cells were enumerated after 4 hr of exposure to the amikacin/metabolite combinations. Finally, the potentiator effect was similarly examined in other UTI relevant species.**Results:** The amikacin MIC range for the 10 *E. coli* isolates was 1-4 μg/mL. Enhanced killing of up to 7 orders of magnitude of *E. coli* persisters was seen (see example in the figure below). Essentially no killing of persister cells occurred upon exposure to as high as 128 μg/mL of amikacin alone. The highest concentration of metabolite tested (40 mM) also did not kill cells when tested alone. In addition, a potentiation effect was observed, as examples, in *P. aeruginosa* and *K. pneumoniae.* **Conclusions:** The combination of amikacin with a metabolite potentiator has the capacity to revitalize existing and novel aminoglycosides through eradication of bacterial persisters, with broad spectrum potential for the treatment of CAUTIs.

Activity of Plazomicin in Combination with Other Antibiotics Against Multidrug Resistant Enterobacteriaceae

Author Block:

M. Thwaites[1], D. Hall[1], D. Shinabarger[1], A. Serio[2], K. Krause[2], **C. Pillar**[1]; [1]Micromyx, Kalamazoo, MI, [2]Achaogen, San Francisco, CA

Abstract Body:

Background: Plazomicin (PLZ), a novel aminoglycoside, is currently undergoing development for the treatment of severe Gram-negative (GN) infections. Combination therapy is often used for the treatment of multi-drug resistant (MDR) GN infections. To confirm PLZ activity against MDR GN bacilli and whether there was synergy with PLZ, PLZ combined with other GN agents was evaluated in checkerboard assays against MDR Enterobacteriaceae (EB), including isolates with characterized resistance to currently marketed aminoglycosides and beta-lactams. **Methods:** Fractional inhibitory concentrations (FIC) were determined by broth microdilution (CLSI M7) against 30 GN EB clinical isolates (10 *E. coli*, 6 *K. pneumoniae*, 2 *K. oxytoca*, 6 *E. cloacae*, 4 *E. aerogenes*, and 2 *C. freundii*) using test panels containing a dynamic concentration range of plazomicin and other agents alone and in combination. GN agents included ceftazidime (CAZ), piperacillin/tazobactam (P/T), meropenem (MEM), levofloxacin (LVX), tigecycline (TIG), and colistin (COL). FIC indices (FICI) were calculated by row as the MIC of PLZ in combination/MIC of PLZ alone + MIC of the GN agent in combination/MIC of GN agent alone. The FICI was interpreted as follows: $\leq$0.50, synergy; >0.50 - 4, indifference; >4, antagonism. **Results:** Overall, PLZ had an $MIC_{50/90}$ (µg/mL) of 1/2, which was comparable to COL (0.25/0.5) and TIG (1/4) and more potent than CAZ (128/>512), P/T (256/>512), MEM (0.12/64), and LVX (16/64). FICI values indicative of synergy were observed for PLZ in combination with P/T for 17/30 isolates. In general, the majority of combinations evaluated were characterized as indifferent, though there was some synergy observed for PLZ with MEM (6/30 isolates), CAZ and LVX (5/30 isolates), and TIG and COL (3/30 isolates). **Conclusions:** PLZ maintained potent activity against MDR EB including those with characterized resistance to other aminoglycosides. Synergy between PLZ and P/T was commonly observed and synergy with the other evaluated agents, though infrequent, was observed for select concentrations. PLZ has potential as a monotherapy and in combination for the treatment of serious GN infections caused by MDR EB.

An Evaluation of the Bactericidal Activity of Plazomicin and Comparators Against Multidrug Resistant Enterobacteriaceae

Author Block:

M. Thwaites[1], D. Hall[1], D. Shinabarger[1], A. Serio[2], K. Krause[2], **C. Pillar**[1]; [1]Micromyx, Kalamazoo, MI, [2]Achaogen, San Francisco, CA

Abstract Body:

Background: Plazomicin (PLZ) is a novel aminoglycoside (AG) under development for the treatment of serious Gram-negative (GN) infections. Few available agents have potent activity against multidrug resistant (MDR) GN bacilli. In this study, the bactericidal activity of PLZ, comparator AG, and other GN agents was evaluated by determining the minimum bactericidal concentration (MBC) and evaluating the time-kill (TK) kinetic of these agents against MDR Enterobacteriaceae (EB), including isolates with characterized AG and beta-lactam resistance.**Methods:** MICs/MBCs were determined by broth microdilution (CLSI M7/M26) for 30 strains of EB (MDR and characterized AG and beta-lactam resistant isolates; 10 *E. coli*, 6 *K. pneumoniae*, 2 *K. oxytoca*, 6 *E. cloacae*, 4 *E. aerogenes*, and 2 *C. freundii*). PLZ, amikacin (AMK), gentamicin (GM), ceftazidime (CAZ), meropenem (MEM), levofloxacin (LVX), tigecycline (TIG), and colistin (COL) were evaluated. The MBC was reported as the concentration where a 99.9% kill was observed. MBC:MIC ratios ≤4 were considered as bactericidal. TK for PLZ was determined (CLSI M26) for 10 isolates at 2X, 4X, 8X, and 16X the MIC at 1, 2, 4, 6 and 24 hr; comparators (AMK, GM, MEM, COL) were tested at 8X the MIC or 64 µg/mL for resistant isolates.**Results:** MIC/MBC results are summarized for 30 MDR EB in the table below. PLZ and COL were the most potent bactericidal agents.

Agent	**MIC_{50}/MIC_{90} (µg/mL)**	**MBC_{50}/MBC_{90} (µg/mL)**	**MBC:MIC ratio ≤ 4 n/N[a] (%)**
PLZ	0.5/2	0.5/4	29/30 (96.7)
AMK	32/128	64/256	29/30 (96.7)
GM	32/128	64/>512	25/27 (92.6)
CAZ	64/>512	128/>512	21/21 (100)
MEM	0.06/64	0.12/64	30/30 (100)
LVX	16/64	16/64	29/30 (96.7)
TIG	0.5/4	>4/>16	7/29 (24.1)
COL	0.12/0.25	0.12/0.5	28/28 (100)

[a] isolates with MIC/MBC values that were undefined/off-scale were not included for analysis of MBC:MIC ratio

By TK, a sustained 3-log kill through 24 hr was apparent as early as 1 hr with PLZ for *E. coli* (16X MIC; n=3), *K. pneumoniae* (4X/8X/16X MIC; n=3), and *Enterobacter* spp. (4X/8X/16X MIC; n=3). For *K. oxytoca* (n=1) a 2.87-3.05 log kill was observed at 4-24 hr for PLZ at 16X MIC. Though 3-log kills were observed early for the comparators at the evaluated concentrations (8X MIC or 64 µg/mL) there was typically regrowth at 24 hr excluding MEM (3-log kill at 24 hr for 5 of 10 isolates).**Conclusions:** PLZ and COL were the most potent agents by MIC and MBC against MDR EB and PLZ and by TK where rapid and sustained 3-log kills were apparent with PLZ against MDR EB isolates.

A Comprehensive Study of Plazomicin Activity against a Panel of Aminoglycoside Resistance Enzymes

Author Block:

G. Cox[1], L. Ejim[1], A. Sieron[1], A. W. Serio[2], K. M. Krause[2], G. D. Wright[1]; [1]McMaster Univ., Hamilton, ON, Canada, [2]Achaogen, San Francisco, CA

Abstract Body:

Background: Aminoglycoside (AG) modifying enzymes (AMEs) chemically alter AGs via *N*-acetylation (AACs), *O*-adenylylation (ANT) or *O*-phosphorylation (APHs). Methyltransferases (AMTs) have also emerged, which modify the ribosome and reduce AG binding. Plazomicin (PLZ) is a derivative of sisomicin under development for the treatment of infections due to multi-drug resistant (MDR) Enterobacteriaceae. The addition of a hydroxyl-aminobutyric acid moiety and a hydroxyethyl substituent are thought to protect the drug against AMEs. Despite many studies revealing PLZ activity against a variety of MDR clinical isolates, a study of PLZ activity in the presence of individual AMEs has not been performed. **Methods:** The MIC of PLZ was measured in *Escherichia coli* BW25113 and BW25113 Δ*bamB*Δ*tolC* (hyper permeable and efflux deficient strain) containing 17 individually cloned AMEs and 2 AMTs. PLZ modification was next assessed utilizing kinetic enzyme assays. To detect *N*-acetylation, 5,5'-Dithio-bis (2-Nitrobenzoic Acid) was used as an indicator. Phosphorylation was detected using a pyruvate kinase/lactate dehydrogenase assay and adenylylation detected using a pyrophosphatase assay. Assays were performed with purified AAC(2')-Ia, AAC(3')-Ia, AAC(3)-II, AAC(3)-IV, AAC(6')-Ii, APH(2")-Ib, APH(2")-Id, APH(3")-Ia, APH(3')-IIIa, APH(4)-Ia, APH(6)-Ia, APH(9)-Ia and ANT(2")-Ia. **Results:** Expression of only two of the AMEs tested led to elevated PLZ MICs (compared to vector alone); *aac(2')-Ia* (>8-fold MIC increase) and *aph(2")-IVa* (*Id*) (>4-fold MIC increase). Expression of either *armA* or *rmtB* AMTs led to high-level MICs (>64 µg/ml and >512 µg/ml, respectively). *In vitro* enzymatic assessment confirmed that only AAC(2')-Ia and APH(2'')-Id were able to utilize PLZ as a substrate with a K_m of 280 µM and 42 µM, respectively. **Conclusion:** Overall, the majority of AMEs tested in this study did not impact PLZ MICs and were not able to utilize PLZ as a substrate, whereas AMT expression led to high-level PLZ MICs. The two AMEs capable of modifying PLZ in this study, AAC(2')-Ia and APH(2")-Id, are limited in their distribution to *Providenica stuartii* and Enterococcus, respectively. Taken together, these data suggest that PLZ will exhibit increased clinical usefulness in comparison to older-generation AGs.

A Cross Sectional Survey: Attitude Towards Adult Vaccination in Karachi-Pakistan

Author Block:

N. Z. Siddiqui; Univ. of Karachi, Karachi, Pakistan

Abstract Body:

As per the estimates of *National Interview Health Survey* (*NHIS*) -2012, adult vaccination is extensively ignored and a very less number of adults could receive recommended vaccine doses. Thus, a cross sectional study was conducted to evaluate the knowledge and attitude towards adult vaccination programs among the adult citizens of Karachi, Pakistan. The survey covered about 54.28% of the total areas of Karachi, Pakistan. A questionnaire comprising of 11 questions was designed and a total of 500 individuals ranging from 11-61 years of age participated in the study. Responses to each question were statistically analyzed and the associations between different variables were established using SPSS 16. According to the results, majority (93.4%) of the individuals considered vaccines safe for health and more than 80% agreed that adult immunization is as necessary as child immunization however, a significant difference ($p<0.05$) was noticed between the vaccination schedule follow up rates during childhood and adulthood and only a few individuals could receive the recommended adult vaccines. A significant association ($p<0.05$) was also found between the frequency of infections and the factors that may affect the efficiency of immune system such as sleeping disorders, smoking, persistent depression/anxiety, alcohol intake and the use of anti-depressive drugs/steroids/cortisones. Results showed that a number of reasons may increase the reluctance of people towards any vaccination program such as the cost, risk of quality assurance and requirement of booster doses. Thus, the study emphasizes on the need of awareness programs for adult vaccination as the lack of awareness and ignorance in this sector may render masses susceptible to serious & life threatening infections.

Efficacy of Measles Virus Vaccine in Different Age Groups of Children in Lahore, Pakistan

Author Block:

T. Ijaz[1], **S. Ijaz**[2], S. Ahmad[3]; [1]Mayo Hosp.,King Edward Med. Univ., Lahore, Pakistan, [2]Shalamar Med. and Dental Coll. Lahore Pakistan, Lahore, Pakistan, [3]CEMB, Lahore Pakistan, Lahore, Pakistan

Abstract Body:

Background: Measles continues to be a serious public health problem in developing as well as developed countries, despite the availability of effective vaccine, the disease causes an estimated 1.4 million deaths annually,even in presence of well-established immunization program. In Pakistan, measles vaccines have been administered at the age 9 to 15 months to prevent the infection, however due to limited resources the vaccine efficacy was not detected. In a recent epidemic , thousands of children suffered due to measles and its complications in Punjab.The study has been designed to, Measure the level of measles antibodies in different age groups in children and to study the increase in the titre of antibodies. **Material and Method:** Children at age of six, nine, twelve and fifteen months were investigated for detection of Measles IgG level pre and post vaccination. The blood samples were drawn for their serological and haematological profiles. After initial blood sample the children were followed after one and two months like 0-1-2 months as follow-up samples. Data obtained from ELISA technique and haematological values were analyzed by one way ANOVA test. **Results:** After the administration of first dose of measles vaccine, an increase in serological titre was observed after 30 days and further 60 days of vaccination. It was observed that among the group of six month of age, 90% were found to be protected by the end of 60 days; the range of titre was 14 - 41 NTU/mL, while 10% were unprotected, however, the Protection level was low in 9 months old children group as 30% of children was found unprotected even after 60 days having a titre ranging between 2-8 NTU/mL, while 70% were protected having a range of 13-25 NTU/mL. The status of protection level in 12 months old children describes that 20 % of the children were unprotected while remaining 80% children were at the protection level having titre range 14-20 NTU/mL. The status of protection level in 15 months old children describes that 10 % of the children were observed unprotected while remaining 90% children were at the protection level having titre range 15-35 NTU/mL. **Conclusions**: The result of this research to be helpful in recommendation of a well established vaccination schedule for children in the area.

Children Travelling from Athens to International Destinations: An Airport-based Study

Author Block:

H. Maltezou[1], A. Pavli[1], S. Patrinos[1], M. Theodoridou[2]; [1]Hellenic Ctr. for Disease Control and Prevention, Athens, Greece, [2]Aghia Sophia children Hosp., Athens, Greece

Abstract Body:

Background: The number of children who travel to tropical and subtropical areas has increased. The aim of the current study was to assess the preparedness of children departing from Greece to Africa and Asia, in terms of vaccination and malaria chemoprophylaxis. **Methods:** Airport-based survey conducted from November 2011 through April 2013.**Results:** 183 children were studied, of whom 122 (66.7%) had a foreign nationality. Their main destinations were the Indian subcontinent (79 children; 43.2%), South-East Asia (56 children; 30.6%), and sub-Saharan Africa (26 children; 14.2%). Children traveled mainly to visit friend and relatives (VFRs) (134 children; 73.2%) and to stay in local residences (137 children; 74.9%). Forty (21.9%) children had received pre-travel consultation. VFRs sought pre-travel consultation less frequently compared with non-VFRs (17.9% versus 32.7%; p-value=0.033) and planned to travel for longer periods (p-value <0.001). Factors significantly associated with an increased probability for seeking pre-travel consultation were female sex and having the Greek nationality (p-values=0.007 and <0.001, respectively). The rabies and the typhoid fever vaccines were administered inadequately to children travelling to endemic areas. Malaria chemoprophylaxis was generally justified.**Conclusions:** Despite the increasing number of pediatric international travelers, only one every five children travelling to Africa and Asia seeks pre-travel consultation. Travel vaccines, and especially the rabies and the typhoid fever vaccines, were provided inadequately to children travelling to endemic areas. Malaria chemoprophylaxis was generally justified. Travel medicine services for children in Greece should improve. There is a need to develop communication strategies to access VFRs.

Epidemic Strains of Fmd (1998-2007 Gg.) in Armenia

Author Block:

T. Yesayan, K. Sargsyan; SSFS of the MOA RA, Yerevan, Armenia

Abstract Body:

The main objective of the single integrated system of Foot and Mouth Disease (FMD) measures in Armenia was to create buffer zones to contain exotic FMD viral types coming into the country from Turkey and Iran. Implementation of systematic mass vaccination of cattle, sheep and goats utilizing a polyvalent vaccine with a high protective activity helped to stabilize the situation by 1990. However, circulating strains have undergone antigenic drift making the vaccines ineffective. From 1998 to 2007 the following FMD virus strains were found in Armenia: A-98 (Amasia and Akhuryan regions, 1998), Asia-1 (Amasia region, 2000) and strain O (Ashotsk region, 2002). In all cases, outbreaks of FMD were caused by drifting from neighboring Turkey in the border areas of summer pasture. The highest rate of infection in 2000 was in Amasia (73.0%) and in 2002 was in Ashotsk (68.0%). Outbreaks of FMD type Asia-1 in the Shirak zone caused considerable damage initially, leading to development of a specific prevention plan. Implementation of a large-scale double dose of the vaccine strain Az-48 (for cattle), with an interval of 7-10 days and a single vaccination of sheep managed to eliminate FMD in the primary foci. Disease caused by the above strains of FMD virus have not been recorded since 2001. FMD virus type O is now the most common virus type, by all indicators of epizootic process. During the analyzed period, the number of foci and cases of FMD virus type O was significantly higher than those of the FMD types A and Asia-1. In addition, the most severe disease occurs in cows and calves up to 3-4 months age. Breakthrough infection in the repeatedly immunized population and the severity of disease in adult cattle was due to the mismatch of epizootic and production strains leading to low efficacy of the applied Antiepizootic series of vaccines. Due to the complexity of the epizootic situation of FMD, it is necessary to provide for emergency immunization of animals, in order to eliminate the disease in the event of primary foci and replace the production strains. For example, Vladimir Research Institute for Animal Health used, a polyvalent vaccine, AOAziya-1 in the farm border area of Armenia in 2003 during spring vaccinations, in the framework of the program "FMD buffer zone." Obtained from field strains, the vaccine has high immunogenic properties, thereby eliminating FMD types A, O, and Asia-1 in primary foci.

Seasonal Influenza Vaccination Coverage Improvement Through Implementation of an Immunization Strategy Bundle: A Pre-Post-Intervention Study

Author Block:

M. St-Amant, M-A. Pearson, C. Amireault, J. Beaudoin-Maitre, M. Landry, A. Chapdeleine, **S. Grandjean Lapierre**; Ctr. Hosp. Univ. de Montréal, Montreal, QC, Canada

Abstract Body:

Background: Nosocomial outbreaks of seasonal *Influenza* have been described. Increasing vaccination coverage among hospitalised patients is challenging. The objective of this study was to evaluate the efficacy of an immunization strategy bundle for the improvement of vaccination coverage among hospitalised patients. **Methods:** An immunization strategy bundle was implanted after 2012 and before 2015 *Influenza* seasons on our tertiary care institutions' internal medicine ward. The bundle included an immunisation status form, patient counselling and delegation of vaccine prescription authority to hospital pharmacists and trained nurses. Patients hospitalised in November 2012 and 2015 were included and respectively considered as the pre intervention and post intervention study groups. No impactful changes occurred among health care professional teams, hospitalisation setting or concomitant immunization strategies between both periods. Data were retrospectively collected through medical chart review.**Results:**

Table 1 - Baseline characteristics		
	Pre intervention (n=89)	Post intervention (n=108)
Average age - yr	61.4	64.5
Vaccine indication - no. (%)	72 (80.1)	99 (91.7)
Vaccine contraindication - no. (%)	1 (1.1)	0 (0)
Average no. of indications per patient	1.8	2.8
Most frequent indications - no. (%)		
Age > 60 yr	49 (55.1)	65 (60.2)
Pulmonary disease	21 (23.6)	33 (30.6)
Diabetes	20 (22.5)	41 (38.0)

Health care teams showed a compliance rate of 47.5% to proper filling of the immunization status form. As presented in table 2, rates of immunization status evaluation and rates of vaccination when indicated increased with the implementation of the bundle. The observed increase in vaccination coverage was found to be statistically significant (p=0.0362).

Table 2 - Bundle performance			
	Pre-intervention	Post-intervention	P value
Vaccination status evaluation - no (%)	15 (16.9)	49 (45.4)	< 0.001
Vaccination when indicated - no (%)	15 (20.8)	33 (33.3)	0.0362

Conclusion: Our data shows that the implementation of a standardised immunisation status evaluation form along with counselling on vaccination and delegation of vaccine prescription authority can improve seasonal *Influenza* vaccination coverage in a hospital setting.

Impact of 10-Valent Pneumococcal Conjugate Vaccine Introduction on Pneumococcal Carriage in Fiji: Results from Four Annual Cross-Sectional Carriage Surveys

Author Block:

E. M. Dunne[1], C. Satzke[1], T. Ratu[2], E. Rafai[2], M. Kama[2], R. Devi[2], K. Bright[1], L. Tikoduadua[2], J. Kado[2], C. L. Pell[1], M. L. Nation[1], J. Smyth[1], M. Habib[1], B. D. Ortika[1], S. Matanitobua[2], K. Gould[3], J. Hinds[3], K. Jenkins[4], K. Mulholland[1], F. M. Russell[1]; [1]Murdoch Childrens Res. Inst., Parkville, Australia, [2]Ministry of Hlth.and Med. Servies, Suva, Fiji, [3]St. George's, Univ. of London, London, United Kingdom, [4]Fiji Hlth.Sector Support Program, Suva, Fiji

Abstract Body:

Fiji introduced the 10-valent pneumococcal conjugate vaccine (PCV10) in 2012 using a 3+0 schedule. As part of the New Vaccine Evaluation Project, we are measuring the impact of PCV10 on nasopharyngeal carriage, invasive pneumococcal disease, and pneumonia. Cross-sectional nasopharyngeal carriage surveys were conducted annually prior to and for three years post-PCV10 introduction to measure direct and indirect PCV10 effects in infants (5-8 wk), children (12-23 mth, and 2-6 y), and adult caregivers. Nasopharyngeal swabs were collected from healthy participants (n≈500 per age group per year), stored in STGG, and frozen at -80°C until analysis. Pneumococci were detected by *lytA* qPCR and molecular serotyping performed by microarray. Results from 2012 - 2014 indicate that overall pneumococcal carriage declined following PCV10 introduction: carriage rates were significantly lower in 2014 than 2012 for all four age groups ($P < 0.05$). For 12-23 mth old children, the total pneumococcal carriage rate was 50%, 47%, and 30% in 2012, 2013, and 2014 respectively. Of the pneumococci identified, 38%, 32%, and 21% were PCV10 serotypes in 2012, 2013, and 2014, respectively. Carriage of multiple serotypes was common in this age group, with 9% of samples containing more than one pneumococcal serotype. Non-typeable pneumococci were the most common type observed, with their carriage increasing following vaccine introduction. Serotyping of other age groups is underway. This multiyear study in Fiji will provide important data on the impact of PCV10 introduction on pneumococcal carriage on both vaccinated and unvaccinated members of the population, as a decline in carriage is likely to translate to a decline in disease. Examining pneumococcal carriage is a practical means for evaluating vaccine impact in resource-limited settings, where disease surveillance is difficult.

Incidence and Serotype Variations of Invasive Pneumococcal Disease After Conjugate Vaccines Introduction in Gipuzkoa, Northern Spain

Author Block:

J. M. Marimón[1], M. Ercibengoa[2], M. Alonso[1], M. Lopez-Olaizola[2], G. Cilla[1], E. Perez-Trallero[3]; [1]CIBERES & H.U.Donostia-IIS Biodonostia, San Sebastián-Donostia, Spain, [2]H.U.Donostia-IIS Biodonostia, San Sebastián-Donostia, Spain, [3]EHU/UPV, CIBERES & H.U.Donostia-IIS Biodonostia, San Sebastián-Donostia, Spain

Abstract Body:

Background: Pneumococcal conjugate vaccines (PCV) were sequentially introduced in Spain: PCV7 in 2001, PCV10 in 2009, and PCV13 in mid-2010. Not subsidized by Government, an estimated coverage of around 70% was estimated for children <5 year-old in our region. Objective: analyze the evolution of the epidemiology of invasive pneumococcal disease (IPD) in different age groups before and after the introduction of the different PCVs. **Methods:** The study was performed between 1996 and 2014 in the University Hospital Donostia, San Sebastian, Spain that attends a population of about 400,000 people (between 15,000 and 20,000 children <5 years). All cases of IPD were recorded and pneumococcal serotypes were determined with the Quellung reaction. All incidence data were expressed as annual cases per 100,000 population. **Results:** In children <5 year-old, IPD incidence progressively decreased from 48.1 in 1996-2000 to 25.1 in 2011-2014, due to a progressively decrease in PCV7 cases (from 31.2 to 3.8) but also to a decrease between 2006-2010 and 2011-2014 in the incidence of PCV13 serotypes not included in PCV7 (1, 3, 5, 6A, 7F, 19A): from 30.4 to 10.0. The incidence of these 6 PCV13 serotypes had increased from 13.0 to 30.4 between 1996-2000 and 2006-2010. In adults (>14 year-old), incidence increased from 15.6 to 21.3 between 1996-2000 and 2001-2005, mainly due to an increase in non-PCV7 serotypes (principally serotypes 1, 3, 7F, and 19A). Since then, it progressively decreased to reach 10.0 in 2011-2014, due to a decrease in both PCV7 (from 6.6 to 0.8) and PCV13 serotypes since 2006-2010 (from 9.2 to 3.4). **Conclusions:** Despite being used only young children, PCV have contributed to a decrease in IPD in all age-groups in our region. An initial increase in the overall incidence of IPD in adult population after introduction of PCV7 was observed decreasing to a minimum between 2011-2014 after PCV13 introduction. Incidence variations of IPD in adults mimicked that of vaccinated young children, showing the great effect of PCV in carriage.

Immunogenicity And Safety Of 13-Valent Pneumococcal Conjugate Vaccine (Pcv13) In Heart Transplant Candidates And Recipients

Author Block:

H-Y. Sun[1], A. Cheng[2], C-I. Tsao[1], S-S. Wang[1], C-C. Hung[1], S-C. Chang[1]; [1]Natl. Taiwan Univ. Hosp., Taipei, Taiwan, [2]Natl. Taiwan Univ. Hosp., Hsin-Chu Branch, Hsin-Chu City, Taiwan

Abstract Body:

Background:PCV13 is recommended for patients with end stage heart disease and heart transplant recipients who are vulnerable to invasive pneumococcal diseases, but the immunogenicity and safety of PCV13 in this population is unknown. The present study aimed to assess the immunogenicity and safety of PCV13 in heart transplant candidates and recipients.**Methods:**Heart transplant candidates during transplant evaluation and recipients during follow-up were invited to receive 1-dose PCV13. Anti-capsular antibody responses against 4 serotypes (6B, 14, 19F and 23F) at baseline and 1, 3, 6, 9, and 12 months following vaccination were measured. Significant antibody responses were defined as 2-fold or greater increase of antibody levels compared with the baseline level.**Results:**From 2013/10/1 to 2015/7/3, one dose PCV13 was given to 12 heart transplant recipients (Group 1) with a median age of 54 and 23 heart transplant candidates (Group 2) with a median age of 56. Group 1 received PCV13 after a median of 1788 days (interquartile 816-2169) after transplantation. Significant responses to the 4 serotypes at 1, 3, 6 months post PCV13 developed in 45.5-72.7%, 27.3-72.7%, 28.6-85.7% of Group 1, and 66.7-85.7%, 44.4-72.2%, 46.2-53.8% of Group 2, respectively. Pain, erythema, and fever within 1 week after vaccination occurred in 16.7%, 8.3%, and 0% of Group 1 and 17.4%, 0%, 0% of Group 2, respectively. No differences in immunogenicity and safety were observed between the two groups.**Conclusions:**PCV13 is immunogenic and safe in heart transplant candidates and recipients although long-term follow-up is needed to assess the durability of its immunogenicity in this population.

Comparison of Immunogenicity of a Next Generation Pneumococcal Conjugate Vaccine in Different Animal Models

Author Block:

J. Xie, I. Caro-Aguilar, L. Indrawati, W. J. Smith, C. Giovarelli, M. Winters, J. McNair, J. He, Y. Zhang, A. Espeseth, C. Abeygunawardana, L. Musey, M. Kosinski, J. M. Skinner; Merck & Co. Inc, West Point, PA

Abstract Body:

Several animal models have been used to evaluate pneumococcal conjugate vaccines prior to evaluation in humans. We have developed a 15-valent pneumococcal conjugate vaccine (PCV15) which includes polysaccharides (PS) from serotypes (1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19A, 19F, 23F, 22F and 33F). All polysaccharides are conjugated to CRM197 and formulated with an aluminum adjuvant. The objective of this study is to investigate the immunogenicity of PCV15 in infant Rhesus monkey, CD1 mice, and New Zealand white rabbit.Animals were intramuscularly immunized with PCV15 vaccine (17 animals/group) and sera were collected before each immunization and after the final immunization. Functional antibodies were measured by multiplexed opsonophagocytic killing assay (MOPA). Geometric mean and 95% confidence interval were calculated and used to compare the titers between the two groups.PCV15 was immunogenic and increased functional antibodies titers by 10-1000 fold for most serotypes in all species. All serotypes except ST5 had higher OPA titers in rabbits compared to that in monkeys and mice. Serotypes 3 had very low OPA titers in monkeys. Serotypes 23F and 33F showed lower immunogenicity in mice while induced high titers in monkeys and rabbits. PCV15 also induced high anti-ST14 OPA titer in mice and protected mice from serotype 14 intraperitoneal challenge.These results demonstrate that PCV15 is immunogenic across multiple animal species; however, there are also some significant differences in some serotypes across animal species. These data will be analyzed relative to clinical immunogenicity data to determine which animal model is most predictive of human responses.

Trivalent Pneumococcal Protein Vaccine Protects Against Acute Otitis Media in an Infant Murine Model

Author Block:

Q. Xu, K. Pryharski, M. E. Pichichero; Rochester Gen. Hosp., Rochester, NY

Abstract Body:

Background: *Streptococcus pneumoniae* (*Spn*) infections are a major public health concern. Current licensed serotype-based pneumococcal vaccines are effective in preventing invasive pneumococcal diseases, but less effective in preventing non-bacteremic pneumonia and acute otitis media (AOM). We previously reported that a pneumococcal trivalent recombinant protein vaccine (PPrV) protected against pneumonia murine model. Here we evaluated PPrV protection against AOM in an infant murine model.**Methods:** C57BL/6J mice were intramuscularly vaccinated at 1-3 weeks of age with either a monovalent pneumococcal histidine triad protein D (PhtD), pneumococcal choline binding protein A (PcpA), detoxified pneumolysin (Ply), or trivalent vaccine, and transtympanicly challenged at 7-8 weeks of age with 100 CFU of *Spn* strain BG7322 (6A) or $1x10^4$ CFU of *Spn* nontypeable strain 0702064. Serum IgG titers were determined by ELISA. At 24 and 48 hours post infection (hpi), animals were sacrificed and middle ear fluid (MEF) samples were collected to count CFU of *Spn*.**Results:** We found that intramuscular vaccination of infant mice with monovalent and trivalent pneumococcal proteins elicited significant serum IgG antibody responses to corresponding component proteins. Vaccination with PhtD led to a tendency to reduce bacterial burdens in MEF at both 24 ($p=0.05$) and 48 hpi ($p=0.16$). Vaccination with PcpA significantly reduced bacterial burdens in MEF at both 24 ($p=0.02$) and 48 hpi ($p=0.004$); with PlyD1 significantly reduced *Spn* burden in MEF at 48 hpi ($p=0.02$), but not at 24 hpi ($p=0.24$). Vaccination with trivalent significantly reduced *Spn* burdens in MEF at both 24 ($p=0.001$) and 48 hpi ($p<0.0001$). Similar reductions of bacterial burdens were found when the vaccinated animals were challenged with the nontypeable strain.**Conclusions:** Trivalent PPrV confers protection against AOM in an infant murine model.

Phtd Pneumococcal Vaccine Protects Against Invasiveness by Preventing Pneumococcal Density in the Nasopharynx from Exceeding a Pathogenic Threshold during a Viral Upper Respiratory Co-Infection

Author Block:

M. Khan, Q. Xu, M. E. Pichichero; Rochester Gen. Hosp., Rochester, NY

Abstract Body:

Background: Unlike pneumococcal conjugate and polysaccharide vaccines, it would be desirable for protein-based, non-serotype specific vaccines not to eliminate all pneumococci from the nasopharynx (NP). Rather the goal of protein based pneumococcal vaccines would be to prevent the level of pneumococcal NP carriage to exceed a pathogenic threshold as occurs during a viral co-infection.**Methods:** Using pneumococcal clinical serotype strain 6A and mouse adapted PR8 Influenza virus (H1N1), we developed a mouse co-infection model and established pneumococcal NP carriage thresholds correlated with invasion and bacteremia (pathogenic) versus thresholds correlated with non-invasiveness (non-pathogenic). Infant mice (1 week old) were vaccinated with pneumococcal histidine triad protein D (PhtD) and vaccine efficacy in protection against pneumococcal pathogenic carriage during co-infection was ascertained. In order to assess the role of PhtD specific CD4+ T cells and *antisera* in protection, vaccinated and control mice were depleted of their CD4+T cells. Anti PhtD immunity (CD4+ T cells/antisera) was further transferred into naïve infant mice to assess the vaccine efficacy in protection against pneumococcal carriage.**Results:** An immune response to PhtD prevented pneumococcal NP carriage density to exceed the pathogenic threshold and cause disease. In adult mice, antigen specific CD4+T cell responses correlated with protection associated with enhanced phagocytic function of macrophages in the NP. In an infant colonization model, neither PhtD induced CD4+ T cells or antisera alone led to a significant reduction of NP pneumococcal colonization. However, simultaneous transfer of CD4+ T cells and antisera from vaccinated mice significantly reduced the NP bacterial density.**Conclusions:** PhtD vaccination did not eliminate all pneumococci from the NP thereby averting potential adverse consequences of other pathogens occupying the emptied NP niche. We conclude that PhtD vaccination may protect against pneumococcal disease without elimination of the organism from the NP.

Pneumococcal Protein Vaccine Gen-004 Reduces Experimental Human Pneumococcal Carriage in Healthy Adults

Author Block:

M. Skoberne[1], D. M. Ferreira[2], **S. Hetherington**[1], R. Fitzgerald[3], S. B. Gordon[2]; [1]Genocea BioSci.s, Cambridge, MA, [2]Liverpool Sch. of Tropical Med., Liverpool, United Kingdom, [3]Royal Liverpool Univ. Hosp., Liverpool, United Kingdom

Abstract Body:

Rationale: *Streptococcus pneumoniae* remains the leading cause globally of respiratory tract infections among young children and the production of universal inexpensive vaccine a global health priority. GEN-004 vaccine, developed with Genocea's ATLAS™ technology, is based on stimulation of T cell responses to 3 universal pneumococcal protein antigens. The vaccine was designed to protect against colonization of nasopharynx, a prerequisite step to pneumococcal disease.**Objectives:** Using an experimental human pneumococcal carriage (EHPC) model, we measured the effect of GEN-004 vaccine on carriage acquisition, density and duration following intranasal challenge of healthy adult subjects.**Methods:** 96 healthy participants aged 18–50 years received either GEN-004 (n = 46) or placebo (n = 50). Following 3 intramuscular doses at 4 week intervals subjects were inoculated with 80,000 CFU of *S. pneumoniae* 6B per naris. Subjects were followed for safety throughout the study. Blood samples were collected before and after immunization to assess immunogenicity. Nasal washes were collected 2, 7, and 14 days after inoculation to measure pneumococcal carriage by microbiological culture and qPCR.**Results:** The vaccine was well tolerated and highly immunogenic as measured by antibody response. A smaller number of vaccinated subjects compared to control group developed carriage (2 days after inoculation: 18/46 vs 26/50 measured by culture and 19/46 vs 30/50 measured by PCR). When comparing across multiple time points and methods, the impact on acquisition of carriage, ranged consistently between 18 and 36 percent lower compared to placebo. None of the individual endpoints were statistically significant, as the study was powered to observe >50% reduction in acquisition. **Conclusions:** GEN-004 was well tolerated, immunogenic and showed a consistent reduction in pneumococcal colonization in this small study. Further EHPC studies of pneumococcal protein vaccines should power to detect reductions in carriage density of 20-30% in this model. The clinical importance of the observed magnitude of reduction is unknown but should be explored in future studies.ClinicalTrials.gov Identifier: NCT02116998

An *in Vitro* Adherence Inhibition Assay For *bordetella Pertussis* Vaccine Antigens

Author Block:

Y. Gorantla, E. Kim, L. Choi, J. Schiffer, **G. Rajam**; CDC, Atlanta, GA

Abstract Body:

Background: Pertussis, caused by *Bordetella pertussis* (Bp) infection, is the least controlled vaccine-preventable bacterial disease despite high vaccine coverage. Acellular pertussis vaccines (aP), Tdap and DTaP, contain a range of Bp antigens including inactivated pertussis toxin (Pt), pertactin (Prn), filamentous hemagglutinin (Fha), and fimbriae 2/3 (Fim2/3). Bp infection requires nasopharyngeal (NP) colonization. CDC has developed an *in vitro* pertussis antigen adherence inhibition assay (pAAIA) to evaluate the contributions of anti-aP antibodies in preventing Bp NP adherence.**Methods:** Fluospheres covalently bound to each of four aP target antigens, Pt, Prn, Fha and Fim2/3 were tested for their adherence to Detroit 562 epithelial cells, detected fluorometrically and expressed as median fluorescence intensity (MFI). Antigen specific fluospheres were mixed with a panel of human anti-Tdap sera (n=10) and tested for reduction in adherence. The percent inhibition of adherence (IA) was calculated using the following formula: [%IA = 100-(test MFI x 100)/(mean control MFI)]. The dilution effecting a 50% IA of antigen conjugated fluospheres was reported (ED50). The reference antiserum NIBSC 06/140 was tested to determine the potency of different antibodies and expressed as the IC50 (ED50 * known antibody concentration in IU/mL).**Results:** At normalized bead count/well, max MFI (±1SD) was recorded for Fim (28066±1544 MFI) followed by Fha (17676±4810 MFI) and Prn (10725±16 MFI). Pt fluospheres exhibited poor adherence to Detroit 562 cells. Anti-Tdap sera exhibited high IA against Prn-coated fluospheres (ED50 range 10 - 270; median - 90), Fim (ED50 range 10 - 90; median - 30), and Fha (ED50 range 10 - 60; median - 30). Relative anti-aP adherence inhibition potency was anti-Fim (IC50 = 0.15 IU/ml), anti-Prn (0.55 IU/ml) and anti-Fha (2.00 IU/ml).**Conclusions:** Bp-antigen coated fluosphere adherence to Detroit 562 cells was mediated by Fim, Fha, and Prn but not by Pt. Anti-Tdap antiserum demonstrated concentration dependent IA. Pertussis AAIA is a novel *in vitro* technique to quantify antibodies inhibiting the adherence of Bp antigens to Detroit 562 cells.

Characterization of Gene Expression Patterns in Pbmcs of Children Who Are Low Vaccine Responders Compared to Normal Vaccine Responders

Author Block:

R. Kaur[1], R. Kennedy[2], M. E. Pichichero[1]; [1]Rochester Gen. Hosp., Rochester, NY, [2]Mayo Clinic, Rochester, MN

Abstract Body:

Background: Low vaccine responders (LVRs) are infants who fail to respond or respond with sub-protective immunity to routine pediatric vaccines after their primary series at 2, 4, and 6 months of age. We used transcriptomic high-dimensional Next-Generation Sequencing to characterize the gene expression profile of peripheral blood mononuclear cells (PBMCs) from children who are LVR (showing a subprotective response to >50% of the 6 antigens tested) compared with normal vaccine responders (NVR).**Methods:** RNA was extracted from PBMCs of 12 children age between 9-15 months and sequenced using the Illumina HiSeq 2000 platform. Differential expression analysis comparing the LVR relative to the NVR children was done using the edgeR package in R**Results:** Results are reported as $\log_2$ of the fold change for the LVR relative to the NVR, with corresponding p-values and false discovery rates. Following normalization 13,221 genes were analyzed for differential expression between LVR and NVR subjects. Despite the relatively small sample size we were able to identify significant expression differences in 46 genes ($p < 0.0005$ and $q \leq 0.1$) in LVRs (Top genes listed in figure). A KEGG pathway enrichment analysis identified the Calcium Signaling Pathway as being differentially expressed ($p=0.000015$) in LVR subjects. This pathway controls T and B cell receptor signaling as well as cellular responses to neurotransmitter, growth factors, and hormones.**Conclusions:** LVR children are characterized by differential expression of genes mostly related to T and B cell receptor signaling.

Naturally Acquired Mucosal Antibody Levels to Pneumococcal Protein Vaccine Candidates Prevent Acute Otitis Media Caused by *Streptococcus pneumonia* in Young Children

Author Block:

Q. Xu[1], J. Casey[2], A. Almudevar[3], M. E. Pichichero[1]; [1]Rochester Gen. Hosp., Rochester, NY, [2]Legacy Pediatrics, Rochester, NY, [3]Univ. of Rochester, Rochester, NY

Abstract Body:

Background: Acute otitis media (AOM) is a common pediatric bacterial infection often caused by *Streptococcus pneumonia* (*Spn).* We previously found that nasopharyngeal (NP) colonization by *Spn* elicits mucosal antibody responses to 3 pneumococcal protein vaccine candidates: pneumococcal histidine triad protein D (PhtD), pneumococcal choline binding protein A (PcpA), and pneumolysin (Ply). The objective of this study was to assess association of mucosal antibody levels to these three proteins with protection against NP colonization and acute otitis media (AOM) caused by *Spn.***Methods:** Healthy infants without previous episodes of AOM were enrolled in study at 6 months of age, and NP samples were collected at 6-24 months of age. Whenever a child was diagnosed with AOM, tympanocentesis was performed and middle ear fluid samples collected to confirm the diagnosis with microbiologic culture for otopathogens. NP mucosal IgG and IgA titers to PhtD, PcpA and Ply were quantified by ELISA. The correlation of antibody levels with NP colonization and AOM were analyzed using logistic regression in a generalized estimating equation model.**Results:** Compared with children who did not experience an AOM, children who experienced 1-3 episodes of AOM caused by *Spn* within 12 months had 4-fold lower IgG levels to PcpA in the NP ($p=0.0005$), 7-fold lower IgA to PhtD ($p<0.0001$); 3-folder lower IgA to PcpA ($p=0.004$), and 2-fold lower GM of IgA to Ply ($p=0.08$). NP mucosal antibody IgG level to PcpA, and IgA titers to all three proteins correlated with subsequent occurrence of AOM caused by *Spn* ($P<0.0001$). However, mucosal antibody titers to the three proteins did not correlate with protection against NP colonization with *Spn.***Conclusions:** NP mucosal IgG levels to PcpA, IgA to PhtD, PcpA and Ply, and IgG to PcpA correlated with protection of AOM in young children but not with protection against NP colonization.

Virulence Of Ciprofloxacin Resistant *escherichia Coli* Obtained On Pre-Prostate Biopsy Rectal Screens From Infected And Non-Infected Patients In Galleria Mellonella

Author Block:

C. Miglis[1], T. Zembower[2], A. Schaeffer[2], C. Qi[2], M. Malczynski[2], K. Maxwell[2], G. Pais[1], M. Scheetz[1]; [1]Midwestern Univ., Downers Grove, IL, [2]Northwestern Mem. Hosp., Chicago, IL

Abstract Body:

Background: Postprocedural infections are a known complication of prostate biopsies and can be due to host defenses, efficacy of prophylaxis and organism virulence. We utilized a Galleria mellonella (GM) model to quantify the virulence of *E.coli* isolated from infected and non-infected patients who had undergone transrectal ultrasonography of the prostate (TRUSP) with biopsy.**Methods:** Ciprofloxacin-resistant E.coli isolates were obtained from rectal swabs of patients prior to TRUSP procedures who developed infection (n=4) and did not develop infection (n=4). Organism identification and susceptibility testing were performed according to standard procedures. GM weighing between 250-350 mg (n=20) were inoculated with 1-2 x 10^5 CFU per 10 uL aliquot into the GM hemocele for each isolate. Experimental controls consisted of GM receiving an equivalent volume of 1) normal saline and 2) no injection. GM were incubated at 37 C and observed every 24h for 5 days. Mortality was assessed with Kaplan-Meier survival curves and log rank tests.**Results:** Control GM ultimately experienced mortality in 20% of the saline and 5% of the no-injection groups respectively. GM inoculated with isolates from non-infected patients caused greater mortality compared to those from infected patients at 5 days (75% vs. 27.5%, respectively $p < 0.001$, Figure 1). Two isolates harbored ESBLs. ESBL (-) isolates killed 47.5% of GM compared with 62.5% mortality with GM injected with ESBL(+) isolates, p=0.051%.**Conclusions:** E.coli isolates that were obtained from non-infected patients and those that were ESBL + were more virulent.

Evaluation Of Bp82 Lps As Vaccine Adjuvant Against *burkholderia Pseudomallei* in Goats

Author Block:

L. Rice, D. Fletcher, T. Eckstein; Colorado State Univ., Fort Collins, CO

Abstract Body:

Burkholderia pseudomallei is a select agent, gram-negative bacterium that is responsible for causing melioidosis in a multitude of hosts. An auxotroph strain of this bacteria known as *Burkholderia pseudomallei ΔpurM* mutant 82 (Bp82) was developed as a select-agent list exception and is currently being investigated for its potential as a vaccine candidate. This study examined the characteristics of the lipopolysaccharide profile of Bp82 and its potential as an adjuvant in vaccine therapy in the goat model. In a proof of concept study, two goats – goats 35 and 36 – were vaccinated with Bp82. Two other goats – goats 0 and 3 – were left unvaccinated as a control. Two weeks later, all four goats were challenged with the virulent strain of *Burkholderia pseudomallei*. Serum samples were collected weekly, and the experiment was terminated two weeks after the challenge. LPS was isolated from Bp82 culture, and used in an ELISA test to evaluate the reactivity of the goat serum to the molecule. After controlling for media readings, unvaccinated goats 0 and 3 had low amounts of immunoreactivity to the LPS. Goat 35 had a significant serum response to the LPS antigen, and its ELISA reactivity was greatest one week after challenge. Goat 36 had a smaller response and its ELISA reactivity was greatest two weeks after challenge. Additionally, LPS extracted from Bp82 culture was characterized by linearizing the sugars through an alditol acetate protocol. The resulting sample was analyzed through gas chromatography – mass spectroscopy. The study implicates that the lipopolysaccharide of Bp82 may have potential as a vaccine adjuvant, though further studies are needed. Future studies may include evaluating the effectiveness of live Bp82 vaccination in causing immune responses against virulent strain LPS in BSL-3 settings, and increasing the sample size.

Allergic Airway Sensitization Impairs Bacterial-Specific Igg Responses During *Mycoplasma pneumoniae* Infection

Author Block:

A. H. Totten, L. Xiao, D. Luo, D. M. Crabb, K. B. Waites, T. P. Atkinson; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract Body:

Background: *Mycoplasma pneumoniae* (Mpn), an atypical human pathogen, has been associated with both asthma initiation and exacerbation. Asthmatics have been reported to have higher carriage rates of Mpn compared to non-asthmatic controls. We hypothesized that allergic airway sensitization would impair host immune responses to Mpn infection in a murine model.**Methods:** BALB/cJ mice were sensitized and challenged with ovalbumin (OVA) to induce allergic airway inflammation and then infected with Mpn. Immune parameters were studied by analysis of cellular profiles in bronchoalveolar lavage fluid (BALF), serum IgG and IgE antibody levels to a whole bacterial antigen preparation, recombinant Mpn P1 adhesin peptide, and OVA. Total lung RNA was used to examine cytokine transcript levels and bacterial burden was determined by detection of 16S rRNA via RT-qPCR.**Results:** Anti-Mpn and P1-specific total IgG responses were decreased in allergen-sensitized animals compared to unsensitized controls ($p < 0.01$). Decreased titers of IgG1, IgG2b and IgG3 were present in P1-specific responses but not OVA-specific IgG subclass levels. IL-4 and IL-13 mRNA levels were increased in OVA sensitized groups compared to controls. Bacterial burden was two logs lower in OVA-sensitized mice compared to unsensitized controls, and did not correlate with Mpn-specific IgG levels.**Conclusions:** Anti-Mpn IgG antibody titers were decreased in allergic animals, suggesting an inverse relationship between atopic status and humoral immunity. Due to the importance of antibody titers in controlling Mpn infections, this model may explain a reported defect in asthmatic humoral responses during infection.

Examining the Prevalence of Multi-Nucleated Giant Cells (MNGCs) Using Both Inhalational and Intraperitoneal Infection Models of Melioidosis in BALB/c and C57BL/6 Mice

Author Block:

J. J. Bearss, M. Hunter, K. A. Frittspinnock, C. P. Klimko, J. L. Dankmeyer, R. G. Toothman, C. H. Weaver, C. W. Schelhase, J. A. Bozue, K. Amemiya, P. L. Worsham, S. L. Welkos, **C. K. Cote**; USAMRIID, Frederick, MD

Abstract Body:

Burkholderia pseudomallei, the etiologic agent of melioidosis, is a gram negative bacterium designated a category B threat agent by the CDC. This bacterium is endemic in Southeast Asia and northern Australia and can infect humans and animals by several routes of infection. Inhalational melioidosis has been associated with monsoonal rains in endemic areas and is also a primary concern in the biodefense community. There are currently no effective vaccines for B. pseudomallei and antibiotic treatment can be hampered by non-descript symptomology and also the high rate of naturally occurring antibiotic resistant strains. Multinucleated giant cells (MNGCs) arise when monocytes or macrophages fuse forming phenotypically distinct giant cells. MNGCs are associated with the pathogenesis and progression of some bacterial infections, and their presence has sometimes been referred to as a "hallmark of melioidosis". MNGCs are well established in Burkholderia-infected in vitro cell cultures; however, there have been limited demonstrations of in vivo MNGCs in the literature. To date they have been observed in mouse and Madagascar hissing cockroach models, and in human post-mortem autopsy findings. However the significance and prevalence of the MNGCs in vivo is still questioned. Female BALB/c and C57BL/6 mice were infected with low doses of B. pseudomallei K96243 delivered via intraperitoneal injection or exposure to aerosolized bacteria. Mice were euthanized on selected days for pathological analyses. We characterized the differences in the prevalence of MNGCs found in BALB/c and C57BL/6 mice which had been infected with similarly low infectious doses of B. pseudomallei. Additional evidence is provided which clearly demonstrates that infection with B. pseudomallei can induce the formation of multi-nucleated giant cells (MNGCs) in vivo.

Urinary Tract Infection Symptoms In Women Relate To Uropathogens While False Negatives Of Standard Urine Cultures May Delay Patient Treatment

Author Block:

T. Dune, E. Hilt, T. Price, C. Brincat, C. Fitzgerald, L. Brubaker, A. Wolfe, P. Schreckenberger, E. Mueller; Loyola Univ., Maywood, IL

Abstract Body:

Background: Urinary tract infections (UTIs) are often conceptualized as a single uropathogen inappropriately growing in an otherwise sterile bladder. Compelling evidence argues against this dogma, revealing urinary microbiota within the typical female bladder. UTIs rarely lead to systemic infection, thus patient symptoms may guide treatment. The goals of this study were to compare 2 urine culture methods for uropathogen detection, relate uropathogens to classic UTI symptoms, and assess standard urine culture for its effect on patient care.**Methods:** Following IRB approval, we enrolled 150 urogynecologic patients and dichotomized them on their perception of the presence of a UTI (YES/NO). Both groups also rated severity and bothersome nature of 7 classic UTI symptoms on a Likert-type response scale using a validated UTI symptom assessment (UTISA) questionnaire. The YES group was later contacted to complete a follow-up UTISA survey. Each patient's catheterized urine sample was processed with standard urine culture (SC) and enhanced quantitative urine culture (EQUC) methods. MALDI-TOF mass spectrometry identified bacteria. Women were treated clinically as needed.**Results:** In the YES group (N=75), dysuria, urinary frequency and urgency were the most common symptoms. When SC was positive, EQUC was always positive. Of the SC+ women, 72% (54/75) were assessed clinically; the majority [81% (44/54)] was treated with antibiotics. EQUC detected uropathogens in 92% (69/75) of the YES group, but 20% (15/75) were SC negative. Of the 15 SC-/EQUC+ women, only 1 was treated with antibiotics. More SC-/EQUC+ women [66.6%] reported the same or worsening UTI symptoms than SC+/EQUC+ women [38.5%].**Conclusions:** EQUC detected uropathogens more often than SC. While UTI symptoms improved in SC+ women with antibiotic treatment, SC-/EQUC+ women were not treated despite uropathogen presence. These women often had no symptom improvement. Coupling the UTISA questionnaire with EQUC highlights the troublesome false negative rate of SC. Clinicians can improve patient care with the additional information available from EQUC.

Transcriptional Profiling of the Host Immune Response to Virulent and Attenuated Vaccine Strains of Mycoplasma Gallisepticum

Author Block:

J. Beaudet, E. Tulman, K. Pflaum, X. Liao, L. Silbart, S. Geary; Univ. of Connecticut, Storrs, CT

Abstract Body:

Additional in-depth information regarding the mechanism leading to the dysregulated host response to *M. gallisepticum* is needed to understand this complex immune process and to enable us to develop a more efficacious vaccine that would limit inflammation and aid in the clearance of the bacteria. Previous *in vivo* studies analyzing the host immune response to R_{low} infection through qRT-PCR have shown an upregulation in expression of pro-inflammatory chemokine and cytokine genes such as lymphotactin, CXCL13, -14, RANTES, and MIP-1β between days one and eight post infection. Studies exposing tracheae *ex vivo* and cultured tracheal epithelial cells *in vitro* to *M. gallisepticum* revealed a similar yet transient upregulation of chemokine and cytokine gene expression profiles at 1.5, 6, and 24 hours post infection using qRT-PCR and microarray analysis.In an effort to gain a broader understanding of the molecular events that underpin the host immune response to *M. gallisepticum* we are investigating the complete transcriptomic profile of chickens infected with *M. gallisepticum* R_{low} compared to uninfected chickens. In preliminary studies, RNA from infected and uninfected white leghorn chickens seven days post inoculation were analyzed using Illumina RNA sequencing. This high-throughput analytical method allowed us to map over 21 thousand genes to the chicken genome and to identify over three thousand genes with statistically significant differential expression, of which 122 encode immune-related functions. Many of these genes are active in signaling pathways that may contribute to chronic inflammation, immune dysregulation and disease.To expand on these data we have conducted a *M. gallisepticum* R_{low} time course infection study to assess the transcriptional changes in host genes that occur day-to-day over the first 7days post-infection. Key steps in the pathways leading to the maladaptive immune response to *M. gallisepticum* may prove to be important targets for future vaccine constructs.

Host Cytokine Response in *Staphylococcus aureus* Bacteremia Specific to Source of Infection and Its Impact on Outcomes

Author Block:

N. Bui[1], E. Minejima[2], P. Nieberg[1], K. Trinh[2], A. Wong-Beringer[2]; [1]Huntington Hosp., Pasadena, CA, [2]Univ. of Southern California Sch. of Pharmacy, Los Angeles, CA

Abstract Body:

Background: Sources of *Staphylococcus aureus* bacteremia (SAB) have been associated with mortality risk, with rates ranging from 5% for low risk up to 45% for high risk sources (i.e. endovascular). Our study aims to determine if host cytokine response varies with source of infection and thus impacts outcome of SAB. **Methods:** A prospective observational cohort study was conducted at three medical centers on adults hospitalized for SAB during 7/12 to 4/15. Plasma was obtained at onset of SAB and 72h after start of effective therapy to measure pro- (TNFα, IL6, IL8) and anti-inflammatory (IL10) cytokine levels (pg/mL) by multiplex Luminex assays. Medical records were reviewed to obtain relevant demographics, laboratory, and clinical details for comparison between patients grouped based on source of infection: high risk source (HRS: endovascular, pneumonia, intraabdominal), intermediate (IRS: skin soft tissue or osteoarticular infection, unknown), and low (LRS: catheter-related).**Results:** 237 patients were included; 53 HRS, 126 IRS, and 58 LRS. Median age was 59 y with MRSA causing 1/3 of the cases. More HRS patients were admitted from a healthcare facility (44% vs 2% vs 19%, p=0.0039) and presented with septic shock (22% vs. 6% vs 12%, p=0.0078) at initial presentation compared to IRS and LRS patients, respectively. Cytokine levels were similarly elevated for HRS and LRS groups with TNF, IL8, and IL-10 at both timepoints, but lower for IRS group. Compared to IRS and LRS, HRS patients had higher rates of clinical failure on day 4 (45% vs 34% vs 19% , p=0.012) respectively but 30-day mortality was not statistically different between groups (15% vs 10% vs 10%). Regardless of source of infection, high IL10/TNF ratio at 72h was significantly associated with risk of death when comparing non-survivors to survivors (2.26 vs 0.7, p=0.0001).**Conclusions:** Our results indicate that patients with HRS of SAB were more similar to LRS than IRS patients in severity of clinical presentation and cytokine response. A high IL10/TNF ratio predicted mortality while source of infection did not.

Investigating the Role of Traf3 in T Cell Biology

Author Block:

T. White[1], A. Wallis[2], L. Stunz[3], G. Bishop[3]; [1]Towson Univ., Towson, MD, [2]Univ. of Iowa, University of Iowa, IA, [3]Univ. of Iowa, Iowa City, IA

Abstract Body:

T lymphocytes carry out important functions in systemic immunity. They utilize several receptors to allow them to sense their environment and respond accordingly. Understanding how T cells regulate their activation through these receptors is important to further clarifying T cell-mediated immune responses. Our lab focuses on an adapter protein called TNF Receptor-Associated Factor 3 (TRAF3) which has recently been shown to positively regulate the T cell receptor (TCR) signaling pathway. One goal of this project was to explore the role of TRAF3 in TCR signaling. The adaptor molecules GRB2/GADS are recruited to the T cell receptor complex upon activation. Analysis of the amino acid sequences of these proteins predicted potential novel associations between the carboxy terminal domain of TRAF3 and the SH3 domains of GRB2/GADS. We used Human embryonic kidney cell transfection, immuno-precipitation, and western blotting techniques to investigate whether TRAF3 associates with, and thus potentially regulates, the TCR-associated adapter proteins GRB2/GADS.A second goal of this project was to explore the role of TRAF3 in Toll-like receptor (TLR) signaling in T cells. TRAF3 has been previously shown to regulate TLRs in other cell types. Thus, we explored the role of TRAF3 in TLR signaling in T cells by stimulating T cells with various TLR ligands, then examined cytokine production and cell activation marker regulation using the techniques of enzyme-linked immunosorbent assay and Flow cytometry. We hypothesized that TRAF3 positively regulates signals via TLRs 2/5, which predicted that in the absence of TRAF3, TLR-induced cytokine production and expression of cell surface activation molecules would decrease. Our research has shown that TRAF3 associates with GRB2/GADS. Also TRAF3 affects GRB2/GADS recruitment to the cell membrane upon TCR stimulation. Our research has also shown that TRAF3-deficient T cells show an increase in surface expression of the adhesion molecule CD54. Loss of TRAF3 in T cells also increases MHC class II surface molecule abundance before and after TL2 simulation. Our preliminary studies showed that TRAF3 does interact with GADS/GAD upon TCR stimulation, and this broadens our understanding of the ways that TRAF3 may regulate TCR signaling. Furthermore, our preliminary evidence is consistent with TRAF3 regulation of TLR2/5 signaling.

Recent Thymic Emigrants and Chronic Salmonellosis: How New T Cells Combat an Old Infection

Author Block:

J. A. Goggins, J. R. Kurtz, J. B. McLachlan; Tulane Univ. Sch. of Med., New Orleans, LA

Abstract Body:

Typhoid fever, caused by infection with *Salmonella* bacteria affects approximately 21 million people annually, killing nearly 200,000 and yet the immunological response to this infection is poorly understood. Recent thymic emigrants (RTEs) are the youngest subset of peripheral T cells, which are known to differ in how they functionally contribute to the naïve T cell pool. This distinctive cell population is known to contribute to the maintenance of T cell receptor diversity in the peripheral T cell pool, but their involvement in combating chronic bacterial infections, such as typhoid fever, has not been explored. In the present study, we hypothesized that RTEs are essential contributors to the CD4 T cell response during persistent *Salmonella* Typhimurium (ST) infection, which predominantly relies on helper T cell immunity to control bacteria. Here, we show that thymectomy of adult mice prior to oral infection with ST leads to increased mortality in addition to significantly increased bacterial burdens in the spleen, mesenteric lymph nodes and liver 30 days post-infection compared to sham surgical controls, suggesting *Salmonella*-specific RTEs may contribute to bacterial clearance. Surprisingly, thymectomized animals also demonstrated expanded numbers of peripheral *Salmonella*-specific T cells, compared to control animals, implying that these existing cells are somehow incapable of controlling infection in the absence of RTEs. The results of this study provide insight into how new pathogen-specific T cells leaving the thymus participate in combatting a persistent bacterial infection.

Purification and Characterization of a Rabbit Serum Factor That Kills *Listeria* &Lt Other Foodborne Bacterial Pathogens

Author Block:

A. Datta; FDA/CFSAN, Laurel, MD

Abstract Body:

In an *in-vitro* assay, rabbit serum, but not human serum, killed *Listeria monocytogenes*, a foodborne pathogen that causes human listeriosis. The listericidal activity of rabbit serum, termed listericidin, was purified to homogeneity in a single-step by ion-exchange chromatography with DEAE-Sepahdex A-50. The purified listericidin is a protein with a molecular weight of 9 kDa and an isoelectric point of 8.1. It is effective in killing *L. monocytogenes* at 4, 25 and 37^{o} C, but the rate of killing is faster at the highest temperature. It is resistant to acidic conditions (< pH 2), but is sensitive to proteolytic enzymes subtilisin, trypsin and chymotrypsin. The listericidin is heat-stable at 56^{o}C and loses only 50% of its activity when boiled for 30 min at 100^{o}C. Its activity is inhibited in presence of NaCl in a dose-dependent fashion and by various bacterial growth media. The listericidal activity is neutralized by monoclonal antibodies to human complement C3a, but its reaction with the antibodies in an ELISA is very weak. Its activity is not affected by iron but is enhanced by calcium chloride. The first 33 N-terminal amino acid residues of the sequence (SVQLTEKRMDKVGQYTNKELRKXXEDGMRDNPM) show a high degree of homology to various mammalian complement C3a components, but there is no sequence from rabbits in the database that is similar to the listericidin amino acid sequence. In addition to killing selected members of all the major serotypes of *L. monocytogenes*, it is effective in killing other *Listeria* spp. and various foodborne pathogens belonging to the *Vibrio*, *Salmonella*, *Escherichia*, *Cronobacter*, and *Bacillus* genera. However, many of the serovars of *Salmonella enterica* are resistant to listericidin. Results of the study indicate that the rabbit listericidin is constitutively present in rabbit serum and is a C3a-like heat-stable and acid-stable peptide which shares many of the properties of the C3a component of the C3 complement family of proteins, but also exhibits properties that are unique and different from C3a.

Antibody Pretreatment of *Mycoplasma gallisepticum* Does Not Impact Vaccination or Experimental Infection in Chickens

Author Block:

S. A. Leigh, S. Collier, S. Branton, J. Evans; USDA-ARS, Mississippi State, MS

Abstract Body:

Mycoplasma gallisepticum infection in poultry leads to chronic respiratory disease and decreased egg production in chickens and infectious sinusitis in turkeys. The pathological effects of *M. gallisepticum* infection can be prevented by vaccination with one of the live attenuated *M. gallisepticum* vaccines. While these vaccines exhibit varying levels of protection and pathology, the host immune response that provides protection is little understood. Therefore, studies were performed to determine the impact that exposure to anti-*M. gallisepticum* serum prior to vaccination or infection would have on the response of the chicken host to the serum treated mycoplasma. At 8 weeks of age (woa), chickens were vaccinated with either a commercial F-strain vaccine, or the vaccine mixed with hyperimmune anti-*M. gallisepticum* chicken serum for 60 minutes prior to vaccination. Six weeks following vaccination (14 woa), chickens were infected with *M. gallisepticum* strain R-low, with one group being infected with *M. gallisepticum* strain R-low mixed with hyperimmune anti-*M. gallisepticum* chicken serum for 60 minutes prior to infection. At one week post infection (15 woa), chickens were bled to obtain serum, killed, and examined for airsacculitis. The presence of anti-*M. gallisepticum* chicken serum had no impact on either the vaccination results or the presence of airsacculitis following infection. This provides further evidence that the humoral immune response likely has a minimal role in host protection from *M. gallisepticum* colonization and infection.

Protective Efficacy of Antibody to Poly-N-Acetyl Glucosamine (Pnag) Against *Streptococcus pneumonia* and *Staphylococcus aureus* Conjunctivitis

Author Block:

T. S. Zaidi[1], T. H. Zaidi[1], Z. Ge[2], G. B. Pier[1]; [1]Brigham and Women's Hosp. and Harvard Med. Sch., Boston, MA, [2]Shandong Eye Inst., Qingdao City, China

Abstract Body:

Introduction: The ocular conjunctiva is highly susceptible to infectious agents, of which ~80% are viral. The remaining causes are bacterial, with *Streptococcus pneumonia* and *Staphylococcus aureus* being common causes. Little is known about the innate and adaptive immune effectors in this component of the eye and whether local or systemic antibody can gain access to ocular pathogens in this tissue and mediate effective immunity. We evaluated whether opsonic antibody to the conserved surface/capsular polysaccharide, poly-N-acetyl glucosamine (PNAG) was protective against bacterial conjunctivitis. **Methods:** To induce infection, *S. aureus* or *S. pneumoniae* was injected directly into the conjunctiva of 6-7 week old A/J mice. Four, 24 and 32 hours post-infection a human IgG1 monoclonal antibody (MAb) to PNAG or control IgG1 MAb were either injected into the conjunctiva or applied topically. Forty-eight hours post-infection eyes were scored for pathology daily, using a 0 to 4 scale, evaluating palpebral and bulbar conjunctivae for erythema, edema, and exudation. After 48 h animals were euthanized and CFU/conjunctiva determined. **Results:** Both topical and injected antibody to PNAG markedly reduced bacterial levels in the conjunctivae and reduced conjunctival pathology. Histopathologic analysis of infected eyes showed severe edema and lymphocyte infiltration into eyes of mice treated with control MAb, while the conjunctiva of the anti-PNAG treated MAb showed only very mild lymphocyte infiltration. **Conclusions:** Antibody to PNAG demonstrated therapeutic efficacy in models of *S. pneumonia* and *S. aureus* conjunctivitis, and this particular set of animal experiments further validated the capacity of such antibody to protect against divergent microbial species.

The Effect of Coinoculaton with *Bradyrhizobium japonicum* USDA 110 and *Pseudomonas putida* NUU8 on Nitrogen and Phosphorus Availability to Soybean Growth

Author Block:

D. Jabborova; Inst. of Genetics and Plant Experimental Biology, Uzbekistan Academy of Sci., Tashkent, 111226, Uzbekistan, Tashkent, Uzbekistan

Abstract Body:

We studied the effect of *Bradyrhizobium japonicum* USDA 110 alone and in combination with *Pseudomonas putida* NUU8 on nutrient contents of nitrogen and phosphorous uptake efficiency of soybean (*Glycine max* L.) plants grown under hydroponic conditions in a greenhouse. Plants were grown for 45 days in a greenhouse with an average temperature of 23/20^{o}C (day/night), and relative humidity of 48/83% v/v (day/night). At harvest, soybean shoots, roots and nodules were separated. Shoots, roots and nodules were oven-dried to a constant weight at 75^{o}C for 48 hours. The total nitrogen content in plant tissues was determined following the semi-micro Kjedahl procedure using a nitrogen analyzer (Kjedahl 2300; FOSS, Hoganas, Sweden). The phosphorous content was determined spectrophotometrically using the classic method. The effect of bacterial inoculation on nitrogen (N) and phosphorus (P) was determined under non saline and saline conditions. In general, the nitrogen content in soybean tended to increase in response to bacterial and salt treatments. The results showed that when soybean was inoculated with *B. japonicum* USDA 110 strain alone up to 25% of the amount of root N content, the amount of P in the root and shoot the amount of N and P content increased to 20% compared to control. When the symbiont *B. japonicum* USDA 110 was co-inoculated with *P. putida* NUU8, the nitrogen and phosphorus contents of soybean were as significantly increased compared to uninoculated. The increase in nodule P and N contents was significant for soybean grown in LN (Low Nitrogen) and LP (Low phosphorus) solutions and co-inoculated with *B. japonicum* USDA 110 and *P. putida* NUU8 compared that plants inoculated with *B. japonicum* USDA 110 alone. According to the analysis of the results obtained, giving a soybean processing plant B.japonicumUSDA110 food nutrition has improved compared to the control elements of the shadows. Especially soybean plants co-inoculated with *B. japonicum* USDA 110 and *P. putida* NUU8 strains N, P nutrients were found to be relatively high.

Lactic Acid Bacteria Reduce *salmonella* Javiana-Induced Epithelial Cell Cytotoxicity and Decrease Pathogen Virulence Gene Expression

Author Block:

L. Gileau, D. Fletcher, R. Camire, S. Goudreau, K. Burkholder; Univ. of New England, Biddeford, ME

Abstract Body:

Salmonella enterica is a foodborne bacterial pathogen that causes severe gastrointestinal infections. An emerging strain of *Salmonella enterica*, *S.* enterica Javiana, has recently surfaced as a leading cause of deadly Salmonellosis, but little is known of mechanisms by which *S.* Javiana interacts with host cells, or of potential methods for ameliorating the bacterial-host interaction. Using the mucus-producing HT29-MTX human intestinal epithelial cell line, we examined the adhesion, invasion and cytotoxic effect of *S.* Javiana on host cells. We also evaluated the potential inhibitory effect of probiotic lactic acid bacteria (LAB), including *Lactobacillus acidophilus*, *Lactobacillus rhamnosus*, *Lactobacillus casei*, *Lactobacillus plantarum* and *Lactobacillus mesenteroides*, on *S.* Javiana-induced infection. Using adhesion, invasion and lactate dehydrogenase release assays, we observed that *S.* Javiana exhibits modest adhesion and invasion, but has a strong cytotoxic effect on intestinal epithelial cells. When host cells were pre-treated with *L. rhamnosus*, *L. acidophilus* or *L. casei* prior to infection, *S.* Javiana-induced cytotoxicity was significantly reduced. We further sought to determine the mechanism by which the LAB decreased *S.* Javiana-induced cytotoxicity, and found that none of the LAB tested affected *S.* Javiana viability, or *S.* Javiana adhesion to or invasion of host cells. However, *S.* Javiana exposed to *L. acidophilus* and *L. rhamnosus* did exhibit decreased expression of toxin genes *pltA* and *cdtB*, as well as the gene *invA*, which facilitiates toxin secretion via a Type III Secretion System. Data suggest that *L. acidophilus* and *L. rhamnosus* might be useful if taken as prophylactics to reduce incidence or severity of *S.* Javiana Salmonellosis, and that these probiotics may work by preventing *S.* Javiana from secreting key toxins that would otherwise damage host intestinal cells.

Inflammasome Activation of Macrophages Co-Infected with *Mycobacterium tuberculosis* and HIV-1

Author Block:

M. B. Huante[1], R. J. Nusbaum[1], V. Calderon[2], P. Sutjita[1], J. K. Actor[3], J. Aronson[1], R. L. Hunter[3], J. J. Endsley[1]; [1]The Univ. of Texas Med. Branch, Galveston, TX, [2]The Univ. of Texas El Paso, El Paso, TX, [3]The Univ. of Texas Hlth.Sci. Ctr., Houston, TX

Abstract Body:

Mycobacterium tuberculosis (*M.tb*), the etiological agent of tuberculosis (TB), is the leading cause of death in people living with Human Immunodeficiency Virus (HIV). Treatment of co-infected persons is challenging due to the aggressive course of both individual diseases, and often is further complicated by drug interaction and malabsorption issues when combining antiretroviral treatment and TB chemotherapy. The molecular basis for pathogen synergy that leads to an aggressive course of TB in those with HIV-1 infection, however, is poorly defined. This is especially true at earlier stages of disease prior to the immune suppression that occurs due to $CD4^+$T cell loss. Using our newly developed humanized mouse model of TB/HIV co-infection, we find that initial acute co-infection in the lung is characterized by excessive inflammation. We observed greater pathology, inflammatory influx, and increased pro-inflammatory cytokines (e.g. IL-1β, TNFα) in co-infected HuMouse lung. Using primary human monocyte-derived macrophages (MDM) and an *in vitro* co-infection system, we further observed greater cell death and increased expression of pro-inflammatory cytokines in co-infected MDMs compared to mono-infection with either HIV-1 or *M.tb*. Analysis of cellular lysates demonstrates that increased caspase-1 activation due to HIV, and increased production of pro-IL-1β due to *M.tb*, may promote the overall increase in active IL-1β and cell death observed in co-infected MDMs. These studies suggest that convergence of pathogen pattern recognition signaling in macrophages may promote an exacerbated pro-inflammatory response and tissue damage in the *M.tb*/HIV co-infected lung.

Role of Systemic Inflammation in Hiv, Tb and Hiv Tb Co Infected Individuals

Author Block:

S. N. Shaukat[1], E. Eugenin[2], S. Kazmi[1]; [1]karachi uni, Karachi, Pakistan, [2]PHRI, NJ, NJ

Abstract Body:

The dysregulation of T-helper 1 and T-helper 2 immune subsets is a feature of TB/HIV co-infection. The geographic and immune overlapping effects of *M.tb* and HIV enable both pathogens to spread and synergize the pathogenesis of both organisms. *M.tb* is confined by Type 1 immune responses, mainly IFN-γ, whereas, HIV infection drives the immune shift to Type 2 responses such as IL-10 & 1L-4. Several studies have shown the predominant occurrence of signature cytokines in the context of *M.tb* and HIV infection, however, the comprehensive assessment of cytokines pool remain uncharacterized, particularly in the co-infection of *M.tb* & HIV. Therefore, in order to understand theTH1 & TH2 immune profile in the microenvironment of TB /HIV, we have performed a detailed transcriptomic analysis of various TH1 & TH2 inflammatory cytokines. Messenger RNA was obtained from PBMCs of infected individuals i.e. 31 TB patients, 44 HIV-1 Patients, 16 TB/HIV-1 co-infected individuals and 25 uninfected healthy controls. After screening the RNA quality, an appropriate amount of RNA was transcribed into cDNA. Gene arrays were customized with 84 immune markers related to TH1 & TH2 subsets. Sequentially, RT2 profiler PCR array was carried out on total of 60cDNA samples. Significantly, more than 2 fold up regulated (TH1) genes are IL-27 (3.5) & IL-12 (7.8) in monoinfection of TB & HIV respectively. In contrast, the significant down regulated genes are CXCR3 (-7.6) & CD 28 (-2.5) in TB, whereas CCR2 (-2.02) in co-infected group. In TH2 profile, the significant 2 folds down modulation was seen in IL4, IL-24 in HIV/TB group, 1L-24 in HIV group & IL-24, PTGDR2 in TB group, whereas IL-10, showed significant up-regulation(4.4) only in HIV group. Similarly, 2 folds enhancement in gene expression was also noted in CD4 Cell markers such as CTLA4 (HIV) & LAG 3 (HIV& HIV/TB) while CD40 (-1.8) was found to be under expressed only in HIV/TB group. Most notably, the combine effects of down modulation of CCR2, CD40 & over expression of LAG 3 indicate high level of immune inhibition in co-infected (HIV/TB) group. In addition, IL-27 partially, and IL24 predominantly recognized as common immune modulator in our study. Therefore, we conclude that cumulative role of IL-24 in TB, HIV and its co-infection, suggests a unique perspective to further investigate IL-24 marker as therapeutic target in the management of HIV/TB co-infection..

Release of Invasive *Streptococcus pneumoniae* Is Stimulated by *Staphylococcus aureus* Biofilms on Human Pharyngeal Cells

Author Block:

G. L. Matzkin, F. Khan, F. Sakai, **J. E. Vidal**; Emory Univ., Atlanta, GA

Abstract Body:

Background: *Streptococcus pneumoniae* (Spn) and *Staphylococcus aureus* (Sau) colonize the human nasopharynx during early childhood forming bacterial aggregates often referred as biofilm structures. Epidemiological studies from my laboratory, and others, demonstrate a negative association between Spn and Sau when colonizing the nasopharynx of healthy children. In vitro studies have shown that planktonic cultures of Spn kills planktonic Sau cells which provided an explanation for the observed effect. However, lysis of Sau by Spn has not been characterized in colonizing (biofilms) structures. In this work colonization dynamics of mixtures of Spn and Sau, and release of planktonic (invasive) cells, was studied using life-like models. **Methods:** Biofilm mixtures containing Spn strain TIGR4 (serotype 4, vaccine type), or D39 (serotype 2, vaccine escape type), and Sau (Newman strain) were produced on polystyrene microplates, on immobilized human pharyngeal Detroit 562 cells, or in a biofilm bioreactor (biBio) mimicking conditions found in the human nasopharynx. Viable counts were obtained by dilution and plating, and confocal micrographs were obtained. **Results:** When biofilms were produced on polystyrene both Spn strains induced a reduction of Sau biofilms, 8 h post-inoculation, but only TIGR4 eradicated most Sau cells. Confocal microscopy images demonstrated that Spn D39, or TIGR4, was structurally linked to Sau cells while forming biofilm mixtures. Micrographs also confirmed reduction induced by D39 and almost complete eradication produced by TIGR4 8 h post-inoculation. On immobilized human pharyngeal cells, however, TIGR4 and D39 killed planktonic cells, as expected, but Sau biofilms were protected as no significant reduction of the Sau biomass was observed. Accordingly, experiments in the biBio showed similar Sau planktonic or biofilm cells when incubated with Spn for 8 or 24 h. Experiments revealed, however, a significant 6-fold increase (p=0.01) of released Spn planktonic cells when co-incubated with Sau (median, $3.2x10^6$ cfu/ml) in comparison to biBio chambers containing only Spn (median, $5.2x10^5$ cfu/ml). **Conclusion:** Our experiments demonstrate survival of Sau biofilms when co-incubated with Spn on human pharyngeal cells. Release of invasive Spn cells was stimulated by the presence of Sau in a life-like microenvironment.

Role of Alveolar Macrophages and Inflammatory Monocytes in *Streptococcus pneumoniae* (*spn*) Super Infection during an Influenza Co-Infection

Author Block:

M. Khan, M. E. Pichichero; Rochester Gen. Hosp., Rochester, NY

Abstract Body:

Background: *Spn*-Influenza lung coinfection is a major cause of global mortality. However, pulmonary mechanisms and the immune environment correlated with protection against influenza induced *Spn* pathogenesis remains largely enigmatic.**Methods:** We developed lung mono-infection (*Spn* strain 6A or PR8 Influenza) and co-infection (PR8-Spn) mouse models to study immune events in lung leading to resolving pneumonia or non-resolving pneumonia and bacteremia. Lung immunophenotyping was done to discern the differences in immune cell recruitment during mono Spn/PR8 or co-infection and lung homogenate was used to investigate cytokines and chemokines. To understand the role of recruited monocytes on CD4 T cell proliferation, monocytes from PR8 or control mice were FACS sorted and mixed with CFSE labeled naïve CD4 T cells in the presence CD3 antibody. To understand the role of alveolar macrophages in the restoration of lung anti-bacterial immunity during co-infection, PR8 infected mice were re-constituted with alveolar macrophages (FACS sorted) before pneumococcal infection.**Results:** We found that *Spn*/influenza co-infection depleted lung alveolar macrophages and simultaneously led to a robust recruitment of inflammatory monocytes that correlated with *Spn* invasiveness and bacteremia. Accumulation of monocytes was associated with increased vascularization and lung pathology. Re-constitution of influenza infected lungs with alveolar macrophages significantly reduced *Spn* invasiveness during co-infection. Pulmonary monocytic lymphopoesis during co-infection also correlated with increased levels of chemokines CCL-1, CCL-2, CCL-3, CCL-7 and CCL-9. Compared to control (un-infected) or *Spn* infected lungs, the levels of cytokines such as IL-1β, IL-6, MCP-1 and M-CSF were higher in PR8 infected lungs and *Spn* co-infection further increased their levels. However, TNF-alpha and IL-10 were the only two cytokines that were upregulated during co-infection.**Conclusions:** We conclude that inflammatory monocytes and alveolar macrophages in lung inversely correlate with susceptibility to *Spn* super infection during an influenza co-infection and a balance of these two immune subsets in lung is indispensable for protection against influenza induced *Spn* pathogenesis.

Morphological and Physiological Changes Induced by Contact-Dependent Interaction between *Candida albicans* and *Fusobacterium nucleatum*

Author Block:

B. Bor, L. Cen, M. Angello, W. Shi, **X. HE**; UCLA, Los Angeles, CA

Abstract Body:

Candida albicans and *Fusobacterium nucleatum* are two well-known oral commensal microbes with pathogenic potential that are involved in various oral polymicrobial infectious diseases. However, the biologically relevant interactions between these two clinically important microbes remain elusive. In a recent study, we demonstrated that *F. nucleatum* ATCC 23726 coaggregates with *C. albicans* SN152, a process mainly mediated by RadD and FLO9, two membrane proteins from *F. nucleatum* and *C. albicans*, respectively. This study was aimed at investigating the potential biological impact of this inter-kingdom interaction. We showed that *F. nucleatum* ATCC 23726 inhibits growth and hyphal morphogenesis of *C. albicans* SN152 in a contact-dependent manner. Further analysis revealed that the observed contact-depended inhibition of *Candida* hyphal morphogenesis is mediated via the membrane protein FLO9 in *C. albicans* and RadD in *F. nucleatum*, the same protein pair that is involved in facilitating physical attachment between these two microorganisms. Using mouse macrophage cell line as an *in vitro* model system, we demonstrated that *F. nucleatum*-induced inhibition of hyphal morphogenesis in *C. albicans* increased survival rate of *C. albicans* when exposed to RAW macrophage cells. Furthermore, *F. nucleatum* negatively impacted *C. albicans'* macrophage-killing capability; while yeast form of *C. albicans* repressed *F. nucleatum*-induced MCP-1 and TNFα production in the same macrophages. Our study suggested that by inhibiting each other's virulence, *C. albicans* and *F. nucleatum* might promote a commensal life-style to achieve long-term fitness within oral cavity. This finding could impact our understanding of inter-kingdom signaling communications and affect clinical treatment strategy.

***Vibrio cholerae In Vivo* Horizontal Gene Transfer and Antagonistic Attack to Neighboring Bacteria Cells Mediated by Cell-Cell Contact During Infection**

Author Block:

Y. Fu, B. T. Ho, J. J. Mekalanos; Harvard Med. Sch., Boston, MA

Abstract Body:

Vibrio cholerae, a gram-negative pathogenic organism, is the causative agent of the severe diarrheal disease cholera. Whether the success of the current (7^{th}) pandemic El Tor O1clade is driven by its improved environmental fitness or properties related to its interaction with the human host remains a poorly answered question. We have previously used transposon mutagenesis sequencing analysis (Tn-Seq) and competition assays to investigate *V. cholerae* El Tor C6706 strain intestinal colonization in the modified infant rabbit model. Several strong pieces of evidence that *V. cholerae* cell-cell competition occur *in vivo* are provided, including phenotypes related to the Type VI Secretion System (T6SS) activation *in vivo* and the intestinal colonization deficiency exhibited by multiple metabolic mutants was exacerbated by competing these mutants against the prototrophic parental strain. Because the T6SS is thought to deliver toxic effectors to neighboring cells only through direct cell-cell contact, we investigated whether plasmid-based DNA conjugation *in vivo* might be used to indirectly measure the extent of cell-cell contact in the rabbit model. We show that cell-cell contact occurs early during infection in the distal small intestine. We also provide evidence that *V. cholerae* can deploy its T6SS to attack neighboring cells within this microenvironment very early during the infection process. Our data also revealed that *in vivo* horizontal genes transfer can also occur by cell-cell contact mediated processes such as conjugation. Finally, we have observed that there are a limited number of intestinal niches suitable for initial colonization of *V. cholerae* and another enteric bacteria, EHEC *E. coli*. The infant rabbit animal model and assays we described in this work could be potentially be used for the development of probiotics and novel anti-virulence therapeutics that can be delivered by transmissible elements *in vivo*.

The Human Gut Microbiota Predicts Susceptibility to *Vibrio cholerae* Infection

Author Block:

F. S. Midani[1], A. A. Weil[2], F. Chowdhury[3], A. Khan[3], Y. Begum[3], R. Charles[2], S. B. Calderwood[2], E. T. Ryan[2], J. B. Harris[2], F. Qadri[3], R. Larocque[2], L. A. David[1]; [1]Duke Univ., Durham, NC, [2]Massachusetts Gen. Hosp., Boston, MA, [3]Intl. Ctr. for Diarrheal Disease Res., Bangladesh, Dhaka, Bangladesh

Abstract Body:

Susceptibility to *Vibrio cholerae* infections is known to be influenced by epidemiological factors of age, blood type, and pre-existing immunity. Yet, infection is likely also affected by microbial ecological forces, as *V. cholerae* must outcompete gut microbiota for resources and epithelial attachment sites. Here, we test whether gut microbiota composition predicts susceptibility to cholera infection within humans. We studied the gut microbiota of a cohort of 76 subjects from Dhaka, Bangladesh: 22 later developed infections and 54 remained uninfected. Using machine learning techniques, we identified a subset of operational taxonomic units (OTUs) that are predictive of human susceptibility to infection (cross-validated ROC with area of 0.72). Further analysis demonstrated that predictive bacterial taxa tend to be rare among susceptible individuals. In contrast, the gut microbiota of the unsusceptible cohort is distinguished by higher abundance of both rare and common subset of OTUs. These results suggest that cholera infection is associated with a gut microbiota that facilitates presence of rare gut bacterial taxa. This study also suggested interactions between select OTUs and *V. cholerae* that we have tested experimentally. We showed that growth of *V. cholerae* is enhanced in media conditioned with *Paracoccus aminovorans.* Finally, discriminatory OTUs may be associated with several epidemiological factors such as host diet, physiology, and immunity. These findings have implications for prophylactic measures for prevention and control of cholera infections.

Dynamic Interaction between Epiparasitic TM7x and Its Bacterial Host *A. odontolyticus*

Author Block:

B. Bor, X. He, L. Cen, W. Shi; UCLA, Los Angeles, CA

Abstract Body:

Recently, we characterized a unique and intimate association between two oral commensal bacterial species, a TM7 phylotype (TM7x) and *Actinomyces odontolyticus* subsp. *actinosynbacter* (XH001). TM7x is the first cultivated representative of the TM7 phylum. It is characterized as an obligate epibiotic parasite that lives on the surface of its basibiont, XH001. In the current study, the TM7x/XH001 interaction was further analyzed by investigating morphological and physiological changes during symbiotic growth. TM7x and its basibiont XH001 were cultivated under various gas and nutrient conditions to determine the optimal and stressed growth conditions. The morphological changes in TM7x and XH001 were analyzed by FISH fluorescence microscopy, phase contrast microscopy, and SEM. Stress response in XH001 induced by environmental changes as well as TM7x association was determined by targeted qRT-PCR. XH001 cells manifested as short rods in monoculture, but displayed elongated and hyphal morphology when physically associated with TM7x. These morphological changes in XH001 were also induced by depletion of oxygen in the absence of TM7x. Both the physical association with TM7x and oxygen depletion triggered up-regulation of key stress response genes in XH001. Under nutrient-replete conditions, TM7x and XH001 co-exist well with relatively uniform cell morphologies. However, upon nutrient depletion, TM7x-associated XH001 displayed a variety of cell morphologies, including swollen cell body, clubbed ends and even cell lysis; while a large portion of TM7x cells transformed from ultra-small cocci to larger filamentous cells. Our study demonstrates a highly dynamic interaction between epibiont TM7x and its basibiont XH001 in response to physical association as well as environmental cues, as reflected by their morphological and physiological changes during symbiotic growth. Our TM7x/XH001 pair provides an ideal model system to better understand this new type of inter-bacterial interaction.

Cross-Kingdom Interactions Between *C. albicans* and *S. oralis* Mediated by Bacterial and Fungal Glucan Synthases

Author Block:

M. Bertolini[1], H. Xu[1], T. Sobue[1], A. Thompson[1], J. Mansfield[2], M. Vickerman[2], A. Dongari-Bagtzoglou[1]; [1]Univ. of Connecticut Hlth.Ctr., Farmington, CT, [2]Univ. at Buffalo, Buffalo, NY

Abstract Body:

The commensal *Streptococcus oralis* interacts with the opportunistic pathogen *Candida albicans* to form complex biofilm communities on the oroesophageal mucosa, promoting disseminated infection and exacerbating host inflammatory responses. However the mechanisms of cross-kingdom interactions which lead to pathogenic biofilms remain to be elucidated. The objective was to explore the role of streptococcal α-glucans and fungal β-glucans in early or late mixed bacterial-fungal biofilm development. For this *C. albicans* reference strain and a heterozygous deletion mutant, with reduced β-1,3 glucan biofilm matrix biosynthetic capacity (*FKS1/fks1−*, kindly provided by Dr. D. Andes), were used. A *gtfR* deletion mutant in the *S. oralis* 34 strain background, that produces no α-glucans, was constructed by allelic replacement of an internal segment of *gtfR* with an aad9 gene encoding spectinomycin resistance. A complemented strain with a plasmid-borne *gtfR* gene, was used as control. Microorganisms were grown together in biofilms on poly-L-lysine coated chamber slides for 6 or 16 hours. In adhesion assays *C. albicans* was allowed to germinate for 6 hours on chamber slides and *S. oralis* was then added for additional incubation periods of up to 2h, followed by washing. Biofilm media consisted of RPMI, 10% FBS, 10%BHI. Immunofluorescence combined with FISH staining was used to simultaneously visualize both microorganisms. We found reduced co-aggregation interactions between *C. albicans* and the *gtfR* deletion mutant, compared to the parental and complemented S. oralis strains in both early (6h) and late (16h) biofilms, especially along hyphal filaments. Adhesion of the *gtfR* mutant on *C. albicans* hyphae was also diminished, compared to parental and complemented strains. The FKS1/*fks1* heterozygous *C. albicans* deletion mutant did not aggregate with the *S. oralis gtfR* deletion mutant, the parent or the complemented strain. Our data suggested that the biosynthetic enzymes for alpha 1,3 glucans in *S. oralis* and β-1,3-glucan in *C. albicans* strongly affect cross-kingdom interactions between the two organisms and enhance the adhesive interactions and aggregation of *S. oralis* on the hyphae surface.

No Evidence of Synergistic or Antagonistic Effects During Experimental Co-infection Between *Salmonella, Campylobacter* and Apec in Broiler Chickens

Author Block:

P. Wigley, Williams, N.J, Humphrey, S., Chaloner, G., Humphrey T.J., Lacharme Lora, L.; Univ. of Liverpool, Neston, United Kingdom

Abstract Body:

Background: *Campylobacter* and *Salmonella* are important foodborne zoonotic pathogens in poultry production. Recently Avian Pathogenic *Escherichia coli* (APEC) has emerged as an increasingly important pathogen of broiler chickens . A number of epidemiological studies in the UK have found an association between APEC and *Campylobacter*. Here we develop an experimental approach to determine how interactions between bacterial species in the chicken influence both disease and pathogen carriage . **Methods:** 80 Ross 308 broiler chickens were reared under biosecure conditions and divided into 8 groups of 10. At 22 days of age birds were infected by oral gavage with 5×10^6 CFU in a volume of 0.2ml in phosphate buffered saline (PBS) or mock infected with PBS alone Isolates used: *Salmonella enterica* serovar Typhimurium 4/74, *Campylobacter jejuni* M1 and an O78 Avian Pathogenic *Escherichia coli* isolate χ7122. 48h later birds were challenged with a secondary infection or mock infected . At 3d post secondary challenge, birds were killed. Heart, liver, spleen, lung and cecal samples taken aseptically. Bacterial load of *S.* Typhimurium, *C. jejuni* and APEC in these samples was determined on BG, mCCDA and EMB selective agar respectively. Birds were examined for any gross pathology and samples taken for histopathology.**Results:** Co-infection does not affect bacterial numbers in the liver, spleen or lungs. No bacteria were isolated from the heart samples. Numbers of *Salmonella* in the ceca were unaffected by APEC or *C. jejuni* co-infection, though numbers of *C. jejuni* were reduced by prior *S.* Typhimurium infection, though not statistically significant. No changes in pathology were observed in birds co-infected with two bacterial species over single infections.**Conclusions:** Experimental co-infection with two enteric bacterial species has little effect on the progression of either. Only *Salmonella* infection prior to C*ampylobacter* challenge appears to have any effect upon the numbers able to colonise the ceca, probably though a competitive exclusion effect in the same niche. Whilst field studies show an association between APEC and *C. jejuni*, there are more variables in a production environment that could impact on both host and pathogen such as stress that are absent in a controlled laboratory experiment.

***Streptococcus oralis* and *Candida albicans* Synergistically Activate μ-Calpain to Degrade E-cadherin from Oral Epithelial Junctions**

Author Block:

H. Xu, T. Sobue, M. Bertolini, A. Thompson, A. Dongari-Bagtzoglou; UConn Hlth.Ctr., Farmington, CT

Abstract Body:

Background: *Streptococcus oralis*, an oral commensal found in the majority of healthy humans, forms a robust biofilm with *Candida albicans*. Studies have shown that when both organisms form a biofilm on the oral mucosa, fungal invasion and PMN infiltration are exaggerated, which may be enhanced by epithelial cell junction dissolution.To investigate whether co-infection with *S. oralis* and *C. albicans* affects mucosal cell junctions and dissect related mechanisms.**Methods:**Organotypic mucosal constructs and a mouse model were used for infection with *C. albicans* and *S. oralis* 34. qPCR was performed for gene expression analysis. Immunofluorescence and FISH staining were used to visualize junction proteins and microorganisms. ELISA is to quantify soluble E-cadherin and western blots to detect E-cadherin and calpain proteins. A fluorogenic assay was performed to measure calpain activity. Data were analyzed for statistical differences using the Graph-Pad Prism® software. **Results:** Using organotypic mucosal constructs and a mouse model of co-infection, we demonstrated that in the presence of *S. oralis* 34, *C. albicans* penetrated through oral epithelial intercellular junctions, while E-cadherin protein levels were reduced. We also showed that *C. albicans* SC5314 and *S. oralis* 34 decreased E-cadherin protein levels in oral epithelial cell lysates and increased soluble E-cadherin release, which was inhibited by a calpain activity inhibitor. Similarly, in the mouse oral co-infection model, reduced E-cadherin protein levels in tongue tissues were accompanied by increased levels of μ-calpain protein, increased fungal invasion in the oral mucosa and kidney dissemination. To directly rule out involvement of fungal secreted aspartyl proteases (sap) 4, 5 and 6 in this process a *sap456* triple mutant was tested. Co-infection of *the* mutant with *S. oralis*34 increased μ-calpain protein levels in organotypic mucosal constructs and triggered fungal invasion into the mucosal layer. There were similar findings were in mice infected with the *sap456* mutant where *S. oralis* 34 triggered increased calpain expression and fungal kidney dissemination. **Conclusions:** *C. albicans* and *S. oralis* synergize to activate host enzymes that cleave tight junction proteins. This may play a role in fungal mucosal invasion and systemic dissemination.

Metabolite Exchange Drives Antimicrobial Activity of *Pseudomonas aeruginosa* against *Staphylococcus aureus*

Author Block:

A. T. Nguyen, J. W. Jones, M. A. Kane, A. G. Oglesby-Sherrouse; Univ. of Maryland, Baltimore, Baltimore, MD

Abstract Body:

Pseudomonas aeruginosa is a Gram negative opportunistic pathogen that affects people with compromised immune systems, such as cystic fibrosis (CF) patients. Early infection of the CF lung with *Staphylococcus aureus* is common, while infection with *P. aeruginosa* occurs as disease progresses. This shift in microbial population is associated with increased exacerbation and a decline in pulmonary function. Emergence of *P. aeruginosa* as the dominant CF lung pathogen is likely multifactorial, and includes the production and secretion of 2-alkyl-4-(*1H*)-quinolones (AQs), which have antimicrobial activity against *S. aureus*. We recently showed that AQ-dependent antimicrobial activity against *S. aureus* is enhanced by depletion of iron, an essential and limiting nutrient in the CF lung. We hypothesize that iron-regulated antimicrobial activity against *S. aureus* allows *P. aeruginosa* to outcompete *S. aureus* in iron limiting environments. Here we show that iron-regulated antimicrobial activity is observed in numerous laboratory strains and CF isolates of *P. aeruginosa,* including strains that do not produce AQs in mono-culture. We previously found that co-culture with *S. aureus* can restore AQ production to *P. aeruginosa* strains that are deficient for AQ production in mono-culture. We show here that precursors in the AQ metabolic pathway restore AQ production to these strains in a manner similar to co-culture with *S. aureus,* suggesting a metabolic exchange between these two species in polymicrobial environments. This work demonstrates the importance of considering how virulence traits exhibited by bacteria in pure culture may be altered in polymicrobial environments that are relevant to human disease.

Nasopharyngeal Colonization with *Streptococcus pneumoniae* Exacerbates Pneumonia Following Influenza Virus Infection in a Mouse Model

Author Block:

S. Kimura[1], K. Mimura[1], M. A. Schaller[2], Y. Ishii[1], S. L. Kunkel[2], K. Tateda[1]; [1]Toho Univ. Sch. of Med., Tokyo, Japan, [2]Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Secondary bacterial infections after influenza virus are an important cause of morbidity and mortality worldwide. It is considered that these bacteria infected in lung endogenously derived from nasopharyngeal colonization with bacteria in patients. However, the most common mouse model of secondary bacterial infection has been infected with *S. pneumoniae* exogenously after influenza virus infection. In this study, we constructed and analyzed by using mouse colonized with *S. pneumoniae* in nasopharynx. **Methods:** C57BL/6J mice (Charles River Laboratories Japan) were used in this study. For colonization model with *S. pneumoniae* (ATCC 6303), a 10-µL bacterial suspension (2.0 x 10^5 CFU/mouse) was intranasally administered to anesthetized mice by slow delivery over several minutes. These mice were intranasally challenged with influenza A virus (A/PR/8/34, 10^3 PFU/mouse) 7 days after colonization. Whole lungs were homogenized in 1.0 mL of saline using a tissue homogenyizer. Nasal passages were washed with 400 µL of saline. Serial dilutions of the lung homogenates and nasal washes were plated on 5% sheep blood agar plate. Cytokine/chemokine production in the lung was evaluated by quantitative RT-PCR.**Results:** Nasally colonized mice consistently harbored 10^4 to 10^5 CFU of bacteria within the nasal cavity throughout day 28 post colonization. Under this condition, drastic decreases in survival were observed in *S. pneumoniae*-colonized mice infected with influenza A virus, whereas no mortality was observed in *S. pneumoniae*-colonized mice with saline or influenza A virus infected mice ($P<0.001$). On the 5 days post influenza A virus infection, bacteria was detected in lung (10^8 CFU) in *S. pneumoniae*-colonized mice. However, no bacterial burden was observed in lung in *S. pneumoniae*-colonized mice treated with saline instead of influenza A virus.**Conclusions:** We successfully constructed secondary pneumonia mouse model after influenza A virus infection by using mouse colonized with *S. pneumoniae* in nasopharynx. This model may provide a clinically acceptable approach for pneumonia derived from nasopharyngeal colonization with bacteria and also may be useful for evaluating mechanisms of secondary bacterial infection.

Efg1 Regulates Interactions Between *C. Albicans* and *S. Oralis* in Mucosal Polymicrobial Infection Models

Author Block:

T. Sobue[1], H. Xu[1], M. Bertolini[1], A. Thompson[1], C. J. Nobile[2], A. Dongari-Bagtzoglou[1]; [1]UCONN Hlth., Farmington, CT, [2]UC Merced, Merced, CA

Abstract Body:

Background: *C. albicans* and *S. oralis* are oral commensal organisms, which form hypervirulent polymicrobial biofilms in oropharyngeal mucosal infection, characterized by increased fungal mucosal invasion and dissemination. *C. albicans* biofilm formation is controlled by 6 master transcription regulators: Bcr1, Brg1, Efg1, Tec1, Ndt80, and Rob1. The objective of this work was to identify the biofilm regulators involved in the invasive response of *C. albicans* to *S. oralis* and the downstream genes under control of this regulators. **Methods:** *C. albicans* wild type, *BCR1*, *BRG1*, *EFG1*, *TEC1*, *NDT80*, and *ROB1* deletion mutants and revertants strains were used for biofilm growth with *S. oralis*. Biofilm interactions with these strains were initially examined on plastic wells. Organotypic mucosal constructs and a mouse model of oropharyngeal infection were used to further analyze biofilm growth, *C. albicans* gene expression and fungal invasion. Data were analyzed for statistical differences using Graph-Pad Prism® software. **Results:** By screening the 6 *C. albicans* biofilm transcription regulator reporter strains in biofilms growing on plastic we identified *EFG1* as a regulator strongly activated by interaction with *S. oralis* in late biofilms. None of the biofilm regulators were activated by *S. oralis* in early biofilms. Real time qRT-PCR showed that *EFG1* gene expression was increased in polymicrobial biofilms after 24h growth on abiotic surfaces and mucosal constructs. None of the other regulators were upregulated in response to *S. oralis*. These findings were confirmed in a mixed infection model where expression of *EFG1* was increased at days 5 and 6 post-infection. The *EFG1* gene was required for the induction of a more invasive phenotype in *C. albicans* by *S. oralis*, since invasion of mucosal constructs was enhanced in the *EFG1*-revertant strain but not the *efg1* deletion mutant. We also found that *ALS1* gene expression was increased by *S. oralis* in the *EFG1*-revertant strain but not the *efg1* mutant strain in mucosal biofilms. **Conclusion:** We conclude that *S. oralis* modulates *C. albicans* virulence by increasing *EFG1* expression in late stages of biofilm growth. This, in conjunction with upregulation of downstream adhesions such as *ALS1*, is responsible for the increased fungal mucosal invasion phenotype in the presence of *S. oralis*.

Targeted Therapies are Effective at Preventing Polymicrobial Pneumonia

Author Block:

J. J. Hilliard, O. Jones-Nelson, C. Stover, B. R. Sellman; MedImmune, Gaithersburg, MD

Abstract Body:

Background: *S. aureus* (Sa) is frequently present with Gram-negative organisms in polymicrobial lung infections. The potential interplay between these opportunistic bacteria is of interest for developing strategies to prevent or treat serious drug-resistant infections. We therefore investigated the effect *S. aureus* has on infection with Gram-negative opportunists in a co-infection model. The protective capacity of pathogen specific antibodies was also explored in this context..**Methods:** : Mice were challenged intranasally with a sub-lethal dose of *Sa* along with *P. aeruginosa* (*Pa*), *A. baumannii* (*Ab*) or *K. pneumoniae* (*Kp*). Post-challenge survival and bacterial lung burdens were monitored and compared to mice infected with a single pathogen. Additionally, survival and bacterial CFU in the lungs were assessed in mice passively immunized with pathogen specific antibodies relative to an isotype control. **Results:**Intranasal co-infection with a sub-lethal dose of *Sa* with *Pa*, *Kp* or *Ab* resulted in dramatically increased proliferation ($p<0.002$) of the Gram-negative pathogen and reduced survival ($p<0.0001$) of the mice relative to infection with the individual bacteria. Although the co-infection did not increase *Sa* proliferation, it did reduce the rate of *Sa* clearance in the lung ($p<0.0001$). Additionally, prophylaxis with a pathogen-specific antibody protected from death ($p<0.0001$) and significantly reduced *Pa* ($p=0.002$), *Kp* ($p=0.005$) or *Ab* ($p=0.001$) in the lungs of co-infected mice.**Conclusions:** *Sa* and Gram-negative co-infection resulted in enhanced disease and increased proliferation of the Gram-negative pathogen in this model. Targeting *Sa* or the Gram-negative bacteria in a mixed infection afforded protection and reduced the bacterial burden of *Pa*, *Kp* and *Ab*. These findings suggest that co-colonization or co-infection with *Sa* may potentiate or increase the risk of Gram-negative pneumonia and that a pathogen-specific prophylactic or treatment approach targeting *Sa* or the Gram-negative organism may prevent or limit the severity of mixed infection.

Delineating the Role of Enhanced Urease Activity in Tissue Damage and Bacteremia During Polymicrobial Urinary Tract Infection

Author Block:

C. E. Armbruster, S. N. Smith, K. Eaton, V. S. DeOrnelles, H. L. T. Mobley; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

Catheter-associated urinary tract infections (CAUTIs) are among the most common healthcare-associated infections and are frequently polymicrobial, yet few studies experimentally address the consequences of polymicrobial infection. *Proteus mirabilis* and *Providencia stuartii* are two urease-positive uropathogens that co-colonize catheters, and infection with either can result in urinary stones (urolithiasis) and potentially bacteremia. We previously observed that coinfection in a murine model of urinary tract infection results in an increased incidence of urolithiasis, tissue damage, and bacteremia, without a corresponding increase in the total bacterial burden within the urinary tract. We also observed enhanced total urease activity during co-culture of *P. mirabilis* and *P. stuartii*, which requires production of catalytically active urease from *P. mirabilis*, but not *P. stuartii*. Our present work utilizes *P. mirabilis* and *P. stuartii* urease mutants to define the role of enhanced urease activity in the pathogenesis of polymicrobial urinary tract infection, and to unmask additional virulence factors that contribute to infection severity. Mice were transurethrally inoculated with *P. mirabilis* HI4320 and *P. stuartii* BE2467 or their respective urease mutants, and urine pH was measured at 6, 24, 48, 72, and 96 hours post infection. Mice coinfected with the parental isolates exhibited the highest pH values, mice coinfected with *P. mirabilis ureF* and the parental *P. stuartii* isolate exhibited lower urine pH values, and mice coinfected with *P. stuartii ure*$^{-}$ and the parental *P. mirabilis* isolate exhibited intermediate values, indicating that enhanced urease activity occurs during experimental coinfection and requires urease activity from *P. mirabilis* but not *P. stuartii*. Similarly, *P. stuartii* urease was not required for development of urinary stones, tissue damage, and dissemination to the bloodstream during coinfeciton. Together, these data indicate that *P. stuartii* urease is dispensable for development of the severe consequences of experimental coinfection. Ongoing work focuses on the molecular mechanism of enhanced urease activity and identifying additional virulence factors that contribute to coinfection severity.

***Pseudomonas aeruginosa* Benefits from Respiratory Viral Infection in Cystic Fibrosis**

Author Block:

J. A. Melvin, M. R. Hendricks, J. M. Bomberger; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Chronic *Pseudomonas aeruginosa* infection is the primary cause of morbidity and mortality in cystic fibrosis (CF) patients. *P. aeruginosa* enters a biofilm mode of growth during interaction with the CF lung, which displays vastly increased resistance to clearance by the immune system and antimicrobials. Clinical studies have found a correlation between respiratory viral infection and pulmonary colonization with *P. aeruginosa*, though the mechanism underlying this phenomenon is unknown. Using a unique model of the initial interaction of *P. aeruginosa* with respiratory epithelium, we have demonstrated that respiratory viral infection of airway epithelium stimulates rapid biofilm biogenesis by *P. aeruginosa*, providing a potential mechanism by which respiratory viral infection supports establishment of *P. aeruginosa* infection. Unexpectedly, the primary source of the biofilm stimulatory effect is extracellular vesicles secreted by the airway epithelium during viral infection. We are investigating the mechanism by which *P. aeruginosa* is able to take advantage of the pulmonary environment following viral infection, characterizing the nature of biofilms produced during viral co-infection, and defining the interaction of *P. aeruginosa* with the extracellular vesicles secreted by the airway epithelium. Preliminary data suggest that *P. aeruginosa* utilizes multiple iron uptake pathways to scavenge increased iron in apical secretions from airway epithelial cells and alters its metabolism to adapt to the conditions created by the viral co-infection. The results of these studies will aid in the development of novel therapeutic agents and treatment strategies to prevent and clear chronic *P. aeruginosa* infections in CF patients.

The Role of *S. aureus* in Establishment and Maintenance of *P. aeruginosa* Biofilms in Cystic Fibrosis

Author Block:

T. W. Beaudoin, Y. Yau, V. Waters; Hosp. for Sick Children, Toronto, ON, Canada

Abstract Body:

Background: The primary cause of morbidity and mortality amongst CF patients arises from pulmonary inflammation secondary to bacterial infections. It is well documented that *Staphylococcus aureus* (SA) is the most common pathogen seen in young children with CF, and *Pseudomonas aeruginosa* (PA) transitions to become the predominant pathogen during young adulthood. This transition is associated with PA biofilm formation and phenotypic changes. It is unclear how bacterial interactions within the CF lung microbiome can affect this transition and influence antibiotic treatment.**Hypothesis and Aims**: We hypothesize that secreted bacterial products from SA will impact the formation and maintenance of PA biofilms. This study aims to determine the effects of SA on initial PA biofilm formation and maintenance of established biofilms with regards to antimicrobial resistance and phenotypic diversity.**Methods**: Multiple SA clinical isolates (n=10) were obtained from children with cystic fibrosis that uninfected with PA. Bacterial filtrates were derived during planktonic and biofilm growth by separation of secreted material from bacterial cells. Newly acquired PA isolates were used to represent initial acquisition and interaction with SA. The effects of filtrates on PA biofilms grown in a slide chamber were measured using confocal microscopy to visualize biofilm viability and thickness and CFU counts were performed.**Results**: The presence of most SA filtrates did not impact the formation of *P. aeruginosa* biofilms grown in a slide chamber as no difference in thickness or architecture was observed. However, the presence of SA filtrates led to increased aggregation in established PA biofilms, resulting in an average of 50% reduction in the thickness of the biofilm. Interestingly, PA biofilms grown in the presence of filtrates were more resistant to tobramycin killing (60% kill at 1000g/mL in media only, 30% kill in 10% filtrate). Additionally, we have identified a filtrate of SA obtained from one patient that is able to inhibit PA biofilm formation, in fact killing PA biofilms.**Conclusions:** Clinical SA strains can impact PA biofilm growth and its resistance to antibiotics. Thus, microbial interactions play a key role in bacterial susceptibility to antibiotics and impact patient treatment.

An *in Vitro* Model Of The Subgingival Microbiome

Author Block:

A. Hoare[1], P. D. Marsh[2], P. I. Diaz[1]; [1]Univ. of Connecticut Hlth.Ctr., Farmington, CT, [2]Univ. of Leeds, Leeds, United Kingdom

Abstract Body:

Background: Periodontitis is associated with shifts in microbiome composition characterized by a decrease in health-associated species and an increase in periodontitis-associated taxa, with a group known as "core species" remaining at a constant relative abundance. Considering the need to understand the nature of the interactions among these species during shifts, we developed batch and continuous culture subgingival community models under oral-like conditions, including prevalent species from the three groups. **Methods:** For the batch model, individual cultures were grown in appropriate media and normalized aliquots were inoculated in hog gastric mucin medium enriched with human serum and hemin. Community growth was monitored for 10 days by viable counts on selective media or via qPCR. Frozen inocula were used for the continuous culture model and two different chemostat protocols were tested: (i) one inoculation, dilution rate (D) of 0.1 h^{-1} (T_d= 6.7h), or (ii) three inoculations, D=0.046 h^{-1} (T_d=15h). Viable counts and qPCR were also used to monitor cultures, which reached steady-state after 15 generations. **Results:** A 6-species community formed by the health-associated and core species *Actinomyces oris*, *Veillonella parvula*, *Fusobacterium nucleatum*, *Streptococcus sanguinis*, *Rothia dentocariosa* and the periodontitis-associated *Porphyromonas gingivalis* was successfully grown in both models. In batch, health-associated and core species reached maximum biomass 1 day after inoculation. In contrast, *P. gingivalis* reached its maximum biomass at day 5 or 6. A comparison of the two chemostat protocols tested showed that health and core species were not affected by changes in D, reaching ~10^8 CFU/mL. In contrast, *P. gingivalis* yield was 10^4 cells/mL at D=0.046 h^{-1}, compared to ~10^7 cells/mL obtained at D=0.1 h^{-1}. **Conclusion:** We established a 6-species community model with some of the most prevalent subgingival species. Work is currently underway to increase the complexity of the inoculum to better resemble the diversity of the subgingival microbiome. This defined-inoculum model will allow the study of inter-species interactions and evaluation of the effect of environmental conditions on the community for a better understanding of microbiome shifts.

Amino Acid Labeling, Detection and Characterization of Respiratory Pathogens

Author Block:

K. Binder, S. Lucas, R. Hunter; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

The genetic disease cystic fibrosis (CF) is characterized by chronic polymicrobial lung infections, which have been implicated as the major cause of morbidity and mortality. However, there is relatively little known about how the bacterial community within the lung is causing severe disease. Previous studies characterizing the bacteria using 16S sequencing and metabolomics have been unable to find a trend that associates microbial activity with disease state. Conventional proteomics have also been unable to yield this information as it is difficult to detect microbial-derived proteins among the background noise of host derived proteins. Furthermore, these studies reveal little about the timing of protein synthesis. To examine the link between microbes and disease, in this study we used click chemistry to label newly synthesized proteins and identify metabolically active bacterial populations within sputum derived from CF patients.Sputum was obtained from patients during routine clinic visits, and subjected to labeling via bioorthogonal noncanonical amino acid tagging (BONCAT) during 1-hour incubations. Samples were then subjected to LC-MS/MS and fluorescence microscopy to identify proteins that were synthesized and bacteria that were translationally active immediately post-expectoration. In a subset of patients, we have been able to identify actively growing bacteria by their morphological characteristics. In particular, cocci and rod shaped bacteria have been identified which we propose are the species of *Porphyromonas* and *Streptococcus*. In addition, our preliminary data obtained from mass spectrometry has identified proteins from actively growing bacteria including the 50S ribosomal protein of *Staphylococcus aureus* and a hypothetical protein found in *Veillonella* spp., and we are currently using these techniques to follow patients through the course of their disease.Our findings suggest that BONCAT could be a crucial tool in understanding chronic respiratory infections. Using this technique, we are able to examine the proteomics of the community over a relatively short period of time such that specific activities can be linked to changes in disease, and ultimately can be used to help inform therapeutic strategies.

Differentiating Combinations of Microorganisms in Polymicrobial Bacteremia

Author Block:

A. Sato[1], I. Nakamura[1], T. Matsumoto[2]; [1]Tokyo Med. Univ. Hosp., Tokyo, Japan, [2]Tokyo Med. Univ., Tokyo, Japan

Abstract Body:

Background: We sometimes detect cases of polymicrobial bacteremia in blood culture. The objectives of our study were to describe the clinical characteristics of polymicrobial bacteremia and to determine which organs were affected according to the combination of bacteria.**Methods:** We retrospectively analyzed infectious diagnosis, combinations of microorganisms, and mortality of cases becoming bacteremia from January 1, 2012 to December 31, 2015 at Tokyo Medical University Hospital and Tokyo Medical University Hachioji Medical Center.**Results:** Of 44786 bottles, 5958 (13.3%) were positive and 473 (1.1%) (129 cases) were polymicrobial. One hundred and two (79.1%) patients had some sort of immunodeficiency disorder as an underling disease, such as malignancy (35.7%), diabetes mellitus (13.2%), or hematological malignancy (7.8%). Fifteen (11.6%) patients died within 7 days after the blood culture became positive, and 10 (66.7%) had Gram-positive cocci (GPCs). Among the 129 polymicrobial cases, the diagnosis of bacteremia was catheter-related bloodstream infection (CRBSI) in 34 (26.4%), complicated urinary tract infection (UTI) in 24 (18.6%), biliary tract infection (BTI) in 19 (14.8%), unknown focus in 15 (11.6%), and perforation of the digestive tract in nine (7.0%). Twenty-seven cases of CRBSI had GPCs and six cases of digestive tract perforation had anaerobic bacteria. There were 13 combinations of *Enterococcus* and Gram-negative rods (GNRs); six (46.2%) were in UTI and five (38.5%) in BTI. Of the 16 combinations containing GNRs, six (37.5%) each were in UTI and BTI. Of 10 cases containing *Candida*, 8 (80.0%) were CRBSI. **Conclusions:** Polymicrobial bacteremia was seen most frequently in patients with immunodeficiency. Combination of GPCs and *Candida* raises the possibility of CRBSI, and including GNRs in polymicrobial bacteremia, raises the possibility of UTI and BTI. It is possible to infer the diagnosis of infection by the combinations of microorganisms. Our results suggest a diagnostic aid in cases of polymicrobial bacteremia.

The Effects of Inhaled Aztreonam on the Cystic Fibrosis Lung Microbiome

Author Block:

A. Heirali[1], M. Workentine[1], N. Acosta[1], A. Nguyen[1], D. Storey[1], H. Rabin[1], R. Somayaji[1], F. Whelan[2], M. Surette[2], M. Parkins[1]; [1]Univ. of Calgary, Calgary, AB, Canada, [2]McMaster Univ., Hamilton, ON, Canada

Abstract Body:

Aztreonam lysine solution for inhalation (AZLI) is an inhaled antibiotic, cycled in a 28-day "on/off" fashion, used to treat chronic *Pseudomonas aeruginosa* (PA) infections in CF[1]. AZLI achieves high sputum concentrations which may extend its spectrum of activity to a wide range of organisms compared to its IV formulation [2]. We hypothesize that AZLI is active against a diverse number of organisms within the CF lung microbiome thereby exerting its clinical benefit. Accordingly, we sought to determine if the initiation of AZLI induced changes within the CF lung microbiome.The Calgary Adult CF Clinic prospectively collects and stores sputum samples from all patients. 24 patients with chronic PA who had ≥2 sputum samples collected within one year before and after initiation of AZLI were included. DNA was extracted from 162 sputum samples and the V3 region of the 16S rRNA gene was sequenced using Illumina MiSeq. Alpha-diversity measurements of species richness and evenness were determined using Shannon indices. Beta-diversity measurements were conducted using Bray-Curtis distance and visualized with principal coordinate analysis. Patients experiencing a median increase of 3% in lung function as measured by FEV_1 values after AZLI initiation were classified as responders. Differential abundance of OTU levels between responders and non-responders was calculated using the DESeq2 package in R.There was no significant difference in alpha and beta diversity measures before and after AZLI therapy indicating the microbiome was resilient to AZLI perturbation. However, changes were detected when the patients were on systemic antibacterial therapies. Patients classified as responders (14/24) had higher levels of *Pseudomonas* (p=1.0E-2), *Capnocytophaga* (p=2.3E-5), *Veillonella* (p=5.0E-3) and reduced levels of *Fusobacterium* (p=1.5E-19), *and Gemella* (p=9.0E-3) species.Significant changes in microbiome diversity were not induced following initiation of AZLI. However, certain microbiome constituents were associated with response to AZLI suggesting the microbiome may be linked to patient-treatment responsiveness. Analysis of the CF microbiome and its association with patient treatment response may enable personalization of CF chronic antibacterial therapies.

The *B. bronchiseptica* Type III Secretion System Does Not Negatively Affect the Protective Immunity Induced by Influenza A Virus Vaccines

Author Block:

T. L. Nicholson[1], A. L. Vincent[1], S. L. Brockmeier[1], D. S. Rajão[1], E. J. Abente[1], P. C. Gauger[2]; [1]Natl. Animal Disease Ctr., Agricultural Res. Service, USDA, Ames, IA, [2]Dept. of Vet. Diagnostic and Production Animal Med., Iowa State Univ., Ames, IA

Abstract Body:

B. bronchiseptica is a widely prevalent respiratory bacterial pathogen that infects a variety of wild and domesticated animals, including swine. Infection results in long-term colonization of the upper respiratory tract resulting in a range of clinical outcomes from asymptomatic carriage to lethal pneumonia. *B. bronchiseptica* expresses many virulence factors a type III secretion system (T3SS). The *B. bronchiseptica* T3SS is required for maximal disease severity and persistence throughout the lower swine respiratory tract. Additionally, the T3SS dampens the adaptive immune response by hindering the development of serum anti-*Bordetella* antibody levels and inducing an IL-10 response, enabling *B. bronchiseptica* to persistently colonize the respiratory tract. Influenza A virus (IAV) is an economically important zoonotic pathogen that causes an acute respiratory infection in swine and is considered a public health concern. Vaccination is the main strategy used to control and diminish disease burden. The hemagglutinin (HA) protein is the primary target of protective immune responses and the major component in swine (IAV) vaccines. Given the ability of the *B. bronchiseptica* T3SS to diminish adaptive immune responses, we hypothesized that T3SS would negatively affect the protective immunity in pigs vaccinated against IAV while concurrently colonized with *B. bronchiseptica*. To test this hypothesis, pigs were intranasally inoculated with a wild-type *B. bronchiseptica* strain or a T3SS *B. bronchiseptica* mutant. After 14 days, pigs were vaccinated against H3N2 as a live-attenuated influenza virus (LAIV) vaccine or as a whole inactivated virus (WIV) vaccine. To maximize the detection of any decrease in vaccine strain efficacy, pigs were subsequently challenged with a H3N2 strain from a separate antigenic cluster. No differences in clinical disease, virus titers, or lung lesions were observed among pigs colonized with wild-type *B. bronchiseptica* or the T3SS *B. bronchiseptica* mutant regardless of the vaccine platform used. Our results demonstrate that the *B. bronchiseptica* T3SS does not negatively affect the protective immunity induced by influenza A virus vaccines.

Partners In Crime: Enhanced Urease Activity During Co-Culture Of Bacterial Uropathogens

Author Block:

A. O. Johnson[1], C. E. Armbruster[1], S. N. Smith[1], A. Yep[2], V. S. DeOrnellas[1], H. L. T. Mobley[1]; [1]Univ. of Michigan, Ann Arbor, MI, [2]California Polytechnic State Univ., San Luis Obispo, CA

Abstract Body:

Catheter associated urinary tract infections (CAUTIs) are common health-care associated infections, which in some cases, progress to sepsis. These infections are often polymicrobial, with urealytic organisms being common culprits. These organisms increase urine pH, causing the formation of painful bladder or kidney stones, and an overall more severe infection. Previous studies have indicated that the urealytic bacteria, *Proteus mirabilis* and *Providencia stuartii*, frequently co-colonize, and experimental infections indicate that co-infection increases disease severity due to enhanced urease activity. We developed an *in vitro* assay to assess urease activity of co-cultures of at least 17 isolates of these bacterial species. Clinical isolates of *P. mirabilis* and *P. stuartii* were cultured in LB medium to mid-log phase. Cultures were centrifuged and the bacteria were resuspended in filter sterilized human urine (pH 6) and incubated either separately, or in a 50:50 mixture of both species. Urease activity was assessed at 30, 60 and 90 minutes. Our data show that increased urease activity occurs with many different isolates when co-cultured. Furthermore, using urease negative mutants of both bacterial species indicates that *P. mirabilis* urease is required to enhance overall activity, whereas *P. stuartii*'s urease is not required. Co-culture of *P. mirabilis* with additional CAUTI causing species such as *Klebsiella pneumoniae, Pseudomonas aeruginosa* and *Acinetobacter baumanii* also enhances activity, indicating that this is a broad phenomenon. Future work will assess enhanced urease activity involving co-cultures of additional species and define the mechanism responsible. As well, we will use this *in vitro* data to guide experimental infection studies. As neither *P. stuartii* nor *P. mirabilis* have "canonical" quorum sensing systems, our data may also uncover a novel form of microbe-microbe communication, in addition to increasing the understanding of mechanisms that influence the severity of polymicrobial infections.

Expression Pattern of Kir3ds1/ Kir3dl1 Gene Markers in HIV-1/Tb Co-Infection

Author Block:

F. Nasir[1], S. N. Shaukat[2], S. U. Kazmi[1]; [1]Dadabhoy Inst. of Higher Ed. - Karachi, Karachi, Pakistan, [2]Dept. of Microbiol.- Univ. of Karachi, Karachi, Pakistan

Abstract Body:

Natural Killer cells are the major arm of the early host defense system . NK has been well studied, due to its ability to act spontaneously in clearing the microbial infection as well as cancerous cells. The complex pathway of regulatory genes that are involved in the modulation of NK cells, are the potential investigating spot for researchers nowadays. Recently, the members of Killer cell immunoglobulin-like receptor (KIR) family has been evaluated in context with HIV infections and overall activity of NK cells are reported to be down regulated in HIV milieu. Altered expression of NK Cells is influenced by various activating and inhibitory receptors (KIR2DLI, KIR2DL2, KIR3DL1). Since, KIR3DS1 (activating receptor) and KIR3DL1 (inhibitory receptor) have interesting attributes in HIV -1 infection, whereas the utmost complication of HIV-1 infection is likely to be a co-infection state with Tuberculosis, we invetigated the expression pattern of these selected genes(KIR3DS1/ KIR3DL1) in HIV, TB and their co-infection settings. PBMCs were isolated from 44 HIV-1 infected individuals, 31 TB patients, 16 HIV-1/TB Co-infected patients and 25 uninfected healthy controls. RNA extraction was performed from PBMCs, followed by reverse transcription process into cDNA and finally, these cDNA samples were analyzed through RT-PCR. Fold changes were calculated using ▲▲CT method. Significantly, higher expression of inhibitory receptor (KIR3DL1) was observed in co- infected patients with fold regulation 2.7 (p=0.016), whereas in case of mono infection of HIV and TB, alike pattern of up-regulation was observed with 1.7 (p=0.29) and 1.6 (0.33) folds respectively, which is low compared to co-infection. In contrast the activating marker, KIR3DS1 was dramatically found to be down-regulated, particularly in HIV mono-infection cases (-240 fold regulation, p=0.17), followed by TB (-88 fold regulation, p=0.30) and HIV/TB co-infected cases (-56 fold regulation,p=0.54). Our findings indicate that enhanced expression of inhibitory receptor (KIR3DL1) may reflect impaired functional activity of NK cells particularly in co-infected (HV-1/TB) settings. Secondly, huge differences in the expression level of KIR3DS1 in TB and HIV-1alone, further state the importance of causative agents of infections in altering the NK response.

Publishing Title:

Role of Espfu in an O55:H7 Atypical Enteropathogenic *Escherichia coli* Strain

Author Block:

F. H. Martins, C. M. Abe, W. P. Elias; Inst. Butantan, Sao Paulo, Brazil

Abstract Body:

Atypical enteropathogenic *Escherichia coli* (aEPEC) is amongst the major etiological agent of diarrhea worldwide. The hallmark of aEPEC pathogenesis is the ability to induce attaching and effacing (A/E) lesions on intestinal epithelium. The proteins involved in A/E phenotype are encoded by a chromosomal pathogenicity island called locus of enterocyte effacement (LEE). In addition, non-LEE encoded proteins as EspFu may contribute to aEPEC pathogenesis, although this has not been extensively investigated. Thus, the aim of this study was to assess the role played by EspFu on aEPEC pathogenesis. For this purpose, an aEPEC strain (serotype O55:H7) and its isogenic *espFu* mutant were compared regarding the motility, interaction to cultured epithelial cells and intestinal colonization in a murine model. The deletion of the *espFu* gene did not affect the motility and adherence of aEPEC O55:H7, but impaired the ability to induce actin polymerization and pedestal formation on HeLa cells. Complementation with an EspFu-Myc-producing plasmid restored actin polymerization activity, indicating that the ability of aEPEC O55:H7 to promote A/E lesions is dependent of EspFu. Both wild type and *espFu* mutant strains established colonization in the intestine of streptomycin-treated mice. However, wild type strain showed higher efficiency than *espFu* mutant on colonization from 6 to 14 days post inoculation ($p<0.0001$), suggesting that EspFu is involved on the latest stages of this process. Together, these data suggest that EspFu protein contributes to relevant aspects of the aEPEC O55:H7 pathogenesis such as pedestal formation and late-stage intestinal colonization.

Induction and Signaling of the Immuno-regulatory Receptor B7-H1 in Oral Epithelial Cells

Author Block:

F. Jarzina[1], S. Gröger[1], U. Mamat[2], J. Meyle[1]; [1]Justus-Liebig-Univ. Giessen, Giessen, Germany, [2]Leibniz-Ctr., Borstel, Germany

Abstract Body:

Background: Up-regulation of the immuno-regulatory receptor B7-H1 on host cells may contribute to the deterioration of immune response which may promote the development of human cancers. Inflammation induces this receptor on normal epithelial cells that negatively regulate T-cell responses while tumor-associated expression of B7-H1 is associated with mechanisms of immune escape. *P. gingivalis* is known as one of the keystone pathogens in chronic periodontal infections and exhibits various virulence factors. The aim of this study was to investigate if bacterial protein fractions, e.g. membrane proteins, of *P. gingivalis* up-regulate B7-H1 on oral squamous cell carcinoma cells and primary human gingival keratinocytes and which signaling pathways may be involved. **Methods:** Squamous cell carcinoma cells (SCC-25) and primary human gingival keratinocytes (PHGK) were seeded (1 x 10^6 cells) in cell culture wells and infected with *P. gingivalis* W83 total, inner and outer membrane fractions, cytosolic proteins, as well as LPS and peptidoglycans. After 48h cells were harvested and prepared for Western blot and immuno-staining analysis. Up-regulation of B7-H1 RNA was analyzed using quantitative real time PCR.**Results:** It was demonstrated that the total membrane fraction induced the highest up-regulation in B7-H1 expression, 7-fold in SCC-25 cells and 3-fold in PHGK after 48h ($p<0.05$). The outer and inner membrane caused 3-fold induction in SCC-25 cells whereas cytosolic proteins and LPS caused no regulation of B7-H1. PD98059, an inhibitor of ERK, attenuated the *P. gingivalis* membrane induced B7-H1 expression. B7-H1 RNA in SCC-25 cells was up-regulated 10.3 fold by the total membrane fraction ($p < 0.01$), 7.5 fold by the inner membrane fraction and 6.5 fold by the outer membrane fraction ($p < 0.05$). In PHGK RNA was up-regulated 7.9 fold by the total membrane fraction ($p < 0.01$), 10.1 fold by the inner membrane (IM) and 5.3 fold by the outer membrane ($p < 0.05$).**Conclusions:** The results of this study demonstrate that the membrane fraction of *P. gingivalis* is responsible for up-regulation of B7-H1 in oral epithelial cells which may help to elucidate the possible role of the immunoregulatory B7-H1 in the immune evasion of this pathogen.This study was supported by a grant of the von Behring-Röntgen-Foundation

Neurological Tick-Borne Lyme Disease: Investigating the Role of a *Borrelia burgdorferi* Gene Important for Invasion of the Blood Brain Barrier

Author Block:

L. Hritzo[1], M. Lichay[2], A. Smith[3], X. Yang[3], V. Culotta[4], U. Pal[3], J. Dumler[5], D. Grab[2]; [1]Wheeling Jesuit Univ./Johns Hopkins SOM, Wheeling, WV, [2]Johns Hopkins SOM, Baltimore, MD, [3]Univ. of Maryland, College Park, MD, [4]Johns Hopkins Univ. Bloomberg Sch. of Publ. Hlth., Baltimore, MD, [5]Univ. of Maryland, Baltimore, MD

Abstract Body:

Lyme disease, caused by the spirochete *Borrelia burgdorferi* (*Bb*) that is transmitted by *Ixodes* species ticks, is the most common vector-borne illness in the United States and Europe. Newly revised estimates from the Center for Disease Control (CDC) suggest that there are likely to be over 300,000 new cases per year in the United States. The infection can be difficult to diagnose and a substantial fraction of untreated patients develop neurological complications known as neuroborreliosis, although how the spirochetes invade the brain and central nervous system remains enigmatic.Using an in-vitro model of the human blood brain barrier (BBB) of immortalized human brain endothelial cells (HBMEC), we compared gene expression of *Bb* both before and after their transmigration across the BBB. Of 92 *Bb* genes known to be expressed when interacting with mammalian cells, one gene, *lmp1*, displayed an average 41-fold increase in gene expression among the transmigrated spirochetes vs. those that did not.To confirm *lmp1's* role, wild type (WT) *Bb* (B31-A3 clonal strain), Δ*lmp1* mutants (KO) and in *Bb* KO in which *lmp1* was complemented, were compared for their ability to transmigrate across confluent HBMEC monolayers grown on Transwell inserts. Dark-field microscopy and quantitative polymerase chain reaction (qPCR) was used to assess spirochete number and viability after transmigration. Compared to WT, the Δ*lmp1 Bb* mutants showed a decreased HBMEC crossing phenotype, while complementing *lmp1* to the *Bb* Δ*lmp1* strain restored the WT *Bb* BBB crossing phenotype. In conclusion, these studies suggest a role for *Bb lmp1* as a virulence factor in neuroborreliosis.

Chlamydial Infection Alters Mhc Class I Antigen Presentation in a Human Lymphoblastoid Cell Line

Author Block:

A. Palmer, E. Cram, D. Rockey, B. Dolan; Oregon State Univ., Corvallis, OR

Abstract Body:

Incidences of chlamydial infection are increasing and although the current method of treatment is still effective, cases of tolerant infections are ongoing. As an obligate intracellular microbe, Chlamydia relies on host cell processes to complete its life cycle. Additionally, Chlamydia must evade the adaptive immune response of the host, specifically the cytotoxic $CD8^+$ T cell responses which eliminate cells infected with intracellular pathogens. The ability for Chlamydia to alter host MHC I antigen presentation is important for Chlamydia immune evasion, but the mechanism remains unknown. In this study, we investigated the ability of different species of Chlamydia to alter the presentation of self-peptides derived from a model protein. Additionally, we investigated how Chlamydia infection altered levels of poly-ubiquitinated proteins. An increase in peptide presentation was observed following infection, but interestingly, this increase in presentation only occurred when the peptide source was limited to host-derived Defective Ribosmal Products or DRiPs. Western blot analysis determined that poly-ubiquitin protein levels differed between mock and bacterial infection as well as levels of ubiquitin-like protein NEDD8 demonstrating perturbations to the ubiquitin proteasome system, an essential pathway for generating antigenic peptides coupled to MHC I molecules. The capability to alter host antigen presentation can potentially help Chlamydia subvert the immune system lending to the idea of a mechanism for tolerance. Ongoing experiments will identify candidate gene products secreted by Chlamydia during infection that can affect this host system in an effort to further understand chlamydial disease progression.

The Leptospiral Adhesion Lsa23 Inhibits the Lytic Activity of the Human Alternative & Its Classical Complement Pathways

Author Block:

A. L. Nascimento[1], G. Siqueira[1], S. Vasconcellos[2]; [1]Inst. Butantan, Sao Paulo, Brazil, [2]Univ.e de Sao paulo, Sao Paulo, Brazil

Abstract Body:

Background: Pathogenic *Leptospira* are the etiological agent of leptospirosis, a disease of human and veterinary concern. It has been previously described that pathogenic *Leptospira* are resistant to normal human serum (NHS) due to their ability to evade the complement immune system by interacting with factor H (FH) and C4- binding protein (C4BP) regulators. Moreover, plasmin generating on leptospiral surface diminishes C3b and IgG deposition, decreasing opsonophagocytosis by immune competent cells. We have earlier reported that Lsa23 (LIC11360) is capable of binding purified human FH, C4BP and plasminogen (PLG)/plasmin in the presence of PLG activators. We decided to assess the consequences of Lsa23 on the activity of complement system **Methods:** The effect of Lsa23 on classical pathway of complement was assessed by hemolytic assay using antibody-coated sheep erythrocytes, while the effect on alternative pathway was evaluated measuring the deposition of C5b9 on zymosan. Interaction with factor H (FH), C4BP and plasminogen was evaluated by ELISA. Cofactor activity of complement regulators and proteolytic activity of plasmin were assessed by immunoblotting. **Results:** We show that Lsa23 has the ability to acquire FH, C4BP and PLG from NHS. The binding with the complement regulators FH and C4BP preserve factor I (FI) activity, leading to C3b and C4b degradation products, respectively. C3b and C4b alpha chains cleavage were also observed when Lsa23 bound to PLG generate plasmin, an effect blocked by the protease inhibitor aprotinin. Lsa23 also inhibited lytic activity by NHS mediated by both classical and alternative pathways. Furthermore, NHS-treated with Lsa23 confers partial serum resistance phenotype to *L. biflexa*, whereas blocking this protein with anti-Lsa23 renders pathogenic *L. interrogans* more susceptible to complement mediated-killing. **Conclusions:** The reduction of C3b and C4b amount might obstruct MAC formation by classical and alternative pathways, as observed by hemolytic inhibition and decrease C5b-9 deposition, respectively. The complement-inhibitory activity mediated by plasmin bound to Lsa23 leading to C3b and C4b degradation offers an interesting strategy to understand how this resourceful pathogen uses PLG/plasmin to evade the host immune system.

Two Lytic Transglycosylases in *Neisseria gonorrhoeae* Impart Resistance to Killing by Lysozyme and Human Neutrophils

Author Block:

S. Ragland[1], R. Schaub[2], K. Hackett[2], J. Dillard[2], A. Criss[1]; [1]Univ. of Virginia, Charlottesville, VA, [2]Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Symptomatic infection by the obligate human pathogen *Neisseria gonorrhoeae* (Gc) induces a potent inflammatory response involving a neutrophil-rich exudate. Although neutrophils readily detect and kill microbes, a population of Gc resists neutrophil killing. Gc differs from most Gram-negative bacteria by releasing extracellular monomeric peptidoglycan (PG), which is dependent on the activity of two nonessential and nonredundant lytic transglycosylases (LTs), LtgA and LtgD. PG released by LtgA and LtgD is a pathogen-associated molecular pattern that stimulates immune responses, but LTs in other bacteria can contribute to envelope integrity. To test how PG turnover and monomer release affects Gc survival from neutrophils, we infected interleukin 8-treated, adherent primary human neutrophils with *ltgA ltgD* mutant Gc. In the presence of neutrophils, *ltgA ltgD* was significantly decreased in survival compared with the parent or double complement. Resistance to neutrophil killing required LT activity, but addition of PG monomer failed to rescue the survival of *ltgA ltgD*, indicating that LtgA and LtgD protect Gc from neutrophil killing independently of monomer release. We found two reasons for increased sensitivity of *ltgA ltgD* to neutrophils. First, *ltgA ltgD* was more sensitive to two neutrophil antimicrobial proteins, lysozyme and neutrophil elastase (NE). Lysozyme sensitivity was linked to decreased envelope integrity, shown by increased permeability to propidium iodide, increased extracellular ATP, and increased vancomycin sensitivity. Second, neutrophils exposed to *ltgA ltgD* had increased secondary and primary granule exocytosis by flow cytometry and increased secondary granule fusion to the Gc-containing phagosome by immunofluorescence. Notably, secondary granules contain lysozyme, and primary granules contain lysozyme and NE. We conclude that LtgA and LtgD protect Gc from lysozyme and neutrophils by maintaining membrane integrity and limiting neutrophil activation that could increase bacterial exposure to antimicrobials. This work underscores the importance of envelope integrity in Gc as a means to avoid neutrophil killing and adds to a growing literature linking bacterial degradation by lysozyme to increased immune activation.

Immune System Modification by *Salmonella typhimurium*

Author Block:

J. Geddes-McAlister, M. Mann, F. Meissner; Max Planck Inst. for Biochemistry, Martinsried, Germany

Abstract Body:

Background: Intracellular bacterial pathogens are capable of causing a diverse array of diseases in humans and represent a significant threat to global health. These pathogens have evolved sophisticated strategies to interfere with host cell functions and to perturb immune responses. Of major importance, are pathogen proteins termed virulence factors, which manipulate key molecular checkpoints and signaling pathways in host cells and provide the pathogen with a tailored advantage for survival within the host, making them a desirable area for investigation. Furthermore, the increased emergence of acquired antibiotic resistant strains of pathogenic bacteria has greatly increased the demand for the discovery of alternative drug targets.**Methods:** Here, we investigated immune system modifications by the gram negative, pathogenic bacteria, *Salmonella typhimurium*, in macrophage host cells. To provide a comprehensive view of the pathogen and host prior to infection, we performed intracellular proteome and secretome profiling of the *S. typhimurium* wild-type (SL1344) and type 3 secretion system (T3SS) mutant (dspi-1 and dspi-2) strains, and proteome profiling of the host macrophage cells. Next, we performed temporal proteomic profiling of the macrophage cells following co-culturing with *S. typhimurium* at 0.5, 1.0, 2.0, 6.0, and 24.0 hours post infection.**Results:** Bioinformatic analyses for post-translational modifications showed changes to host proteins and signal transduction pathways during infection. Our approach highlighted modifications of known host cell targets of the *S. typhimurium* T3SS, in addition to the identification of novel host cell targets. Furthermore, we report the first comprehensive proteomic profiling of the *S. typhimurium* wild-type and T3SS mutant strains, emphasizing the extensive role of the T3SS in the release of virulence factors and subsequent host infection.**Conclusion:** Overall, proteomic profiling of the host immune system during infection identified important pathogen-related modifications associated with the host defense response and highlighted an opportunity for novel target discoveries and for the development of innovative therapeutic agents to combat infection.

Molecular Interactions of Bacterial Tir Domain Proteins Tcpb and Tcpc with Human Adapter Proteins Tirap and Myd88

Author Block:

G. Snyder; Univ. of Maryland, Baltimore, Baltimore, MD

Abstract Body:

Microbial pathogens have evolved mechanisms to regulate and evade host responses. One mechanism involves the subversion of innate immune Toll/IL-1 receptor (TIR) signaling proteins by bacterial TIR mimics. Bacterial TIRs are thought to function by direct disruption of host TIR signaling pathways. For example, the TIR proteins TcpB from *Brucella and* TcpC from uropathogenic *E. coli* inhibit TIR signaling through direct interaction with host adapter TIR proteins TLR4, TIRAP and MyD88. We have previously reported the crystal structure of human MyD88 and characterized its interactions with TcpC for developing TcpC peptides capable to inhibit TLR4 and MyD88 signaling. We now report the X-ray crystal structure of *Brucella* TIR protein TcpB and characterize its interactions with TIRAP using hydrogen/deuterium (H/D) exchange mass spectrometry. The crystal structure of the TcpB reveals the BB loop microtubule-binding site as well as a symmetrical dimer involving the DD and EE loops. This interface is identifies a set of candidate TcpB blocking peptides. A comparison between the microbial TcpB, TIRAP and MyD88 crystal structures reveal differences in the region that encompasses the BB loop. These findings lend insight into the molecular mechanisms of microbial mimicry of human host signaling adapter proteins and provide a framework for identification and development of novel microbial based therapeutics.

Identification of *Klebsiella pneumoniae* Virulence Factors Necessary to Withstand Interactions with the Innate Immune System in the Lungs Using Tnseq

Author Block:

M. Paczosa, J. Mecsas; Tufts Univ., Boston, MA

Abstract Body:

K. pneumoniae is a leading cause of nosocomial diseases both in the USA and internationally, and causes a range of infections, including pneumonias, sepsis and UTIs. In order to identify virulence factors that *K. pneumoniae* uses to successfully infect the lungs of healthy hosts, as well as those needed to protect against neutrophils, we used TnSeq. Specifically, we screened an arrayed K. pneumoniae library consisting of ~13,000 transposon mutants through a lung infection model in both immunocompetent and neutrophil-depleted mice, and then used deep sequencing to quantify and compare the frequency of each mutant before and after infection of wildtype and neutropenic mice. Using this approach, we identified 151 genes required by K. pneumoniae to cause pneumonia in wildtype mice. Of these, 86 genes were specifically required to promote infection by *K. pneumoniae* in the presence of neutrophils. In order to confirm a number of these hits, we retrieved ~60 *K. pneumoniae* transposon insertions mutants from our ordered array and evaluated their fitness in this lung infection model. We also used this smaller library of transposon mutants to evaluate whether there is a role for these genes in *K. pneumoniae* growth in nutrient poor environments, protection against neutrophil effectors, such as hydrogen peroxide and nitric oxide, and non-specific immune effectors, such as complement. In summary, we found several distinct subsets of genes, where some genes are critical for *K. pneumoniae* infection regardless of the immune status of the host and others are critical for responding to specific bactericidal effectors of innate immunity.

Molecular Analysis of the Interaction of Leptospiral LigB and Tropoelastin

Author Block:

C-L. Hsieh, C. Ptak, E. Chang, R. Oswald, **Y. Chang**; Coll. of Veterianry medicine, Cornell Univ., Ithaca, NY 14850, Ithaca, NY

Abstract Body:

Leptospira deploy surface adhesins for host binding, the first step of bacterial infection and colonization. LigB, a surface adhesin, mediates leptospiral attachment to the host by binding to a number of extracellular matrix (ECM) components such as fibronectin and elastin. LigB contains 12 Ig-like domains arranged like a string of beads with certain flexibility extending from the pathogenic bacterial surface. Tropoelastin, the building block of elastin, confers resilience and elasticity to lung, blood vessels, uterus and other tissues. It has been shown that the terminal LigB Ig-like domain (LigB12) interacts with human tropoelastin (HTE). The ability of LigB12 to interact with HTE is likely to promote Leptospira adhesion to lung tissue, the main cause of pulmonary hemorrhage in cases of severe leptospirosis.The aim of this study is to develop a comprehensive understanding of the molecular details that contribute to the LigB12-HTE binding interface. Using truncated HTE constructs, we fine-mapped the LigB12 binding site on HTE by ELISA and characterized the binding kinetics of the LigB12-HTE interaction by surface plasmon resonance (SPR). A LigB12 binding site on HTE with a sub-micromolar binding affinity was identified on the N-terminal region of the 20th exon of HTE (HTE20N). Alanine mutants of specific basic and aromatic residues on HTE20N significantly reduced binding to the LigB12. The conformations of complexes of LigB12 with various HTE constructs were investigated using both small-angle X-ray scattering (SAXS) and nuclear magnetic resonance (NMR) spectroscopy. With the high-resolution solution NMR structure of LigB12 in hand, we plan to use NMR-based chemical shift perturbation experiments to further study the LigB12-HTE20N complex. We have begun to decipher the molecular details of the LigB12-HTE20N binding interface, which should expand our understanding of leptospiral pathogenesis and also assist in the future design of alternative therapeutics for leptospirosis.

HCV Proteins Modulate TLR8 Mediated NF-κB Signaling in THP-1 Cells

Author Block:

T-M. Lin[1], C-H. Huang[2], Y-Y. Hsu[3], H-L. Eng[3]; [1]E-DA Hosp./I-shou Univ., Kaohsiung, Taiwan, [2]Natl. Cheng Kung Univ., Tainan, Taiwan, [3]Kaohsiung Chang Gung Mem. Hosp. and Chang Gung Univ. Coll. of Med., Kaohsiung, Taiwan

Abstract Body:

Hepatitis C virus (HCV) infection is a worldwide threat to public health. Monocytic cells, key players in the immune response to infection, represent one possible site of HCV replication. Toll-like receptors (TLRs) play pivotal roles in the innate immune system, particularly, TLR8 that senses HCV ssRNA to initiate the production of a variety of nuclear factor (NF)-κB-mediated cytokines in monocytes. In our preliminary study, we demonstrated that monocytes of HCV infection patients produced higher TLR8 mRNA expression and increased four-fold IL-12p40 mRNA in response to CL075 stimulation. HCV might thus modulate TLR8 signaling in monocytes to induce inflammation and enhance liver damage. In the present study, the modulatory effects of HCV proteins on TLR8 mediated NF-kB signaling in THP-1 cells were investigated. Enhanced NF-κB activation was observed by HCV core protein, but suppressed by HCV E2 protein (115±17.5%, p=0.03 and 77±9.4%, p< 0.001; respectively) in THP1-XBlue cells (a human TLR reporter monocytic cell line expressing an NF-κB-inducible secreted embryonic alkaline phosphatase reporter gene), that transfected with plasmids of HCV proteins. However, after stimulation of the transfected cells with TLR8 agonists, 5 μM CL075, both HCV E1 and E2 proteins were able to enhance TLR8 induced NF-κB signaling (125±5.9%, p=0.002 and 131±9%, p=0.004; respectively). In contrast, TLR8 induced NF-κB signaling was down-regulated by HCV core, NS2 and NS4 proteins to 70±3.3%, 62±10.7%% and 68±10.5%, respectively (p< 0.001). Our results indicate that HCV proteins modulate TLR8 mediated NF-κB signaling in monocytes during HCV infection.

***Histophilus somni* Survives Within Bovine Macrophages Through Inhibition of Lysosome-Phagosome Fusion**

Author Block:

T. J. Inzana[1], Y. Pan[1], A. Champion[1], Y. Tagawa[2]; [1]Virginia Tech, Blacksburg, VA, [2]Natl. Inst. of Animal Hlth., NARO, Tsukuba, Japan

Abstract Body:

Background: *Histophilus somni* is a gram-negative bacterial pathogen of cattle that can survive within phagocytic cells. The fic motif within the IbpA surface protein is toxic for phagocytes, but it is not clear whether *H. somni* persists within phagocytic cells through an evasive mechanism or due to cell toxicity. Mutants with deletions in *ibpA* and following intracellular trafficking were used to determine the mechanism of *H. somni* intracellular survival.**Methods:** Disease and commensal isolates, and strains with mutations within *ibpA* were used with bovine peripheral blood monocytes and macrophage cell line BM to determine intracellular survival and trafficking following incubation of bacteria with phagocytic cells. Intracellular trafficking of bacteria was determined using confocal microscopy and Alexa Fluor 488 or 546-labelled monoclonal antibodies to early phagosome and late lysosomal markers. Phagosome acidification was determined using Lysotracker.Results: Incubation of *H. somni* strain 2336, and other IbpA-positive strains¸ with BM cells caused the cells to round up, but the bacteria survived within these cells for at least 72 h. In contrast, commensal strain 129Pt, and other IbpA-negative strains, were not toxic for macrophages and did not survive 24 h within BM cells. Transposon and allelic exchange mutants of strain 2336 containing mutations in *ibpA* outside the fic motif remained toxic for BM cells and survived intracellularly. However, mutants with the entire *ibpA* gene, or only the fic motif, deleted were no longer toxic for BM cells, but still survived intracellularly as well as the parent. Early phagosomal marker EEA-1 co-localized with both strains 2336 and 129Pt. However, strain 2336 prevented acidification of phagosomes and did not co-localize with late lysosomal marker LAMP-2 ($P<0.05$).**Conclusions:** *H. somni* strains expressing IbpA containing the fic motif were toxic to bovine macrophages and survived within these cells. Deletion of the fic motif from IbpA eliminated toxicity, but these mutants remained capable of surviving within macrophages. The failure of strain 2336 to co-localize with LAMP-2 and lack of phagosome acidification suggests that intracellular survival was in part due to prevention of phagosome-lysosome fusion, and that *H. somni* may be a permissive intracellular pathogen.

Recombinant Variant of *Fasciola hepatica* Fatty Acid Binding Protein Impairs the NF-κB Activation in Response to Toll-Like Receptors Agonists

Author Block:

M. J. Ramos-Benítez, C. Ruiz-Jimenez, A. M. Espino; Univ. of Puerto Rico - Med. Sci. Campus, San Juan, Puerto Rico

Abstract Body:

Background: In recent years, it has been demonstrated that a strong Th2 immune response is able to suppress the inflammatory type or Th1 response; this Th1 response is linked to septic shock and some autoimmune diseases. *Fasciola hepatica* modulates the host immune system by promoting a Th2 response during chronic infections, hence the production of anti-inflammatory and regulatory cytokines (1). Our research group demonstrated that fatty acid biding protein (FABP) purified in native form (Fh12) from *F. hepatica* adult worm impairs the inflammatory cytokines storm from macrophages typically induced by exposure to Lipopolysaccharides (LPS) (2). The current work aimed to determine whether a recombinant variant of FABP could have a similar anti-inflammatory effect than Fh12. **Methods:** We optimized the expression in *Escherichia Coli* of an isoform of FABP named Fh15. We also performed western blot analysis to confirm an immunological similarity between Fh12 and Fh15. Human monocytes cell line THP1-CD14 treated with Fh15 were stimulated separately with specific activation ligands for TLR 2, 4, 5 and 8 to determine the capacity of Fh15 to block the NF-κB activation in comparison to Fh12. We used Quanti-Blue medium to detect the inhibition. **Results:** Fh15 was purified with a high degree of purity. Western blot analysis using an anti-Fh12 antibody demonstrated that both proteins are immunologically similar. Also, that Fh15 was able to significantly block the NF-κB activation induced by specific TLR ligands in a dose dependent manner up to 95%. **Conclusions:** The results indicate that Fh15 exhibits similar capacity as Fh12 to suppress the NF-κB activation. The use of bacterial expression system lead us to conclude that the potential glycosylation sites described for Fh12 are not required for the effect. Based on these results we can anticipate that Fh15 has the potential to exhibit a strong capability of suppressing inflammatory cytokines, as proved for Fh12. Also, both proteins impairing the NF-κB activation induced by different TLR-ligands suggest a broad spectrum of action. Studies are in progress to elucidate the mechanisms for this effect and examine the potential of Fh12 and Fh15 as anti-inflammatory molecules in animal models for experimental septic shock and autoimmune diseases.

Degradation of Incretin by the Prokaryotic Dipeptidyl-Peptidase 4 from *Porphyromonas gingivalis*

Author Block:

Y. Shimoyama[1], Y. Ohara-Nemoto[2], T. K. Nemoto[2], M. Nakasato[1], T. Yaegashi[1], T. Ishikawa[1], M. Sasaki[1], S. Kimura[1]; [1]Iwate Med. Univ. Sch. Dent., Morioka, Japan, [2]Nagasaki Univ., Nagasaki, Japan

Abstract Body:

The incretins, glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP), are the major regulators of post-prandial insulin secretion, which are rapidly degraded to inactive forms with the cleavage of Ala^2-Glu^3 bond by dipeptidyl-peptidase 4 (DPP4). Recent studies demonstrated that *Porphyromonas gingivalis*, one of the major causative organisms of chronic periodontitis in human, possesses various exopeptidases such as four DPPs (DPP4, DPP 5, DPP 7 and DPP 11) to incorporate nutritional amino acids as di- and tri-peptides. Since the prokaryotic DPP4 is a structural homologue to mammalian DPP4, it is possible that *P. gingivalis* infection could lead to the onset/progression of type 2 diabetes mellitus through the degradation of incretins by *P. gingivalis* DPP4 (PgDPP4). In this study, we assessed the degradation of GLP-1 and GIP by PgDPP4 using bacterial whole cells (*P. gingivalis* ATCC 33277 and a *dpp4*-disruped mutant strain) and recombinant PgDPP4 (rPgDPP4), by means of MALDI-TOF MS in vitro. The results indicated that both GLP-1 and GIP were cleaved Ala^2-Glu^3 bond and degraded to the inactive forms by the incubation with the wild type of *P. gingivalis* cells and/or rPgDPP4 in dose and time dependent manners. Accordingly, the present findings indicate that *P. gingivalis* DPP4 can possibly function to degrade incretins as does human DPP4, and thus the periodontitis with *P. gingivalis* infection could be an important risk factor for type 2 diabetes mellitus.

Regulation of Intestinal Epithelial Cell Serotonin Transporter by *Lactobacillus* and *Bifidobacterium spp.*

Author Block:

C. Visuthranukul, M. Engevik, B. Ganesh, B. Luk, M. Esparza, J. Versalovic; Baylor Coll. of Med., Houston, TX

Abstract Body:

Background: The metabolite and neurotransmitter serotonin (5-HT) has a diverse physiological repertoire. In the gut, 5-HT can be produced by the conversion from dietary tryptophan by commensal bacteria. Lactic acid-producing bacteria (LAB), particularly the probiotic *Lactobacillus* and *Bifidobacterium* groups, have hypothesized to beneficially influence the serotonergic system. To address the potential role of LAB in 5-HT regulation, we sought to define 5-HT production by *Lactobacillus* strains and examine how the presence of these species may affect serotonin transporter (SERT) expression *in vitro* and *in vivo*. We hypothesized that select *Lactobacillus* and *Bifidobacterium* strains would stimulate 5-HT production and upregulate SERT.**Methods:** 24 *Lactobacillus* strains were cultured anaerobically in a fully defined media (LDM4) and serotonin production measured by MS/MS analysis. The human intestinal cell lines, HT29, were exposed to LAB conditioned media for 24 hrs and SERT expression was analyzed by qRT-PCR. To address serotonin production *in vivo*, germ-free mice were colonized with *B. dentium* or *L. reuteri* as well as ileum and colon luminal serotonin levels were examined via ELISA. Mouse intestinal SERT expression was examined by qRT-PCR.**Results:** Of the 24 *Lactobacillus* strains screened for serotonin production, none of the strains secreted detectable serotonin levels. However, addition of *L. reuteri* conditioned media to HT29 epithelial cells resulted in significant upregulation of SERT expression after 24 hrs. Likewise, germ-free mice mono-associated with *B. dentium* exhibited increased ileal serotonin levels demonstrating that LAB colonization can promote 5-HT production.**Conclusions:** These data demonstrate that the commensal microbes, *L. reuteri* and *B. dentium*, are capable of regulating key components of the intestinal serotonergic system. As downregulation of SERT has been implicated in the pathophysiology of several functional gut disorders, our data supports the consideration of next generation probiotics as therapies for serotonin-associated disorders.

***Yersinia* Overcomes Reactive Oxygen Species in Tissues through the Action of the Nucleoid Associated Protein Fis**

Author Block:

E. R. Green, S. Clark, J. Mecsas; Tufts Univ. Sch. of Med., Boston, MA

Abstract Body:

All three pathogenic *Yersinia* species share a conserved virulence plasmid that contributes to growth and virulence in mammalian infection. However, in the absence of this plasmid, strains of the enteric pathogen *Yersinia pseudotuberculosis* (*Yptb*) retain the ability to colonize and grow within host organs. Because studies of chromosomal factors that contribute to *Yptb* infection have been limited, we previously utilized TnSeq to uncover chromosomal factors that contribute to pathogenicity of *Yptb* in the absence of the virulence plasmid. This approach identified nearly 50 genes, including several that were previously uncharacterized, that contribute to *Yptb* infection. In a follow-up to this work, we utilized a deep sequencing-based approach to validate and further characterize the phenotype of 18 of these genes by infecting mixed pools of in-frame knockouts into immunocompetent mice, as well as into mice lacking phagocytic cells. Using this approach, we identified a role for the nucleoid associated protein Fis in *Yptb* infection. Specifically, we found that mutants containing deletions of the *dusB-fis* operon were attenuated for virulence in mice following systemic infection. Interestingly, this virulence defect was apparent at late time-points, and was ablated when mice lacked phagocytic cells, suggesting that Fis may be protecting *Yptb* from restriction by the innate immune response, potentially by initiating a global transcriptional response that enables bacterial survival during these conditions. To identify potential stress(es) Fis may be responding to, we monitored the sensitivity of Δ*dusB-fis* and WT bacteria to several conditions that reflect mechanisms used by phagocytes to restrict bacterial survival, and found that Fis is crucial for resistance to oxidative stress *in vitro*. In agreement with this result, we found that the Δ*dusB-fis* mutant was fully virulent in mice unable to produce ROS, suggesting that Fis is critical for promoting resistance to oxidative stresses imposed by phagocytic cells during mammalian infection.

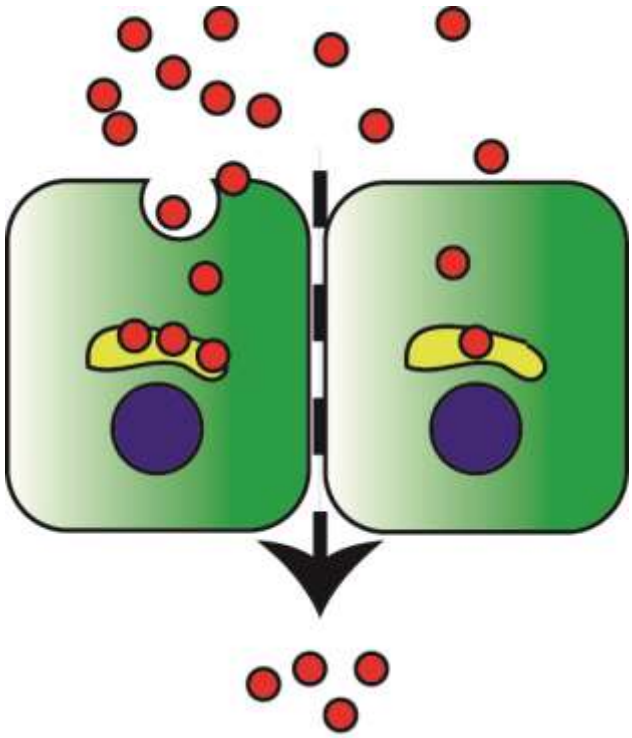
***Bacteroides thetaiotaomicron* Outer Membrane Vesicles Traverse and Alter the Intestinal Epithelial Barrier**

Author Block:

C. A. Hickey[1], M. Wegorzewska[1], D. Donermeyer[1], R. Glowacki[2], E. Martens[2], P. Allen[1], T. Stappenbeck[1]; [1]Washington Univ., St. Louis, MO, [2]Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: *Bacteroides thetaiotaomicron* (*B. theta*) produces abundant outer membrane vesicles (OMVs) that engage host cells and potentially contributes to inflammatory bowel disease. We previously found OMV antigens in host intestinal macrophages after *B. theta* triggered colitis in a genetically susceptible mouse model. How OMVs traverse the epithelium and access macrophages is unclear. We hypothesize that OMVs enter the intestinal epithelium and alter paracellular permeability, thereby enhancing their access to macrophages.**Methods:** Primary murine colonic epithelial stem cells were plated on either Matrigel coated slides or Transwells, and the subsequent monolayers were treated apically with pre-labeled fluorescent *B. theta* OMVs. A time course of cellular entry and pharmacological and genetic manipulation of the epithelial cells to determine the mode of OMV entry were measured. Epithelial monolayer barrier function and OMV ability to pass through the monolayer were also evaluated.**Results:** *B. theta* OMVs were internalized by colonic epithelial cells, and this process was disrupted by inhibitors of lipid raft formation. OMV antigens were localized in scattered cytoplasmic foci and concentrated within lysosomes. By 4 hours, tight junctions at cell-cell borders opened, and *B. theta* OMVs were found in the media below the Transwell, confirming passage through this layer.**Conclusion:** *B. theta* OMVs enter epithelial cells, are targeted for degradation, and disrupt tight junctions, thereby potentially allowing OMVs to pass through this barrier. These results further elucidate how OMVs access and alter host cells, a key factor in how commensal bacteria may trigger disease in the host.



Cartoon of *B. theta* OMV (red) internalization into host epithelial cells (green) then degradation in lysosomes (yellow). Tight junctions are affected and OMVs traverse the epithelial barrier.

Role of *Neisseria gonorrhoeae* Lytic Transglycosylases in Mediating Resistance to Host Phagocytic Killing

Author Block:

C. Weng[1], K. Knilans[1], J. Dillard[2], J. Duncan[1]; [1]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Background: *Neisseria gonorrhoeae* is a gram negative bacteria that most commonly infects the urogenital tract causing either urethritis or cervicitis. *N. gonorrhoeae* has evolved mechanisms to modify the host response to the presence of the bacteria. Host cells can recognize *N. gonorrhoeae* by detecting the presence of peptidoglycan (PGN), the primary building block of the cell wall. PGN polymers are broken down and released from the remodeling cell wall during bacteria growth. Most bacteria recycle released PGN limiting host detection. The activity of lytic transglycosylases, *LtgA* and *LtgD*, causes *N. gonorrhoeae* to release large amounts of biologically active monomeric PGN containing 1,6-anhydro muramic acid moiety, rather than recycling PGN. In previous studies, *N. gonorrhoeae* with genetic deletions of *ltgA* and *ltgD* were found to release multimers instead of monomers of PGN. Duncan lab found that *N. gonorrhoeae* lacking *ltgA/D* cause increased host cytokine production when compared to the parental strain. Furthermore, conditioned media released by this mutant strain stimulates increased activation of NOD2, an intracellular receptor for PGN, in reporter cell lines. These data suggest that *LtgA* and *LtgD* many provide immune - evasive activities to *N. gonorrhoeae*. In this study we investigated whether *N. gonorrhoeae* lytic transglycosylases allow the bacteria to evade host phagocyte induced killing. **Methods:** Bone Marrow Derived Dendritic (BMDC) cells were generated from both C57BL6 mice and *Nod2-/-* mice. *N. gonorrhoeae* strain FA1090 and an isogenic derivative lacking both *ltgA* and *ltgD (ΔltgA/ltgD*) were inoculated into the BMDC cultures and the quantity of surviving bacteria colonies was enumerated over time.**Results:** *ΔltgA/ltgD* was killed more rapidly by BMDC than the isogenic parental strain FA1090. Under the same culture media conditions with no BMDC the strains survived equally, although they did not grow. There was no difference in killing of *N. gonorrhoeae* between C57BL6 and *Nod2-/-* under the conditions we tested.**Conclusions:** *LtgA* and *LtgD* appear to increase *N. gonorrhoeae* viability against the pressure of host cell phagocytic killing. Though *ΔltgA/ltgD N. gonorrhoeae* are more readily recognized by host NOD2, their enhanced susceptibility to BMDC killing is not NOD2 dependent.

Immunosuppressive *Yersinia* Effector YopM Binds Dead Box Helicase DDX3 to Control Ribosomal S6 Kinase in the Nucleus of Host Cells

Author Block:

L. Berneking[1], M. Schnapp[1], M. Alawi[2], M. Aepfelbacher[1]; [1]Univ. Med. Ctr. Hamburg-Eppendorf (UKE), Hamburg, Germany, [2]Heinrich-Pette-Inst., Hamburg, Germany

Abstract Body:

YopM is a crucial immunosuppressive effector of the plaque agent Yersinia pestis and other pathogenic Yersinia species. YopM enters the nucleus of host cells but neither the mechanisms governing its nucleocytoplasmic shuttling nor its intranuclear activities are known. Here we identify the DEAD-box helicase DDX3 as a novel interaction partner of Y. enterocolitica YopM. Knockdown of DDX3 or inhibition of the exportin CRM1 increased the nuclear level of YopM suggesting that YopM exploits DDX3 to exit the nucleus via the CRM1 export pathway. Increased nuclear YopM levels caused enhanced phosphorylation of Ribosomal S6 Kinase 1 (RSK1) in the nucleus. In Y. enterocolitica infected primary human macrophages YopM increased the level of Interleukin-10 mRNA which required interaction of YopM with RSK. We propose that the DDX3/CRM1 mediated nucleocytoplasmic shuttling of YopM determines phosphorylation of RSK in the nucleus to control transcription of immunosuppressive cytokines.

Mutations Inactivating the *Streptococcus pyogenes* Multiple Gene Regulator Decrease Host Inflammatory Responses and Promote Persistent Mucosal Carriage

Author Block:

K. M. Jacob, I. L. Laczkovich, S. Ahmed, S. R. Dawid, **M. E. WATSON, Jr**; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

Streptococcus pyogenes is a human bacterial pathogen causing inflammatory infections at multiple mucosal tissues, including pharyngitis and vulvovaginitis. The Multiple Gene Regulator (Mga) controls transcription of up to 10% of the genome, including activation of adhesins and virulence factors. Spontaneous mutations resulting in the inactivation of Mga have been identified among asymptomatic carriage strains isolated from humans and mouse models, suggesting that Mga may represent a key switch from virulence to an avirulent state. This study examined the ability of *S. pyogenes* lacking Mga to persist in a murine model of mucosal carriage and the associated host inflammatory responses. An in-frame deletion mutation of the *mga* gene was constructed in virulent serotype M28 *S. pyogenes* (MEW123), producing a ΔMga mutant strain. A murine vaginal colonization model was used to assess mucosal carriage. Murine Bone-Marrow Dendritic Cells (mBMDCs) were examined for cytokine production via ELISA after exposure to streptococcal strains. Characterization of the ΔMga strain demonstrated it had no growth defect in broth culture and lacked SpeB protease expression in comparison to the parent strain, suggesting Mga-dependent activation of SpeB expression in this strain. Mice vaginally-colonized with the ΔMga strain exhibited a longer duration of streptococcal mucosal carriage compared with mice inoculated with the parent strain. Examination of vaginal smears showed a significant neutrophil recruitment in mice colonized with the parent strain, whereas those colonized by the ΔMga mutant exhibited no significant inflammatory response, appearing similar to non-inoculated controls. Stimulation of mBMDCs by the ΔMga strain produced significantly less pro-inflammatory cytokine IL-1β and IL-6 secretion compared to the parent strain. In summary, inactivation of the *mga* gene led to prolonged mucosal carriage and an absence of any significant inflammatory response typically observed following inoculation with the virulent parent strain. These results support the hypothesis that Mga is a central determinant in streptococcal virulence and that loss of Mga function results in a switch to an avirulent persister-like state that may allow for prolonged carriage.

Effect of 3-(2-Aminoethyl)-5-Hydroxy-(2,3-Benzopyrrole) on EHEC Virulence

Author Block:

A. Mishra[1], V. Sperandio[2]; [1]UT Southwestern MEdical Ctr., Dallas, TX, [2]UT Southwestern Med. Ctr., Dallas, TX

Abstract Body:

Host bacterial associations have a profound impact in health and disease. Prokaryotes and eukaryotes have co-existed for millions of years. The gastrointestinal (GI) tract is one of the most prominent sites in the human body where host/microbial associations are paramount. The GI tract is inhabited by trillions of commensal bacteria that comprise the microbiota, which aid in the digestion of food, vitamin production, and play crucial roles in human physiology and development. Both the host and microbiota produces cohorts of signaling molecule which can regulate the virulence expression of a pathogen. We assessed the role of molecule 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) produced in the mammalian GI tract in the virulence expression of Enterohemorrhagic *E.coli*(EHEC). EHEC has a pathogenicity island, the locus of enterocyte effacement(LEE) that is essential for virulence. EHEC was grown in low glucose DMEM at 37°C till mid log phase either in presence or absence of 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole). The presence of 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) in the media changed the levels of LEE gene expression as measured by quantitative real time PCR, and western blot. To assess the effect of 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) as a signaling molecule regulating LEE *in-vivo* studies involving mice that are able to accumulate increased levels of mucosal 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) in the GI tract were performed. Mice having normal levels of mucosal 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) and those with increased levels of mucosal 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) were infected with *C.rodentium*, which is used as a surrogate model for EHEC infection. Levels of CFU/ml, survival and histology assays were performed. The mice with increased levels of mucosal 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) were more susceptible to *C.rodentium* infection. Thus molecule 3-(2-Aminoethyl)-5-hydroxy-(2,3-Benzopyrrole) present in the mammalian GI tract seems to serve as a signaling molecule for EHEC, and affect its virulence by regulating the LEE.

Impact of Amoebal Endosymbiont *Neochlamydia* on Host Defense against Harmful *Legionella* Infection and Its Defense Mechanism

Author Block:

C. Maita[1], T. Yamazaki[1], J. Matsuo[1], S. Nakamura[2], T. Okubo[1], H. Nagai[3], H. Yamaguchi[1]; [1]Hokkaido Univ., Sapporo, Japan, [2]Juntendo Univ., Tokyo, Japan, [3]Osaka Univ., Suita, Japan

Abstract Body:

We have previously established an amoeba strain (S13WT amoebae) from environmental soil harboring obligate intracellular symbiont *Neochlamydia*, an environmental chlamydia; the endosymbiont has an amoebal infection rate of 100%, but does not cause amoebal lysis with lacking transferability to other host amoebae (Environ Microbiol Rep, 2: 524-33, 2010; Microbes Environ, 27: 423-9, 2012). Also, our recent work intriguingly has shown that the amoebal endosymbiont has a critical role into host amoebal defense against harmful *Legionella* infection (PLoS ONE, 18: e95166, 2014). Here, to explore the defense mechanism, we performed the following experiments with three distinct GFP-expressing *Legionella pneumophila* [JR32 ($T4ASS^+/T4BSS^+/Tra^-$), Lp01 ($T4ASS^-/T4BSS^+/Tra^+$), Lp02 ($T4ASS^-/T4BSS^-/Tra^+$)], and S13WT ameobae and its aposymbiotic amoebae (S13RFP amoebae) in addition to C3 reference amoebae. Uptake experiment revealed that S13WT amoebae could hardly ingest not only all *Legionella* strains also FITC-latex beads when compared to the aposymbiotic S13RFP or C3 amoebae. The CFU count assay showed that the *Legionella* minimally could infect and grow into S13WT amoebae. The 2D-DIGE showed that major spots into S13WT amoebae significantly decreased in these of aposymbiotic S13RFP amoebae; the LC/MS identified the proteins to be actin. Meanwhile, the DNA microarray revealed that JR32 infection dramatically increased the *Neochlamydia* gene expression to high levels, although the gene expression levels minimally changed at any time regardless of Lp01 or Lp02 infection. Thus, the host defense mechanism is very complicated. However, we found a crucial piece that amoebal endosymbiotic *Neochlamydia* specifically could sense *Legionella* T4ASS (Lvh) but not T4BSS (Dot/Icm), presumably connecting to the host defense against harmful *Legionella* infection.

Zebrafish Embryo Infection Model of Pneumococcal Meningitis

Author Block:

K. Jim[1], A. M. van der Sar[2], A. van der Ende[1], M. C. Brouwer[1], D. van de Beek[1], W. Bitter[2], C. M. J. E. Vandenbroucke-Grauls[2]; [1]Academic Med. Ctr., Amsterdam, Netherlands, [2]VU Univ. Med. Ctr., Amsterdam, Netherlands

Abstract Body:

Background*Streptococcus pneumoniae* is the most important cause of meningitis, with high morbidity and mortality. The aim of our study was to develop a pneumococcal meningitis model in the zebrafish embryo, to study host-microbe interactions.**Methods**Zebrafish embryos (60 per group) were infected in the bloodstream or hindbrain ventricle with green fluorescent *S. pneumoniae* D39*wt* or pneumolysin-deficient D39 (D39*ply*). A *kdrl:mCherry* transgenic zebrafish line was used to visualize blood vessels. Phagocytic cells were visualized by anti-L-plastin or by using double labeled *mpo:gfp* x *mpeg:mCherry* zebrafish to visualize neutrophils and macrophages individually. Embryos were imaged using confocal and time-lapse microscopy.**Results**Inoculation of *S. pneumoniae* in bloodstream and hindbrain ventricle induced dose-dependent mortality (fig. a). Whereas bloodstream injection resulted in fulminant systemic disease with meningitis, hindbrain ventricle injection caused local brain infection. The D39*ply* mutant was attenuated (fig. b) and difference in phagocyte recruitment was observed (fig. c). Time-lapse imaging showed that upon infection the initial innate immune response consists mainly of neutrophils without involvement of macrophages.**Conclusions**Pneumococcal meningitis in zebrafish embryos occurs both after bloodstream or hindbrain ventricle injection. This meningitis model permits detailed visualization of meningitis pathogenesis in real time and appears as a powerful tool to study pneumococcal host-microbe interactions, thereby providing the opportunity to study host and pathogen factors that play a role in the pathogenesis of this infection.

Simultaneous Rna-Seq Analysis of Gram Negative Pathogen and Host Transcriptomes During *In Vitro* And *In Vivo* Infections Using a Capture Based Technique

Author Block:

A. LaBauve, Kunal Poorey, Zachary W. Bent, Anupama Sinha, Steven S. Branda, and Robert J. Meagher; Sandia Natl. Lab., Livermore, CA

Abstract Body:

Detailed global understanding of the mechanisms utilized by bacteria over the course of an infection could aid in the discovery of novel targets for much needed therapeutics for emerging and drug-resistant bacterial pathogens. Bacteria adapt rapidly with concerted shifts in gene expression in response to changing conditions: from external environment or host organism to a new host, or between different cell or tissue microenvironments within the host. However, most studies of pathogenesis focus primarily on a handful of genes at a time, or conversely only focus on the response of the host. RNAseq analysis is a promising approach to understanding the global shifts in bacterial gene expression patterns over the course of an infection, but applying RNAseq techniques to *in vitro* or *in vivo* bacterial infection models is technically challenging because bacterial transcripts make up an exceedingly small fraction of the total RNA in an infected sample containing both host and bacteria. To address this issue, we have developed a method to separate bacterial transcripts from host transcripts prior to sequencing. Using this unbiased capture-based technique we are able to enrich for all possible bacterial transcripts leading to gene level analysis of the entire bacterial transcriptome while host transcriptomes from the same sample can also be analyzed. This enrichment strategy was used in conjunction with RNA-seq to further our understanding of host-pathogen interactions by analyzing both host and pathogen transcriptomes of *Pseudomonas aeruginosa* and *Klebsiella pneumoniae* in the context of acute murine lung infections. Combining this powerful tool with host transcriptome analysis simultaneously will provide details about host-pathogen interactions that have not previously been possible and could provide insight into targetable bacterial pathways which could circumvent the ever-growing problem of resistance to conventional broad spectrum antibiotics.

Using Capture Based Enrichment And Rna-Seq To Study Host Pathogen Interaction Dynamics In Emerging Superbugs

Author Block:

K. Poorey; Sandia Natl. Labs, Livermore, CA

Abstract Body:

To develop early diagnostics, new treatment strategies, and new antibiotics drugs it is necessary to understand the biology of both host and pathogen in detail. We studied the gene expression profile of host and pathogen simultaneously for the infection time course of different pathogens with RNA-seq. For pathogen transcriptomics we have developed a solution-phase hybridization-based capture approach to enrich specifically for pathogen transcripts and significantly increasing the number of pathogen reads by >100-fold. This enabled the study pathogen transcription in much greater detail. We have demonstrated the application of the capture technique to in vitro tissue culture infections with *Yersinia enterocolitica* and *NDM-1 Klebsiella pneumomiae*, as well as a detailed study the dynamics of *Burkholderia* infection in primary cells over the whole time course. We have developed new RNA-seq analysis pipeline called MAnTra which is a parallel & multithreaded software which uses existing and novel tools to perform RNA-seq and profile transcription fidelity. Through the detail transcriptomics analysis we discover new active virulence pathways in *Yersinia*, how superbug *NDM-1 Klebsiella pneumomiae* and multidrug resistant *Burkholderia* behaves in infection. Also from the host transcriptomics time series we characterized the immune response to infections to these bugs over the period of infection. Further we want to discover biomarkers of infection in the host data and new targets in pathogens to tackle antibiotic resistance.

Exploiting the Zebrafish Embryo Model to Characterize the Divergent Virulence Potential Among *Cronobacter* spp

Author Block:

A. K. Eshwar[1], B. D. Tall[2], J. Gangiredla[3], G. R. Gopinath[4], I. R. Patel[4], R. Stephan[1], **A. Lehner**[1]; [1]Univ. Zurich, Zurich, Switzerland, [2]U. S. Food and Drug Admin., Laurel, MD, [3]U. S Food and Drug Admin., Laurel, MD, [4]U.S. Food and Drug Admin., Laurel, MD

Abstract Body:

Background: Bacteria belonging to the genus *Cronobacter* spp. have been recognized as causative agents of life-threatening systemic infections primarily in premature, low-birth weight and immune-compromised neonates. Apparently not all *Cronobacter* spp. are linked to infantile infections and it has been proposed that virulence varies among strains. In a previous study, the zebrafish embryo model was successfully established to study the pathogenesis of these organisms. In the current study, we combined data obtained from *in silico* analysis of the genome content of strains with the ability of the strains to cause infections *in vivo*.**Materials and Methods**: *Cronobacter* type strains (9), two RepFIB cured strains, the *C. sakazakii* BAA894 *cpa* mutant and *E. coli* complemented with *cpa* were included in this study. The strains were characterized to the genome level using a recently developed pan genome DNA microarray. For infection studies, bacteria were injected into the yolk sac of zebrafish embryos (2 days post fertilization, 30 embryos per strain) and pathogenicity was assessed by determining mortality rates over 96 hours post infection (hpi).**Results:** Pathogenicity varied among *Cronobacter* spp. type strains with *C. sakazakii, C. turicensis* showing 100 % mortality rate within 36 hpi whereas a 100 % survival rate was observed for all embryos injected with *C. muytjensii.* The latter strain does not harbour the RepFIB plasmid which has been proposed as a „virulence plasmid", thus being most likely the reason for the apathogenic behaviour of this strain. Infection experiments using RepFIB plasmid cured derivatives of the highly pathogenic strains *C. turicensis and C. sakazakii* supported this hypothesis. In addition, the involvement of one of the genetic determinants located on this plasmid, the *Cronobacter* plasminogen activator (*cpa*) in pathogenicity was confirmed in infection experiments using a *cpa* knock out mutant and an apathogenic *E. coli* strain complemented with this determinant.**Conclusion:** The combination of genome content related data with *in vivo* pathogenicity data enables a molecular dissection of the virulence spectrum of these organisms.

Assessment of Early Events in *E. coli* o157:H7 Infection of Human Cells at the Single Cell Level Using a Novel Acoustic Wave Device

Author Block:

R. Katani, P. Li, A. M. Pedley, L. Li, T. J. Huang, S. J. Benkovic, V. Kapur; Pennsylvania State Univ., University Park, PA

Abstract Body:

Adherence to host cells by a pathogen is often regarded as the first and key step in pathogenesis. However, relatively little is known about the changes that occur within the microbe and the host cell during the very early time points (seconds to minutes) of host - pathogen interactions. Acoustic wave technology holds considerable promise in enabling single cell bacteria-host interactions to be controlled and monitored with high spatio-temporal resolution. We have sought to examine the effects of acoustic wave on bacteria (*Escherichia coli* O157:H7) and host cells (Hela and Caco2), and identify conditions that result in minimal perturbation to their normal cellular processes. The results suggest that acoustic wave coupled with RNA-seq may enable a precise temporal resolution of the very early (seconds to minutes) biochemical events that occur during the interaction of microbes with their host cells at the single cell level. In the long-term, studies such as these are likely to provide key missing insights on the very early stages of microbial pathogenesis, and aid in the identification of potential novel targets for the development of the next generation of therapeutics and vaccines.

Coevolution of the Hingut Microbiota of Xylophagous Termites & Cockroaches

Author Block:

M. Berlanga[1], R. Duro[2], R. Guerrero[2]; [1]Univ. of Barcelona, Barcelona, Spain, [2]Barcelona Knowledge Hub-Academia Europaea, Barcelona, Spain

Abstract Body:

Background: The rapid growth in microbiome research has revealed the crucial contributions of microbial communities to numerous physiological functions in animals, including digestion, immunity and reproduction. Fundamental physiological processes, such as tissue development, nutrient absorption, immunity, and circadian regulation, are emergent properties of the interactions between the host and its microbiota. Those emergent properties involve multiple microbial species and genotypes, reflecting the microbe composition at the level of community rather than individual microbial taxa.**Methods:** In this study, high-throughput 454 pyrosequencing of 16S rRNA was used to investigate the diversity of metagenomic hindgut bacterial communities of *Cryptocercus punctulatus* and *Reticulitermes grassei*.**Results:** Our results revealed that the hindgut prokaryotic communities of both xylophagous Dictyoptera are dominated by members of four *Bacteria* phyla: Bacteroidetes, Firmicutes, Proteobacteria, and Actinobacteria. In the case of *Reticulitermes*, Spirochaetes was also a dominat phyla. Phylogenetic analysis based on the characterized clusters of Bacteroidetes, Spirochaetes, and *Deltaproteobacteria* showed that many OTUs present in *Cryptocercus* and *Reticulitermes* clustered with sequences previously described in other termites and cockroaches, but not with those from other animals or environments.**Conclusions:** One of the most important factors in the fitness of the organisms is nutrition. Insect symbionts have provided the enzymatic capabilities that enable the insect to feed on recalcitrant plant polymers (cellulose, hemicellulose, pectin or lignin). This work describes the relationships between the hindgut microbiotas of two xylophagous Dictyoptera (namely *Reticulitermes*, a lower termite, and *Cryptocercus*, a cockroach), to understand the characteristics that have determined bacterial fidelity over generations and throughout evolutionary history. Symbiotic interactions have probably played a central role in the evolutionary success of these insects, allowing their adaptation to unexploited ecological niches that are nutritionally deficient and/or unbalanced.

Brain Meta-transcriptomics from Harbor Seals to Infer the Role of the Microbiome and Virome in a Stranding Event

Author Block:

S. M. Rosales; Oregon State Univ., Corvallis, OR

Abstract Body:

Marine diseases are becoming more frequent, and tools for identifying pathogens and disease reservoirs are needed to help prevent and mitigate epizootics. Meta-transcriptomics provides insights into disease etiology by cataloguing and comparing sequences from suspected pathogens. This method is a powerful approach to simultaneously evaluate both the viral and bacterial communities, but few studies have applied this technique in marine systems. In 2009 seven harbor seals, Phoca vitulina, stranded along the California coast from a similar brain disease of unknown cause of death (UCD). We evaluated the differences between the virome and microbiome of UCDs and harbor seals with known causes of death. Here we determined that UCD stranded animals had no viruses in their brain tissue. However, in the bacterial community, we identified Burkholderia and Coxiella burnetii as important pathogens associated with this stranding event. Burkholderia were 100% prevalent and ~2.8 log2 fold more abundant in the UCD animals. Further, while C. burnetii was found in only 35.7% of all samples, it was highly abundant (~94% of the total microbial community) in a single individual. In this harbor seal, C. burnetii showed high transcription rates of invading and translation genes, implicating it in the pathogenesis of this animal. Based on these data we propose that Burkholderia taxa and C. burnetii are potentially important opportunistic neurotropic pathogens in UCD stranded harbor seals.

Genome-Wide Identification Of Fitness Genes In Carbapenem-Resistant St131 *escherichia Coli* During Urinary Tract Infection

Author Block:

J. Marzoa, S. N. Smith, S. Crepin, H. T. L. Mobley; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

The *E. coli* pandemic multidrug resistant clone ST131, the major etiologic agent of urinary tract infections internationally, is responsible for spreading the β-lactamase CTX-M-15 worldwide. Carbapenem-resistant *Enterobacteriaceae* are an emerging threat to public health worldwide because these agents are often the last line of effective therapy available for the treatment of serious infections. Recently, the *H*30-R ST131 clone has been reported as the principal *E. coli* clone harboring the carbapenemase (KPC)-encoding gene *bla*KPC. Because of the unprecedented global spreading of ST131 clone, *bla*KPC-positive ST131 strains are of particular concern and new targets must be identified for antimicrobial therapies. Using a Tn-seq approach, we are defining essential genes required for infection in a murine model of UTI and evaluating their suitability as therapeutic targets. To address this, we first characterized the *bla*KPC positive O25b:H4-B2-ST131 clinical isolate UMCRE19. UMCRE19 belongs to the subclone *H*30-R and the virotype C, and displayed reduced susceptibilities to ertapenem, cefazolin, cefotaxime, ampizilin/sulbactam, aztreonam, ciprofloxazin, levofloxacin and gentamycine. UMCRE19 was sequenced using PacBio sequencing (100X coverage, P6-C4 chemistry). The chromosome of UMCRE19 contains a 5,148,820 bp, 5,334 coding sequences and 110 RNA features. At least two plasmids are present in strain UMCRE19: pUMCRE19_1 and pUMCRE19_2, of 113 and 51 kb, respectively. Female CBA/J mice were transurethrally inoculated and at 6 h and 24 h post-inoculation, the urine, bladder, kidneys and spleen were harvested, homogenized and plated for CFU enumeration. At 6 h post-inoculation the urine, bladder, kidneys and spleen were efficiently colonized and the bacterial burden in those organs was comparable to the produced by the prototypic uropathogenic *E. coli* strain CFT073. Secondly, to determine the genes required for UTI, a transposon library of 50,000 mutants was constructed. Transposon mutants with fitness defects in bladder will be identified by sequencing and comparing the frequency of transposon insertion sites from the inoculum (input) and bacteria that colonized the bladder (output). These fitness factors may represent novel targets to develop antimicrobial therapy against carbapenem-resistant *E. coli*.

Identification Of *in Vivo* Fitness Genes For Opportunistic Pathogens Of The *enterobacteriaceae* Family

Author Block:

M. T. ANDERSON, L. A. Bradford, H. L. T. Mobley; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

Serratia marcescens and *Citrobacter freundii* are opportunistic human pathogens that are capable of causing severe infections and are frequently resistant to antibiotic treatment. Risk factors for these infections include extended hospital stays, prolonged antibiotic treatment, and a compromised immunological state. In contrast to other members of the *Enterobacteriaceae*, the genetic factors that facilitate survival and replication within the mammalian host have not been thoroughly characterized for these two organisms. To identify fitness factors on a genome-wide scale, human bacteremia isolates were subjected to transposon insertion sequencing analysis. Using input populations of 50,000 random transposon mutants of each species, a total of 127 *S. marcescens* and 187 *C. freundii* genes were found to encode fitness factors important for bacterial survival in a mouse model of bacteremia. Further analysis of the insertion sites in the initial transposon mutant populations identified an additional >600 putative essential genes for each organism. Among the mutated *S. marcescens* genes conferring a significant fitness defect, 11 were located within a large 18-gene cluster that has predicted function in the production and assembly of an extracellular polysaccharide. Further investigation of this locus through comparative analysis of 11 newly determined *S. marcescens* genomic sequences revealed a high degree of heterogeneity, indicating the genetic potential for surface-antigen diversity within this species. For *C. freundii*, one of the most highly represented (12 genes) categories of fitness factors were genes encoding homologous recombination and DNA repair functions. Although the significance of this finding is under investigation, one interpretation of this result is that the inability to repair DNA damage within the host is detrimental to *C. freundii* survival. *S. marcescens* and *C. freundii* were also found to share several homologous fitness factors, leading to the hypothesis that these organisms have conserved *in vivo* survival strategies. Together, these newly identified fitness genes of *S. marcescens* and *C. freundii* provide a more complete understanding of the genetic requirements for bacterial survival in the mammalian host and provide a framework for the development of alternative therapeutic interventions.

Development of Bioluminescent *Salmonella* Strains for *In Vivo* Chicken Pathogenesis Studies

Author Block:

G. Chaloner, L. Lacharme-Lora, P. Wigley; Univ. of Liverpool, Neston, United Kingdom

Abstract Body:

Background:*Salmonella enterica* subspecies *enterica* infection remains a serious problem in a wide range of animals and in man. Poultry meat is the main source of human infection for serovars such as *S.* Enteritidis whilst *serovars such as S.* Gallinarum, the causative agent of fowl typhoid, are an important cause of disease in poultry. These two serotypes behave quite differently in the chicken, S. Gallinarum is invasive, non-colonising and produces typhoid whereas *S.* Enteritidis is invasive, able to colonise and non-typhoidal. The aim of this study was to develop bioluminescent *Salmonella* strains, which could be used for *in vivo* pathogenesis studies.**Methods:**Plasmids carrying the luminescence genes (*luxABCDE*) were inserted into *S.* Gallinarum 287/91 and *S.* Enteritidis PT4 P125109 to construct bioluminescent strains of these pathogens. Day old chicks were then orally infected with these strains. Birds were sacrificed at 1 and 3 days post-infection. Birds were first imaged whole using the IVIS Spectrum machine at the Centre for Preclinical Imaging of the University of Liverpool to determine whether *lux* signal could be detected in the organs and gastro-intestinal sites before removing the gastro-intestinal tract, liver and spleen to image *ex vivo*. Bacteria were also enumerated from liver, spleen, ileal and caecal contents.**Results:**Limited bacterial *lux* signal was detected in the birds when the gastro-intestinal tract and organs were imaged i*n vivo* at 1 day post infection. However at 3 days post-infection bioluminescence was detected in the ceca of birds infected with both *S.* Enteritidis P125109 and *S.* Gallinarum 287/91 *ex vivo*.**Conclusions:**This study demonstrates for the first time the potential to image bioluminescent *Salmonella ex vivo* in the gastro-intestinal tract of chickens and allow more detailed studies of the interactions between *Salmonella* and the avian host. By using IVIS technology we are able to study these interactions while reducing animal numbers and morbidity.

***galleria Mellonella* Applied In The Study Of *paracoccidioides Spp* - Host Interaction**

Author Block:

L. Scorzoni, A. de Paula e Silva, J. Singulani, F. Sangalli-Leite, H. de Oliveira, C. Maria Marcos, R. Moraes da Silva, A. Fusco-Almeida, M. Mendes-Giannini; UNESP- Univ. Estadual Paulista, Araraquara, Brazil

Abstract Body:

Background: Paracoccidioidomycosis is an endemic fungal disease in Latin American, caused by dimorphic fungi *P. brasiliensis* and *P. lutzii.* Alterations in fungi characteristics are described after successive subcultures; the recovery of these characteristics can be re-established after passage in mammalian animals. Because of ethical issues with mammalian, alternative animal has been investigated. Invertebrates, as *G. mellonella,* represent a good alternative for *in vivo* assays. In this study, we compared the virulence of *P. brasiliensis and P. lutzii* in *G. mellonella* model.**Methods:** We evaluated survival curves, phagocytosis, hemocyte density (flow cytometer), hemocyte fungal interaction (flow cytometer) and adhesins gene expression (real time PCR). Additionally, we compare the interaction profile by flow cytometry and adhesin genes expression profile by real time PCR of a subcultivated *P. brasiliensis* culture and after passage in mice and in *G. mellonella*. **Results:** The survival curves of larvae infected with *P. brasiliensis* or *P. lutzii* showed a similar virulence (p=0.3051), and both species were able to reduce the hemocyte number in 3 times after 1 and 3 hours. Additionally, the phagocytosis rate was 5% for both species, but when we analyzed hemocyte-*Paracoccidioides* spp. interaction, *P. lutzii* showed higher interactions with hemocytes (48%), while in *P. brasiliensis* the interaction was 14% after 3 hours. The gene expression of gp43 was higher for *P. lutzii,* and this expression may contribute to a greater interaction to hemocytes. Moreover, *P. brasiliensis* passage to *G. mellonella* was able to increase the interaction to pneumocyte cells in a similar way that occurs after passage in mice (p=0.2926) and the expression of the enolase, gp43, 14-3-3 and triose phosphate isomerase adhesins were also similar.**Conclusions:** These results helped us evaluate the behavior of *Paracoccidioides* spp. and indicate that *G. mellonella* is a suitable model to reactivate one of the most studied virulence mechanism of *P. brasiliensis*, the adhesion, beside the different behavior of *P.lutzii* as gp43 expression.

Novel Insights Into *Salmonella* Typhi Pathogenesis from *Ex Vivo* Human Tissue Models

Author Block:

K. P. Nickerson[1], S. Senger[1], M. B. Sztein[2], A. Fasano[1], M. R. Fiorentino[1]; [1]Massachusetts Gen. Hosp., Boston, MA, [2]Univ. of Maryland, Baltimore, MD

Abstract Body:

Salmonella enterica serovar Typhi is the causative agent of Typhoid fever, a disease with an estimated 22 million cases annually, resulting in 200,000 deaths. In some areas of the globe, the incidence of Typhoid fever is as high as 500 cases out of every 100,000 children. At present, much remains to be uncovered concerning the host responses to *S.* Typhi infection. Available vaccines are moderately protective. Current therapeutic strategies include antibiotic treatment; however the frequency of antibiotic-resistant serovars is increasing worldwide. Additionally, in some individuals chronic *S.* Typhi colonization of the gall bladder culminates in gall bladder cancer, therefore highlighting the significant short and long-term consequences of infection. To design alternative therapeutic strategies, there is an immediate need to better understand *S.* Typhi infection and pathogenesis. To interrogate human responses to *S.* Typhi infection, terminal ileum biopsies were collected from donors for direct infection *in vitro* or generation of organoids. Terminal ileum derived organoids give rise to a diversity of epithelial cells, including goblet, Paneth and M cells, which are grown as a monolayer *in vitro*. Use of the epithelial monolayer and whole biopsy models identified specific contributions of the epithelium in response to *S.* Typhi infection as assessed by RNA-sequencing, qPCR, and cytokine secretion. Differences in cellular association of bacteria were assessed using immunofluorescence and transmission electron microscopy. To identify how the gut mucosa responds to infection, apical and basolateral culture supernatants were collected for ELISA analysis. These studies demonstrated differences in interleukin (IL)-8, IL-1β and IL-12p70 cytokine production depending on the infection model and the secretion location. Interestingly, infected monolayers showed the highest levels of basolateral cytokine release. Taken together, our data characterizes key aspects of terminal ileum response to *S.* Typhi infection addressing a critical gap in our current understanding of Typhoid fever pathogenesis.

Manual Collection, Ontological Representation, and Bioinformatics Analysis of over 5000 Microbial Virulence Factors and Related Host-Pathogen Interactions

Author Block:

Y. He[1], S. Sayers[1], S. Deng[1], G. Fu[1], Y. Li[2], B. Yang[1], S. Zhang[1], Y. Lin[1], B. Zhao[1], Z. Xiang[1]; [1]Univ. of Michigan, Ann Arbor, MI, [2]Inst. for Animal Husbandry and Vet. Sci., Beijing, China

Abstract Body:

Background: Virulence factors are those components of microbes that are necessary to overcome host defenses and cause disease in a host. It is critical to systematically collect and analyze virulence factors and how they interact with host.**Methods:** Manual curation from peer-reviewed journal articles was used to identify virulence factors. The mutants of these virulence factors were experimentally found to be attenuated inside host (including human and animals) or host cells. These virulence factors and how they interact with host were also studied using bioinformatics approaches.**Results:** We identified 5,173 virulence factors in total, including 4644 virulence factors for 50 bacteria, 179 for 54 viruses, 105 for 13 parasites, and 245 for 8 fungi. The data of these virulence factors and their interactions with host are stored in the web-based database Victors (http://www.phidias.us/victors). All Victors virulence factor data are queryable through a user-friendly web interface. The virulence factors can also be searched by a customized BLAST sequence similarity searching program. A Clusters of Orthologous Groups (COG) analysis method has been developed for functional annotation of these virulence factors. Furthermore, to support data sharing and integration, we have developed an Ontology of Host-Pathogen Interactions (OHPI, http://www.ontobee.org/ontology/OHPI) that ontologically represents the virulence factor data using machine-readable Web Ontology Language (OWL) format. The ontology information is queryable using a web-based SPARQL query program. As a use case demonstration, the *Brucella* virulence factors and their interactions with host were analyzed with the support of the Victors and OHPI systems. *Brucella* is a facultative intracellular bacterium that causes brucellosis, one of the most common zoonotic diseases in the world in humans and a variety of animal species. Victors stores 439 *Brucella* virulence factors.**Conclusions:** Virulence factors demonstrate their special patterns on how to interact with host and host cells. Overall, Victors and OHPI provide a good platform for integrated studies of microbial virulence factors and host-pathogen interactions.

Investigations Into The Life Cycle Of *drepanocephalus Auritus* In The Double-Crested Cormorant *phalacrocorax Auritus*

Author Block:

N. R. Alberson[1], T. G. Rosser[1], D. T. King[2], L. H. Khoo[3], D. J. Wise[3], E. T. Woodyard[1], L. M. Pote[1], M. J. Griffin[3]; [1]Mississippi State Univ. Coll. of Vet. Med., Mississippi State, MS, [2]United States Dept. of Agriculture Wildlife Services, Mississippi State, MS, [3]Thad Cochran Natl. Warmwater Aquaculture Ctr., Mississippi State Univ., Stoneville, MS

Abstract Body:

Drepanocephalus auritus, a parasite of the double-crested cormorant (DCC) *Phalacrocorax auritus* and the marsh ramshorn snail *Planorbella trivolvis,* has been shown to infect channel catfish *Ictalurus punctatus*. In a recent longevity study, metacercariae were seen in catfish 7 days post infection but a marked reduction in parasite burden was observed by day 21, with infection failing to persist much past 70 days. This called for investigations whether channel catfish can serve as a true intermediate host in the *D. auritus* life cycle. A total of 2,807 *P. trivolvis* snails were collected from a catfish production pond in Mississippi, U.S.A., of which 389 snails (13.9%) were actively releasing *D. auritus* cercariae. Juvenile channel catfish (2-4 cm) were individually exposed to ~150 cercariae/fish. At 5 days post-challenge, a sub-sample of fish was examined histologically to confirm infection. Seven DCC were live-captured, housed indoors in individual pens, and administered praziquantel to clear any residual gastrointestinal helminths. Experimental birds (n=3) were fed *D. auritus* parasitized catfish. Bird fecal samples were collected daily and sedimentations and egg counts performed. Few trematode eggs were observed 6 days post infection. However, at 8 days post-infection adult trematodes were found in the feces. Experimental and control birds were euthanized 18 days post infection. A total of 245 adult trematodes morphologically consistent with *D. auritus* were recovered from the intestines of birds fed *D. auritus* infected fish. No adult *D. auritus* were recovered from control birds. Mitochondrial cytochrome *c* oxidase subunit 1 (CO1) sequences from recovered adults shared 99.6-100% identity with other North American *D. auritus* isolates. This study demonstrates that channel catfish can serve as an intermediate host in the life cycle of *D. auritus* and is the first experimental elucidation of the *D. auritus* life cycle in DCC.

Pathogenesis of the Novel Species *Streptococcus tigurinus* in a *G. mellonella* Bacteremic Model

Author Block:

A. Fadil, N. Tullos; Mississippi Coll., Clinton, MS

Abstract Body:

Background: *Streptococcus tigurinus* is a novel oral viridans species recently separated from *Streptococcus mitis*. Though *S. tigurinus* has been shown to cause lethal bacteremic disease, to date there has only been one study to examine the virulence of this opportunistic pathogen. Therefore we determined to analyze the pathogenesis of *S. tigurinus* (ATCC 15914) in an invertebrate model of bacteremia using the greater wax moth (*Galleria mellonella*). Our hypothesis is that *S. tigurinus* will exhibit a high level of virulence in this model. **Methods:** Fifth instar larva were infected with 5, 6 or 7 LogCFU/larva via injection into the hemocoel. Larva were observed for a 24 hour period at which point they were homogenized in PBS. Lethality was determined by calculating the LD_{50} of *S. tigurinus* using Probit analysis. Bacterial survival was calculated at 24 hours using the CFU plate count method. Immune induction of the melanin deposition pathway was measured by photographic analysis of larval pigmentation using the Gray Scale Value (GSV) assay and phenoloxidase activity (PO) at 24 hours post infection (p.i.). Statistical analysis was performed using a Student's T test. **Results:** The 24 hour LD_{50} of *S. tigurinus* 15914 was calculated as $3.98x10^5$ per larva (n = 150). Bacterial survival was unchanged in larva infected with 5 LogCFU/larva at 24 hours, though larva infected with 6 LogCFU and 7 LogCFU showed significant growth compared to the 5 LogCFU group (6 LogCFU group = 8.96 LogCFU/larva , 7 LogCFU group = 8.41 LogCFU/larva ; $n \geq 4$ per group, $P \leq 0.05$). All three groups showed a significant immune activation as demonstrated by increased larval pigmentation compared to mock infected larva (Mock = 105.3 gsv, 5 LogCFU/larva = 89.2 gsv, 6 LogCFU/larva = 53.81 gsv, 7 LogCFU/larva 47.31 gsv; $n \geq 12$ per group, $P \leq 0.01$). Interestingly all three groups showed significant decreases in PO activity at 24 hours compared to mock infected larva (Mock = 1.842 abs , 5 LogCFU/larva 0.997 abs , 6 LogCFU/larva = 0.814 abs, 7 LogCFU/larva = 0.756 abs ; $n \geq 4$ per group . $P \leq 0.041$).**Conclusions:** This study is the first to examine *S. tigurinus* pathogenesis in a *G. mellonella* model and only the second virulence study *in vivo*. *S. tigurinus* demonstrated significant lethality, survivability and induced a robust immune response in this bacteremic model. Therefore this study provides new information regarding the bacteremic pathogenesis of this novel Streptococcus species.

A Novel Method For Proteomic Profiling Of *burkholderia* grown Under Diverse Environmental Conditions

Author Block:

M. Franco, M. Liou, Y. Haider, J. Pena, B. Segelke, S. El-Etr; Lawrence Livermore Natl. Lab., Livermore, CA

Abstract Body:

Burkholderia sp is a diverse gram-negative genus that includes pathogenic species that are of great medical importance (e.g. *B. mallei* and *B. pseudomallei*, the causative agents of glanders and melioidosis, respectively). Although the advancement of 'omics' technologies made headway in expanding our understanding of *Burkholderia* sp. biology, proteomic methods for studying bacterial responses to various growth environments or for identifying secreted bacterial effectors are lacking. To address this need, our study takes advantage of orthogonal amino acid labeling method, which allows for an easy purification of newly synthesized proteins expressed by bacteria growing in virtually any condition. The expression of mutant variant of methionyl-tRNA synthetase (NLL-MetRS) in *B. thailandensis* (a nonpathogenic model strain) allows for the substitution of azidonorleucine (Anl) in the place of Methionine (Met) in newly synthesized bacterial proteins (1). NLL-MetRS gene from *E.coli* was codon optimized for optimal expression in *Burkholderia* sp. and stably expressed in *B. thailandensis* using MiniTn7 transposon insertion method. In this study, Anl-tagged proteins are then affinity purified using alkyne-functionalized biotin and identified by mass spectrometry. We believe that this 'pulse-chase' proteomic method represents a new powerful approach in the *Burkholderia* field to quickly purify bacterial proteins and to study the changes that occur at the proteomic level in response to different growth environments (e.g. extracellular or while replicating within an eukaryotic host). The results from this study will be presented.

Pathogenesis of *Pseudomonas aeruginosa* in Microgravity

Author Block:

E. PAUL, A. Shresta; Southwestern Oklahoma State Univ., Weatherford, OK

Abstract Body:

BackgroundStressors during space flights take their toll on the human body, particularly the immune system, increasing the susceptibility of astronauts to opportunistic pathogens like *Pseudomonas aeruginosa*. *P. aeruginosa*, a bacterium found in soil, water and on the skin, can cause urinary tract, lung, and kidney infections especially under microgravity conditions encountered during space flights.**Methods**It would be interesting to study if the microbe adapts to microgravity and changes its virulence profile. To undertake this study *P. aeruginosa* was grown in conditions mimicking microgravity using a rotating wall vessel reactor for a period of 48 hours and compared to cultures grown at normal gravity conditions. The cultures were then studies for motility characteristics using 0.3% Tryptic soy agar plates. The morphology of the colonies produced was recorded. In addition bioassays using lettuce leaves were conducted by measuring the zones of necrosis. All experiments were conducted more than 5 times and were reproducible. Previous research in our lab optimized conditions required to mimic microgravity conditions.**Results**Twitching assays were conducted to examine if microgravity conditions enhance twitching and disease establishment. After growth periods of 48hours, *P. aeruginosa* grown under microgravity conditions showed a significant difference in the spreading or twitching growth on 0.3% agar motility plates. The microgravity grown cultures showed an average increase of 12% in colony size compared to normal cultures in multiple replicates. In addition these microgravity cultures exhibited differences in colony morphology; microgravity conditions microbes grew 120% taller than cultures grown under normal gravity conditions.**Conclusions**We also observed that microgravity cultures caused greater necrotic zones in bioassays using lettuce leaves compared to the culture grown in normal conditions. These results led us to believe that *P. aeruginosa* displays increased virulence under micro-gravity conditions. We have identified three potential proteins involved in increased twitching/motility. We plan to further examine the function of the three proteins.

A Virulence Comparison of Two Temporally Separated *Mycoplasma gallisepticum* Strains

Author Block:

K. Pflaum, E. R. Tulman, J. Beaudet, X. Liao, S. J. Geary; Univ. of Connecticut, Storrs, CT

Abstract Body:

Since 1994, *Mycoplasma gallisepticum*, a respiratory pathogen of poultry, has emerged as a significant pathogen of the American house finch (*Carpodacus mexicanus*), causing severe conjunctivitis in the eyes of the birds. Over the course of the ensuing epizootic event, the house finch-related *M. gallisepticum* (HFMG) strains demonstrated rapid spread and increased virulence in the house finch host. In this current study, we assessed two temporally separated HFMG isolates also differing in virulence for house finches - VA1994, the virulent index isolate of the epizootic, and highly virulent VA2013. To compare virulence of these isolates in domestic poultry hosts, chickens were experimentally challenged and assessed pathologically and for bacterial recovery. Here we report a significant difference between these two HFMG isolates for virulence in chickens. Interestingly, VA2013, more virulent in the house finch, demonstrated a significant reduction in virulence in chickens relative to VA1994, displaying decreased pathology and recovery from the respiratory tract. Genomic sequencing of VA2013 and comparison to VA1994 indicated genomic changes potentially affecting observed phenotypic differences. Overall, these data indicate a reciprocal evolution of HFMG virulence in house finch and poultry hosts, and provide insight to bacterial adaptation and HFMG virulence evolution in a novel host.

Establishing *Dugesia japonica* as a Model System to Study *Mycobacterium avium* Subspecies *Avium* Pathogenesis

Author Block:

I. A. Adekola Estinville, R. J. Major, V. Irani; Indiana Univ. Of PA, Indiana, PA

Abstract Body:

Mycobacterium avium is an opportunistic environmental pathogen causing disseminated and respiratory infections in healthy and immunocompromised humans. It has been determined that the host gut is one of the portals of entry for this bacterium, leading to the development of bacteremia and systemic disease. Through our studies using host murine macrophage (mø) cell line, J774A.1, we have demonstrated that *M. avium* serovar 8 glycopeptidolipid (ssGPL) is responsible for modulation of a variety of host innate immune responses (pro- and anti-inflammatory cytokine production, MAPK signaling, phagosome-lysosome fusion) and *M. avium* survival. To determine if these host immune responses are linked to *M. avium* survival, it is important to have a host model system so as to dissect these immune pathways in a sequential fashion. We have selected *Dugesia japonica*, a planarian, as our host model organism-it offers a means to characterize the innate immune responses conserved from yeast to man. In addition, (i) the planarian gastrovascular cavity branches throughout the body, which is useful to study the effect of *M. avium* colonization on host gut and (ii) unlike a "one type of cell" host system of mammalian møs, being multicellular and having the ability to live indefinitely is a powerful tool to study long term *M. avium* infection in a host. Using green fluorescent protein-expressed *M. avium* serovar-8 wild type and the serovar-null (no ssGPL) mutant, we are currently establishing the *M. avium* infectious process in *D. japonica*. With the help of bacterial (survival) counts, whole in situ hybridization (WISH) technology and pharmacological inhibitors, we will start the process of finally understanding and piecing together the complex *M. avium* infection process and modulation of host innate responses in *D. japonica*. This could provide an effective strategy for manipulating host innate responses to counteract bacterial survival in diseases beyond *M. avium*.

A New Player in Bioluminescence Quorum Sensing in *Vibrio fischeri*

Author Block:

I. Ster[1], R. Foxall[1], K. L. Visick[2], C. A. Whistler[1]; [1]Univ. of New Hampshire, Durham, NH, [2]Loyola Univ. Med. Ctr., Maywood, IL

Abstract Body:

Bacteria use phosphorelay systems to sense and respond to environmental stimuli, and to direct cell density quorum sensing (QS). The phosphorelay system that controls QS bioluminescence by *Vibrio fischeri* transduces signal from the hybrid-histidine kinases (HHK) LuxQ and AinR, which use kinase activity to phosphorylate a histidine phosphotransferase protein (HPT) LuxU, which in turn phosphorylates a response regulator (RR) LuxO, a repressor of bioluminescence. When LuxQ and AinR accept QS signals at high cell density they act as phosphatases on LuxU, relieving repression of bioluminescence by dephosphorylation of LuxO. Following experimental evolution of squid-naïve *V. fischeri* strain in the squid *Euprymna scolopes*, a previously uncharacterized HHK (VFMJ11_A0397) was identified as an activator of bioluminescence in strain MJ11. Here, we investigated how this regulator interfaces with the known QS machinery using native and mutant forms of VFMJ11_A0397. We hypothesized that this HHK is prototypical and requires a C-terminal REC domain to interact with bioluminescence-specific HPT and RR partners. To identify downstream RR partners, the wild-type allele was overexpressed in a series of RR null mutants of the well-characterized strain ES114. The VFMJ11_A0397 gene did not significantly increase bioluminescence in a *luxO* null mutant or in the presence of a LuxO allele locked in the phosphorylated state, suggesting that LuxO is a downstream partner. Expression of a truncated VFMJ11_A0397 lacking the REC domain did not increase bioluminescence by wild-type strain ES114 to the same extent as the full-length copy, suggesting loss of activity. Interestingly, the REC domain alone increased bioluminescence. Together, these results suggest that VFMJ11_A0397 promotes bioluminescence like the known *lux* HHKs LuxQ and AinR in a REC-dependent manner, likely by phosphatase activity. Future work will further elaborate how this new player integrates with the well-insulated *lux* regulatory pathway and provide insight into the evolution of the QS pathway as a key player in symbiosis.

The Effect of an Anti-Virulence Therapy on Virulence, Pathogen Fitness, Pathogen Behavior and Host Responses

Author Block:

M. Weigert[1], A. Ross-Gillespie[1], G. Pessi[1], S. P. Brown[2], R. Kümmerli[3]; [1]Univ. of Zurich, Zürich, Switzerland, [2]Georgia Inst. of Technology, Georgia, GA, [3]Univ. of Zürich, Zürich, Switzerland

Abstract Body:

Anti-virulence treatments aim to disarm rather than kill pathogens, and that is why selection for drug resistance should be relatively weak. However, in order to develop effective and evolutionarily robust anti-virulence treatments we need a detailed understanding of how anti-virulence drugs affect pathogen fitness and virulence. Additionally, we also need to understand potential side effects of these drugs, including changes in pathogen behavior (through altered gene expression) and host defense mechanisms.In this study we address these questions using the human pathogen *Pseudomonas aeruginosa* and the insect host *Galleria mellonella* as a model system. In particular, we are focusing on pyoverdine, an iron scavenging siderophore, which is an important virulence factor. We reduced pyoverdine availability by using gallium (an iron mimic), which quenches pyoverdine outside the cell, but also studied the effect of increased pyoverdine availability by adding purified pyoverdine to infections. We examined how these treatments affected host survival (as a proxy for virulence), bacterial fitness, the expression of genes linked to pyoverdine, and host responses.We found that virulence scales linearly with pyoverdine availability, which indicates that anti-virulence drugs can efficiently and predictively reduce virulence. Pathogen fitness, however, peaked at intermediate pyoverdine availability, showing that this anti-virulence therapy does not curb bacterial growth in a predictable way. Next, we used qPCR to show that pyoverdine quenching also reduced the availability of two other virulence factors (exotoxin A and protease IV), highlighting that anti-virulence therapy can affect multiple traits. Finally, we found that pyoverdine availability significantly affected host immune responses, which in turn might modulate pathogen and host fitness.Our findings show that gallium in particular and anti-virulence treatments in general could become important tools against nosocomial infections caused by multi-resistant bacteria. However, our results also reveal that a deeper engagement with the intrinsic complexity of host-pathogen systems is required to realize effective and evolutionarily robust anti-virulence therapies.

Examining the Nodulation Pathway in *Burkholderiatuberum*

Author Block:

A. Arnell, H. Abdulla, M. Lum; Loyola Marymount Univ., Los Angeles, CA

Abstract Body:

Nitrogen is the most limiting macronutrient for plant growth despite its abundance in the Earth's atmosphere, as plants are incapable of harnessing atmospheric N_2. Some bacteria are capable of fixing N_2 into ammonia (NH_3), a form usable by plants. Nitrogen-fixing bacteria known as rhizobia engage in a symbiotic relationship with legumes and trigger the formation of nodules on roots within which the bacteria are housed and fix nitrogen for the plant in exchange for carbohydrates. The bacterial *nod* genes are induced by flavonoids secreted by plants experiencing nitrogen stress, which results in the production of Nod factor, a critical signal triggering nodule formation. In the well-studied α-rhizobia, *nodD* encodes a constitutively expressed regulatory protein sensitive to these flavonoids and induces the expression of the *nod* genes, It is thus far believed that β-rhizobia function similarly to α-rhizobia both genotypically and phenotypically, however few studies have addressed the regulatory mechanisms in the β-rhizobia. In order to shed light on the nature of the nodulation pathway in *B. tuberum*, we are investigating the role of *nodD* in nodulation and regulation of the *nod* genes by characterizing a *nodD* deletion mutant and expression of a *nodC* transcriptional fusion to the *lacZ* reporter gene. The *nodC* gene was selected as the target of a promoter-reporter fusion due to its regulation by NodD in α-rhizobia and its importance in the nodulation pathway. Nodulation assays indicate that the deletion of *nodD* does not negatively affect the bacteria's ability to interact with the host plant, as functional nodules are observed in plants inoculated with the mutant. Through a series of Miller assays we discovered a significant increase (>400%, $p<0.01$) in the expression of *nodC* in *B. tuberum* in the presence of genistein and daidzein, flavonoids known to induce the nodulation response in α-rhizobia.

Investigating Partner Choice of *Medicago polymorpha* as It Evolves in Non-Native Regions

Author Block:

K. J. Wozniak[1], M. L. Friesen[1], S. S. Porter[2]; [1]Michigan State Univ., East Lansing, MI, [2]Washington State Univ., Vancouver, WA

Abstract Body:

The *Medicago polymorpha-Ensifer medicae* mutualism increases legume growth due to symbiotic nitrogen fixation in nodules and has evolved from the Mediterranean coast to all continents except Antarctica. This legume-rhizobia symbiosis has agricultural and ecological importance and is a model system of how mutualisms operate in diverse ranges. To determine whether the legume's ability to choose bacteria has evolved as a consequence of invading new habitats, *M. polymorpha* from California (invasive) and Portugal (native) was inoculated with single and mixed strains of co-evolved and naive *E. medicae.* We hypothesized that if native legume genotypes exhibit a specialist behavior, they would have increased biomass when inoculated with single strains of co-evolved rhizobia. Conversely, increased fitness would be observed in invasive legume genotypes inoculated with a mixed range of rhizobia due to relaxed selection on host partner choice. After legumes reached reproductive maturity, dry weights were taken of nodules, shoots, and roots to determine how partner choice influenced fitness according to region. The Portugal legumes outperformed California legumes in overall biomass and had slightly higher biomass when inoculated with a single co-evolved strain. California legumes had higher shoot and root biomass when given a mixed inoculation of co-evolved strains. Additionally, invasive *M. polymorpha* genotypes appear to have relaxed symbiont selection because they performed better with mixed inoculation and native genotypes maintain their specialist behavior when given co-evolved *E. medicae*. Taken together, these findings suggest that both native and invasive *M. polymorpha* perform well when interacting with co-evolved strains.

A Multi-Omics Investigation of the Response of *Setaria viridis* to Growth Promoting *Azospirillum brasilense* Rhizobacteria

Author Block:

A. P. Ferrieri[1], C. K. Ansong[1], E. M. Zink[1], A. Dohnalkova[1], R. K. Chu[1], J. B. Cliff III[1], C. R. Anderton[1], L. Paša-Tolić[1], M. Schueller[2], G. Stacey[2], R. Ferrieri[2]; [1]Environmental and Molecular Sci. Lab., Richland, WA, [2]Univ. of Missouri, Columbia, MO

Abstract Body:

Plant growth-promoting rhizobacteria are considered to have a beneficial effect on host plants; however, it is controversial whether biological nitrogen fixation from associative interaction contributes to growth promoting effects. This project uses S*etaria viridis* as a model C4 grass to explore the mechanisms underpinning biological nitrogen fixation in association with the plant growth promoting rhizobacteria, *Azospirillum brasilense*. Using a systems biology approach, *S. viridis* plants have been extensively studied at the physiological and biochemical levels using compositional and flux analysis with radioactive (^{11}C, ^{13}N) tracers. Here we highlight new results using a high-throughput, isobaric tags for relative and absolute quantitation (iTRAQ)-based, quantitative proteomic approach to analyze changes in protein profiles of *S. viridis* roots inoculated with an ammonium-excreting strain of *A. brasilense* (Hm053). General features of the *S. viridis* root proteome included the up-regulation of proteins related to amino acid biosynthesis (e.g. glutamate and glutamine metabolic processes), carbon transport and metabolism, and protein turnover in the presence of *A. brasilense.* These findings provided direction for multi-scale mass spectrometry imaging (MALDI, nanoSIMS) studies aimed to understand the trafficking of ^{13}C- and ^{15}N-labeled compounds between bacteria and roots. Together these studies offer insight into the mechanisms by which rhizobacteria establish themselves as symbionts within their hosts during early stages of infection, and a deeper understanding of the mechanism for their promotion of plant growth through associative nitrogen fixation and other phytostimulatory actions. Knowledge gained from this effort will directly translate to next-generation bioenergy cropping systems fostering more robust plants.

Developing a Genetic System for *Frankia*

Author Block:

R. Oshone, S. Hurst, C. Pesce, L. Tisa; Univ. of New Hampshire, Durham, NH

Abstract Body:

Background: *Frankia* are soil-dwelling actinobacteria that form a nitrogen-fixing symbiotic association with 8 different families of angiosperms. Despite over two decades of research in the area, the genetics of *Frankia* is still in its infancy. There are no known systems for gene transfer in *Frankia*. For an increased understanding of *Frankia* physiology and plant-microbe interactions, it is essential that transformation and targeted mutagenesis protocols are established. Here, we report the introduction of a plasmid (pHTK1) that could stably replicate and express both an antibiotic resistance gene and the green fluorescent protein marker (GFP) in *Frankia*. **Methods**: *Frankia* sp. CcI3 was conjugated with *Escherichia coli* BW29427 (DAP^-) containing the pHTK1 plasmid. The conjugants were plated on minimal growth medium containing tetracycline (20 µg/ml) and kanamycin (50 µg/ml). After three weeks, single colonies of transformants were inoculated into broth growth medium containing both antibiotics. The plasmid was extracted using a modified alkaline lysis method and visualized on an agarose gel. A PCR approach was used to confirm the plasmids by amplifying the REP and the *tetA* genes. The Transformed *Frankia* cells expressing the GFP protein were examined under UV light. **Results:** The filter mating between *Frankia* sp. CcI3 and *E. coli* BW29427 containing pHTK1 produced a conjugation frequency of 10^{-4} to 10^{-5} transconjugants/recipients. Single colonies of transformed *Frankia* cells were isolated and propagated in minimal growth medium containing tetracycline and kanamycin. Isolated transconjugants were stably maintained in culture suggesting that the pHTK1 plasmid was replicating in *Frankia* and the *tetA* gene on the plasmid was being expressed. The plasmid was re-isolated from *Frankia* transconjugants and visualized on an agorose gel. PCR amplification of the *tetA* and REP regions confirmed the presence of the plasmid in transconjugants. The copy number of the plasmid in *Frankia* was determined to be two per genome. Transconjugants fluoresced under UV light indicating the expression of the GFP protein in *Frankia*. **Conclusion:** This is the first report on the induction of a plasmid that could stably replicate in *Frankia* and is a major breakthrough in *Frankia* genetics. We are currently trying to use the pHTK1 plasmid to engineer a codon-optimized CRISPR/Cas9 system for site specific gene disruption in *Frankia*.

Single Molecule Real-Time Sequencing of Two *Bradyrhizobium* genomes Reveals Differences That May Account for Symbiotic Effectiveness and Viral Predation

Author Block:

N. Place; Delaware Biotechnology Inst., Newark, DE

Abstract Body:

Ensuring crop production is vital to food security and is a pressing issue in light of predicted world population increase. Legumes, which are rich in protein and critical to the diets of humans and animals, require a steady supply of nitrogen, provided through root symbiosis with nitrogen-fixing bacteria, such as those in the genus *Bradyrhizobium*. This work sought to provide broad-based information on bradyrhizobia biology through whole genome sequencing and analysis of two strains differing in their symbiotic effectiveness with soybean.Using Pacific Biosciences single molecule real-time (SMRT) sequencing, >100X coverage of the genomes of *B. elkanii* USDA 76 and *B. diazoefficiens* USDA 122 was obtained and the genomes were closed through sequence assembly (ca. 9.1 Mbps each). The Rapid Annotation using Subsystem Technology (RAST) was used to predict and annotate genes. These genomes were found to be novel showing only distant homology to publically available complete genomes. One intact prophage was found in USDA 76 by PHAST (PHAge Search Tool). As no *Bradyrhizobium* phage genome sequences are currently available, this and other prophage segments provide a first glimpse into the potential impact of viral predation on the host. SMRT sequencing indicated a m6A modification in GANTC motif in both strains; this methylation is different from whole genome to prophage-like regions in USDA 122, 0.73% and 0.83% respectively.The location of genes related to symbiosis have been found in symbiotic islands and plasmids. Rhizobitoxine, a protein necessary for nodulation can be detrimental if overproduced. Using reference rtx operon genes, these genes were found in the sequenced genomes. USDA 76 continues to support this theory of an operon, but USDA 122's genes matching rtx genes were spread across the chromosome. Comparing the arrangement of these genes in the two strains divulges information about gene regulation affecting symbiosis. Analyzing the genomes of bradyrhizobia and their constitutive viruses discloses the symbiotic effectiveness due to population levels.

Dictyostelium discoideum* as a Model Organism to Identify Virulence and Virulence Regulatory Factors in *Escherichia coli

Author Block:

M. Weichseldorfer, M. Qureshi, P. Phan, B. Leicht, D. Parker, T. White, M. Hemm, N. Alkharouf, M. Snyder; Towson Univ., Towson, MD

Abstract Body:

Escherichia coli (*E. coli*) is normally found as part of the human gut microbiota, however a number of diarrheagenic strains have emerged, such as enterohemorrhagic *E. coli*. Identification and disruption of the virulence factors that promote infection could lead to a reduction in infection period of these *E. coli* strains and potentially species with homologous means of virulence. In order to identify *E. coli* strains with certain characteristics of virulence, we have turned to *Dictyostelium discoideum* (*D. discoideum*), a social amoeba that phagocytizes bacteria for nutrition and shares similar properties with mammalian macrophages. Using random mutagenesis, we created two mutant stocks of *E. coli*, each exposed to a different concentration of mutagen. These stocks were individually allowed to be phagocytized by *D. discoideum* over a period of time, enriching the culture and selecting for mutants resistant to the intracellular methods that *D. discoideum* employs to kill. After several rounds of selection, highly resistant mutants were isolated and we found that some of the resistant strains showed increased survival when compared to the wild-type strain. Once isolated, the full genomes of our resistant mutant strains were sequenced using Illumina's next generation MiSeq technology. While analyzing the sequencing data from these mutant strains, we found several potential genes of interest, including genes related to flagella, oxidoreductases, and acid resistance. We have begun to characterize genes of interest through various qualitative and quantitative assays using individual gene knockout strains. These studies should allow for identification of novel factors associated with regulation of virulence in *E. coli*. In addition, given that the development of mechanisms to resist *D. discoideum* predation may have contributed to the selection and maintenance of bacterial virulence factors against mammalian hosts, these studies may provide insight on the evolution of host-pathogen interactions.

Dna Inversion Regulates Outer Membrane Vesicle Production in *Bacteroides fragilis*

Author Block:

H. Nakayama-Imaohji, T. Kuwahara; Kagawa Univ., Faculty of Med., Kagawa, Japan

Abstract Body:

Background: Phase changes in *Bacteroides fragilis*, a member of the human colonic microbiota, mediate variations in a vast array of cell surface molecules, such as capsular polysaccharides and outer membrane proteins through DNA inversion. Three master DNA invertases that globally control promoter inversions at many distant regions have been identified in *B. fragilis*: Mpi, Tsr0667 and Tsr19 (corresponding to the BF2766-encoded DNA invertase in *B. fragilis* YCH46). BF2766 inverts two distantly localized promoters, IVp-I and IVp-II. In this study, these BF2766-regulated invertible promoters of *B. fragilis* were further analyzed to determine the role of their associated proteins in surface structure modification.**Methods:** A series of BF2766 mutants were constructed in which the two promoters were locked in different configurations (IVp-I/IVp-II=ON/ON, OFF/OFF, ON/OFF or OFF/ON). Cell surface morphology of the four mutants were analysed by scanning electron microscopy and transmission electron microscopy. DNA microarray analysis was performed with the four locked mutants to identify genetic regions whose alterations in expression were specifically associated with a hypervesiculating ON/ON. To examine the role of outer membrane vesicle (OMV) production in adaptation to cell envelope stress, we compared the survival of the four mutants following contact with antimicrobial compounds (bile, LL-37 and human defensins).**Results:** ON/ON *B. fragilis* mutants exhibited hypervesiculating, whereas the other mutants formed only a trace amount of OMVs. By comparing the transcriptomes of the four BF2766 deletion mutants, we found that the transcription of the genes downstream of IVp-II markedly elevated in a hypervesiculating ON/ON strain. The ON/ON mutants showed higher resistance to treatment with bile, LL-37, and human β-defensin 2. Incubation of wild-type cells with 5% bile increased the population of cells with the ON/ON genotype.**Conclusions:** These results indicate that *B. fragilis* regulates the formation of OMVs through DNA inversions at two distantly related promoter regions in response to membrane stress, although the mechanism underlying the interplay between the two promoters remains unknown.

Pseudomonas Quinolone Signal: A Cross-Species Outer Membrane Vesicle Inducer

Author Block:

A. M. Horspool, J. W. Schertzer; Binghamton Univ., Binghamton, NY

Abstract Body:

Abstract: Microbial communities in nature rely on cellular communication and transport for regulating essential processes governing microbial growth, viability, and pathogenesis. Utilization of quorum sensing molecules by bacteria to monitor cell density within an environment is necessary to establish synchronized expression of virulence factors required for pathogenesis. Previously, quorum sensing molecules and virulence factors have been discovered to be transported within vesicles produced from the outer membrane of *Pseudomonas aeruginosa*. These Outer Membrane Vesicles (OMVs) are capable of delivering virulence factors to host cells and can induce cytotoxicity.It has been shown that the quorum-sensing molecule 2-heptyl-3-hydroxy-4-quinolone (PQS) is capable of inducing the formation of OMVs in *P. aeruginosa* in a manner independent of its receptor or *de novo* protein synthesis. We showed that PQS was capable of inducing membrane curvature in model membranes and developed the Bilayer-Couple model to describe this phenomenon. We further hypothesized that biophysical control of OMV formation by small molecules may play an important role in the physiology of other Gram-negative organisms. To test this hypothesis, we exposed other species of bacteria known to produce OMVs to exogenous PQS and quantified the resulting OMV production. The rationale was that if PQS exerts a biophysical effect on membranes, OMV production would be increased in the other species when exposed to exogenous PQS. Here we show that introduction of PQS to cultures of *P. aeruginosa, Escherichia coli, Proteus mirabilis, Proteus hauseri*, or *Klebsiella pneumoniae* results in increased OMV formation in all cases. Consistent with our work using model membranes, this suggests that PQS has a biophysical effect on the outer membranes of many common Gram-negative organisms and that membrane curvature-induction by small molecules may be a feature involved in OMV formation across species.

Enteroaggregative *Escherichia coli* Antiaggregation Protein Shields Multiple Surface Proteins Involved in Autoaggregation

Author Block:

L. J. Bowers[1], C. O. Hale[1], L. V. Blanton[1], L. T. Wang[1], J. Hofmann[1], J. W. DuBow[1], I. N. Okeke[2]; [1]Haverford Coll., Haverford, PA, [2]Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Enteroaggregative *Escherichia coli* (EAEC) cause diarrhea and show exceptional autoaggregation and biofilm-formation abilities. Among the surface factors contributing to autoaggregation of EAEC strain 042 are aggregative adherence fimbriae II (AAF/II) and the heat-resistant agglutinin 1 (Hra1), which is sufficient but not necessary for autoaggregation. We hypothesized that double mutations in these genes and the antiaggregation protein, Aap, would identify autoaggregation factors that are masked by Aap. **Methods:** Single and double mutants in the *aafA, hra1* and *aap* genes were constructed by allelic exchange. Autoaggregation was quantified in settling assays and the ability of strains to initiate biofilms on a vertical glass surface was monitored qualitatively. **Results:** We confirm that *aap* mutants autoaggregate faster and to a greater extent than wild type and that an *hra1* mutant is not deficient in autoaggregation. Deletion of *aafA* reduced autoaggregation but autoaggregation was actually enhanced in the *aap* and *aafA* double mutant, suggesting that other adhesins were unmasked by removal of these factors. Autoaggregation phenotypes largely predicted the formation of aggregates in a vertical biofilm, with the important exception that the *hra1* mutant, but not the *hra1-aap* double mutant, was defective in this phenotype. We additionally observed autoaggregation mediated by an unidentified phase-variable factor in the *hra1-aap* double mutant. **Conclusions:** Autoaggregation and biofilm formation are robust in 042 because of contributions from different adhesins. AAF/II and Hra1 make subtly separate contributions to these phenotypes. Aap sterically masks afimbrial surface proteins involved in autoaggregation including Hra1 and an as yet unknown, potentially phase-variable factor.

Enteroaggregative *Escherichia coli* Surface Proteins Modulating Intercellular Interactions

Author Block:

M. A. Levine[1], J. Hofmann[1], I. N. Okeke[2]; [1]Haverford Coll., Haverford, PA, [2]Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Enteroaggregative *Escherichia coli* (EAEC) are diarrheal pathogens defined by the characteristic 'stacked brick' or aggregative adherence pattern they produce on epithelial cells. EAEC are exceptional colonizers and express several factors involved adherence to eukaryotic cells. We studied adherence of EAEC strain 042, focusing on aggregative adherence fimbriae II (AAF/II), antiaggregation protein (Aap) and heat-resistant agglutinin 1 (Hra1). All three have separately been shown to contribute to eukaryotic cell adherence, and Aap and AAF/II are transcriptionally regulated by AggR. We hypothesized that Aap, Hra1 and AAF/II interact to optimize adherence. **Methods:** We qualitatively studied hemagglutination and epithelial cell adherence of EAEC strain 042 as well as its single and double isogenic mutants in the *aap, aafA* and *hra1* genes. **Results:** The *aggR* master regulator gene was required for all phenotypes and *aafA* was required for hemagglutination. However, all other single deletions produced no or modest changes in eukaryotic cell adherence. The *aap* mutant did not elicit true aggregative adherence at one hour but the phenotype was similar to wild type after three hours incubation. Deleting *hra1* or *aafA* produced a similar slowing of stacked-brick formation, unless *aap* was also deleted, in which case aggregative adherence occurred at wild type levels by one hour. **Conclusions:** Aap and AAF/II both appear to interact with Hra1 and/or another adhesin, likely by steric inhibition. Deletion of *aap* and *hra1* impedes stacked brick formation, suggesting that these might be important early-stage factors in EAEC adherence.

Detergent-Based Purification of *Shigella* Invasion Plasmid Antigen C Provides Superior Stability and Facilitates Direct Characterization of Membrane Interaction

Author Block:

A. Bernard[1], P. Kumar[2], N. E. Dickenson[1]; [1]Utah State Univ., Logan, UT, [2]Univ. of Kansas, Lawrence, KS

Abstract Body:

Shigella spp. infection results in shigellosis, a severe form of bacillary dysentery. *S. flexneri* utilizes a Type III Secretion System (T3SS) to provide a direct conduit between the bacterial and host cell cytoplasm and allow direct transfer of effector proteins into the host cell cytoplasm. Invasion Plasmid Antigen C (IpaC) is a critical component of the secretion system as it not only serves to polymerize the host cell cytoskeleton and promote pathogen uptake, but it also localizes to the tip of the T3SS where it is believed to play a crucial role in membrane interaction and translocon insertion. While the precise roles of IpaC within the context of the T3SS are not fully understood, *Shigella's* reliance on IpaC for virulence and its localization on the pathogen surface make it a particularly attractive target for anti-infective therapeutics. Progress on this front has proven challenging, however, as difficulties obtaining recombinant soluble IpaC have prevented a full understanding of the mechanism and driving forces behind the IpaC host membrane interaction. Traditionally, purification of IpaC has relied on either collection from *Shigella* culture supernatant or use of the chaotropic agent urea, imposing certain limitations on *in vitro* characterization. Here, we have developed alternative purification methods to obtain purified recombinant IpaC and present data finding that these conditions provide IpaC in an appropriate state for further *in vitro* characterization. Specifically biophysical characterization including liposome flotation assays, encapsulated dye release and circular dichroism found that the developed methods provide significantly higher levels of active protein with superior stability characteristics compared to traditional methods. Additionally, recent findings made possible by these advancements in IpaC purification are presented, providing new insight into the IpaC/host membrane interaction.

Inhibition of Pilus Assembly by the Small Molecule Nitazoxanide

Author Block:

J. J. Psonis, P. N. Chahales, D. G. Thanassi; Stony Brook Univ., Stony Brook, NY

Abstract Body:

Uropathogenic *Escherichia Coli* (UPEC) is the primary causative agent of urinary tract infections (UTIs), which afflict more than 50% of women and 15% of men. Critical to the establishment of UTIs by UPEC are pili. The pili (or fimbriae) expressed by UPEC are virulence-associated surface structures that are assembled by the chaperone/usher (CU) pathway and mediate bacterial adhesion to host cells. We have discovered that the small molecule nitazoxanide (NTZ) inhibits pilus biogenesis via the CU pathway in UPEC. We have determined that the inhibitory effect of NTZ on pilus biogenesis is due to interference with proper maturation of the usher protein in the bacterial outer membrane (OM). The usher is required for assembly of the pilus fiber and secretion of the fiber across the OM to the cell surface. The usher is folded and inserted into the OM by the ß-barrel assembly machinery complex (Bam), which in *E. coli* consists of five proteins, BamA-E. We are using a variety of approaches to determine the mechanism by which NTZ interferes with usher folding, including measuring binding of NTZ to the usher, to individual Bam proteins, or to the intact Bam complex. In addition, we are using lipid nanodisc technology to reconstitute the folding pathway of the usher in the outer membrane. Lipid nanodiscs are self-assembled, discoidal, nanoscale particles of lipid bilayer stabilized in solution by two encircling amphipathic helical proteins, termed membrane scaffold proteins. As soluble and stable membrane mimetics, nanodiscs represent an attractive model system for biophysical and biochemical studies of membrane proteins such as the usher. We have successfully reconstituted the Bam complex into lipid nanodiscs and are using these to compare the ability of nanodisc-reconstituted Bam complex to fold urea-denatured PapC, in the presence or absence of NTZ. These studies will help to identify the specific target of NTZ and its mechanism of action, and will facilitate the design of new therapeutic agents that target bacterial adhesion. In addition, these studies will reveal new details by which proteins such as the usher fold in the outer membrane.

Homo-Trimeric Structure of Type IV Minor Pilin CofB of CFA/III from Human Enterotoxigenic *Escherichia coli*

Author Block:

H. Oki, K. Kawahara, S. Fukakusa, T. Yoshida, T. Maruno, Y. Kobayashi, D. Motooka, T. Iida, T. Ohkubo, S. Nakamura; Osaka Univ., Suita, Japan

Abstract Body:

In gram-negative bacteria, the assembly of type IV pilus (T4P) and its evolutionally related pseudopilus of type II secretion (T2S) system, involving characteristic structural proteins called pilins or pseudopilins respectively, is dynamically regulated for enhancing bacterial functions, such as protein transport, adherence, and motility. Despite their importance for bacterial pathogenesis, the question of how (pseudo) pilins are assembled to form such filamentous appendage is still remains to be answered. Previous studies suggested that the structural "tip" like ternary complex formed through the interaction of minor (pseudo) pilins, for example GspK, GspI, and GspJ from the T2S system of enterotoxigenic *Escherichia coli*, plays an important role in this process, while some members of the pathogenetic type IVb subfamily are known to have only one such minor subunit whose function is unknown. Here we determined the crystal structure of the type IVb minor pilin CofB of CFA/III from human enterotoxigenic *Escherichia coli* at a resolution of 1.88 Å. The structure, in conjunction with physicochemical analysis in solution, clearly showed the homo-trimeric arrangement of CofB. Each CofB monomer in the trimer has unique three-domain architecture, in which C-terminal lectin-like domain could effectively initiate the trimer association of its pilin-like N-terminal domain by extensive hydrophobic interactions followed by domain-swapping occurred at middle domain. Coupled with the result of *cofB* deletion mutant of *Escherichia coli* showing phenotype with no pili formation, we found by the molecular modeling study that the minor pilin CofB of CFA/III does promote the T4P assembly by forming homo-trimetric structural "tip" like complex. This study further enhances our understanding of the conserved mechanism of (pseudo) pilus assembly among these systems.

Characterization of a Novel K88-/Cs13-Like Pili of a Biofilm-Forming Enteroinvasive *Escherichia coli* (Bf-Eiec) Emergent Strain

Author Block:

C. Zhang, D. R. Leal-Barrera, 37232, O. G. Gomez-Duarte, 37232; VANDERBILT Univ., Nashville, TN

Abstract Body:

Biofilm-forming enteroinvasive *Escherichia coli* (BF-EIEC) is an emergent pathotype identified from a child with moderate to severe diarrhea in Bucaramanga, Colombia. Transposition mutagenesis of the isolate designated BC/Ac52.1 resulted in a mutant negative for biofilm formation. Preliminary sequencing analysis revealed that the transposition event occurred at a fimbrial operon homologous to K88 and CS13 pili. The objective of the study was to characterize the K88-/CS13-like pili at the genetic and phenotypic levels. Based on whole genome DNA sequence BLAST analysis, this BF-EIEC pili operon, putatively designated as *epl* (*E. coli* pili locus), is composed of seven structural genes including four fimbrial minor subunits C (504 bp), F (492 bp), H (798bp), and I (753 bp); one major subunit G (825 bp); one usher protein D (2397bp) and one chaperone protein E (783bp). Potential transcriptional regulators were found upstream and downstream of the operon in close proximity. The C, F, H, I minor subunits have the highest protein sequence homology with aalA of CS23 (90%), faeF, faeH, faeI of K88 (100%) of ETECs, respectively. The G major subunit has highest protein sequence homology with cshE of CS13 (ETEC) (99%) but low homology to major subunits in other closely related pili operons (23% to 37%). The operon contains eight overlapped nucleotides between C and D genes and three atypical initiation codons (ATT, TTG, and GTG) in three genes. Transmission Electron Microscopy (TEM) imaging showed the presence of the pili-like structure on the cell surface of the wild-type strain but not the transposition mutant strain. We cloned, expressed, and purified the pili major subunit *epl* G *in vitro*, indicating that the major subunit gene is intact and may likely be expressed in the wild type strain. This study provides preliminary evidence that the *epl* operon may be expressed in BF-EIEC that it may be implicated in adherence and gut colonization.

Fima2 Fimbriae are Required for *Acinetobacter baumannii* Biofilm Formation and Motility *In Vitro*

Author Block:

S. Singh, S. O'Dell, C. N. McQueary, J. L. Kessler, J. Luka, D. V. Zurawski; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

Acinetobacter baumannii is an important nosocomial bacterial pathogen due to its virulence, multidrug resistance (MDR), and prolonged survival in a desiccated state. *A. baumannii* has been a significant militarily-relevant pathogen in past wars such as Vietnam as well as the recent conflicts of Iraq and Afghanistan. *A. baumannii* is also responsible for ≥10% infections acquired in U.S. hospitals, and poses a formidable threat to post-operation patients. There are some strains that have been classified as extensively drug resistant and even pandrug-resistant, which is fueling the current research to develop novel therapeutics. Factors that may contribute to *A. baumannii* pathogenicity include biofilm formation, motility, dissemination, secreted toxins, and adherence. Fimbriae have been previously implicated in both motility and biofilm formation, qualities that are thought to contribute to *A. baumannii* colonization, and ultimately virulence. After sequencing and annotation of our model strain, AB5075, we have identified two other fimbrial operons, which we are now calling FimA1 and FimA2 because of their homology to the FimA-like fimbriae from other bacterial species. We hypothesized that a disruption in either of these two systems may impact motility and/or biofilm formation. Using a sequenced, Tn5 transposon library of AB5075, we analyzed mutants of the major fimbrial subunit in each system, fimA1::Tn*5* and fimA2::Tn*5* (fimA1- and fimA2-) and a pilA- mutant as a control. We found that the fimA2- mutant made less biofilm in comparison to wild-type AB5075 and to the other mutants tested. Further, a fimA2- mutant had decreased twitching motility when compared to its wild-type parent and pilA-. Upon analysis of proteins being secreted during late log/stationary phase, we identified the FimA2 protein by mass spectrometry as being one of five major proteins secreted into the extracellular milleu in minimal media. FimA2 protein was overexpressed, purified, and monoclonal antibodies were generated. We are currently testing the antibody as a possible treatment and comparing wild-type, mutant, and complemented strains in virulence models of infection. Overall, these results suggest that FimA2 is the major fimbrial subunit of a previously unidentified fimbriae that is required for biofilm and motility in *A. baumannii*.

The Genomic Sequence of a Ciprofloxacin-Resistant Strain of *Francisella tularensis* Identified an LPS Mutation Which Leads to a Severe Attenuation in Murine Models of Tularemia

Author Block:

J. A. Bozue, R. Toothman, J. Chua, T. Kijek, J. Ladner, C. Cote, G. Koroleva, S. Lovett, F. Biot, S. Mou, G. Palacios, N. Vietri, P. Worsham; USAMRIID, Fort Detrick, MD

Abstract Body:

Background: *Francisella tularensis* is a gram-negative facultative intracellular bacterial pathogen that can infect many mammalian species, including humans. Because of its ability to cause a lethal infection, its low infectious dose, and aerosolizable nature, *F. tularensis* subspecies *tularensis* (*Ft*) is considered a potential bioterrorism agent. The potential of bacteria to become resistant to antibiotics through natural or intentional genetic alteration increases our risk to biothreat agents. The fluorinated quinolone, ciprofloxacin is one of the antibiotics of choice for treating many of these infections. However, there are several examples of laboratory derived resistant *Francisella* species in the literature.**Methods:** A naturally selected ciprofloxacin resistant mutant of the Schu4 strain was further characterized, including whole genome sequencing.**Results:** Alterations to the *gyrA* and *parE* genes were confirmed, most likely leading the ciprofloxacin resistance. Most other mutations were missense mutations. However, a frame shift to *kdsD* which encodes for arabinose phosphate isomerase was identified. This enzyme catalyzes the conversion of the pentose pathway intermediate D-ribulose 5-phosphate into D-arabinose 5-phosphate (A5P). A5P is a precursor of KDO, an integral part of the LPS. A *kdsD* mutation in Schu4 *Ft* was constructed using a modified TargeTron mutagenesis system and characterized. In addition, a transposon mutant in the homologous gene (*kpsF*) of the subspecies *F. novicida* (*Fn*) U112 strain was also examined. The virulence of these mutant strains was characterized through in vitro macrophage assays and various murine models of tularemia. Both mutant strains were affected in their ability to infect macrophages and to cause disease in mice. Virulence could be restored via genetic complementation.**Conclusions:** The A5P isomerase is essential for tularemia, in murine models of infection. This enzyme appears to be an attractive target for future therapeutic studies to combat antimicrobial resistance for biothreat agents.

Adherent to a New Set of Rules: Adhesin Gene Maintenance and Expression in *Shigella flexneri* Infection

Author Block:

R. B. Chanin, K. P. Nickerson, D. K. Vijaya Kumar, C. S. Faherty; Massachusetts Gen. Hosp., Boston, MA

Abstract Body:

Shigella flexneri is a Gram-negative, facultative intracellular pathogen that invades the colonic epithelium and causes significant diarrheal disease in children of the developing world. Based on the current infection paradigm, *Shigella* transits M cells in the colon prior to invasion, but it remains unknown how contact is initiated with these cells. *Shigella* is closely related to *Escherichia coli* and maintains many of the same fimbrial gene operons; however, at least one critical gene component in each operon is mutated. These mutations, coupled with the immunostimulatory nature of adherence factors, have led the field to hypothesize that *Shigella* is unable to produce fimbriae. With previous data suggesting that *S. flexneri* can adhere to epithelial cells, our goal is to determine if the pathogen utilizes adhesins to initiate infection. Using RT-PCR, we have detected expression of conserved Type 1 *fim* genes and five additional adherence gene clusters. Expression of these genes was further enhanced by *S. flexneri* growth in glucose, as determined by quantitative RT-PCR. Furthermore, bacterial adherence to colonic HT-29 cells was enhanced 10-fold following glucose exposure. Interestingly, transmission electron microscopy of *S. flexneri* grown in the presence of glucose revealed mostly afimbriated bacteria. However, in a related project, imaging of bacteria grown in the presence glucose and bile salts revealed highly adhesive bacteria with fimbrial-like structures. Since we have previously shown that bile salts induces protein secretion in *S. flexneri*, we hypothesize that the coordinated exposure to glucose combined with a secretion signal, such as host cell contact or bile salts, is required for the proper assembly and expression of *S. flexneri* adhesins. We are currently performing targeted mutagenesis and protein interaction studies to identify the specific genes required for producing these structures. Our work demonstrates that conditions present endogenously in the host, such as glucose and bile salts, offer key stimuli needed for proper adherence factor expression in *Shigella*. This work may translate to other enteric pathogens; and importantly, these fimbrial-like structures could become novel vaccine targets for *Shigella.*

The *Shigella flexneri* OspE1 and OspE2 Proteins Form a Bile Salt-Induced Complex to Facilitate Adherence

Author Block:

K. P. Nickerson[1], R. B. Chanin[1], J. R. Sistrunk[2], D. A. Rasko[2], C. S. Faherty[1]; [1]Massachusetts Gen. Hosp., Boston, MA, [2]Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Globally, the *Shigella* species cause watery diarrhea and bacillary dysentery, resulting in significant pediatric morbidity and mortality in developing countries. Attempts to develop an effective vaccine remain unsuccessful, possibly due to a limited understanding of early steps in *Shigella* pathogenesis. Following oral ingestion and transit through the gastrointestinal tract, which includes bile exposure in the small intestine, *Shigella* invades the colonic epithelium to establish infection. We have previously demonstrated that bile salts promote adherence to colonic epithelial cells through the induced expression and localization of the homologous OspE1 and OspE2 proteins to the bacterial outer membrane. In this study, we have continued to characterize the mechanism of OspE1/2-mediated adherence. First, we have demonstrated that pre-treatment of bacteria with an OspE1/2 antibody inhibited bile salt-induced adherence to colonic epithelial cells. Furthermore, bile salts promoted bacterial adhesion to several extracellular matrix components including laminin, fibronectin and mucin. These interactions were dependent on OspE1/2 since a Δ*ospE1/2* mutant was unable to reproduce the phenotype. We hypothesize that OspE1/2 adhesion to ECM components is a mechanism by which *Shigella* identifies the colonic epithelium prior to infection. Finally, through co-immunoprecipitation and protein purification experiments, we have identified bacterial protein candidates that bind OspE1/2. RNA-sequencing analysis has demonstrated that the genes encoding some of these proteins are also induced by bile salts exposure. We are currently performing additional mutational analyses to determine which candidates interact with OspE1/2. We hypothesize that the interacting proteins form an adhesion complex with OspE1/2 to facilitate bile salt-induced adherence. In all, our data demonstrate that bile salts exposure represents a critical gastrointestinal signal that coordinates *Shigella* OspE1/2-dependent adhesion during infection.

***Aliivibrio salmonicida* Requires O-Antigen for Optimal Virulence in Its Salmonid Host**

Author Block:

S. F. Nørstebø, H. Sørum, A. M. Bjelland; Norwegian Univ. of Life Sci., Oslo, Norway

Abstract Body:

Aliivibrio salmonicida is the causative agent of coldwater vibriosis, a hemorrhagic septicemia of farmed salmonids and cod. In the early years of Norwegian aquaculture, the disease caused major losses for the industry. Today, it is being well controlled by the use of vaccines. However, the virulence factors of *A. salmonicida* are still poorly understood. Several authors have reported the presence of VS-P1, an outer membrane complex comprised of rough-type LPS and a protein moiety, in the serum of moribund fish. A role in virulence for VS-P1 through modulation of the host immune response has been postulated.To investigate the role of LPS in the pathogenesis, we have constructed in-frame deletion mutants for O-antigen ligase, *waaL*. As this gene exists in two copies in the genome of *A. salmonicida* as part of a 29 kb duplication, we have constructed single and double mutants to explore potential effects of the gene duplication. Virulence was assessed by challenging Atlantic salmon parr (*Salmo salar* L.) through intraperitoneal injection (i.p.) of mutant or wild type bacteria.The Δ*waaL* mutant did not differ significantly from WT in terms of mortality. For Δ*waaL*Δ*waaL* on the other hand, mortality was reduced five-fold. In addition, bacterial colonization of the host blood stream was delayed for the double, but not the single mutant.The results suggest that *A. salmonicida* requires O-antigen for optimal disease development in Atlantic salmon. Even though two copies of the *waaL* gene is present, one is sufficient for function in virulence. Also, O-antigen does not seem to be necessary for survival *in vivo*, as some mortality was still seen after challenge with the double mutant.

Delineating Protein-Protein Interactions between Components of the Cpi-2 Encoded Type-III Secretion System from the Opportunistic Pathogen *Chromobacterium violaceum*

Author Block:

K. Zoccola, S. James, **H. Betts-Hampikian**; Clarion Univ. of Pennsylvania, Clarion, PA

Abstract Body:

Virulent bacteria are equipped with proteins capable of disrupting host cells. In order for many species to be able to infect a host, the pathogen must be able to transport and translocate virulence factors from the bacterial cytosol to the host cell cytoplasm. The evolution of bacterial secretion systems have allowed for this type of movement. Out of the six known secretion pathways, our focus is the type-III secretion system (T3SS). T3SSs are found only in Gram negative bacteria and resemble a molecular syringe, consisting of approximately 25 proteins housed within the cell envelope, collectively forming a hollow conduit. Distal to this basal apparatus is an extracellular needle-like structure which facilitates interaction with the host cell plasma membrane, and allows for the translocation of anti-host effector proteins directly into the eukaryotic cell. Recently an emerging opportunistic pathogen of humans and mammals, *Chromobacterium violaceum*, has been shown to harbor gene clusters encoding two T3SSs. A comprehensive bioinformatics analysis assigned these clusters as Chromobacterium pathogenicity islands 1 and 2 (Cpi-1 and Cpi-2 respectively). Genes on the loci of both Cpi-1 and Cpi-2 are evolutionary related to those in the Spi-1 and Spi-2 encoded T3SSs of *Salmonella enterica*. Based on this evidence, it has been proposed that Cpi-1 may function early in infection, and Cpi-2 may be required for survival within host cells. While some research pertaining to Cpi-1 has been accomplished, very little is known about Cpi-2. We have begun delineating the structure and function of the Cpi-2 apparatus by investigating protein-protein interactions between 11 putative inner membrane and needle apparatus components. Using the yeast two-hybrid (Y2H) system and assaying pair-wise for direct interactions, we have found the following: Interactions between CsaQ-U indicate they likely comprise the inner membrane ring structure, CV2588 interacts with itself in a manner consistent with its putative role as the needle protein, CseB1-4 may be capable of forming an extra-cellular filament, and CV2578 (putative class-II chaperone) interacts with the putative translocator proteins CV2576 and CV2676. We are currently in the process of performing further analyses to confirm our Y2H data.

***clostridium Sordellii* Exosporial Proteins Play A Role In Spore Viability And Gut Colonization**

Author Block:

R. Rabi, M. Awad, S. Larcombe, D. Lyras; Monash Univ., Clayton, Australia

Abstract Body:

Clostridium sordellii causes a range of often fatal diseases in humans and animals. Crucial to the infectious cycle of *C. sordellii* is its ability to form spores, the outermost layer of which, the exosporium, is the initial contact point between the spore and the host or environment. Despite the importance of spores in the clostridial life cycle, the *C. sordellii* spore structure remains largely unknown. In particular, its exosporium has not been investigated.The *C. sordellii* exosporial proteome was determined using mass spectrometry and two uncharacterised proteins, Protein A and Protein B, were identified in high abundance. Genes encoding Protein A and Protein B were insertionally inactivated and spore morphology was characterised by electron microscopy. Mutant A spores had a polar exosporium compared to the central, uniformly distributed exosporium seen in wild-type spores. Mutant B spores lacked an attached exosporium, however, exosporial fragments were seen in the spore preparation. Thus, both Protein A and B may play a role in correct attachment of the exosporium to the spore. Sporulation assays determined that mutant A produced 10% less viable spores than the wild-type strain. Treating spores to a range of harsh conditions identified that mutant A had up to four times less resistance to acids and bases compared to wild-type spores and were therefore less hardy.*C. sordellii* has been identified as the cause of enteric disease in many animals. We therefore developed a mouse gut infection model and used this model to study the phenotypic effects of the exosporial mutations. Mice ($n \geq 5$) were orally gavaged with spores of each strain and faecal spores from each mouse were enumerated for four days post infection. Mice infected with wild-type and mutant A strains showed a steady decrease in faecal spore numbers by about one log per day. However, mice infected with mutant B did not show a decrease in faecal spore numbers, with spore numbers remaining high for the duration of the experiment. This phenotype was restored to that of the wild-type upon complementation. These results suggest that either the absence of Protein B or an exosporium, resulted in the persistence of spores in the gut. This is in line with *Clostridium difficile*, where research has shown that spores lacking an exosporium resulted in increased adherence to gut epithelial cells.

Regulation of the Enterotoxin Gene Cluster and Role in *Staphylococcus aureus* Infective Endocarditis

Author Block:

A. M. Martini[1], C. S. Stach[2], J. M. King[1], W. Salgado-Pabon[1]; [1]Univ. of Iowa, Iowa City, IA, [2]Univ. of Minnesota, St. Paul, MN

Abstract Body:

Infective endocarditis (IE) is a microbial infection of the heart characterized by inflammation and deposition of host factors on the endocardium. Left-sided, native valve IE caused by *Staphylococcus aureus* (SAIE) is notably aggressive, resulting in frequent cardiac, neurological, and renal complications and carries a mortality rate of 30-40%. Among the myriad virulence factors produced by *S. aureus*, Staphylococcal enterotoxins (SEs) (e.g., SEA, SEB, and SEC) and non-emetic superantigens (SAgs) (e.g., TSST-1) are well-established agents of diseases such as food poisoning and toxic shock syndrome. The enterotoxin gene cluster (*egc*) is a locus of five to six SE-like genes with previously indirect association with disease and high prevalence in nasal and toxemia isolates of *S. aureus*. Previous work performed in our laboratory has demonstrated a critical role for SEC in a rabbit model of IE, suggesting *egc* SEs may also play a role in the development of SAIE. We utilize a rabbit model of left-sided, native valve IE and heterologous expression constructs to demonstrate the involvement of both TSST-1 and the *egc* in vegetation formation. Concomitant deletion of *tstH* and *egc* results in a significant decrease in vegetation size, while heterologous expression of either *tstH* or *egc* from a non-pathogenic strain produces vegetations. To investigate potential regulatory mechanisms of the *egc*, promoter-GFP fusions, immunoblotting, qPCR, and *in vitro* DNA-binding assays were performed. The global regulator MgrA was identified by EMSA to specifically bind upstream regions of *selo* and *selu*; however, transcriptional fusions in MgrA and an array of global regulator mutants known to modulate other virulence factors did not show alterations in promoter activation, suggesting a more complex level of control beyond global regulators. In contrast to other characterized SEs and SAgs, qPCR suggests expression of *egc* during exponential phase. Finally, immunoblotting suggests proteases do not impact the ability to detect native *egc* proteins from culture supernatant. Our data demonstrate a significant role for the *egc* in development of SAIE. Molecular mechanisms controlling *egc* expression appear distinct from those of the well-characterized SEs and SAgs, suggesting a novel mechanism of regulation for this locus.

Humanized Non-obese Diabetic Severe Combined Immunodeficient Common Gamma Chain-deficient (Nsg) Mice as Novel Models to Study the Acute and Chronic Effects of *Staphylococcal superantigens* on the Human Immune System *In Vivo*

Author Block:

A. Krogman, **G. Rajagopalan**; Mayo Clinic Coll. of Med., Rochester, MN

Abstract Body:

Background: Superantigens (SAg) are a family of potent exotoxins produced by *Staphylococcus aureus*. We systematically investigated the impact of SAg on the human immune system from the *in vivo* perspective using immunodeficient NSG mice reconstituted with human immune cells. Materials: Eight to ten-week old NSG mice were adoptively transferred with 50 million peripheral blood mononuclear cells isolated from healthy donors through intravenous route (n=6-8 mice/group). For the acute exposure model, mice were challenged with 10 μg of staphylococcal enterotoxin B (SEB), bled at 3 hours and sacrificed at 72 hours. For chronic exposure model, mice were subcutaneously implanted with mini osmotic pumps capable of releasing 10 μg of SEB or saline over a 7-day period and sacrificed on day 8. Results: In the acute model, unreconstituted NSG mice challenged with SEB as well as mice reconstituted with human PBMC but challenged with saline had undetectable levels of 26 human cytokines/chemokines at 0, 3 as well as 72 hours measured using a multiplex assay. However, NSG mice reconstituted with human PBMC and challenged with SEB had significantly elevated levels of Th1, Th2 as well as Th17 families of cytokines, with some elevated at 3 hours and some at 72 hours. Notable among them were IL-2 (10778±1886 pg/ml), IL-17A (330±20 pg/ml) and IFN-γ (9296±850 pg/ml) at 3 hours. Lungs, livers and kidneys only from this group of mice had significant infiltration with human CD4+ and CD8+ T cells mimicking classical multi-organ failure. Serum AST/ALT levels were also elevated in this group. In the chronic exposure model, SEB group had splenomegaly (Total splenocytes count = 79±11 million) compared to PBS group (Total splenocytes count = 21±6.5 million). The CD4+ as well as CD8+ T cell numbers were also increased in the SEB group (21±2 and 9.5±0.1 million) compared to PBS group (1.8±0.8 and 0.4±0.2 million). This was also accompanied by severe infiltration of various organs with T cells in mice from SEB group compared to PBS group. Summary: Overall, using humanized NSG mouse model we demonstrate for the first time that both acute as well as chronic exposure to staphylococcal SAg can elicit significant immunopathology and our observations could have significant clinical implications.

Report of the *egc* Cluster and Exotoxin Genes in a Blood Culture Strain of *Staphylococcus epidermidis* by Whole-Genome Sequencing

Author Block:

L. Pinheiro, V. C. Pereira, J. P. Araújo Jr, M. R. S. Cunha; Inst. de Biociencias de Botucatu, UNESP, Botucatu - SP, Brazil

Abstract Body:

Despite being considered as avirulent organisms for decades, the Coagulase-Negative Staphylococci (CoNS) have emerged as important cause of opportunistic infections, mainly associated to medical devices. The objective of this study was to investigate the toxigenic features of a *Staphylococcus epidermidis* strain (H-1006/91) isolated from blood culture of a patient hospitalized at a teaching hospital in Brazil. By PCR, the enterotoxin genes *sec*, *seg* and *sei* were identified in the strain. The isolate lacked the *sea*, *seb*, *sed*, *see*, and *seh* genes. Using the RT-PCR, it was found that H-1006/91 expressed both *seg* and *sei* mRNAs. The whole genome sequencing was performed using Illumina technology. Eighteen contigs contained parts or the complete sequence of enterotoxin genes of the *egc* cluster, including *seo*, *sem*, *sei*, *sen* and *segL29P* (*seg*), non-coding regions and integrase sequences, besides 89% and 99% of identity, respectively, to the *selv* and *selu* genes, and part of the pseudogenes *φent1* and *φent2*. The sequences were very similar (>70%) to the *S. aureus egc* cluster; *sem* and *seo* sequences presented the highest identities to the *S. aureus* genes. An 84-bp region of plasmid replication, very similar to the pETB (exfoliatin B plasmid) replication protein was also observed. There were identified very similar sequences to other exotoxins of *S. aureus* (*set8*, *set20*, *set13*, *set14*) and recombination genes were found. A large portion of the sequenced plasmid showed high relatedness to phage genes and a truncated transposase of the SCC*mec* type IV. In fact, the strain was *mecA*-negative. To our knowledge, this is the first report of the presence of all the coding sequences of the *egc* cluster by whole-genome sequencing in a strain of *S. epidermidis*. The *egc* is considered as an enterotoxin gene nursery, which could form new superantigen genes by recombination. In *S. aureus*, several allelic variants of this operon have been found, but its presence in CoNS is controversial. Here we show that the *egc* cluster may also confer selective advantage for *S. epidermidis* and, although possessing identity to the *S. aureus egc*, it contains several regions of recombination and SNPs. These events may lead to misidentification of these toxin genes and also cause generation of new superantigens in CoNS species.

Sphingomyelinase and Dna Biofilm Ligase Activities of *Staphylococcus aureus* β-Toxin Promote Infective Endocarditis and Sepsis

Author Block:

A. HERRERA[1], B. G. Vu[1], C. S. Stach[2], J. A. Merriman[3], A. R. Horswill[1], W. Salgado-Pabon[1], P. M. Schlievert[1]; [1]THE Univ. OF IOWA, Iowa City, IA, [2]Univ. of Minnesota, Minneapolis, MN, [3]Washington Univ., St. Louis, MO

Abstract Body:

Background: Infective Endocarditis (IE) is a life threatening infection of native/prosthetic valves and lining of the heart caused by bacteria. IE is characterized by the formation of vegetations composed of bacteria and host factors. Each year there are as many as 100,000 cases of IE in the United States. *Staphylococcus aureus* is the most commonly identified pathogen (up to 40%) in patients with IE. β-toxin is an important virulence factor in the arsenal of *S. aureus*, contributing to its ability to colonize and cause disease. This cytolysin has two distinct mechanisms of action: sphingomyelinase activity and DNA biofilm ligase activity. While a role for β-toxin has been demonstrated in IE, the mechanism of action that it uses to cause its effects has not been elucidated. **Methods:** Considering the active site of the DNA biofilm ligase activity of β-toxin is unknown, we began its characterization by examining deficiencies in site-directed mutants by use of *in vitro* DNA precipitation and biofilm formation assays. Possible conformational changes in mutant structure compared to wild type toxin were assessed via trypsin digestion analysis, retention of SMase activity, and a predicted model structure. We addressed the significance of each mechanism of action in producing IE *in vivo* during infections in a rabbit model of IE and sepsis.**Results:** We determined mutants T149A, H162A, and D163A were deficient in a DNA precipitation assay, and mutants T149A and H162A were no longer able to form biofilms comparable to wild type β-toxin in biofilm formation assay. All mutants were still able to lyse sheep erythrocytes and maintained the predicted folding conformation. Mutants H162A and D163A had similar stability to heat, and trypsin treatment as wild type. The β-toxin mutant, H289N, lacking sphingomyelinase activity, was decreased in lethality and vegetation formation compared to wild type. β-toxin mutants disrupted in biofilm ligase activity did not decrease lethality, but were deficient in vegetation formation compared to wild type.**Conclusions:** Our study begins to characterize the DNA biofilm ligase active site of β-toxin and demonstrates β-toxin plays an important role in IE via both mechanisms of action.

Bacillus thuringiensis* Secreats Some Virulence Factors to Disrupt Intestinal Epithelial Junctions and Accelerate the Invasion in *Caenorhabditis elegans

Author Block:

J. Lin, D. Peng, C. Pang, H. Du, L. Wan, S. Ju, L. Ruan, **M. Sun**; Huazhong Agricultural Univ., Wuhan, China

Abstract Body:

Bacillus thuringiensis (Bt), which is widely accepted as an entomopathogen, has been used to control agriculture pests. Some *B. thuringiensis* strains have high toxicity to nematodes and crystal (Cry) proteins are commonly known as the main virulence factors. It has been proposed that the culture mixtures of Cry proteins and spores (spore/crystal mixtures) can invade the nematodes, leaving the undigested cuticle which serves as a bag to form the "Bob" or bag-of-bacteria phenotype. To date, no study reveals the details about this significant phenomenon. Here we describe spores play an important role in the formation of "Bob" phenotype. We found that spore/crystal mixtures are able to disrupt intestinal cells in *C. elegans* to accelerate the invasion of *Bt* cells, leading eventually to the death of the worms, whereas the crystal proteins alone could only damage the gut, causing the shrinkage of the intestinal cells. The transcriptional regulation factors in *Bt* such as PlcR, NprR, CodY, AbrB and LuxS, which were reported to be responsible for the expression of multiply virulence factors, proved to be involved in the formation of "Bob". To deeply analysis the differences between the nematicidal mechanisms between crystal proteins and spore/crystal mixtures, we proposed that the epithelial junction of intestinal cells may serve as the underlying target of virulence factors regulated by these transcriptional regulation factors in *Bt* spores. The metalloproteinase ColB and Bmp1, which were proved to be regulated by PlcR in our previous work, were found capable of disrupting epithelial junctions directly. On the other hand, when these transcriptional regulation factors were knocked out in *Bt*, the disruption of intestinal epithelial junctions would decline rapidly, as well as the toxicity of these bacteria, indicating that the presence of the transcriptional regulation factors could accelerate the invasion of *Bt* in *C. elegans*, leading to the more effective nematicidal activity. Our findings present a novel perspective of the interaction between pathogenic bacteria and its nematode hosts and provide a convenient method to identify new virulence factors against nematodes, thus constructing the more efficient products of *B. thuringiensis*.

Screening Anthrax Toxin Inhibitors from Natural Plant Extracts

Author Block:

P. Jacques, K. Borrego, R. Skouta, **J. Sun**; Univ. of Texas at El Paso, El Paso, TX

Abstract Body:

Bacillus anthracis, the etiologic agent of anthrax diseases, is a gram-positive, spore-forming, rod-shaped bacterium. While naturally occurring anthrax is rare in United States, *B. anthracis* is classified by the Centers for Disease Control and Prevention (CDC) as a category A select agent, representing the biological agents most at risk of being weaponized. The major symptoms of anthrax diseases are caused by anthrax toxin action. Therefore, development of anti-toxin inhibitor is of great importance for biodefense and national security.Plant-derived natural compounds are a rich potential source of compounds that treat infectious diseases. Successes like artemisinin and a recently reported antimicrobial remedy with anti-staphylococcal activity as well as many others encourage us to screen anthrax toxin inhibitors from a group of antioxidant-enriched herb extracts. We discovered that the extract of rosemary, even at a very low concentration, had a very strong inhibitory effect on anthrax toxin action, thus rescued mammalian cells (mouse and human macrophage cell lines) from anthrax lethal toxin-induced cytotoxicity in a dose-dependent manner, while the extract alone had no cytotoxic effect on the cells. Further, we found that the extract strongly inhibited pore-formation of anthrax protective antigen on the liposomal membranes. Identification and characterization of the active component in the extract is currently in progress. This study has the potential to develop a novel natural compound inhibitor against anthrax toxin.

Inhibition of Cholera Toxin and Other AB Toxins by Polyphenolic Compounds

Author Block:

P. Cherubin[1], M. C. Garcia[1], D. Curtis[1], C. B. T. Britt[1], J. W. Craft, Jr.[2], H. Buress[1], C. Berndt[1], S. Reddy[1], J. M. Briggs[2], K. Teter[1]; [1]Univ. of Central Florida, Orlando, FL, [2]Univ. of Houston, Houston, TX

Abstract Body:

All AB-type protein toxins have intracellular targets despite an initial extracellular location. These toxins use different methods to reach the cytosol and have different effects on the target cell. Broad-spectrum inhibitors against AB toxins are therefore hard to develop because the toxins use different surface receptors, entry mechanisms, enzyme activities, and cytosolic targets. We have found grape seed extract provides resistance to five different AB toxins: cholera toxin (CT), Shiga toxin (ST), ricin, diphtheria toxin, and exotoxin A. To identify individual compounds in grape extract that can inhibit the activities of these AB toxins, we used a cell culture system to screen twenty common phenolic compounds of grape extract for anti-toxin properties. Twelve compounds inhibited CT, one inhibited ricin, three inhibited diphtheria toxin, and four inhibited exotoxin A. No individual compound generated resistance against ST, although a cocktail of all 20 compounds conferred partial resistance to ST. Additional studies were performed to determine the mechanism of inhibition against CT. Two compounds inhibited CT binding to the cell surface and even stripped CT from the plasma membrane of a target cell. Two other compounds inhibited the enzymatic activity of CT, and four blocked cytosolic toxin activity without directly affecting the enzymatic function of CT. We have thus identified individual toxin inhibitors from grape extract and some of their mechanisms of inhibition against CT. This work will help formulate a defined mixture of polyphenolic compounds that could potentially be used as a therapeutic against a broad range of AB toxins.

Purification And Identification Of Two Novel Toxins Implicated In Mucormycosis Pathogenesis

Author Block:

S. Soliman, M. Liu, J. Edwards, Jr., **A. S. Ibrahim**; Los Angeles BioMed. Res. Inst. at Habor-UCLA Med. Ctr., Torrance, CA

Abstract Body:

Background: Mucormycosis, caused by *Mucorales* fungi, is a life-threatening infection, occurring predominantly in immunocompromised patients and characterized by extensive vessel thrombosis and tissue necrosis. We previously discovered that killed *Mucorales* cause considerable damage to host cells, suggesting that a toxin(s) might be operative during infection. We sought to purify these toxins and characterize their role in damaging host cells and causing disease.**Methods:** *Rhizopus* mat was separated from the supernatant by filtration. The supernatant was extracted with ethyl acetate, dehydrated with Na_2SO_4 anhydrous, and evaporated before reconstituting in host cell medium. The separated fungal mat was ground in liquid nitrogen, extracted with either sterile water or host cell medium. Both extracts were filter sterilized prior to assessing their role in causing damage to alveolar epithelial (A549) cells by ^{51}Cr-release assay. The sterile extracts were also assessed for their ability to cause disease in CD-1 neutropenic mice injected i.v. qod with both extracts for a total of 3 doses. To further purify the extracts, fractionation-based A549 cell damaging assay was performed using size exclusion, PAGE, capillary force, silica and cellulose chromatography. Fractions with A549 cell damaging activity were trypsinized and the peptide sequenced by LC-MS.**Results:** Both crude extracts caused damage to A549 cells. Injection of the concentrated crude extracts in mice resulted in behavior highly suggestive of sudden circulatory shock within 30 min of injection. Further, mice injected with the toxin-like extracts lost weight (~30% drop in 5 d vs. water injected mice) and ultimately required euthanasia, similar to mice infected i.v. with live spores (70% and 100% mortality for extracts and live spores injected mice, respectively). LC-MS data of the purified active fractions from supernatant and hyphae extracts revealed a peptide that had sequence similarity to type VI bacterial toxin secretion system (T6SS) and ricin-like toxin, respectively.**Conclusions:** We have purified and characterized two novel *Mucorales* toxins that have similarities to (T6SS) and ricin-like toxins. These two toxins are likely to play a major role in the pathogenesis of mucormycosis and further investigations into this role are warranted.

The Toxin Pneumolysin Promotes Transmission of *Streptococcus pneumoniae*

Author Block:

M. A. Zafar, Y. Wang, S. Hamaguchi, M. Kono, J. N. Weiser; NYU Med. Sch., New York, NY

Abstract Body:

Streptococcus pneumoniae serially and sequentially colonizes the mucosal surface of the human nasopharynx beginning in the early childhood (the carrier state). Transmission occurs from carriers to non-carriers and is most frequent in settings of close contact, such as among siblings. Both colonization and transmission are more common in the setting of recent viral infection. Our previous work established an infant mouse model for pup to pup transmission of pneumococci using influenza A co-infection, which led to transit of the bacterium from inoculated index mice to uninfected contact mice. Here we show that without influenza A co-infection infant mice still shed pneumococci at moderate levels in a strain dependent manner. By employing a well-shed isolate, we showed that shedding was age dependent as four day old mice inoculated with pneumococci shed the organism from the nares at an increased level compared to mice inoculated at either eight or twelve days of age. Using this isolate in four day old mice, we established that this moderate level of shedding correlated with bacterial transmission, albeit at lower level when compared to the influenza A co-infection model where pneumococci are shed in higher amounts. Expression of its pore-forming toxin, pneumolysin (Ply) was necessary for transmission in the absence of influenza A co-infection. Intranasal administration of purified toxin stimulated a dose dependent effect on bacterial shedding. This elevated level of shedding was not caused by altered colonization density. Rather shedding correlated with an increased inflammatory response as determined by numbers of neutrophils and level of pro-inflammatory cytokines in nasal lavages. Furthermore, PdB, which contains a single amino acid mutation and lacks the ability to oligomerize to form pores, did not elicit an inflammatory response or promote shedding. Our results suggest that Ply promotes inflammation to enhance shedding and facilitate host to host transmission. Taken together, this work provides a mechanistic understanding of how *S. pneumoniae* takes advantage of the host response during carriage.

High Glucose Sensitizes Host Cells to Necroptosis in Response to Bacterial Pore-Forming Toxins and Inflammatory Signals

Author Block:

T. J. LAROCCA; Albany Coll. of Pharmacy and Hlth.Sci., Albany, NY

Abstract Body:

Necroptosis is a RIP1-dependent programmed cell death (PCD) pathway in host cells that is relevant to bacterial and viral diseases as well as inflammatory conditions including sepsis. Additionally, necroptosis is an inflammatory PCD that is distinct from apoptosis. Damaging agents in necroptosis include advanced glycation end products (AGEs) and reactive oxygen species (ROS), both of which depend on glycolysis. This suggests that increased cellular glucose may sensitize cells for necroptosis. Here we show that exposure to hyperglycemic levels of glucose enhances necroptosis in primary RBCs, Jurkat T cells, and U937 monocytes in response to bacterial pore-forming toxins and inflammatory cytokines including TNF and CD178 (Fas ligand). Pharmacologic (nec-1s) or siRNA inhibition of RIP1 prevented the enhanced death, confirming it as RIP1-dependent necroptosis. Hyperglycemic enhancement of necroptosis depends upon host cell glycolysis with AGEs and ROS playing a role. Total levels of RIP1, RIP3, and MLKL increased following treatment with high levels of glucose during necroptosis and was not due to transcriptional regulation. The observed increase in RIP1, RIP3, and MLKL protein levels suggests a potential positive feedback mechanism that drives hyperglycemic enhancement of necroptosis. Extrinsic apoptosis was inhibited by exposure to high levels of glucose suggesting a PCD shift to necroptosis under these conditions. Moreover, hyperglycemia resulted in increased infarct size in a mouse model of brain hypoxia-ischemia injury. The increased infarct size was prevented by treatment with nec-1s, strongly suggesting that increased necroptosis accounts for exacerbation of this injury in conditions of hyperglycemia. This work reveals that hyperglycemia represents a condition in which cells are extraordinarily susceptible to necroptosis, that local glucose levels alter the balance of PCD pathways, and that clinically relevant outcomes may depend on glucose-mediated effects on PCD. As diabetes increases the risk for bacterial infections, this work suggests that necroptosis may emerge as the principal PCD in response to bacterial pathogens in diabetic individuals. A shift from non-inflammatory apoptosis to necroptosis during bacterial infections may explain the exacerbation of bacterial infections and associated pathologies in diabetes.

Induction of Shiga Toxin-encoding Bacteriophage is Required for Lethal Disease in a Mouse Model of Enterohemorrhagic *Escherichia coli* Infection

Author Block:

S. Balasubramanian, M. S. Osburne, H. K. BrinJones, J. M. Leong; Tufts Univ., Sch. of Med., Boston, MA

Abstract Body:

Enterohaemorrhagic *Escherichia coli* comprise lysogenic bacteria that colonize the colonic mucosa and can produce phage-encoded Shiga toxin (Stx), resulting in life-threatening hemolytic uremic syndrome. Stx2 genes, located in a "late" phage operon, are repressed in the lysogenic state. Induction of the SOS response leads to lytic phage growth and Stx2 production *in vitro* and in a **germ-free** mouse model, but the role of Stx2 phage induction during infection of a host with a complete microbiome has not been determined. For example, do released phage lysogenize or lytically infect other enteric bacteria, potentially amplifying Stx production?We used a derivative of the mouse pathogen *Citrobacter rodentium* lysogenized by Stx2-encoding *E. coli* lambdoid phage Φ1720-2a. This strain colonizes C57BL/6J mice to high levels, causing lethal disease featuring colitis, weight loss, proteinuria and renal pathology. Deletions in Cr(Φ1720-2a) genes were generated, and Stx2 levels and free phage were measured by ELISA and qPCR, respectively. Lysogenization of gut bacteria was assessed by deep sequencing.Phage-linked DNA sequences from feces of Cr(Φ1720-2a)-infected and diseased mice showed no integration into the chromosomes of other gut strains or species, suggesting such integration and subsequent induction is not required in this disease model. In addition, secondary lytic infection of other such strains by phage induced from Cr(Φ1720-2a) was not required for disease, as Cr(Φ1720-2a) mutant lysogens unable to package phage particles still caused lethal infection. Phage integrase, required for phage excision and integration, and phage lysis genes S and R, were not required for Stx2 production *in vitro* or for mouse lethality. In contrast, phage anti-terminator protein Q, required for late gene transcription, was essential for both functions. Consistent with the hypothesis that the host SOS response is required for phage induction leading to Stx2 production, disruption of Cr(Φ1720-2a) *recA* abrogated the ability to cause disease. Phage production by the various mutants is being quantified *in vitro* and *in vivo*. The mechanisms and extent of prophage induction required for disease is under study using *C1* repressor mutants.

***Helicobacter pylori* Vaca-mediated Mitochondrial Dysfunction Induces Global Disruption of Host Cell Metabolic Homeostasis**

Author Block:

I-J. Kim, M. Hamad, S. Kim, S. R. Blanke; Univ. of Illinois, Urbana, IL

Abstract Body:

The consequences of pathogen-mediated disruption of host cell metabolic homeostasis on the infection microenvironment are poorly understood. Here, we evaluated the hypothesis that infection of gastric epithelial cells with the human gastric pathogen *Helicobacter pylori* disrupts host cell metabolism in a manner that impedes the capacity of host cells to appropriately respond to infection. *H. pylori* induce mitochondrial dysfunction in host cells through the action of the organism's only secreted cytotoxin, VacA. In these studies, we addressed a major gap in knowledge, which is the extent to which localized organelle dysfunction induced by VacA results in global cellular consequences. These studies revealed that VacA induced mitochondrial stress leads to inhibition of mammalian target of Rapamycin (mTOR), a master cellular metabolic regulator that integrates a variety of cellular stress signals. VacA-mediated mTOR inhibition was detected at low nM concentrations of VacA, and detected within the first several hours of VacA intoxication. mTOR inhibition was dependent on the capacity of VacA to form ion-conducting membrane channels. Consistent with the idea that mTOR inhibition occurs concurrently with a global cellular switch from anabolic to catabolic metabolism, protein synthesis was suppressed in VacA intoxicated cells. Proteomic analysis revealed decreased levels of key regulatory components in VacA intoxicated cells versus control cells that are important for maintaining cellular function. Unexpectedly, our data also revealed that VacA-induced protein synthesis inhibition resulted in derepression of the master inflammatory regulator, nuclear factor kB (NF-κB) by inhibiting the synthesis of the inhibitor of NF-κB (IκB), a short-lived repressor of NF-κB. Together, these results support a model that VacA manipulation of host metabolic homeostasis directly affects development of the *H. pylori* infection microenvironment.

Causal Or Independent? Evaluating The Interrelatedness Of Host Cell Alterations Induced By The Vacuolating Cytotoxin Of Helicobacter Pylori

Author Block:

K. D. Bosi, R. L. Holland, S. R. Blanke; Univ. of Illinois at Urbana Champaign, Urbana, IL

Abstract Body:

Secreted bacterial exotoxins modulate host cell physiology without requiring direct pathogen contact. Pore-forming toxins form ion-conducting channels and/or disrupt host membranes, resulting in a plethora of consequences associated with the loss of membrane integrity. Here, we evaluated the causal relationships between several well-characterized consequences of the vacuolating cytotoxin (VacA), a pore-forming toxin secreted by the human gastric bacterium *Helicobacter pylori*. Once internalized in a host cell, VacA causes the formation of large membrane bound vacuoles and mitochondrial dysfunction. Although current literature suggests these two cellular phenotypes are independent consequences of VacA intoxication, a major gap in knowledge is understanding the mechanism by which one population of toxin is able to induce two apparently disparate outcomes. To evaluate the hypothesis that the internalization of VacA and subsequent mitochondrial damage precedes and is directly linked to vacuolation, cellular systems previously shown to be important in vacuolation were evaluated for a role in VacA mediated mitochondrial dysfunction. Our studies revealed that vacuolation and mitochondrial dysfunction are both dependent on the same cell surface receptor, suggesting a model of linear and independent targeting of VacA. VacA-mediated vacuolation, but not mitochondrial dysfunction, was shown to be an actin dependent phenotype. The requirement of actin for vacuole formation supports a model of VacA-mediated mitochondrial dysfunction preceding cellular vacuolation, or alternatively, vacuolation and mitochondrial dysfunction are two independent consequences of toxin action. Studies to evaluate a causal relationship revealed both localization of VacA to and induction of mitochondrial dysfunction precede vacuolation and localization to vacuoles. Cumulatively, these data support a linear model of VacA trafficking where mitochondrial dysfunction occurs upstream of vacuolation. Demonstrating that VacA mediated mitochondrial dysfunction precedes and is directly linked to vacuolation not only provides insight into the consequences of VacA intoxication, but highlights the potential interrelatedness of cellular activities associated with the larger class of pore-forming bacterial toxins.

Subversion of Host Cell Autophagy by Genotoxic Pathogenic Bacteria

Author Block:

D. J. Lieu, J. Kryza, Z. P. Schaefer, B. Tamilselvam, H. Mok, H. Chen, H. Phillips, S. R. Blanke; Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract Body:

During infection, the host employs several strategies in an attempt to maintain physiological homeostasis. An important strategy for relieving pathogen-induced stress is the induction of cellular autophagy, a catabolic process for engulfment and degradation of intracellular components within specialized vacuoles. Here, we report the unexpected finding that host cell autophagy is down regulated in response to genotoxic stress induced by clinically prominent human mucosal bacterial pathogens secreting the cytolethal distending toxins (CDTs). CDTs comprise an unusual class of protein toxins that are taken up into host cells, localize to the nucleus, and activate DNA damage repair responses. Autophagy is regulated in part by the cellular pool of LC3-I, which must be converted to LC3-II as an obligate step in the formation of autophagic vesicles. In epithelial cells exposed to potent inducers of autophagy, the formation of autophagosomes, and the concurrent increase in cellular LC3-II levels, were both inhibited in the presence of CDT. Unexpectedly, a significant decrease in cellular LC3-I levels was observed in CDT-exposed cells. The decrease in cellular LC3-I was dependent on CDT-dependent DNA damage, as autophagy was not inhibited in cells exposed to either mutant forms of CDT unable to induce DNA damage or inhibitors of the eukaryotic DNA damage repair response. Cellular depletion of LC3-I was not due to decreases in gene expression, as LC3 transcript levels were identical in CDT-treated and untreated cells. Instead, LC3-I depletion was correlated with increased proteasome activity, as proteasome inhibitors rescued both cellular LC3-I, as well as autophagosome formation. Our data support a here-to-fore unrecognized strategy by which some pathogens may subvert the host autophagic response, and suggest a new role for CDTs during establishment of the infection microenvironment.

Identification of a New *Helicobacter pylori* vaca Motif Important for Receptor Specificity

Author Block:

S. J. Oh, P. Mahinthichaichan, M. Perisin, E. Tajkhorshid, S. R. Blanke; Univ. Illinois,, Urbana, IL

Abstract Body:

The cellular tropism of intracellular-acting bacterial exotoxins is largely dictated by specific receptors that couple surface bound toxins to existing cellular uptake pathways. *Helicobacter pylori* secrete VacA, which causes intracellular vacuole formation, mitochondrial depolarization, and ultimately cell death. The abundant membrane sphingolipid, sphingomyelin (SM), is a VacA receptor important for binding the toxin to the surface of sensitive cells. In this study, we evaluated the molecular details underlying the poorly understood interactions of VacA with the phosphorylcholine headgroup of SM. Based on previous work suggesting that tryptophan (W) side chains stabilize the positively charged amine head group of SM via pi-cation interactions, alanine scanning of the eleven VacA W residues identified a specific W residue in the carboxyl-terminal p55 domain important for both the cellular activity and plasma membrane binding of VacA. Computational modeling of VacA-SM binding indicated close interactions of the SM headgroup with the VacA p55 W residue, as well as 2 arginine (R) residues, which we propose to interact with the negatively charged phosphate moiety of SM. Solid state SM binding assays indicated that alanine substitutions for the three residues comprising the WRR structural pocket significantly reduced toxin-SM binding. Analysis of VacA binding to mammalian cells, which previous work indicated has both specific and non-specific components, indicated that a mutant form of the toxin lacking the proposed WRR-SM-binding pocket no longer specifically bound to a component on the cell surface of epithelial cells, although non-specific binding was retained. Taken together, our data suggest that VacA-SM interactions confer specific binding of the toxin to the surface of host cells required for toxin activity. These results provide the framework for understanding the molecular basis of VacA cellular tropism.

Effect of Environmental Salt Concentration on Composition of the *Helicobacter pylori* Exoproteome

Author Block:

R. R. Caston, B. J. Voss, C. A. Snider, T. L. Cover; Vanderbilt Univ. Sch. of Med., Nashville, TN

Abstract Body:

Background*: Helicobacter pylori* infection and a high salt diet are each associated with an increased risk of gastric cancer. In response to changes in environmental salt concentration, specific *H. pylori* proteins such as CagA undergo changes in relative abundance. In a previous study, we used mass spectrometry-based methodology to identify proteins that were selectively released by *H. pylori* into the extracellular space. In the current study, we tested the hypothesis that the composition of the *H. pylori* exoproteome is dependent on the salt concentration of the culture medium. **Methods**: *H. pylori* strain 26695 was grown in Brucella broth filtrate (containing components < 3 kDa plus supplemental cholesterol) overnight, and then subcultured into medium containing various sodium chloride concentrations (0.25%, 0.5%, 1.0%, or 1.25%). Aliquots were removed at 24 h and 36 h, centrifuged to yield supernatant and bacterial pellets, bacteria were fractionated, and samples were analyzed by single dimensional LC-MS/MS. Analysis was based on merged results from two independent experiments. **Results:** By comparing the proportional abundance of proteins in culture supernatants with abundance in cytoplasmic/periplasmic fractions, we identified proteins that were selectively released into the culture supernatant under each of the tested conditions. We then evaluated the effect of salt concentration on release of these proteins. At both 24 h and 36 h time points, VacA was enriched in the supernatant of cultures grown in media containing high salt conditions (1.0% and 1.25%), but was not enriched in supernatant of cultures grown in media containing lower salt concentrations. At the 36 h time point, the proportional abundance of VacA in the supernatant of cultures grown with 1.25% salt was about 8-fold higher than in cultures grown with 0.5% salt. **Conclusions:** The proportional abundance of VacA in the extracellular space increases in response to an elevation in environmental sodium chloride concentration. This change may be attributable to several factors, including increased *vacA* transcription as well as increased secretion and release of VacA. Salt-induced changes in *H. pylori* protein production or secretion may contribute to the increased risk of gastric cancer associated with a high salt diet.

A T6ss Immunity Factor Dictates Social Recognition During Intraspecies Warfare

Author Block:

C. J. Alteri, S. D. Himpsl, N. Musili, K. Zhu, J. E. Miller, H. L. T. Mobley; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

Gram-negative type VI secretion systems (T6SS) function to deliver a lethal payload of proteins into a target cell during interbacterial competition. Many studies have shown that protection against a single, lethal T6SS effector exclusively resides with a cognate antidote immunity protein, which are often located together in two-gene operons. In contrast, we have previously identified an immunity protein called PefE in *Proteus mirabilis* that is necessary and sufficient for immunity and is necessary but not sufficient for killing. Here, we describe a new class of T6SS immunity effectors which differ from the conventional model of effector-immunity pairs. The unique composition of this newly identified effector group is its occurrence as a large operon containing 8 genes that are all required for killing, including *hcp* and *vrgG*, and a single immunity gene. To investigate the relationship between immunity and social recognition, we utilized two swarming *P. mirabilis* isolates that contain identical effector operons that differ only in their immunity genes. Interestingly, despite containing identical effector genes, the less conserved immunity proteins, PefE and PefE2, only provide protection against their native effector operons. We hypothesize that specificity and recognition are dependent on variation within a single dual-function immunity factor. To determine residues within PefE important for specificity, a total of 6 full-length chimeras were designed and constructed using gene fragments of varying lengths from *pefE* and *pefE2*. The chimeras were tested during multicellular behavior using the Dienes line phenomenon and immunity was quantified using a killing assay. All chimeras were functional and each chimera provided immunity in a strain-specific manner. Upon further investigation, the region required for strain-specific immunity was localized. Sequence analysis of PefE from multiple strains indicates the presence of five less conserved variable regions, which in turn create modules that differ between strains. Together, these data demonstrate that 11 residues located within two of the five variable regions are specificity determinants. These findings help clarify the relationship between immunity against lethal T6SS attack and social recognition in bacteria.

Diversity and Distribution of Type VI Secretion Substrates in Epidemic Multidrug-Resistant *Acinetobacter baumannii* Isolates

Author Block:

M. Suzuki, M. Matsui, S. Suzuki, K. Shibayama; Natl. Inst. of Infectious Diseases, Musashimurayama, Tokyo, Japan

Abstract Body:

Background: *Acinetobacter baumannii* is an opportunistic bacterial pathogen in humans. Since 2000, multidrug-resistant *A. baumannii* (MDRAB) has emerged and spread worldwide. *A. baumannii* isolates belonging to international clone II (IC2), the most successful epidemic lineage, are predominantly associated with multidrug resistance carried on mobile gene elements, such as plasmids, and often cause nosocomial outbreaks. So far, it remains unclear how such bacterial high-risk clones emerge and spread. Here we show that type VI secretion system (T6SS) that directly translocates antibacterial proteins into neighboring bacterial cells could be involved in the clonal transmission mechanism of MDRAB epidemic isolates. **Methods:** Whole genome sequencing of 152 isolates of *Acinetobacter baumannii* was performed using the Illumina HiSeq 2500/HiSeq 4000 and/or Pacific Biosciences PacBio RSII platforms. Protein-coding genes, pseudogenes, and non-coding RNAs were annotated using the RASTtk scripts, and prophage regions were predicted using the PhiSpy algorithm. Comparative sequence analysis was performed using the BLAST Ring Image Generator (BRIG), Artemis Comparison Tool (ACT), and Mauve. **Results and Conclusions:** Most of MDRAB IC2 isolates conserved intact T6SS gene clusters for the secretion machine and substrates, whereas drug-susceptive non-IC2 isolates frequently lacked the gene clusters. Whole-genome single nucleotide polymorphism-based phylogenetic analysis revealed that IC2 isolates are further divided into five distinct genetic clades. Comparative genomic analysis between IC2 isolates identified that each IC2 clade harbors own specific antibacterial T6SS substrates encoded within the conserved T6SS gene clusters. Given that T6SS-mediated bacterial competition is known to affect conjugative transfer of drug resistance genes-carrying plasmids, T6SS could be an important key factor for development of MDRAB high-risk clones.

Developing an Innate Immunity Based High Throughput Screen for Small Molecule Inhibitors of the Type III Secretion System

Author Block:

H. Lam, J. M. Morgan, T. Simowitz, W. Bray, R. Linington, V. Auerbuch; UC Santa Cruz, Santa Cruz, CA

Abstract Body:

Antibiotic resistant bacteria are an emerging threat to global public health. New classes of antibiotics and tools for antimicrobial discovery are urgently needed. The type III secretion system (T3SS), which is required by dozens of Gram-negative bacteria for virulence, but is largely absent from non-pathogenic bacteria, is a promising virulence blocker target. The ability of mammalian cells to recognize the presence of a functional T3SS and trigger NFκB activation provides a rapid and sensitive method to identify chemical inhibitors of T3SS activity.Previously, we used host NFκB-driven luciferase as a readout for *Yersinia* T3SS activity in a pilot T3SS inhibitor screen and identified a family of compounds called piericidins. While this pilot screen was successful in identifying T3SS inhibitors, the Z score of the screen was poor. In order to improve our screening strategy in preparation for high throughput screening, we examined 83 different NFκB-driven promoters to identify sequences that provide the most robust signal in response to a functional *Yersinia* T3SS. We generated a HEK293 stable cell line expressing Green Fluorescence Protein (GFP) driven by the most optimal NFκB promoters of those tested. Use of this stable cell line improves our previous screening strategy by eliminating the need for to use a luciferase reagent (which increases cost) or for transient transfection of an NFκB reporter (which increases variability),but with the added ability to measure GFP fluorescence over time. We have screened the natural products library used in our original pilot, confirmed the ability to detect piericidin as a T3SS inhibitor, and report a Z score >0.4, validating our improved screening strategy. In addition, we detect a small portion of compounds from 2880 extracts that can reduce NFκB driven GFP upon *Yersinia* infection. None of the hits have antibiotic activity against *Yersinia.* The strongest hits will be tested for secretion inhibition of *Yersinia* effectors.

A *Vibrio anguillarum* Isocitrate Dehydrogenase Mutant is Highly Attenuated and Immunogenic in Rainbow Trout (*Oncorhynchus mykiss*)

Author Block:

E. Spinard, X. Mou, D. R. Nelson; Univ. of Rhode Island, Kingston, RI

Abstract Body:

We have been investigating the regulation and roles of the hemolysin/cytotoxin genes in pathogenesis by *V. anguillarum*, the causative agent of vibriosis in fish. We have shown that there are three major hemolysin genes (*vah1*, *plp* and *rtxA*) and have created an avirulent strain by knocking out *rtxA*. Currently, we aim to create an avirulent, immunogenic *V. anguillarum* strain that can be used as a live vaccine for fish without knocking out any of the hemolysin genes. Previously, we constructed several strains of *V. anguillarum* M93Sm (serotype O2a) with mutations in TCA cycle genes and showed that the isocitrate dehydrogenase (*icd)* mutant was highly attenuated in virulence against juvenile rainbow trout (*Oncorhynchus mykiss*) that were challenged via IP injection or immersion. The *icd* mutant grew to a cell density lower than wild type in LB20 and Nine Salt Solution supplemented with 200 µg/ml of salmon intestinal mucus (NSSM). Expression levels of the three hemolysin genes were determined by qRT-PCR and the *icd* mutant exhibited either the same or higher expression levels compared to the wild type during exponential phase growth. Further, rainbow trout that were pre-treated by immersion with the *icd* mutant were protected from a subsequent challenge of *V. anguillarum* M93Sm. When *icd* was restored, virulence against rainbow trout and growth in LB20 returned to wild type levels. In this study we examined the cause of the *icd* mutant growth limitation in rich media. The *icd* mutant showed wild type levels of cell density when the LB20 was supplemented with 2% glutamic acid. We also created and characterized a citrate synthase (*gltA*) mutant. Like the *icd* mutant, the *gltA* mutant grew to a lower cell density compared to the wild type in two forms of rich media (LB20 and NSSM), exhibited either the same or higher expression levels of the three hemolysin genes compared to the wild type during exponential phase growth, and showed wild type levels of cell density when LB20 was supplemented with 2% glutamic acid. Our data indicate that *icd* is necessary for virulence and growth to a wild type level in rich media.

Functional Analysis of HlyU, a Transcriptional Regulator of *Vibrio vulnificus*

Author Block:

Z-W. Lee, Y-J. Bang, S. Choi; Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

An opportunistic pathogen *Vibrio vulnificus* produces a large pore-forming toxin, RtxA, which triggers necrotic and apoptotic cell death. Previous studies reported that a transcriptional regulator HlyU upregulates *rtxA* expression by direct binding to the promoter region of the *rtxHCA* operon. To examine the function of HlyU, the *hlyU* mutant was constructed and its virulence was evaluated. Compared with the wild type, the *hlyU* mutant exhibited low cytotoxicity toward mucin-secreting HT-29 MTX cells and reduced mortality in mice, suggesting that HlyU is essential for the virulence of *V. vulnfiicus*. To further identify the genes regulated by HlyU, transcriptomic profiles of the wild type and the *hlyU* mutant were analyzed by RNA-seq. In addition to *rtxA*, genes encoding virulence factors such as hemolysin and phospholipase were down-regulated in the *hlyU* mutant, implying that HlyU contributes to the *V. vulnificus* pathogenesis by regulating various virulence genes. To elucidate the mechanism of HlyU in *rtxA* regulation, the levels of *rtxA* and *hlyU* transcripts in *V. vulnificus* cells grown in different conditions were determined. Induction of the *rtxA* expression occurred in the wild-type cells either exposed to the INT-407 human epithelial cells or grown under anaerobic conditions, but not in the *hlyU* mutant, indicating that HlyU mediated the induction. Since the levels of *hlyU* transcript in the wild-type cells were not significantly changed in those conditions, the *rtxA* activation might be attributed to altered activity rather than amounts of HlyU. To better understand this activity alteration of HlyU, C30, C96, and M87, which were predicted as essential amino acids from structural analysis, were mutated by site-directed mutagenesis. Among the mutants, *V. vulnificus* expressing HlyU-C30S showed a decreased *rtxA* level and cytotoxicity toward the HT-29 MTX cells than the wild type, suggesting that C30 is a critical residue of HlyU for *rtxA* activation. Taken together, HlyU might act as a regulator for the various virulence genes and induce *rtxA* under host environment by altering its activity.

Characterization of the Quorum Sensing Transcriptional Regulator Sdia From Ehec

Author Block:

D. Knowles, V. Sperandio; Univ. of Texas Southwestern Med. Ctr., dallas, TX

Abstract Body:

Enterohemorrhagic E. coli (EHEC) is a Gram-negative pathogen responsible for outbreaks of bloody diarrhea and hemolytic uremic syndrome. To colonize its bovine host, EHEC relies on its LuxR-type acyl homoserine lactone (AHL) sensing transcription factor, SdiA, to coordinate virulence gene expression in response to AHL signaling molecules produced by the host ruminal microbiota. SdiA controls expression of acid resistance genes and the Ler master regulator of the EHEC pathogenicity island, the locus of enterocyte effacement (LEE), necessary for host colonization. Here we study folding, ligand, and promoter-binding of SdiA from EHEC. Purification, denaturation and extensive dialysis was used to generate apo-SdiA, which was subsequently refolded in the absence of ligand. Using circular dichroism (CD) and fluorescence spectroscopy, we show that even in the absence of exogenous ligand, and over a >100-fold protein concentration range, SdiA is able to refold to a fully "native" conformation. We use analytical ultracentrifugation and CD spectroscopy to show that ligand binding affects the monomer-dimer equilibrium, however, in contrast to all other LuxR-type transcription factors studied to date, does not induce large scale folded<->unfolded-type conformational changes in the protein. We use isothermal titration calorimetry (ITC) and intrinsic Trp fluorescence to directly characterize the binding of a set of AHL's spanning a broad range of acyl chain lengths and chemical modifications to apo-SdiA, and the effect of these ligands on SdiA binding to the ler promoter. These observations account for gene-regulation by SdiA in the absence of AHL, and raise the possibility that AHL-sensing LuxR transcription factors may function in roles outside AHL sensing.

Effects of Anaerobic Culture on *In-Vitro* and *In-Vivo* Virulence of *Streptococcus pneumoniae*

Author Block:

K. Nagaoka, S. Konno, M. Nishimura; Hokkaido Univ. Sch. of Med., Sapporo, Japan

Abstract Body:

Background: *Streptococcus pneumoniae*, a facultative anaerobic bacterium, is a leading cause of respiratory infection worldwide. Its pathogenicity, which is thought to be mediated by pneumolysin or autolysin, is examined usually under condition of aerobic culture. Considering its facultative anaerobic nature, we wondered whether the culture condition of either aerobic or anaerobic might be influential to the virulence of this bacterium. **Methods:** In vitro, we incubated *S. pneumoniae* under aerobic or anaerobic condition, and quantitatively examined the production of pneumolysin by Western blot analysis. In vivo, we infected mice by intra-tracheal injection of *S. pneumoniae*, which had been grown until late log phase under either aerobic or anaerobic condition. We then compared survival rates and bacterial loads in the lungs as well as in blood between the two conditions.**Results:** In vitro, the productions of pneumolysin were apparently reduced in both late log phase (8 -10 h) and stationary phase (12-15 h) when culture was done under anaerobic condition compared with aerobic condition (Fig 1 A). In vivo, however, survival rate was lower and bacterial loads both in the lungs and in blood were higher in mice which had been inoculated with bacteria pre-cultured under anaerobic condition compared with under aerobic condition. In particular, significantly higher loads of bacteria in blood were seen even at an earlier phase of infection in anaerobic group (Fig 1 B).**Conclusions:** We here demonstrate that the virulence of *S. pneumoniae* is highly enhanced in vivo when pre-cultured under anaerobic condition compared with aerobic condition. However, it is not likely that pneumolysin mediates the enhancement of virulence.

Virulence in and Molecular Characteristics of Pvl-Negative, Tsst-1 Positive Ca-Mrsa Circulating in Japan

Author Block:

T. Yamaguchi, S. Sonoda, K. Aoki, D. Ono, A. Sato, Y. Ishii, K. Tated; Toho Univ., Tokyo, Japan

Abstract Body:

Background: PVL-positive Community-associated MRSA (CA-MRSA) is now endemic in the United States. However, in the nationwide survey of CA-MRSA in Japan that we have conducted, PVL-positive strains were only 10.3% and TSST-1-positive strains were 31.2% among total 858 CA-MRSA strains. Especially, ST8/SCC*mec* IV/TSST-1+ clone (ST8/IV/T) is isolated from severe skin and soft tissue infections and rarely from sepsis or pneumonia. The virulent potential of PVL-negative CA-MRSA strains has remained controversial. In the present study, to gain an understanding of virulence in the PVL-negative CA-MRSA, we investigated the virulence in ST8/IV/T clone using sepsis mouse model. **Methods:** TUM14604 (ST8/IV/T isolates from necrotizing pneumonia: PVL-, TSST1+) and two reference strains (BAA1556, USA300/ST8/SCC*mec* IV/PVL+; N315, USA100/ST5/SCC*mec* II/TSST-1+) were used. In sepsis model, six week-old female BALB/c mice (n = 6) were injected intravenously with 2-4X10^7 CFU/mouse and were monitored for survival and body weight change over 21 days. In addition, Staphylococcal load in tissues (blood, liver, spleen, kidney, and lung) and cytokine responses in serum and spleen were analyzed on day1 and day3. The virulence genes of TUM14604 strain were detected by whole genome sequence using a MiSeq sequencer (Illumina), and transcriptional levels of several virulence factors (ex. *tst-1*) were examined by real time PCR. **Results:** In sepsis model, TUM14604 strain demonstrated significantly stronger virulence than that of N315 strain (mortality rate of TUM14604 60% vs BAA1556 0% vs N315 0%). The levels of bacterial burdens in kidney and cytokines (IL6, IL1β, and TNFα) were higher in injected mice by TUM14604 strain and BAA1556 strain than N315 strain. High transcriptional levels of *psmα*, *tst-1*, *agrA*, and *rnaIII* in TUM14604 strain were observed, and it may contribute to the high virulence of sepsis model. **Conclusions:** We confirmed the high virulence in PVL-negative ST8/IV/T clone. The activation of agr system and the elevated production of TSST-1 may influence the severity of sepsis. Our study high lights strain-dependent differences, understanding of virulence in PVL-negative CA-MRSA warrants further investigation.

Characterization of the *Borrelia burgdorferi bb0168* Deficient Mutants Indicate *bb0168*-Encoded DnaK Suppressor Protein is a Global Regulator of Gene Expression

Author Block:

W. K. Boyle[1], J. A. Shaw[1], A. Groshong[2], J. S. Blevins[3], F. C. Gherardini[4], T. J. Bourret[1]; [1]Creighton Univ., Omaha, NE, [2]Univ. of Connecticut Hlth.Ctr., Farmington, CT, [3]Univ. of Arkansas for Med. Sci., Little Rock, AR, [4]NIAID, Hamilton, NE

Abstract Body:

Borrelia burgdorferi, the causative agent of Lyme disease, must sense and respond to diverse environmental challenges throughout its natural infectious cycle in *Ixodes spp.* ticks and various mammalian hosts including shifts in temperature, pH, osmolarity, nutrient availability, as well as oxidative and nitrosative stresses. In this study, we set out to characterize the role of the *bb0168*-encoded DnaK suppressor protein (DksA) on *B. burgdorferi* gene expression and infectivity. Microarray analysis comparing the transcriptomes of a wild-type *B. burgdorferi* strain and a *dksA*-deficient mutant revealed that DksA impacts the expression of more than 500 genes in cultures grown under microaerobic conditions (5% CO_2, 3% O_2) in BSK II medium, pH 7.6 at 34 degrees C. When wild-type and *dksA*-deficient *B. burgdorferi* strains were subjected to nutrient limitation by shifting cultures from BSK II medium to RPMI medium lacking serum, the expression of at least 315 plasmid encoded genes were impacted in the wild-type cultures, whereas only 76 plasmid encoded genes were affected in the *dksA*-deficient strain. Additionally, the *dksA*-deficient *B. burgdorferi* show reduced expression of genes required for infectivity in the murine model including *ospC* (30-fold), *dbpA* (52-fold), and *dbpB* (31-fold) compared to wild-type controls. Surprisingly, the expression of the alternative sigma factor S (*rpoS*), which helps coordinate the expression of *ospC*, *dbpA*, and *dbpB*, was unaffected by the loss of *dksA*. Moreover, induction of the *Borrelia* RpoS regulon by shifting cultures from pH 7.6 to pH 6.8, and subsequent immunoblot of the cell lysates showed reduced production of OspC in the *dksA*-deficient mutants compared to wild-type controls. The reduced expression of virulence-associated genes corresponded to the inability of the *dksA*-deficient *B. burgdorferi* strain to infect Swiss Webster mice following subcutaneous injection with inoculums of 10^3 or 10^5 spirochetes/mouse. Collectively, the results indicate that DksA is a global regulator of gene expression in *B. burgdorferi*, and is required for infectivity in a murine model of infection.

Characterization Of The Role Of Transcriptional Regulator Arac Of Francisella Tularensis

Author Block:

D. K. Marghani[1], Z. Ma[2], M. Malik[2], C. S. Bakshi[1]; [1]New York Med. Coll., Valhalla, NY, [2]Albany Coll. of Pharmacy and Hlth.Sci., Albany, NY

Abstract Body:

Background: *Francisella tularensis* is the causative agent of a deadly human disease tularemia. *F. tularensis* has been used in bioweapon programs in the past and now it is feared to be used as a potential biothreat agent. The CDC has classified *Francisella* as Category A Select Agent. *Francisella* possesses very few transcription regulators. A majority of these have been shown to regulate genes involved in virulence and cellular functions. *Francisella* also possesses a transcriptional regulator known as AraC. In several Gram-negative bacteria, AraC is transcribed divergently from, and control *araBAD* operon involved in arabinose utilization. In contrast, in *F. tularensis araC* is transcribed divergently from an operon encoding EmrA multidrug efflux pump and is not required for arabinose utilization, indicating a unique role for AraC. This study is characterizing the role of AraC as a transcriptional regulator of *F. tularensis*.**Methods:** A deletion mutant of *FTL_689* gene encoding AraC (Δ*araC*) of *F. tularensis* LVS and its transcomplemented strain were generated. The Δ*araC* mutant was characterized for its ability to grow in the presence of carbohydrates, sensitivity to oxidants and antibiotics, virulence attributes, and identification of regulated target genes.**Results:** AraC has two conserved helix_turn_helix domains that show homology to DNA binding domain of SoxS of *E. coli*. The Δ*araC* mutant grows similar to wild type *F. tularensis* LVS in the presence of arabinose, indicating that AraC does not regulate arabinose utilization genes. Δ*araC* mutant exhibits enhanced sensitivity towards hydrogen peroxide and Tert-butyl hydroperoxide. The Δ*araC* mutant is not sensitive to tetracycline, nalidixic acid, chloramphenicol and streptomycin. Macrophage cell culture invasion assay shows a 5-fold reduction in the number of Δ*araC* mutant bacteria recovered from infected macrophages as compared to *F. tularensis* LVS indicating a partial attenuation of intramacrophage growth.**Conclusions:** AraC of *F. tularensis* is required for resistance against oxidative stress and not for arabinose utilization. Since SoxS, an oxidative stress transcriptional regulator is absent in *F. tularensis*, results from this study indicate that AraC may assume its role in this pathogen. Studies elucidating the role of AraC in gene regulation are currently underway.

Stringent Response Regulation Of *vibrio Cholerae* Virulence Factors

Author Block:

D. RASKIN; Marian Univ., Indianapolis, IN

Abstract Body:

Cholera is an epidemic diarrheal disease caused by the gram-negative bacterium *Vibrio cholerae*. In order to colonize a host, *V. cholerae* must express the toxin-coregulated pilus (TCP), and diarrheal symptoms are primarily produced by the virulence factor cholera toxin (CT). CT and TCP expression is regulated by the ToxR regulon. Components of the ToxR regulon include ToxT, a transcription factor that directly initiates transcription of the CT and TCP genes. Upstream regulators include the integral membrane proteins TcpP and ToxR, transcription factors necessary for expression of *toxT*. TcpP and ToxR transcription initiation require TcpH and ToxS, respectively. ToxR may also directly initiate transcription of the CT genes independently of ToxT. It is thought that TCP is required early in infection to colonize the small intestine and that CT is expressed later in order to produce diarrhea and escape the host. It is not fully understood how the differential timing of CT and TCP expression occur. We found that stringent response, the low nutrient stress response, was necessary for colonization of the infant mouse small intestine. We made deletions in the stringent response genes and tested stringent response-defective mutants for expression of *ctxA* and *tcpA*, genes coding for components of CT and TCP respectively. Stringent response-defective strains showed greatly reduced expression of *tcpA* and a small but significant reduction in expression of *ctxA*. We tested whether stringent response regulated components of the ToxR regulon. We found that stringent response induced *toxT* and *tcpP* expression, while repressing *toxR*. The gene expression data was consistent with the requirement for stringent response-dependent colonization of the mouse. Stringent response is required for TCP expression, with TCP required for colonization. The gene expression data showing that stringent response had differential effects on components in the ToxR regulon may explain how CT and TCP may be differentially regulated despite being controlled by the same transcriptional activators. We are continuing to investigate how stringent response affects the ToxR regulon and how differential regulation of CT and TCP occurs.

Two Novel Regulators of Capsule and Virulence in *Klebsiella pneumoniae*

Author Block:

M. Palacios, K. A. Walker, V. L. Miller; Univ. of North Carolina, Chapel Hill, Chapel Hill, NC

Abstract Body:

In addition to having a reputation as the causative agent for several types of hospital-acquired infections, *Klebsiella pneumoniae* has gained widespread infamy as a pathogen with a propensity for developing antibiotic resistance. It is capable of causing a range of infections including UTIs, pneumonia, and sepsis. The list of identified virulence factors has mostly been limited to production of capsule, fimbriae, and siderophores. Due to the rapid emergence of resistance among *Klebsiella* strains to the last resort antibiotic, Carbapenem, there is a dire need for a better understanding of virulence mechanisms and identification of new drug targets. MarR (*m*ultiple *a*ntibiotic *r*esistance *r*egulator) is present in several pathogenic bacteria. Interestingly, *Klebsiella* has more copies of genes encoding MarR-like proteins than any other bacterial genera. Given the high number of these proteins in *Klebsiella*, these regulators likely contribute to the ability of this bacterium to respond to, and survive in, a wide variety of environmental conditions such as the human body. In an attempt to expand our understanding of *Klebsiella* virulence determinants, our lab focused on screening potential regulators of virulence by generating mutations in *marR*-like genes and screening them for attenuation in the lungs and spleens of mice. Our lab uses a 'classical' strain, KPPR1, and a mouse model that successfully recapitulates human infection by establishing bacterial colonization of the respiratory tract followed by the development of a systemic infection. While most of the mutations did not affect virulence in this model, we identified two previously uncharacterized regulators of *Klebsiella* virulence and have named these KvrA and KvrB. KvrA and KvrB were found to be required for expression from the *cpsB* promoter (one of the promoters in the capsule locus). Additionally, when testing the corresponding promoter of a 'hypervirulent (*hv*)' strain (liver-abscess derived), KvrA and KvrB also contributed to *cpsB* expression in this *hv* strain suggesting the contribution of our regulators is conserved among pathogenic *Klebsiella* strains. Further work on characterizing the relationship of our novel *Klebsiella* regulators of capsule with other previously identified regulators is under way. Our data demonstrate for the first time the *in vivo* contribution of a MarR homologue to *Klebsiella pneumoniae* virulence.

Spxa2 Coordinates Stress-response and Virulence in *Streptococcus pyogenes*

Author Block:

G. C. PORT, Z. T. Cusumano, P. R. Tumminello, M. G. Caparon; Washington Univ. Sch. of Med., St Louis, MO

Abstract Body:

For *Streptococcus pyogenes* and other pathogens, it is generally assumed that resistance to thermal and oxidative stresses is essential for pathogenesis. In investigating this question, we recently identified the multi-stress regulator ClpX as a regulator of toxin expression, particularly for the secreted SpeB cysteine protease. Although much is known about the conditions that stimulate SpeB expression, including stationary growth phase, low salinity, and low pH, little is known regarding the genetic circuitry that integrates these various signals and its intersection with stress resistance. For many gram-positive bacteria, ClpX regulates stress resistance via interactions with two orthologs of the Spx transcriptional regulator, SpxA1 and SpxA2. Analysis of Spx mutants revealed that while ΔSpxA1 had a defect only for growth under aerobic conditions, ΔSpxA2 was severely attenuated for multiple stresses, including thermal and oxidative stress. When examined in a murine model of soft-tissue infection, ΔClpX and ΔSpxA1 were highly attenuated. In contrast, the highly stress-sensitive ΔSpxA2 was hyper-virulent with higher tissue damage and bacterial burdens than the wild type strain. Furthermore, while the attenuation of ΔClpX and ΔSpxA1 was associated with reduced SpeB expression, ΔSpxA2 virulence was associated with SpeB hyper-expression and ΔSpxA2 virulence could be restored to wild-type levels by deletion of *speB*. Taken together, these data demonstrate that: 1. *S. pyogenes'* ability to damage tissue is combinatorial, involving fine-tuning of toxin expression of and 2. there is no direct correlation between ClpX-mediated multi-stress resistance and virulence. Further examination of ClpX's influence on virulence will provide insight into the genetic circuits that control the fine-tuning of toxin expression.

Changes in Expression of Genes Involved in O-Antigen Chain-Length Regulation and Lipid A Covalent Modification Are Regulated by Fnr in *Salmonella* Enteritidis

Author Block:

P. Fernandez[1], C. A. Silva[2], F. Velásquez[1], F. Amaya[1], H. Garcias[1], C. A. Santiviago[1], S. A. Álvarez[1]; [1]Facultad de Ciencias Químicas, Univ. de Chile, Santiago, Chile, [2]Tufts Univ., Boston, MA

Abstract Body:

The lipopolysaccharide (LPS) is a major component of the outer membrane of Gram-negative bacteria and plays an important role in *Salmonella* virulence. Previously we showed that the LPS of *Salmonella* Enteritidis undergoes changes in both the degree of polymerization of the O-antigen and covalent modifications in the lipid A-core region, in response to oxygen availability. The adaptation of *Salmonella* from aerobiosis to anaerobiosis involves changes in the expression of numerous genes, and the transcription factor FNR is a major regulator of this process. The aim of this work was to determine if the expression of *wzzB* and wzz_{fepE} genes, encoding O-antigen chain-length regulators, and *eptA, lpxO, lpxR* and *pagP* genes, encoding proteins involved in the covalent modification of the lipid A-core, is regulated by the oxygen availability in *S.* Enteritidis, and the involvement of FNR regulator in this process. We determined by qRT-PCR that the expression of these genes is affected by the oxygen availability in *S.* Enteritidis NCTC13349. This differential expression pattern was not observed in a Δ*fnr* mutant strain, indicating that these changes would be dependent on this transcriptional factor. These results are in agreement with bioinformatic analysis that showed the presence of putative FNR boxes in the promoters of these genes. Finally, electrophoretic mobility shift assay (EMSA) revealed that FNR directly interacts with the promoter regions of these genes. In conclusion, FNR directly binds to *wzzB*, wzz_{fepE}, *eptA, lpxO, lpxR* and *pagP* promoter regions in *S.* Enteritidis and this would account for the oxygen-dependent changes observed in the expression of these genes.

The Role of Msab in the Nutrient-Dependent Regulation of Capsule Production in *Staphylococcus aureus*

Author Block:

J. L. Batte, G. Ghag, V. Rangachari, M. O. Elasri; The Univ. of Southern Mississippi, Hattiesburg, MS

Abstract Body:

Capsule production in *Staphylococcus aureus* is controlled by several regulators in response to various environmental stimuli. We have identified a new regulator, MsaB, which specifically binds to its target site upstream of *cap* operon. Furthermore, we have found that MsaB may sense nutrients availability. In this study, we examine the mechanism of capsule regulation by MsaB in response to nutrients. To examine the role of MsaB nutrient-dependent regulation, we examined MsaB sequence to predict putative ligands/nutrients to use in this study. We used nutrient-depleted in the early/mid-phases of growth and nutrient-replenished conditions in the late/post-phases of growth and measured capsule production and MsaB binding to the *cap* promoter. We used binding assays including the electrophoretic mobility shift assay (EMSA) and fluorescent anisotropy in the absence and presence of nutrients to determine if the binding of MsaB is altered by the addition of nutrients. Next, we used Circular dichroism (CD) to determine the secondary structure of MsaB in its native state and in the presence of nutrients. We also used competitive binding assays (EMSA and a fluorescent anisotropy) to explore any interplay between MsaB and other *cap* regulators in presence or absence of nutrients. We found that MsaB binds specifically to the *cap* promoter region to an inverted repeat and that a single nucleotide mutation in the repeat leads to the loss of binding of MsaB. Indeed, we found that nutrients directly affects MsaB binding ability to the *cap* promoter in different growth phases. Under normal nutrient conditions MsaB only binds to the *cap* promoter in late/post-exponential phases. We used a nutrient-depleted medium in the early/mid-phases and found that in low nutrients MsaB now binds to the *cap* promoter. As a result, when MsaB is bound in these conditions capsule is now produced differing from normal conditions when no capsule is produced in this phase of growth. We have also found that MsaB has binding sites for GTP, ATP, and AMP. Further studies will determine the role of these specific nutrients in MsaB binding affinity to its target site. We show that MsaB binds to the *cap* promoter in a nutrient-dependent manner and directly activates the production of capsule. These results suggest that MsaB binding contributes to the nutrient-dependent regulation of capsule production.

Expression Analysis of Universal Stress Proteins in *Edwardsiella ictaluri*

Author Block:

A. AKGUL, A. Akgul, Hasan C. Tekedar, Mark L. Lawrence, Attila Karsi; mississippi state Univ., STARKVILLE, MS

Abstract Body:

Edwardsiella ictaluri is a Gram-negative bacterium that causes enteric septicemia of catfish (ESC). The universal stress proteins (USP) are present in archaea, bacteria, plants and fungi, but humans. USPs are expressed differentially to cope with stress during host invasion. We identified 13 USP genes in the *E. ictaluri* genome, but their protective role in *E. ictaluri* under stress is unknown. In this work, we will present the expression analysis of *E. ictaluri* USPs during three different stress conditions (low pH, high H_2O_2, and antibiotic presence). We expect expression analysis will identify essential USPs in *E. ictaluri*, which can be potential targets for live vaccine development.

Differential Expression of Conserved Functions among Genetically Diverse *Escherichia coli* Is Key to Uropathogenic Phenotypes

Author Block:

H. L. Schreiber, IV[1], M. S. Conover[1], M. E. Hibbing[1], W-C. Chou[2], A. Manson-McGuire[2], A. M. Earl[2], J. Livny[2], S. J. Hultgren[1]; [1]Washington Univ Sch of Med., St. Louis, MO, [2]Broad Inst. of MIT and Harvard, Cambridge, MA

Abstract Body:

The ability of *Escherichia coli* to cause urinary tract infections (UTI) is thought to correlate with carriage of putative urovirulence factors (PUFs) and membership within the B2 clade of the *E. coli* phylogenetic tree. However, 25-50% of all uropathogenic *E. coli* (UPEC) isolated from women with UTI are from non-B2 phylogenetic clades (e.g. clades A, B1, and D). Here, we collected 43 B2 and non-B2 *E. coli* strains isolated from a cohort of women during consecutive recurrent UTIs for extensive study of their: i) phylogenetic history and relatedness; ii) shared gene content and carriage of PUFs; iii) transcriptional profiles of core genes shared amongst all of the strains and; iv) fitness in bladder colonization in representative mouse models of UTI. We found that carriage of PUFs correlated to membership in the B2 clade; however, neither specific gene content nor carriage of PUFs was predictive of bladder fitness. Further, some non-B2 isolates of *E. coli* encoding few PUFs had competitive advantages over B2 strains carrying considerably more PUFs in bladder colonization, indicating that carriage of many PUFs was neither necessary nor sufficient for bladder colonization. However, in comparing transcriptional profiles of *E. coli* grown in identical culture conditions, we identified differences in the expression of core genes shared amongst all *E. coli* strains. Importantly, these differences, which were found in genes mediating core bacterial functions such as motility and nutrient utilization, were associated with bladder colonization in both B2 and non-B2 isolates. Thus, our findings show that differential expression of the E. coli core genome, but not gene content and/or membership in the B2 clade of *E. coli*, best distinguish UPEC virulence.

Elucidation of the Mechanism of Oxidative Stress Regulation in *Francisella tularensis*

Author Block:

Z. Ma[1], V. C. Russo[1], S. M. Rabadi[2], S. V. Catlett[1], C. S. Bakshi[2], M. Malik[1]; [1]Albany Coll. of Pharmacy & Hlth.Sci, Albany, NY, [2]New York Med. Coll., Valhalla, NY

Abstract Body:

Background: *Francisella tularensis* is a highly virulent human pathogen. The ability of *F. tularensis* to cause a fulminate infection is due in part to its ability to survive and replicate in phagocytic cells involved in host's innate immune defenses. In order to establish an intracellular niche, *F. tularensis* has to overcome oxidative stress posed by reactive oxygen and nitrogen species. The genome sequence analysis reveals the presence of OxyR; while both the SoxR/SoxS regulons are absent in *F. tularensis*. The presence of OxyR as the only oxidant stress regulator indicates that regulation of oxidative stress response genes in *Francisella* is unique. However, nothing is known about the wider regulatory role of OxyR during *Francisella* infection. This study investigated the role of OxyR of *F. tularensis* in tularemia pathogenesis and regulation of genes involved in oxidative stress response.**Methods:** We generated a deletion mutant (Δ*oxyR*) and a transcomplemented strain of *oxyR* gene of *Ft* LVS. The *oxyR* mutant was characterized for its sensitivity towards oxidants, capacity to survive in macrophages, and virulence in mice. To investigate the effect of OxyR on gene regulation, we performed iTraq analysis, ChIP analysis and electrophoretic mobility shift assays (EMSA).**Results:** We demonstrate that OxyR of *F. tularensis* is required for resistance to oxidants, survival in macrophages, and virulence in mice. Proteomic analysis revealed differential expression of 123 proteins associated with oxidative stress resistance and cellular functions in the Δ*oxyR* mutant as compared to the wild type *F. tularensis* LVS indicating that OxyR serves as a global regulator of oxidant stress response. Most importantly, OxyR regulates transcription of primary antioxidant enzyme genes *ahpC, katG* and *sodB* by binding directly to their upstream promoter regions.**Conclusions**: These results highlight that OxyR is an important regulator of oxidative stress response and renders *F. tularensis* a pathoadaptive advantage to establish an intracellular niche. An understanding of these unique pathogenic mechanisms is essential for the development of effective therapeutics and prophylactics against this important biothreat agent.

Contributions of a Two-component Regulatory System and C-Di-Gmp to Differentiation of *Legionella pneumophila*

Author Block:

E. D. Hughes; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Legionella pneumophila, the causative agent of Legionnaire's disease, is a gram-negative bacterium common in aquatic environments, where it survives and replicates within predatory amoeba and protists, its natural hosts. *Legionella* is capable of differentiating into multiple morphologically distinct cell types, including a highly infectious, metabolically dormant, cyst-like form known as MIFs (Mature Intracellular Forms). The MIF cell type is thought to equip *Legionella* to persist for extended periods outside a host cell in low-nutrient aqueous environments. For example, when compared to *in vitro* broth stationary phase cultures, we determined that MIF cells generated in either HeLa cells or the ciliate *Tetrahymena tropicalis* are more resistant to either antibiotics or detergents.Although MIFs are likely the form of *Legionella* that survives aerosolization to infect humans, little is known about the mechanisms that coordinate MIF cell differentiation. As one approach to investigate MIF development, we are analyzing the locus that includes *lpg0279*, a gene that is more highly expressed in MIF cells than *Legionella* isolated from macrophages. Immediately 3' of *lpg0279* is a putative two-component regulatory system: *lpg0278* is predicted to encode a histidine kinase and *lpg0277* the response regulator—a diguanylate cyclase whose product c-di-GMP regulates lifestyle changes in multiple bacterial species. Deletion mutants generated for each regulatory gene exhibit a prolonged lag phase in broth culture. Compared to WT, the *lpg0278* histidine kinase mutant cells accumulate increased c-di-GMP and exhibit decreased motility and capacity to infect and replicate in primary mouse macrophages. Further examination of the contribution of these genes to MIF cell differentiation will advance our understanding of the environmental persistence of *L. pneumophila* and its subsequent transmission from water aerosols to human lungs.

Rnpp Family Transcription Factors in *Enterococcus faecalis*

Author Block:

L. D. Jordan, N. Schwarting, L. E. Hancock; Univ. of Kansas, Lawrence, KS

Abstract Body:

Infections caused by enterococci are a serious threat to human health, as they represent one of the three most common hospital-acquired pathogens in the United States and around the world. A dichotomy exists between the many benefits of enterococci as a commensal organism and the harmful effects caused to its host in an infective state. Due to its opportunistic nature, enterococci can readily transition from being commensals to pathogens. We recently discovered a peptide transporter, PptAB, involved in the export of small peptide pheromones that induce a mating response in plasmid harboring donor cells. This same peptide transporter was also shown to contribute to biofilm formation and recent evidence suggests that it contributes to virulence in a catheter-associated UTI (CAUTI) model. In Gram-positive bacteria, the RNPP family of transcription factors are known to contribute to a variety of cellular processes, including biofilm formation and pathogenesis and their activity is regulated by binding to small peptides. Here we identify five uncharacterized and predicted RNPP homologs in *E. faecalis* V583 by querying the genome for characteristic elements of the RNPP family. We generated gene deletion mutants for each predicted RNPP homolog and examined these mutants for affects on biofilm development and compared their role in pathogenesis using a mouse model of a CAUTI by using a mixed infection of fluorescently labeled parental and mutant strains. We found that one such homolog displayed an increase in biofilm biomass and resulted in a significant increase in catheter and bladder colonization compared to the parental strain.

Regulation of Rsma Targets in Mucoid Pseudomonas Aeruginosa

Author Block:

S. D. Stacey, C. Pritchett; East Tennessee State Univ., Johnson City, TN

Abstract Body:

Pseudomonas aeruginosa is an opportunistic pathogen that targets individuals with compromised immune systems like those diagnosed with HIV and cystic fibrosis. Some isolates from cystic fibrosis patients with chronic *P. aeruginosa* infections have a variant phenotype termed mucoid, which is the overproduction of the exopolysaccharide alginate. Alginate synthesis is regulated by the sigma factor AlgU. AlgU is sequestered by the antisigma factor MucA. Cell envelope stress or mutations in the *mucA* gene allow for AlgU hyperactivity resulting in increased alginate biosynthesis. We recently reported that AlgU also regulates the posttranscriptional regulator RsmA, an RNA-binding protein that regulates multiple genes involved in virulence. We propose that an increase in *rsmA* expression leads to increase RsmA activity in mucoid strains. We compared transcriptional and translational fusions of known RsmA targets: *hcnA, tssA1, fha1,* in both PAO1 and *mucA22* to determine RsmA activity. Post-transcriptional activity was increased on the abovementioned RsmA targets in a *mucA22* strain indicating that RsmA had increased activity. We confirmed this result with a leader fusion for *tssA1* and *hcnA.* Increased RsmA activity in *mucA22* strains led us to propose that novel targets of RsmA might exist in mucoid strains. Via iTRAQ labeling in *mucA22* versus *mucA22,* Δ*rsmA* we found known as well as unknown targets of RsmA. Overall, we have shown that in a *mucA* mutant background, RsmA is important in the regulation of genes found in *P. aeruginosa* chronic infections.

Regulation of Flagellar Motility in *Erwinia amylovora* by the Small Rna Arcz

Author Block:

J. K. Schachterle[1], Q. Zeng[2], G. W. Sundin[1]; [1]Michigan State Univ., East Lansing, MI, [2]Connecticut Agricultural Experiment Station, New Haven, CT

Abstract Body:

Background: *Erwinia amylovora*, causative agent of fire blight disease of apple and pear trees, requires flagellar motility for efficient primary infection of flowers. We have shown that the Hfq-dependent sRNA ArcZ positively regulates flagellar motility in *E. amylovora*. However, the mechanism of this regulation is unknown. This study explores the mechanism of ArcZ regulation of flagellar motility and identifies the first known direct target of ArcZ in *E. amylovora*. **Methods:** RNA was isolated from wildtype, *hfq*, and *arcZ* mutant cells, reverse transcribed to cDNA and used in qPCR reactions to determine relative abundances of *fliC*, *motA*, *motB*, *fliA*, *flhD*, and *flhC* mRNA. Translational fusions were developed by cloning of *flhD* 5' UTR in-frame to a GFP reporter. The *arcZ* and *flhD* translational fusion were additionally subjected to site-directed mutagenesis at sites identified using the RNAHybrid online server. Reporter mean fluorescence intensity was measured by flow cytometry.**Results:** Analysis of mutants by qPCR showed that for all genes tested, mRNA levels were significantly lower in *hfq* and *arcZ* mutants relative to wildtype, including the global regulator *flhDC*. RNAHybrid search of ArcZ and *flhD* 5' UTR identified a candidate interaction region. Testing of an *flhD* translational fusion in revealed that translation of FlhD is upregulated 3-fold in *hfq* and *arcZ* mutants. Wildtype *arcZ* complemented the effect, but *arcZ* mutated in the interaction region failed to complement the effect. Introduction of compensatory mutations in the *flhD* translational fusion enabled complementation by the mutated ArcZ.**Conclusions:** These results demonstrate that sRNA ArcZ regulates flagellar motility via regulation of *flhDC*. Mutation and compensatory mutation analysis suggest that the 5' UTR of *flhD* acts as a direct target of ArcZ in *E. amylovora*. However, because mutations of *hfq* and *arcZ* led to opposing effects at the mRNA and translational level, there are likely additional ArcZ targets involved in regulation of flagellar motility.

Poly Adenine Tract Length within the Adhesin Encoding Hopz Promoter Influences Transcription in *Helicobacter pylori*

Author Block:

C. R. Acio, A. A. Acio, M. H. Forsyth; Coll. of William & Mary, Williamsburg, VA

Abstract Body:

Helicobacter pylori is a gram-negative bacterium that colonizes the gastric mucosa of the human stomach. *H. pylori* infection is linked to the formation of ulcers, gastritis, and gastric adenocarcinoma. Pathogenesis is dependent, in part, on the bacterium's ability to respond appropriately to the acidic environment of the stomach and evade the immune and inflammatory responses of the host. *H. pylori* utilizes adhesin proteins, such as SabA and HopZ, to adhere to the gastric epithelial cells, allowing increased access to nutrients and preventing clearance as the gastric mucosa is shed. Our previous studies have demonstrated that SabA expression is controlled by multiple mechanisms, including the ArsRS Two Component System and phase variation via slip-strand mispairing. In this study, we investigated the regulatory effects of the poly-adenine tract of the *hopZ* promoter located from -24 to -37, relative to the transcriptional start site, on *hopZ* expression in *H. pylori* strain J99. Through site-directed mutagenesis, we simulated the extensions and truncations of the poly-adenine tract that occur naturally by slip-strand mispairing, followed by the quantification of *hopZ* expression using quantitative real-time PCR (qRT-PCR). Extending or truncating the poly-adenine tract by five adenines significantly increased expression of *hopZ* by approximately threefold. We hypothesize that these changes in the poly-adenine tract modify the DNA topology and influence the binding ability of RNA polymerase and/or other regulatory proteins.

High-Throughput Identification of Regulatory Pathways of the Locus of Enterocyte Effacement in *Enterohemorrhagic e. coli*

Author Block:

R. Pifer, V. Sperandio; Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract Body:

Enterohemorrhagic *E. coli* (EHEC) O157:H7 is a food borne pathogen of humans that colonizes colonic epithelial cells and causes severe diarrhea. The Locus of Enterocyte Effacement (LEE) of EHEC encodes a type III secretion system that is essential for virulence. The LEE mediates secretion of effector molecules that induce cytoskeletal rearrangements within colonized epithelial cells to form a unique environmental niche. Expression of the LEE is a significant metabolic burden for EHEC and must be carefully regulated. Prior research from us and others have indicated the importance of small molecule metabolites in controlling LEE expression and EHEC virulence; however, uncovering the mechanisms of these signals is often difficult. We have established a high-throughput method using readily available tools to define these LEE regulatory mechanisms. We have developed an ELISA-based approach for evaluating the expression level of EspB, a component of the LEE encoded translocon. Using the *E. coli* K-12 Keio knockout library, we have created a library of LEE-expressing, transcription factor-deficient strains capable of type III secretion and a screen was undertaken to identify genes present in the *E. coli* core genome that regulate the LEE. As a proof of principal of the utility of these tools, we have explored the mechanism of Cysteine as a small molecule regulator of the LEE. We have identified a putative transcription factor, CysR, that is capable of governing type III secretion from K-12. We observe that a *cysR*-deficient strain of EHEC exhibits reduced LEE transcript levels and defective secretion. We observe that this is dependent upon cysteine within the growth media. Using *Citrobacter rodentium* as an EHEC infection model, we have observed that a *cysR*-deficient strain exhibits reduced mortality compared to wild type, suggesting that *cysR* is required for full virulence *in vivo*. The LEE is differentially regulated by a variety of growth conditions and small molecule metabolites, as exemplified in this work by Cysteine. Discovering the mechanism of these processes is often challenging. We describe a framework method that can be used by researchers to quickly determine the requirements of these signaling events.

Rgfd-dependent Quorum Sensing Affects Fibrinogen Binding, Host Cell Association, and Expression of the *rgf* Operon in Group B *Streptococcus*

Author Block:

R. Parker, D. Knupp, R. Al Safadi, S. Manning; Michigan State Univ., East Lansing, MI

Abstract Body:

Group B *Streptococcus* (GBS) is a leading cause of stillbirth, meningitis, and sepsis in neonates, and capable of causing invasive disease in susceptible adults. While GBS is a normal inhabitant in the microbiome, present in up to 40% of healthy adults, this opportunistic pathogen is able to breach restrictive host barriers and persist in harsh and changing conditions during pathogenesis. Quorum sensing (QS) is a form of cell to cell communication that enables an environmentally-dependent response essential to the virulence of many pathogenic bacteria, though few studies have assessed the importance of this phenomenon in GBS. This study sought to identify a role for QS in the regulation of the regulator of fibrinogen-binding (*rgf*) two-component system and the ability to bind to immobilized fibrinogen and host cells, *in vitro*, through the creation of a deletion mutant lacking the putative autoinducing peptide, RgfD. Expression of the *rgf* operon, assessed using qPCR, was significantly decreased in the mutant throughout exponential growth with the biggest difference (~50-fold) at higher cell densities. Attachment to fibrinogen was found to be 1.6-fold higher in the mutant compared to the wild-type suggesting dynamic regulation of this operon is important to functionality. Association with decidualized endometrial host cells was decreased 1.4-fold in the mutant further identifying this putative QS molecule as important for host colonization in GBS. Taken together, these data identify the putative quorum-sensing peptide, RgfD, as important for GBS pathogenesis and offer a novel target for the development of future therapeutics for the prevention and treatment of GBS disease.

The Role of sRNAs in Thermoregulation of Gene Expression in Uropathogenic *Escherichia coli*

Author Block:

M. Sutherland, C. A. White-Ziegler; Smith Coll., Northampton, MA

Abstract Body:

In both commensal and uropathogenic *E. coli*, temperature is an important cue used to regulate gene expression and physiology upon entering a human host (37°C). Small regulatory RNAs (sRNAs) offer an additional level of regulation by altering mRNA stability, translation, or processing. The sequences of forty of eighty known sRNAs have been confirmed in the UPEC genome (Luo, Hu, and Zhu, *BMC Genomics* 10, 552 (2009)). My project explores sRNA participation in UPEC CFT073 thermoregulation, with two aims: I. Determine if sRNAs that regulate thermoregulated genes are themselves controlled by temperature and II. Use knock-outs to establish causality between sRNA expression and thermoregulation of genes contributing to virulence, adaptation and immune evasion. Previous transcriptome experiments in our lab demonstrated the thermoregulation of 423 genes in commensal (K-12) *E. coli* and 227 in UPEC.UPEC expression of eleven sRNAs with known thermoregulated targets was confirmed by transcriptome analysis and qRT-PCR; qRT-PCR on RNA from cells grown for 4 hours at 23°C and 37°C has shown six of those to be thermoregulated. Two of the sRNAs identified by this process target thermoregulated outer membrane proteins (OMPs) in a manner that may facilitate adaptation and immune evasion in the human host (37°C environment). The sRNA OmrA is downregulated 2.6-fold at 37°C as compared to 23°C, which could explain the observed seven-fold upregulation of OmrA's target OmpT, a protein known to cleave antimicrobial peptides (Hui, et al. *Microbiology and Immunology* 54 (2010): 452-459). The sRNA CyaR is upregulated 3-fold; this may similarly explain the observed downregulation of OmpX, an immunogenic OMP whose downregulation may decrease motility in low-glucose environments (De Lay and Gottesman. J. Bacteriology 191, 2 (2009): 461-476). Future experiments intend to knock out OmrA and/or CyaR by λ-red mutagenesis and compare the expression patterns of their target genes in wild-type versus mutant cells. This will establish or reject a causal role for these sRNAs in observed temperature-regulated changes in gene expression and physiology. Taken together, our data indicate that several sRNAs are thermoregulated and may be essential or contributory to adaptive thermoregulatory responses in uropathogenic *E. coli*.

Cellobiose-Specific Phosphotransferase System Regulates Virulence Of *e. Coli* Rs218

Author Block:

D. S. S. Wijetunge, M. Dauran, S. Kariyawasam; Pennsylvania State Univ., University Park, PA

Abstract Body:

Neonatal meningitis-associated *E. coli* (NMEC) is one of the major causes of meningitis in newborn babies . The ability to utilize carbohydrates in a variety of host niches appears to be vital to many bacterial pathogens . It has also been demonstrated that these sugar transport systems have a role in regulation of virulence in some pathogenic bacteria . We have recently sequenced the NMEC reference strain *E. coli* RS218 which harbors a genomic island (GI) that encodes a putative cellobiose phosphotransferase system . Blasting of nucleotide sequence of cellobiose operon has revealed a wide distribution of this operon among extra intestinal pathogenic *E. coli*, including NMEC. In this study, we hypothesized that the cellobiose operon is involved in NMEC virulence regulation and is differentially expressed during the course of the infection. To test this hypothesis, we employed a quantitative real-time polymerase chain reaction to compare cellobiose expression of *E. coli* RS218 strain *in-vitro* under laboratory conditions (grown in Luria Bertani broth or human cerebral endothelial cells) and *ex-vivo* (grown in neonatal blood or serum). Our results indicated more than two-fold change in cellobiose gene expression when *E. coli* RS218 was grown in human cerebral endothelial cells, neonatal blood or neonatal serum as compared to LB. Furthermore, the regulatory effects of cellobiose operon on NMEC virulence was evaluated by comparing the expression of major virulence genes of NMEC (*ompA*, *fimH*, *aslA*, *npl*, *ibeA*, *traJ*, and *cnf*) between a mutant of RS218 lacking cellobiose operon and its wild-type strain.

Characterization Of A Novel Virulence Regulator In Enterohemorrhagic *escherichia Coli* o157:H7

Author Block:

D. Luzader, M. Kendall; Univ. of Virginia Sch. of Med., Charlottesville, VA

Abstract Body:

Enterohemorrhagic *Escherichia coli* O157:H7 (EHEC) is a deadly food-borne pathogen responsible for outbreaks of bloody diarrhea and hemorrhagic colitis. Ingestion of less than 100 cells is enough to cause disease, making EHEC a serious public health concern. With such a low infectious dose, EHEC must be able to efficiently sense the environment and regulate the expression of virulence genes such as the locus of enterocyte effacement (LEE). The LEE encodes a type three secretion system and effector proteins that influence EHEC pathogenesis through the formation of attaching and effacing (AE) lesions. The regulation of virulence genes EHEC involves the integration of multiple signaling cues. Using a bioinformatics approach, we examined epinephrine and ethanolamine regulatory pathways and identified a putative transcriptional regulator in EHEC which we renamed regulator of EHEC virulence or RevA. Because *revA* is differentially expressed when grown in the presence of either epinephrine or ethanolamine, we hypothesize that RevA plays a role in pathogenesis by the regulation of virulence gene expression in EHEC.To test our hypothesis, we generated a deletion strain of *revA* using lambda-red techniques and then examined the expression of LEE-encoded genes in WT EHEC or the *revA* mutant strain by qRT-PCR. Expression of the LEE was significantly decreased in the *revA* mutant compared to WT. To further assess the influence of RevA on EHEC pathogenesis, we measured the number of AE lesions formed on epithelial cells by fluorescent microscopy through a fluorescein actin staining assay. In agreement with the transcriptional data, the *revA* mutant formed significantly less AE lesions compared to WT EHEC. Preliminary data using electrophoretic mobility shift assays indicate that RevA is a direct regulator of the LEE. These data demonstrate a novel role for RevA in the modulation of EHEC virulence traits. We are currently mapping the RevA regulatory circuits in EHEC and confirming the mechanism through which RevA influences gene expression in EHEC.

The Pneumococcal Tpra Is Essential For Host Derived Sugar Utilisation And Virulence

Author Block:

A. S. Motib, P. Andrew, H. Yesilkaya; Univ. of Leicester, Leicester, United Kingdom

Abstract Body:

Background: *Streptococcus pneumoniae* is a major cause of mortality and morbidity around the world; it causes several serious invasive infections. Virulence factors that lead to increase the pathogenicity of this bacterium are regulated in response to different environmental stimuli. TprA is a transcriptional regulator of *Streptococcus pneumoniae*, which is activated by a peptide, PhrA. However, the role of the TprA/PhrA system in pneumococcal physiology and virulence is not known in detail. Hence, the objective of this study was to further the knowledge on the function of the TprA/PhrA system.**Methods:** Insertion deletion mutants were constructed and their growth was tested in chemically defined medium supplemented with different sugars (glucose, galactose, maltose, and N-acetyl glucosamine) under microaerobic condition. In addition, hyaluronidase and neuraminidase activities were assayed using chromogenic substrates. The expression of *tprA* and *phrA* was determined by *lacZ* reporter assay. Finally, mouse model of pneumococcal pneumonia and systemic infection models were used to determine the virulence of mutant strains compared with the wild type D39.**Results:** We showed by reporter gene assays that the TprA/PhrA system is active in the presence of galactose and mannose. TprA and PhrA mutant strains were significantly attenuated in growth on galactose and mannose compared with the wild type D39 strain. In addition, we also demonstrated that mutation of *tprA* abrogates pneumococcal virulence in a mouse model of pneumococcal pneumonia that develops after intranasal infection, as well as in a septicemia model. Analysis of the TprA mutant indicated that the mutant had decreased production of important virulence factors, including neuraminidase and hyaluronidase compared to the wild type D39 strain.**Conclusions:** Our results showed that TprA is crucial for pneumococcal host-derived sugar metabolism and virulence. We also showed that TprA is essential to produce neuraminidase and hyaluronidase that are important to survive *S. pneumoniae* in host tissue. Further work is underway to determine how TprA contributed to pneumococcal virulence.

SNP Combinations Found *In vibrio cholerae* Clinical Isolates Have an Additive Effect on Virulence Capabilities

Author Block:

B. M. Carignan, K. D. Brumfield, M. S. Son; Plymouth State Univ., Plymouth, NH

Abstract Body:

Background: Cholera is a potentially fatal diarrheal disease caused by the Gram-negative, aquatic bacterium *Vibrio cholerae*. This disease is characterized by vomiting and severe watery diarrhea, and, if left untreated, will result in severe dehydration and ultimately death. Recently, *V. cholerae* clinical isolates demonstrated increased virulence capabilities, causing more severe symptoms with a much faster rate of disease progression than previously observed. **Methods:** We have identified single nucleotide polymorphisms (SNPs) in four key regulatory genes (*hapR, hns, luxO,* and vieA) of a *V. cholerae* clinical isolate, known to affect virulence gene expression. Herein, all possible SNP and SNP combinations were introduced into the prototypical wild-type El Tor strain N16961 using an established allelic exchange protocol, and the effects on production of the master regulator of virulence gene expression, ToxT, and the two main virulence factors, the toxin co-regulated pilus (TCP), and cholera toxin (CT) were determined by Western blot analysis and a colorimetric CT assay, respectively. We hypothesize that various SNP and SNP combinations will affect ToxT levels, and the levels of two main virulence factors. Furthermore, we hypothesize that a minimum combination of SNPs is necessary to recapitulate these increased virulence capabilities observed in *V. cholerae* clinical isolates. **Results:** We observed the varying SNP combinations primarily had additive effects on CT, TCP, and ToxT production relative to the prototypical wild-type strain, while some combinations interestingly had the opposite effect. **Conclusion:** These data strongly suggest that these SNPs in a yet-to-be-determined combination are involved in the increased virulence capabilities observed in *V. cholerae*. However, to what capacity and the molecular basis of these observed increases in virulence capabilities is still unclear, and currently under investigation.

***Mycobacterium tuberculosis* phoY Proteins Promote Persister Formation by Mediating Phosphate Signaling between Pst/SenX3-RegX3**

Author Block:

S. B. Namugenyi, A. M. Aagesen, A. D. Tischler; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

The *Mycobacterium tuberculosis* (*Mtb*) phosphate-specific transport (Pst) system controls expression of phosphate (P_i)-responsive genes by negatively regulating SenX3-RegX3, a two-component regulatory system, in P_i-rich conditions. Previously we demonstrated that deletion of *pstA1*, which encodes a trans-membrane component of the Pst system, causes *in vivo* attenuation due to constitutive activation of RegX3 and aberrant expression of P_i-responsive genes. In *Escherichia coli* the Pst system inhibits a homologous two-component system through the negative regulator, PhoU. *E. coli* PhoU is also required for formation of persisters, a sub-population of phenotypically antibiotic tolerant bacteria that are genetically identical to drug susceptible bacteria. *Mtb* has two *phoU* homologs, *phoY1* and *phoY2*, which have not been characterized. To determine which PhoY protein participates in signal transduction, we used qRT-PCR to quantify transcript levels of select P_i-responsive genes in *phoY* deletion mutants. The Δ*phoY1* or Δ*phoY2* single deletions did not affect transcript levels, but significant up-regulation was observed in the Δ*phoY1*Δ*phoY2* double mutant. This phenotype was reversed by complementation with either *phoY1* or *phoY2* or deletion of *regX3*, suggesting that both PhoY proteins can negatively regulate SenX3-RegX3 and that they have redundant function. We analyzed the frequency of persister formation in the *phoY* mutants using combinations of antibiotics. Persister frequency was decreased 20- to 40-fold in the Δ*phoY1*Δ*phoY2* mutant compared to wildtype. This decrease in persister frequency was partially *regX3*-dependent. A Δ*pstA1* mutant exhibited a similar decrease in persister frequency that was also *regX3*-dependent. Our data suggest that disrupting P_i signal transduction mediated by the PhoY proteins can dramatically enhance susceptibility of *Mtb* to antibiotics.

Phosphotyrosine-mediated Regulation of Enterohemorrhagic *Escherichia coli* Virulence

Author Block:

C. Robertson[1], D. A. Rasko[2], J. B. Kaper[1], **A-M. Hansen**[1]; [1]Univ. of Maryland Sch. of Med., Baltimore, MD, [2]Inst. for Genome Sci., Baltimore, MD

Abstract Body:

Although protein tyrosine phosphorylation is a well-established essential regulatory mechanism in eukaryotes, it is understudied in prokaryotes. We previously identified that the number of tyrosine-phosphorylated proteins in *Escherichia coli* is about 10-fold higher than heretofore appreciated. The newly identified phosphorylated proteins relate to fundamental cell functions and virulence, indicating a central regulatory role of tyrosine phosphorylation. Here, we aim to elucidate the regulatory role of phosphotyrosine-mediated signaling in virulence gene expression of the food-borne pathogen enterohemorrhagic *E. coli* (EHEC) with the focus being on the transcriptional regulator Cra. EHEC infection is characterized by an intestinal attaching and effacing (A/E) histopathology, which is due to the activity of a type III secretion system (T3SS) encoded by the locus of enterocyte effacement (LEE) pathogenicity island. Cra, a glycolytic metabolite-responsive DNA-binding global regulator controlling sugar metabolism, is required for LEE expression under gluconeogenic conditions to ensure successful colonization. Since Cra Y47 identified as being phosphorylated is functionally important and is located in the DNA-binding domain, we hypothesize that phosphorylation of Cra controls the expression of virulence and central carbon metabolism genes by affecting Cra DNA-binding capacity. Comparing the regulatory effect of wild type, non-phosphorylatable and phosphomimetic Cra variants on LEE expression, we demonstrate that phosphorylation of Y47 negatively affects the production and secretion of T3SS proteins under glycolytic conditions where LEE expression is unwarranted. EHEC expressing phosphomimetic Cra versus wild type Cra exhibits decreased A/E lesion formation efficiency, suggesting that Cra phosphorylation negatively influences the EHEC virulence potential. Specifically, we demonstrate that phosphomimetic Cra unlike wild type Cra is incapable of binding to a LEE regulatory region. Our findings indicate that tyrosine phosphorylation of Cra negatively controls LEE expression by interfering with Cra DNA-binding capacity resulting in decreased T3SS activity and A/E lesion formation.

Phosphorylated *Pseudomonas aeruginosa* ALGR is Required for Iron Acquisition and Murine Virulence

Author Block:

A. S. Little[1], Y. Okkotsu[1], F. H. Damron[2], M. Barbier[2], A. Oglesby-Sherrouse[3], J. P. Owings[4], J. B. Goldberg[4], W. L. Cody[5], M. J. Schurr[1]; [1]Univ. of Colorado Sch. of Med., Aurora, CO, [2]West Virginia Univ. Sch. of Med., Morgantown, WV, [3]Univ. of Mayland Sch. of Med., Baltimore, MD, [4]Emory Univ. Sch. of Med., Atlanta, GA, [5]Univ. of Dallas, Irving, TX

Abstract Body:

The *P. aeruginosa* AlgZR two-component system controls the expression of several virulence determinants. Three phenotypes (alginate, rhamnolipid and type IV mediated motility) are dependent upon AlgR phosphorylation. A recent ChIP-seq manuscript reported a 154 gene regulon for AlgR. However, this study did not take into account AlgR phosphorylation. While *algR* and *algZ* gene deletions have been assessed in murine infection models, the impact of AlgR phosphorylation on virulence has not been examined. Strains encoding a phospho-mimetic form AlgRD54E and a phospho-defective form AlgRD54N were created to dissect the role of the AlgR phosphorylation state by microarrays and in three different virulence models.Microarrays comparing PAO1*algR*D54E and PAO1*algR*D54N identified differentially regulated genes dealing with iron acquisition. PAO1 *algR*D54N produced considerably less (25%) siderophores than wildtype PAO1. Artificially increased expression of AlgRD54N repressed siderophore production, whereas expression of AlgRD54E had no effect. Mobility shift assays showed that AlgR directly bound to the *prrf, pvdS* and *pvdY* promoters. PAO1*algR*D54N was considerably attenuated in three virulence models. In a *Drosophila melanogaster* oral feeding model, PAO1*algR*54N resulted in 35% mortality compared to near complete mortality of flies infected with PAO1. In an acute murine pneumonia model, PAO1*algR*D54N infected mice had 37.5% mortality, while PAO1 resulted in 100% mortality. PAO1*algR*D54N was also attenuated for growth in a murine wound model.A large group of dysregulated genes were associated with iron, and subsequent assays showed that PAO1*algR*D54N had decreased siderophore production. PAO1*algR*D54N was defective in three different models of virulence, and the dysregulation of iron acquisition genes likely plays a role in the attenuation of virulence with PAO1*algR*D54N, as defects in iron acquisition are known to result in avirulence in several models. However, as the microarray data show a wide range of dysregulated genes, it is unlikely that only one group of related genes resulted in this defect.

Type 6 Secretion System-mediated Killing Generates Clonal Assortment within Microbial Communities

Author Block:

B. K. Hammer; Georgia Inst. of Technology, Atlanta, GA

Abstract Body:

Antagonistic interactions between microbes likely determine the structure and diversity of microbial communities. *Vibrio cholerae* interacts with other microbes in biofilms in aquatic settings and within the digestive tracts of animals including humans, where certain strains can cause fatal cholera. *V. cholerae* utilizes a Type VI Secretion System (T6SS) resembling a phage tail-spike to mediate contact-dependent inter-bacterial antagonism in biofilm communities. The T6SS directly injects toxic effector proteins to lyse neighboring cell that lack cognate immunity proteins. Phenotypic and genomic analyses of a diverse set of >50 isolates we sequenced identified distinct T6SS effector/immunity pairs and several T6SS$^+$ *V. cholerae* isolates that killed one another, i.e. that were mutual killers. By killing competitors but not kin, we reasoned that T6SS-mediated killing could generate structured populations with high clonal assortment. To gain insight into the consequences of T6SS-mediated killing on the dynamics and structure of bacterial populations, we used fluorescence microscopy to visualize competition between two *V. cholerae* mutual killers as they grew from initially well-mixed conditions on solid surfaces. When each isolate was rendered T6SS$^-$ by deletion of an essential apparatus component, a well-mixed population was maintained. Unidirectional killing led to elimination of the T6SS$^-$ mutant by its T6SS$^+$ competitor. In contrast, bidirectional killing generated a structured population with each isolate segregating into distinct clonal patches. These dynamics were recapitulated in an agent-based simulation and partial differential equation models we developed. Imaging of the digestive tract of larval zebrafish by light sheet fluorescence microscopy also revealed that colonization of T6SS$^-$ bacteria was severely impaired in a germ-free host pretreated with T6SS$^+$ but not T6SS$^-$ *V. cholerae*. These results suggest microbes use inter-bacterial antagonism to generate spatial structure, and that T6SSs may have evolved to increase fitness during competition in environmental and host settings. We are currently exploring whether T6SSs establish highly structured populations predisposed to evolving costly behaviors that could not be supported in well-mixed populations.

Rumen Microbial Community Structure of Sheep Fed the Probiotic *Bacillus amyloliquefaciens* H57

Author Block:

B. J. Schofield[1], A. V. Klieve[2], P. Dart[1], O. le[2], N. Lachner[1], Y. Yeoh[1], D. Ouwerkerk[3], D. McNeill[2], P. Hugenholtz[1]; [1]The Univ. of Queensland, St Lucia, Australia, [2]The Univ. of Queensland, Gatton, Australia, [3]Dept. of Agriculture and Fisheries, Dutton Park, Australia

Abstract Body:

The rumen microbiological community in sheep primarily drives the digestion of plant material. Key organisms play specific roles in digestion, ranging from fibre degradation, VFA and microbial protein production, to the regeneration of essential coenzymes such as those involved with methanogenesis. *Bacillus amyloliquefaciens* H57 (H57) is a probiotic isolated specifically for its antimicrobial activities and spore formation. Feeding pregnant Dorper ewes with pellets containing H57 spores at 10^6 g^{-1} led to significantly increased weight gain and nitrogen (protein) retention (Le *et al* 2014). In a project funded by Ridley AgriProducts and the ARC, we examined how H57 might benefit the sheep through effects on the rumen microbial community. Bacterial 16S rRNA genes were sequenced using an Illumina paired-end sequencing platform. There were clear differences in rumen microbial community structure in animals fed H57 compared to the control animals. The dominant organisms in H57 fed animals included a *Prevotella* and *Coprococcus* spp., whereas in the control animals, *Prevotella ruminicola* and a member of the *Succinivibrio* genus dominated. Metagenomic sequencing showed that the dominant *Prevotella* in the H57 fed animals possessed a glycoside hydrolase profile that was dominated by genes for cellulolytic enzymes. By contrast, most known rumen *Prevotella* species are dominated by hemi-cellulolytic gene families that act best on less fibrous materials. The dominance of the cellulolytic *Prevotella* species in the H57 fed animals may have contributed to the increased weight gain observed, as more of the otherwise less digestible cellulosic component of the diet was available for digestion.

Complete Sequences of Plasmids Carrying *bla*$_{IMP-4}$ Carbapenemase Gene from Enterobacteriaceae in Silver Gulls, Australia

Author Block:

M. Dolejska[1], H. Dobiasova[1], M. Medvecky[2]; [1]Univ. of Vet. and Pharmaceutical Sci., Brno, Czech Republic, [2]Vet. Res. Inst., Brno, Czech Republic

Abstract Body:

Background: Carbapenems are among the most important antimicrobials in human medicine. Their clinical efficiency is threatened by carbapenemases disseminated in Gram-negative bacteria worldwide. Recently, we have described high level of colonization by IMP-4-producing Enterobacteriaceae isolates in silver gulls in Five Islands, Australia. The *bla*$_{IMP-4}$ gene was present in the class 1 integron carried by resistance plasmids of various types.
Methods: In this study, a complete nucleotide sequencing of five representative plasmids from Enterobacteriaceae originated from the gulls was performed using MiSeq Illumina system. The sequences were analyzed using bioinformatics tools and compared with *bla*$_{IMP-4}$-carrying plasmids previously reported in clinical isolates in Australia, such as pEI1573.
Results: Multi-drug resistance region (MRR) carrying *bla*$_{IMP-4}$ gene identified in all plasmids was surrounded by IS*26* and showed high similarity to MRR of pEI1573. p1631 was 84 kb IncL/M plasmid with >99 % nucleotide identity with *bla*$_{IMP-4}$-plasmid pEI1573. With respect to pEI1573, the MRR was truncated by 4.5 kb fragment from *Klebsiella pneumoniae* genomes. Plasmid p42.1 contained a typical IncI1 backbone and MRR was bounded by Tn*1721*. p19.1 (185 kb) was related to other multi-drug resistance IncA/C$_2$ plasmids, carrying two variable resistance regions that included *floR-sul2* and pEI1573-like MRR inside Tn*1696*. A 15 kb fragment encoding UV resistance protein, previously identified in pKP13f, was found inside p19.1 backbone. p47.1 (142 kb) had highly mosaic structure formed by conjugative transfer region (tra) of pPry2001 from *Providentia rettgeri*, mercury resistance operon and other segments from genomes of environmental bacteria. Plasmid p77.1 (195 kb) was a mosaic formed by IncHI2 backbone, tra region related to IncX5 plasmids and a novel In*5*-like *bla*$_{IMP-4}$ integron bounded by IS*26*.
Conclusions: We demonstrate high plasticity of resistance plasmids encoding carbapenemase IMP-4 from Enterobacteriaceae in wildlife. This study underscore the spreading potential of large segments carrying resistance determinants, most likely by IS*26* mediated recombination and suggest possible role of environment in evolution of carbapenemase-carrying plasmids.

***Candida albicans* confers ampicillin resistance to *Streptococcus gordonii* in co-cultures**

Author Block:

A. Maddi, 14214, L. M. Yerke, R. Mancuso, 14214, C. Jennifer, N. Sadhak; State Univ. of new York, Buffalo, NY

Abstract Body:

Background: Oral biofilms are complex and contain various microorganisms including bacteria and fungi. The pioneer oral plaque bacteria, *Streptococcus gordonii* and the most abundant oral pathogenic fungus, *Candida albicans* are known to interact with each other. Past studies have shown that *S. gordonii* binds to hyphae of *C. albicans* in a corncob like structure. However, the exact mechanisms and outcomes of their interactions are not clearly understood. We hypothesized that *C. albicans* and *S. gordonii* confer antimicrobial resistance to one another when grown in co-cultures.
Methods: *C. albicans* and *S. gordonii* were grown in a specially prepared synthetic minimal media [Tryptic Soy Broth Yeast Extract (TSBY) + Yeast Nitrogen Base (YNB)] with and without the antibacterial agent, ampicillin, for 2, 4, 6 and 8 hrs. The cultures were then filtered to eliminate *C. albicans* and the resulting filtrate was then plated on TSBY agar and *S. gordonii* colonies were counted. Similarly *C. albicans* and *S. gordonii* were also grown in co-cultures with caspofungin (antifungal agent) for 2, 4, 6 and 8 hrs. These cultures were plated on YNB agar with ampicillin and the resulting *C. albicans* colonies were counted. Proteomic analysis of secreted protein resulting from the co-cultures was performed using SDS PAGE analysis, silver staining and mass spectrophotometric analysis.
Results: The results from the antibiotic testing showed that *S. gordonii* was able to grow significantly greater ($p<0.05$) at 4 and 6 hrs in the presence of ampicillin (antibacterial) and *C. albicans*, as compared to ampicillin alone. However, when caspofungin (antifungal) was present there was no significant growth of *C. albicans* even when *S. gordonii* was present in the culture. Proteomic and mass spectrometric analysis indicate differentially secreted proteins in the co-cultures as compared to single cultures. **Conclusions:** These data indicate that *C. albicans* protects *S. gordonii* from ampicillin dependent killing and may confer ampicillin resistance. However, *S. gordonii* does not protect *C. albicans* from antifungal killing. The secreted proteins may play a role in the interactions between *C. albicans* and *S. gordonii*.

Biostimulation And Microbial Community Profiling Reveal Insights On Rdx Transformation In Groundwater Samples Collected From Los Alamos

Author Block:

D. Wang, H. Boukhalfa, B. Newman, O. Marina, D. Ware, P. Reimus, T. Goering; Los Alamos Natl. Lab, Los Alamos, NM

Abstract Body:

Natural attenuation of RDX (hexahydro-1,3,5-trinitro-1,3,5-triazine) is facilitated by a complex interplay of abiotic and biotics activities. In this study, we aim to understand abiotic and microbial signatures of RDX degradation in groundwater. A survey was performed on the bacterial community of nine groundwater samples containing different levels of RDX collected from monitoring wells intercepting shallow and intermediate aquifers located in Los Alamos, New Mexico using the 16S rRNA profiling approach. A total of 827,454 sequence reads were obtained and classified into 997 genera indicating high microbial diversity. Known RDX degrading bacterial genera were found in all samples with Rhodococcus specifically enriched in the groundwater samples containing higher levels of RDX. To identify factors enhancing microbial activity and RDX degradation, groundwater samples from a selected well were stimulated by the addition of acetate or vegetable oil. Results demonstrated that vegetable oil but not acetate promoted RDX degradation in anaerobic conditions. Upon addition of carbon sources, dominant members of Nocardiaceae were outcompeted by bacteria in the family of Comamonadaceae and Pseudomonadaceae, which were underrepresented in groundwater. One of the retrieved sequences related to a previously described RDX-degrading strain (99% sequence identify) was enriched by vegetable oil under anaerobic conditions. The results of this study expand our current understanding of microbial ecology in RDX-contaminated aquifers and emphasize the potential importance of microbes in RDX transformation.

Effect of Aerial Fertilization on Microbial Communities Inhabiting Oaks Phyllosphere

Author Block:

a. bani, L. Borruso, P. Panzacchi, M. Ventura, G. Tonon, L. Brusetti; Free Univeristy of Bozen Bolzano, Bolzano, Italy

Abstract Body:

It is widely accepted that anthropic activities have increased nitrogen depositions worldwide. The deposition of atmospheric nitrogen compounds is primarily due to rain and snow harboring nitrate and ammonium. This has an effect on forests plant biodiversity and on the associated biota. Several studies have already investigated the effects of differential nitrogen amendments on soil under plants canopies. On the other hand, there is a general lack of knowledge regarding the effects of aerial nitrogen depositions on the canopy and the associated microbial communities. The goal of the present work is to assess the influence of nitrogen deposition on the microbial communities of the phyllosphere in a temperate forest dominated by sessile oak (*Quercus petraea* Liebl.). The study area is located in Monticolo (South Tyrol, Italy) where a long-term experiment of nitrogen deposition simulation has been established. The experimental design considered six plots: three control plots and three plots treated via aerial fertilization. The fertilizer was a liquid solution containing NH_4NO_3. Twenty kg ha^{-1} y^{-1} of the nitrogen solution were applied monthly from May 2015 until September 2015. Fifteen days after the last fertilization, three biological replicates were collected in each plot. Microbial structure resulted to be differentiated via NMDS into two clusters clearly separating the nitrogen-treated from the non-treated samples.

A New Pathway for Synthesis of the Biotin Pimelate Moiety in Bacteria

Author Block:

Y. Hu, J. Cronan; Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract Body:

Background: Biotin is an essential cofactor for carboxylation, decarboxylation and transcarboxylation reactions in various metabolic pathways. The pathways for the biosynthesis of the precursor pimelate moiety of biotin are diverse, while the enzymes responsible for synthesis of the bicyclic rings are conserved in all biotin-producing bacteria, plants and fungi[(1)]. The most common pathway for synthesis of the biotin pimelate moiety in bacteria is recently demonstrated in *E. coli*. This pathway utilizes a SAM-dependent methyltransferase (BioC) to mask the charged carboxyl group of a malonyl-ACP and to hijack the fatty acid biosynthetic pathway; giving a pimeloyl-ACP methyl ester via two classical fatty acid elongation cycles. A short-chain fatty acid esterase (BioH) then hydrolyzes the methyl group of the pimeloyl-ACP methyl ester, to give pimeloyl-ACP[(2-3)]. Interestingly, several *α-proteobacteria* like the pathogens *Agrobacterium* and *Brucella* have a different means to synthesize the pimelate moiety. **Methods and Results:** We report that these bacteria use a 3-ketoacyl-ACP synthase (condensing enzyme-like) protein called BioZ to synthesize the pimelate moiety. BioZ proteins have around 35% sequence identity with FabH, the fatty acid biosynthesis short chain 3-ketoacyl-ACP synthase[(4-6)]. Expression of various BioZ proteins complement the *E. coli bioC* and *bioH* pimelate moiety deletion mutant strains. Moreover, BioZ proteins contain the same conserved catalytic residues and perform the 3-ketoacyl-ACP synthase reaction, but give products that differ from those of FabH. Modeling of these proteins based on FabH crystal structure templates predicts that the structures are almost identical. The predicted amino acid substitutions that comprise the substrate binding tunnel argue that BioZ has different substrate preferences that differ from those of FabH. **Conclusions:** some *α-proteobacteria* use BioZ to synthesize the pimelate precursor for biotin by performing a FabH-like reaction, but with different substrates.

Comparative Genomics of *Devosia* Isolates Involved in the Biotransformation of the Mycotoxin Deoxynivalenol

Author Block:

D. Lepp, Y. I. Hassan, T. Zhou; Agriculture and Agri-Food Canada, Guelph, ON, Canada

Abstract Body:

Deoxynivalenol (DON) is a type B trichothecene mycotoxin that is commonly found in grains infested with fungus of *Fusarium* species. DON contamination is associated with feed refusal and low animal productivity/weight gain, which costs the global economy billions of dollars annually in trade losses. DON is also a documented health hazard for humans, causing both acute and chronic symptoms, and has a maximum tolerable level of less than 2 ppm in human food and 5 ppm in animal feed. Effective methods for controlling DON contamination are therefore urgently needed. We recently reported on the isolation of a bacterial strain (17-2-E-8) that is capable of detoxifying DON, through enzymatic epimerization, with high efficiency under a wide-range of conditions. This strain was subsequently identified as a novel species of *Devosia*, a diverse, poorly characterized genus that includes a number of other strains known for their ability to tolerate or detoxify various toxic chemicals. To identify candidate genes involved in the bio-transformation of DON by strain 17-2-E-8, as well as to characterize the *Devosia* pan-genome, we generated draft genome sequences of eight *Devosia* isolates and performed comparative genomic analyses. An additional 11 publicly available genomes were also included in the analysis, among which two (DBB001 and A16) have been previously reported to bio-transform DON. None of the eight sequenced isolates, aside from 17-2-E-8, were able to epimerize DON, as determined by LC-MS/MS. The total number of predicted genes per genome ranged from 3539[A1] to 5927, which clustered into 9637 orthologous groups and 10854 singletons, as predicted by Orthagogue. The core and pan genome sizes as estimated by PanGP were ~1629 and 20491 genes, respectively. Comparison of 17-2-E-8 with DB001 and A16 identified 307 and 12 conserved genes, respectively, that were not present in any of the non-detoxifying strains, several of which had predicted functions related to the epimerization of DON. Further studies are underway to confirm the function of the identified genes and optimize them for commercial usage, which will both help the feed/food industry and allow for agricultural and industrial applications to mitigate *Fusarium* toxin contamination.

Non-biased Micro RNA Purification from Clinical and Environmental Samples

Author Block:

S. Forman, D. Cabaya; Zymo Res., Irvine, CA

Abstract Body:

Organic extraction, with TRIzol, TRI Reagent or similar, is often a method of choice for pathogen inactivation and sample stabilization and thus plays a significant role in clinical and environmental sample processing prior to nucleic acid analysis. However, the organic extraction methods were shown to introduce significant bias, specifically into the small RNA (miRNA) recovery. We have developed a non-biased method that allows for binding nucleic acids, including miRNAs, directly, i.e., without phase separation or precipitation, following the organic extraction step. We have compared the miRNA profiles obtained through next generation sequencing as well as a hybridization approach with an existing non-biased "double extraction" protocol (Ambion) and confirmed the non-biased purification results. This novel "direct nucleic acid binding" approach is fully automatable and allows the use of organic extraction in high-throughput applications.

Multi-Drug Resistant Bacteria in Wound Infections and Tuberculosis Surveillance in a Philippine Tertiary Hospital

Author Block:

J. Velasco[1], M. Valderama[1], K. Nogrado[1], D. Chua Jr.[2], M. Lopez[3], L. Macareo[1], B. Swierczewski[1]; [1]USAMD-AFRIMS, Bangkok, Thailand, [2]V Luna Gen. Hosp., Quezon City, Philippines, [3]AFPMSS, Quezon City, Philippines

Abstract Body:

Background: Antimicrobial resistance is a serious public health threat. Military populations are especially susceptible to wound bacterial infections and diseases which can be spread in close quarters.
Methods and Results: From Aug 2013 - Dec 2015, 1,516 bacterial isolates from patients at a tertiary military hospital underwent drug susceptibility testing using the Microscan Walkaway 40 Plus System. Of 159 *Klebsiella spp.* isolates, 28.3% [95%CI: 21.6-36.1] were imipenem resistant, 28.9% [95% CI: 22.1-36.7] were meropenem resistant and 102 (64.2%) were identified as suspected extended spectrum beta lactamase producers. Of 146 *Escherichia coli* isolates, 2.7% [95% CI: 0.9-7.2] were imipenem resistant, 2.1% [95% CI: 0.6-6.4] were meropenem resistant, 54 (37.0%) were identified as suspected ESBL producers. Of 76 *Acinetobacter spp*. isolates, 30 (39.5%) were non-susceptible to all antibiotics in the negative breakpoint combo 30 or 34 panels. Of 154 *P. aeruginosa* isolates, 30 (19.5%) were non-susceptible to all antibiotics in the NBPC 30 or 34 panels. Of 135 *S. aureus* isolates, 70.4% [95% CI: 61.8-77.8] were identified as methicillin resistant. To further characterize drug susceptibility patterns, analysis was narrowed down to important drug resistance from 454 wound isolates. Testing for carbapenem resistant genes is ongoing. Multidrug resistance tuberculosis testing was performed (Mar 2015-Feb 2016) on 81 sputum samples using the GeneXpert Cepheid PCR with 18/81 (22%) positive for *M. tuberculosis* and rifampicin resistance detected on 4/18 (22%) *M. tuberculosis* positive samples.
Conclusions: This study describes important MDR bacteria in wound infections and provides data on MDRTB in a special population. Strengthening of MDR microbial pathogen surveillance is needed to better characterize circulating drug resistance patterns and to improve early detection and containment strategies.

Reassessment of Penicillin Resistance Breakpoints for *Bacillus anthracis*

Author Block:

D. Sue, J. Bugrysheva, A. J. Carter, C. Lascols, W. A. Bower, S. V. Shadomy, S. K. Pillai, **L. M. Weigel**; CDC, Atlanta, GA

Abstract Body:

Bacillus anthracis, the etiologic agent of anthrax, is designated as a Tier 1 select agent based on the risk assessment of this organism as a biothreat agent. Amoxicillin (AMX) and penicillin (PEN) are recommended for treatment or post-exposure prophylaxis in patients who cannot take the first-line drugs ciprofloxacin or doxycycline. AMX and PEN are recommended as alternatives for children if the organism is documented to be susceptible to PEN. Penicillin is the first choice for treatment of naturally-occurring anthrax in many parts of the world where the disease commonly occurs. *B. anthracis* isolates that are clinically resistant to PEN are rarely reported, although the organism has two β-lactamase genes on the chromosome. We observed numerous strains of *B. anthracis* for which the MIC of PEN crossed the current breakpoint for resistance (≥0.25 µg/ml), but did not approach the MIC of clinically resistant strains (≥256 µg/ml). We performed broth microdilution susceptibility testing following CLSI guidelines for 52 strains of *B. anthracis*, 4 of which had an MIC of PEN ≥256 µg/ml, to determine the frequency of PEN MICs that cross the CLSI breakpoint. MICs were determined on three consecutive test days for PEN, AMX, AMX-clavulanate, ampicillin (AMP), and AMP-sulbactam. For 26 strains (50%), the MIC of PEN was at or just above the current breakpoint (0.12 or 0.25 µg/ml) on one or more days of testing. For 9 strains (19%), the interpretation as PEN-susceptible or -resistant changed on successive test days. The MIC of AMX ranged from ≤0.03 to 0.12 µg/ml without the variability noted for PEN MICs. These data have been submitted to CLSI with a request to reassess the PEN breakpoint and to set a breakpoint for AMX. A new breakpoint of ≥1 µg/ml PEN for resistance will better represent the natural population of PEN-susceptible *B. anthracis and* eliminate inaccurate reports of PEN or AMX resistance.

Suboptimal Performance of Algorithm Diagnosis of *C. difficile* Infection in Children

Author Block:

E. J. Gomez[1], K. Alby[2], D. P. Robinson[1], S. Montgomery[1], S. S. Roundtree[1], D. L. Blecker-Shelly[1], **K. V. Sullivan**[1]; [1]The Children's Hosp. of Philadelphia, Philadelphia, PA, [2]Hosp. of the Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Background: The "algorithm" approach to *C. difficile* infection (CDI) diagnosis is widely used but performance in children has not been rigorously investigated. We compared the performance of algorithmic diagnosis against 4 commercial assays in a tertiary pediatric population. **Methods:** Stool samples submitted for CDI testing in children between 1-18 years of age were tested prospectively at The Children's Hospital of Philadelphia. Duplicate samples within 30 days were excluded. Samples were tested with: an algorithm (C. diff Quik Chek Complete (QCC) reflexed to *illumi*gene *C. difficile*) (ALG); the AmpliVue C. difficile Assay (ACD); the Lyra Direct *C. difficile* Assay (LCD); the BD MAX Cdiff (BDM); and the Xpert *C. difficile* assay (XCD). Sensitivity (SN), specificity (SP), positive predictive value (PPV), and negative predictive value (NPV) were calculated. The gold standard positive was defined as positivity by two tests with different manufacturers. Samples that were positive by one or more tests underwent toxigenic culture. **Results:** 211 non-duplicate samples were analyzed. 41 tested positive by at least one method, 32 by two methods, with a prevalence of 15%. SN, SP, PPV, and NPV were 87.5%, 98.9%, 93.3%, 97.8% for ALG; 21.9%, 98.9%, 77.8%, 87.6% for QCC's toxin A/B component; 96.9%, 98.9%, 93.9%, 99.4% for ACD; 90.6%, 98.9%, 93.5%, 98.3% for LCD; 96.8%, 99.4%, 96.8%, 99.4% for BDM, and 96.9%, 98.9%, 93.9% and 99.4% for XCD. Nine samples were positive by one test only (2 ALG, 2 ACD, 2 LCD, 1 BDM, 2 XCD). 8/9 tested negative by toxigenic culture as did 11/32 (34.3%) of the gold standard positives. **Conclusion:** GDH-based algorithms may detect CDI with suboptimal sensitivity compared to molecular methods in children. QCC's toxin A/B component had false positive results and a sensitivity of 22%. This necessitated reflex testing and delay in reporting in 70% of CDI cases detected with this method. Comparatively, the 4 molecular assays investigated performed with superior (though similar) sensitivity and specificity.

Ctr. for Diarrhoeal Diseases and Res., Bangladesh, Dhaka, Bangladesh, [3]Univ. of Virginia, Charlottesville, VA, [4]Kilimanjaro Clinical Res. Inst., Moshi, Tanzania, United Republic of

Abstract Body:

Background: Phenotypic drug susceptibility testing is endorsed as the standard for second-line drug testing of *Mycobacterium tuberculosis* however it is slow and laborious. **Methods:** We evaluated the accuracy of two faster and easier methodologies that provide results for multiple drugs: a genotypic TaqMan Array Card and the Sensititre MYCOTB plate. Both methods were tested at three central laboratories in Bangladesh, Tanzania, and Thailand with 212 MDR-TB isolates and compared with the laboratories' phenotypic method in use. **Results:** The overall accuracy for ethambutol, streptomycin, amikacin, kanamycin, ofloxacin, and moxifloxacin versus the phenotypic standard was 87% for TAC (range 70-99%) and 88% for the MYCOTB plate (range 76-98%). To adjudicate discordances we re-defined the standard as the consensus of the three methods, against which the TAC and MYCOTB plate yielded 94-95% accuracy while the phenotypic result yielded 93%. There were isolates with genotypic mutations and high MIC that were phenotypically susceptible, and isolates without mutations and low MIC that were phenotypically resistant, questioning the phenotypic standard. **Conclusions:** In our view the TAC, MYCOTB plate, and the conventional phenotypic method perform similarly for second line drugs, however the former methods offer speed, throughput, and quantitative susceptibility information.

Coexistence of Antibodies to Severe Acute Respiratory Syndrome Coronavirus and Bat Alphacoronavirus in the same *Rhinolophus* Bats

Author Block:

Y-N. Chen[1], B-G. Su[1], H. Chen[2], H-C. Cheng[3]; [1]Chung Yuan Christian Univ., Taoyuan, Taiwan, [2]Natl. Taiwan Univ., Taipei, Taiwan, [3]Endemic Species Res. Inst., Nantou, Taiwan

Abstract Body:

Background Horseshoe (*Rhinolophus*) bats have been identified as natural reservoirs of severe acute respiratory syndrome coronavirus (SARS CoV) affecting about 8000 people worldwide during 2002 to 2003. In Taiwan, SARS CoV (Betacoronavirus) and bat Alphacoronavirus (*Scotophilus* bat CoV 512) were detected in the feces of Formosan lesser horseshoe bats (*Rhinolophus monoceros*). While genomic analysis has proved coinfection of different CoV in the same bats, no serological evidences were documented due to the difficulties to collect serum from insectivore bats. To understand whether the same *Rhinolophus* bats can be infected with both SARS CoV and bat Alphacoronavirus, recombinant nucleocapsid (N) proteins of both CoVs were used by western blot (WB) analysis to detect antibodies to both CoVs. **Methods** Previous studies showed that full-length N protein with a highly conserved motif among all known CoVs could have cross reactivity, so the carboxyl terminal fragment of N protein (N3) without the motif was used for detecting CoV species-specific antibody. Total 63 serum specimens were collected from 50 female and 13 male *Rhinolophus* bats in Taiwan during 2014 to 2015 for WB analysis with the N3 fragments from SARS CoV Tor2 strain and *Scotophilus* bat CoV 512/CYCU-S1/TW/2013. Recombinant N3 fragments with His-tag were expressed by *Escherichia coli* BL21 and purified by NTA agarose resin. **Results** Out of 63 serum samples, 22 were positive to SARS CoV (35%), 27 were positive to *Scotophilus* bat CoV (43%), and 16 were positive to both CoVs (25%). Females had higher detection rate of CoV-specific antibodies. Only 2 out of the same 63 bats had feces tested positive by RT-PCR targeting RNA-dependent RNA polymerase (RdRp) gene and were tested positive for antibodies to SARS CoV. Serological detection had higher sensitivity than genomic method. **Conclusion** It is the first report describing coexistence of antibodies to SARS CoV and bat Alphacoronavirus in the same *Rhinolophus* bats. The findings suggested that both CoVs not only coexist in the same bat population but also have ability to infect the same individuals. It should be noted for public health due to the potential recombination between human and bat CoVs.

Diagnosis of *Capnocytophaga canimorsus* Sepsis by a Novel Cell-free DNA Sequencing Assay

Author Block:

A. Strand[1], D. K. Hong[2], V. G. Fowler, Jr.[1], B. D. Kraft[1]; [1]Duke Univ. Med. Ctr., Durham, NC, [2]Karius, Inc., Menlo Park, CA

Abstract Body:

Background: Sepsis is an increasingly common condition in hospitalized patients and is associated with a high mortality rate. In up to 40% of cases of sepsis, a causative organism is never identified. There is a need for improved, sensitive diagnostics to inform targeted therapy in patients with sepsis. Given its extreme sensitivity and open-ended nature, next-generation sequencing (NGS) has great potential in filling this need. We report a case of septic shock due to *Capnocytophaga canimorsus* that was diagnosed by a novel plasma-based NGS assay. **Methods:** We developed a minimally invasive NGS-based infectious disease assay that takes advantage of circulating cell-free plasma DNA originating from invasive pathogens. After filtering human sequences, remaining sequences are aligned to a comprehensive pathogen sequence database and abundance is computed for detected pathogens. **Results:** A 60 year-old male with history of asplenia was admitted with septic shock. Initial blood cultures were negative and the patient was treated with multiple antibiotics including coverage for typical and atypical bacterial pathogens, such as rickettsia, and herpesviruses. Due to the uncertainty of the etiology of this illness, a novel NGS-based plasma assay was run which identified *C. canimorsus* within 24 hours. These results were returned in a clinically actionable timeframe resulting in narrowing of treatment for the patient and were subsequently confirmed many days later by 16s sequencing of a positive blood culture bottle. **Conclusions:** We report the first use of an open-ended cell-free DNA NGS assay to identify the causal pathogen in a patient with sepsis in a clinically actionable timeframe. This technology has the potential to improve targeted therapy for patients with sepsis of unclear etiology.

Evaluation of HardyCHROM™ ESBL, a Chromogenic Medium Designed to Screen for Extended-Spectrum-Beta-Lactamase Producing *E. coli, K. pneumoniae, K. oxytoca* and *P. mirabilis* and Recovery of *Enterobacteriaceae* with Reduced Susceptibility to Broad Spectrum Cephalosporins

Author Block:

N. Ledeboer[1], E. Palavecino[2], R. Myslymi[3], M. Turner[2], M. Blevins[2], M. Faron[1], J. Connolly[1], S. Whittier[3]; [1]Med. Coll. of Wisconsin, Milwaukee, WI, [2]Wake Forest Univ. Baptist Med. Ctr., Winston-Salem, NC, [3]New York-Presbyterian/Columbia Univ. Med. Ctr., New York, NY

Abstract Body:

Background: HardyCHROM™ ESBL is a chromogenic medium designed to screen for ESBL (Extended-Spectrum-Beta-Lactamase) producing *E. coli* (EC), *K. pneumoniae* (KP), *K. oxytoca* (KO) and *P. mirabilis* (PM) from fecal specimens. The medium can also be used for the recovery of *Enterobacteriaceae* with reduced susceptibility to broad spectrum cephalosporins (BSC). In this study, this medium was compared to traditional culture methods utilizing parallel TSB enrichments with 1µg/mL ceftazidime and with 1µg/mL cefotaxime followed by subculture to MacConkey. The results of the reference method were then compared with results from HardyCHROM™ ESBL read at 18 and 24 hours. **Methods:** A total of 1683 fecal specimens were tested on HardyCHROM™ ESBL in parallel with the TSB enrichments. Overall, 242 ESBL-producing EC, KP, KO, and PM recovered from 214 specimens. HardyCHROM™ ESBL was 97.66% sensitive for the screening of ESBL-producing EC, KP, KO, and PM and 83.05% specific after 18 hours of incubation. The reduced specificity was due to the growth of microorganisms resistant to BSC that did not display ESBL phenotype and presented profiles suggestive of AmpC or KPC production. HardyCHROM™ ESBL was 94.69% sensitive and 99.01% specific for the recovery of *Enterobacteriaceae* which were non-susceptible to BSC regardless of ESBL phonotype or not. **Results:** ESBL-producing EC, KP, KO, and PM were recovered from 4.7% of specimens from WI, 5.8% of specimens from NC, and 22.3% of specimens from NY. A total of 572 organisms showed reduced susceptibility to BSC recovered in this study. Of those, 138 also showed reduced susceptibility to carbapenems. These organisms with reduced susceptibility to carbapenems were recovered from 8.7% of specimens from NC, 2.0% of specimens from WI, and 13.3% of specimens from NY. **Conclusions:** Overall, HardyCHROM™ ESBL is reliable for the selective screening of ESBL-producing microorganisms in fecal specimens, as well as for the confirmation of the presence of *Enterobacteriaceae* with reduced susceptibility to BSC.

Characterization of Multi-drug Resistant *Enterococcus faecalis* Isolated from Research Macaques

Author Block:

M. T. Lieberman[1], S. E. Woods[1], F. Lebreton[2], J. L. Dzink-Fox[1], M. S. Gilmore[2], J. G. Fox[1]; [1]MIT, Cambridge, MA, [2]Harvard Med., Boston, MA

Abstract Body:

Background:
Multi-drug resistant (MDR) *Enterococcus faecalis* is a common and serious cause of nosocomial infections in hospitals. Previous characterization of 14 *E. faecalis* isolates from cephalic recording chambers of research macaques revealed two lineages with marked multi-drug resistance. Lineage A (LA) isolates (n=7) showed differing susceptibilities to gentamicin, with 4/7 isolates displaying high-level gentamicin resistance while Lineage B (LB) isolates (n=7) displayed resistance to neomycin. All isolates displayed marked streptomycin resistance. Resistance to tetracycline, chloramphenicol, erythromycin and trimethoprim-sulfamethoxazole was also noted.
Methods: DNA was extracted from 2 LA and 1 LB isolate and sequenced on a single SMRT cell on a Pacific Biosciences RS2 sequencer. Genomes were assembled and FASTA sequences were analyzed by PubMLST, ResFinder and VirulenceFinder to confirm sequence type (ST) and identify genes of interest.
Results: Two isolates from LA were confirmed to be ST4 and the isolate from LB was confirmed to be ST55. All isolates had a unique antimicrobial resistance gene profile with the *lsa(A)* gene encoding intrinsic resistance to lincosamides and streptogramins A as the only common gene between all 3 isolates. Additional macrolide resistance encoded by *erm(B)* was identified in 2 isolates. Four genes encoding aminoglycoside resistance were identified: *str* and 3 aminoglycoside-modifying enzymes: *aph(3')-III, aac(6')-aph(2")* and *ant(6)-Ia*. Genes encoding tetracycline resistance included mechanisms for efflux pumps (*tetL*) and ribosomal protection (*tetS* and *tetM*). Phenicol resistance was conferred by the *cat* gene and was present in ST4 isolates, but not the ST55 isolate. Trimethoprim resistance encoded by *dfrG* was noted in 1 ST4 isolate. Other virulence factors identified included enterococcal surface protein, aggregation substance, gelatinase, collagen adhesion precursor and endocarditis antigen.
Conclusions: *E. faecalis* isolates from cephalically-implanted macaques display genetic similarities to isolates associated with human nosocomial infections. Macaques represent a unique research model to study human nosocomial infection due to their long-term residence in a healthcare setting and intermittent antimicrobial exposure.

In Vitro Activity Of Ceftazidime-Avibactam (CAZ-AVI) Against CAZ Resistant Isolates Of *Burkholderia pseudomallei* (*Bp*)

Author Block:

K. M. Papp-Wallace[1], S. Chirakul[2], N. Chantratita[3], **H. P. Schweizer**[2], R. A. Bonomo[1]; [1]Cleveland VAMC, CWRU, Cleveland, OH, [2]U of Florida, Gainesville, FL, [3]Mahidol U, Salaya, Thailand

Abstract Body:

Background: *Bp* is an opportunistic and globally emerging pathogen with biothreat potential that is the causative agent of melioidosis. The oxyimino-cephalosporin, CAZ, is used in the treatment of *Bp* infections, but resistance to CAZ (CAZ^R) has been observed. *Bp* possesses class A and class D β-lactamases, PenA and OXA-42-like, which mediate β-lactam resistance. AVI inhibits most class A, C, and some D β-lactamases. Here, we test the ability of AVI to restore susceptibility to CAZ in *Bp*.
Methods: A panel of clinical isolates of *Bp* was tested by broth microdilution MICs using CAZ and CAZ-AVI according to CLSI guidelines; AVI was maintained at 4 µg/mL. All experiments with virulent *Bp* clinical isolates were performed at BSL-3 in Select Agent certified laboratory facilities and employing compliant standard operating procedures. Select agent excluded *Bp* laboratory strains with defined mutations causing CAZ^R were also tested.
Results: MIC testing reveals that AVI restores CAZ activity in several virulent CAZ resistant clinical isolates as well in laboratory generated CAZ^R strains (Table). Strain 1026b, the prototype Thai clinical isolate, is CAZ susceptible, and is the parent to the attenuated derivative, Bp82. Strain 699d is CAZ^R due to deletion of penicillin binding protein 3 (Δ*pbp3*); AVI does not enhance CAZ activity in this strain. The four other strains are CAZ^R due to mutations in the bla_{PenA} gene or its promoter (P↑↑). The CAZ^R mechanism of strain 5041a is unknown, however AVI decreases the CAZ MIC suggesting it is β-lactamase-mediated. Using a panel of select agent excluded Bp82 mutants expressing various CAZ^R PenA variants were found to be susceptible to the CAZ-AVI combination.
Conclusions: With the exception of the clinical isolate of *Bp* Δ*pbp3*, the results suggest that CAZ-AVI is an effective combination against CAZ^R strains of *Bp*. The CAZ-AVI combination offers an opportunity for the treatment of this difficult-to-treat pathogen with biothreat potential.

AmpR Effectors in *Pseudomonas aeruginosa* Regulating β-lactam Resistance

Author Block:

S. Dhar[1], M. Lee[2], D. Hesek[2], H. Kumari[1], S. Mobashery[2], K. Mathee[1]; [1]Florida Intl. Univ., Miami, FL, [2]Univ. of Notre Dame, Notre Dame, IN

Abstract Body:

Pseudomonas aeruginosa is an opportunistic pathogen infamous for causing a wide range of infections in immunocompromised, burn wound and cystic fibrosis patients among others. Extensive resistance to antibiotics confounds its treatment. Resistance to β-lactams that is often used to treat *Pseudomonas* infection is conferred by expression of hydrolytic β-lactamases. The predominant β-lactamase AmpC in *P. aeruginosa* is regulated by AmpR, a LysR-type transcriptional regulator. Activation of AmpR in Enterobacteriaceae is shown to be mediated by signaling molecules generated during cell wall recycling known as muropeptides. The identity of this muropeptide in *P. aeruginosa* is yet to be elucidated. The goal of this study was to identify *P. aeruginosa* AmpR ligand. The objectives were to identify and quantify *P. aeruginosa* muropeptides in the absence and presence of induction using cefoxitin, a strong β-lactamase inducer through liquid chromatography/mass spectrometry (LC/MS). To address this, *ampG* and *ampP* deletion mutants in PAO1 encoding permeases involved in transport of muropeptides into the cytoplasm and periplasm, respectively were constructed. Whole cell LC/MS analyses of PAO1 and the mutant strains led to the identification of 20 muropeptides as compared to the parent PAO1. The total muropeptides decreased in the cell wall recycling mutants. In addition there was also a decrease in the levels of total muropeptides upon induction. The most abundant muropeptide in all the samples were *N*-acetyl glucosamine anhydro-*N*-acetylmuramic acid tetrapeptide. The muropeptide that was detected only upon induction *N*-acetylglucosamine anhydro *N*-acetylmuramic acid (NAG-anhNAM) pentapeptide (L-Ala-γ-D-Glu-m-DAP-D-Ala-D-Ala) was. This finding suggests that NAG-anhNAM pentapeptide may be the ligand for AmpR leading to *ampC* expression. Identifying the AmpR ligand would enable us to synthesize its analogs and disrupt AmpR function impairing *P. aeruginosa* virulence.

Innovative Use of the Tetracyclines to Activate Bacterial Suicide Genes and Combat Antibiotic Resistance Mechanisms

Author Block:

c. chukwudi[1], l. good[2]; [1]Univ. of nigeria, nsukka, nsukka, Nigeria, [2]royal veterinary Coll., Univ. of london, hatfield, United Kingdom

Abstract Body:

The tetracyclines are a broad spectrum group of antibiotics whose antibacterial efficacy has been greatly reduced due to the development of resistance. They have been used for decades as antimicrobials (antibacterial, antiviral and antiprotozooan) and anti-inflammatory. The established 16S rRNA binding mechanism for the antibacterial action does not explain their wide range of activity. We explored possible target sites that could explain their mechanism of action and wide range of activity. This would help improve effective use, provide opportunities to discover new therapeutic usefulness of the drugs and offer insights on how to combat drug resistance. Our recent studies using biophysical and molecular techniques indicate that the tetracyclines bind dsRNA, inhibit processing and function of cellular RNAs under certain conditions. The *hok*/*sok* locus is a well established toxin/antitoxin plasmid stability element, which has been associated with multi-drug (ampicillin, chloramphenicol, kanamycin, streptomycin and sulphonamides) resistance plasmids. It is one of the most frequently reported plasmid addiction systems in ESBL-encoding plasmids, and ensures plasmid maintenance by post-segregational killing of plasmid-free daughter cells via RN:RNA interactions. The *hok*/*sok* locus also occurs in the chromosomes of enterobacteria, and is more abundant in pathogenic strains. We investigated the effect of the *hok*/*sok* locus on bacterial pathogenicity and stress response using *E. coli* growing in various stressful conditions. Our studies showed that the *hok*/*sok* locus enhances host cell survival in conditions such as high temperature, antibiotic stress and low cell concentrations. Interestingly, we also observed that although the *hok*/*sok* locus increases bacterial tolerance to β-lactam antibiotics, it increases the susceptibility of these bacteria to doxycycline by inducing the self-killing plasmid maintenance system due to the interference of the tetracyclines with the RNA:RNA processing pathway. Since the *hok*/*sok* locus ensures the transmission of plasmids containing multi-drug resistance genes, these results may represent a drug target that will open up opportunities for the innovative use of tetracyclines in the global war to contain the rise of antimicrobial resistance.

A Quinolone-type Compound is Showing Surprising Activity as an Efflux Pump Inhibitor on the RND-type Efflux Pump, AdeABC in *Acinetobacter baumannii*

Author Block:

Y. Zhu[1], J. L. Auer[1], S. Jamshidi[1], J. M. Sutton[2], K. M. Rahman[1]; [1]King's Coll. London, london, United Kingdom, [2]Publ. Hlth.England, Salisbury, United Kingdom

Abstract Body:

Introduction: Multidrug-resistant (MDR) clinical pathogens overexpress a series of efflux pumps, which effectively exclude or reduce the intracellular concentration of many antibiotics, making the pathogens significantly more resistant. These efflux pumps are the topic of considerable interest as targets for novel adjunct therapies. We have designed and synthesized a series of quinolone based compounds that have shown notable activity as efflux pump inhibitors (EPI) compared to PAβN which is widely regarded as a potent EPI. **Methods**: The quinolone type EPI compound IZ-75-52 and its analogues were synthesized using solution phase chemistry. All synthesized compounds were fully characterized using NMR and Mass spectroscopic techniques. The activity of the synthesized compounds were tested for their ability to inhibit the AdeABC efflux pump of *A. baumannii* using different types of fluorescence accumulation tests including Hoechst assays. A novel assay, based on the enzymatic-activation of a fluorescent probe by a bacterial enzyme, was also used to evaluate the efflux inhibition. GOLD molecular docking and MD simulations with AMBER were carried to understand the molecular level interaction between IZ-75-52 and the AdeB efflux pump. **Results**: IZ-75-52 showed strong inhibitory activity against AdeABC efflux pump of *A.baumannii* in fluorescent accumulation tests. In Hoechst assay, 25µg/mL of IZ-75-52 showed similar levels of inhibition activity to PaβN and this was exceeded at 50µg/mL. Evaluation of IZ-75-52 using the enzyme-activated fluorescent probe-based efflux assay demonstrated similar levels of efflux inhibition to that seen with PAβN. Computational analysis showed IZ-75-52 binds to the multisite binding pocket of AdeB and the Phe-loop located between the proximal and distal binding pocket plays a key role in the IZ-75-52 mediated inhibition. **Conclusion:** The level of EPI activity observed by IZ-75-52 is surprising due to its relatively low molecular weight (MW 349.3). The scaffold is amenable to medicinal chemistry modifications and the novel assay format together with information obtained from advanced *in silico* techniques will be used to design new EPIs based on IZ-75-52 with a view to develop a pre-clinical candidate.

Mesenchymal Stem Cells Improves Survival in a Mouse Model of Severe Pneumococcal Pneumonia

Author Block:

C. A. Hinojosa[1], L. Reyes[1], D. A. Hunt[2], A. Rodriguez[3], R. Johnson[2], N. Soni[1], A. Anzueto[1], J. Peters[1], M. Moyer[2], C. J. Orihuela[1], X-D. Chen[1], M. Restrepo[4]; [1]Univ. of Texas Hlth.Sci. Ctr. San Antonio (UTHSCSA), San Antonio, TX, [2]Incell Corp. LLC, San Antonio, TX, [3]Hosp. Joan XXIII, Tarragona, Spain, [4]South Texas Veterans Hlth.Care System (STVHCS), San Antonio, TX

Abstract Body:

Background/Purpose: Community acquired pneumonia (CAP) is the leading cause of morbidity, and mortality worldwide. *Streptococcus pneumoniae* is the principal etiologic agent causing CAP. There is a need to identify novel therapies that can further improve the morbidity and mortality in patients with CAP. Novel therapies with Mesenchymal Stem Cells (MSCs) may potentially advance the science by modulating the often excessive host-immune response and enhancing tissue repair. This study assessed the survival effect of two different MSCs, one derived from the adipose tissue (Ad-MSCs) compared to the one derived from the bone marrow (BM-MSCs) in a murine pneumococcal pneumonia model.
Methods: Mice were infected intranasally with 10^7 CFU of *S. pneumoniae.* After 24 hours, mice were randomly assigned to three groups: 1) pre-labeled Ad-MSCs (10^6, n=7); 2) pre-labeled BM-MSCs (10^6, n=6); and 3) control (n=5-8). The primary outcome was survival assessed from the time of inoculation. Secondary outcomes include bacterial burden and time to develop bacteremia, concentration of the cells in the lung parenchyma.
Results: Bacterial burden and pathological analysis uncovered no significant differences between groups. Pre-labeled MSCs were visualized in the lungs. At 60 hours post-inoculation the Ad-MSCs had a survival rate of 43% compared to 0% in the control group (p=0.08). At 120 hours the BM-MS had a survival rate of 80% vs. 0% in the control group (p=0.03).
Conclusions: We observed a beneficial overall survival effect of intratracheal administration of MSCs whether derived from the adipose or the bone marrow tissue in a murine model of pneumococcal pneumonia. Further translational studies should assess the mechanisms, safety and time of administration of MSCs in invasive pneumococcal disease.

Lfnp24 As A Therapeutic Vaccine Candidate: A Phase 1 Randomized, Double Blind, Placebo Controlled Safety And Immunogenicity Study In Hiv-1 Infected Chinese Subjects

Author Block:

Y. Lu[1], T. Zhang[2], W. Xia[2], B. Su[2], R. Wang[2], Y. Ji[2], X. Lu[2], B. Lu[1], Y. Liu[1], S. Yao[1], S. Li[1], H. Peng[3], Y. Ou[3], N. Touzjian[4], N. Kushner[4], A. Strong[4], H. Wu[2]; [1]Haikou VTI Biological Inst., Haikou, China, [2]Beijing You'an Hosp., Beijing, China, [3]Co-CRO Med. Dev. Co., Ltd, Beijing, China, [4]Vaccine Technologies Inc, Wellesley, MA

Abstract Body:

Background: Detoxified anthrax lethal factor fused to HIV-1 p24 of the B/C subtype (LFn-p24B/C) as a therapeutic vaccine can complement the antiretroviral therapy in boosting the host immune system. We report data from the randomized, double-blind, placebo controlled, phase 1 clinical trial of LFn-p24B/C in China**.**
Methods: HIV-1 infected patients with $CD4^+$ T cell counts >350 and viral loads <50 under stable ART were recruited. 32 eligible subjects were randomized into two groups (vaccine:placebo, 3:1): 16 received 300ug of vaccine or placebo and 16 received 450ug of vaccine or placebo im at 0, 4 and 12 weeks. Safety and immunogenicity (ELISA, $CD4^+$ counts, IFN-γ ELISPOT and ICS, as measured by IFN-γ expression) were evaluated up to 48 weeks post first immunization.
Results: Most adverse events were mild or moderate, and no SAEs were reported. All subjects maintained undetectable plasma viral levels throughout the trial. Higher anti-p24 titers were observed in 21/24 vaccinees compared to placebos. $CD4^+$T cell counts increased significantly in vaccinees with durable responses up to 36 weeks following first immunization (p=0.003,p=0.009 and p=0.034 at 2,14 and 36 weeks respectively). No significant change was observed in placebo (p=0.98,p=0.54 and p=0.84 respectively at the same time points). Dose-related gag specific T cell response by IFN-γ ELISPOT assay was observed after three immunizations of LFn-p24B/C (81.8%,450ug and 50%, 300 ug, 25% placebo) Parallel ICS assay demonstrated higher gag-specific $CD8^+$ and $CD4^+$ responses in vaccinees compared to placebo (29.2% for both, p=0.009 and p=0.048 respectively). Vaccinees had decreased expression of HLA-DR on $CD4^+$T cells (-10% p=0.0005) and CD38 on $CD8^+$T cells (-11.5%, p=0.0016) and increase CD38 expression on $CD4^+$T cells (+7.37%, p=0.004). No such observations were found in placebos.
Conclusions: LFn-p24 immunization in virologically suppressed, HIV-1 infected subjects led to increased CD4+T cells, induction of HIV-1 specific response and modulation of immune activation.

ETX2514, a Novel, Rationally Designed Inhibitor of Class A, C and D β-lactamases, for the Treatment of Gram-negative Infections

Author Block:

A. B. Shapiro[1], S. Guler[1], N. Carter[1], M. McLeod[1], B. De Jonge[2], R. McLaughlin[2], H. Huynh[2], N. Gao[2], T. Durand-Reville[1], A. Miller[1], J. Mueller[1], R. Tommasi[1]; [1]Entasis Therapeutics, Waltham, MA, [2]AstraZeneca, Waltham, MA

Abstract Body:

Introduction: A rationally designed series of novel diazabicyclooctenone β-lactamase inhibitors led to the identification of ETX2514 which has Class A, C and broad Class D activity. We tested ETX2514 against eight representative β-lactamases and high-molecular mass PBPs. We evaluated its ability to restore activity to β-lactam (BL) partners against multidrug resistant (MDR) Gram-negative pathogens, with a focus on *A. baumannii* since β-lactamase expression, especially Class D, is a prevalent resistance mechanism in this organism. **Methods:** Rate constants for reaction of ETX2514 with β-lactamases were measured with nitrocefin as substrate. Rate constants for ETX2514 reaction with purified PBPs were measured with a fluorescence polarization BOCILLIN FL competition assay. The *in vitro* antibacterial activity of ETX2514 alone, or of eight BL partners in combination with 4 mg/L of ETX2514 against recent MDR clinical isolates of *Escherichia coli* (n = 202), *Klebsiella pneumoniae* (n = 198), *Pseudomonas aeruginosa* (n = 209) and *A. baumannii* (n = 195) was measured by broth MIC following CLSI guidelines. BL content for select strains was determined by whole genome sequencing. **Results:** ETX2514 reacted with β-lactamases with k_{inact}/K_i of ~10^6 - 10^7 $M^{-1}s^{-1}$ for class A (CTX-M-15 and TEM-1), class C (AmpC and P99) and OXA-48 from class D; and ~10^4 $M^{-1}s^{-1}$ for OXA-10 and OXA-24/40 from class D. ETX2514 reacted with *P. aeruginosa* PBP 1a, 2, and 3 with k_{inact}/K_i of 12, 24, and 57 $M^{-1}s^{-1}$, respectively; with *A. baumannii* PBP 1a, 2, and 3 with k_{inact}/K_i of 180, 1800, and 3 $M^{-1}s^{-1}$, respectively; and with *E. coli* PBP1a, 2, and 3 with k_{inact}/K_i of 120, 17000, and 2, respectively. The MIC_{90} of any BL combined with ETX2514 was $\leq$ 0.12 mg/L against both *K. pneumoniae* and *E. coli.* Imipenem was the most effective BL partner for ETX2514 against *P. aeruginosa* (MIC_{90} of 2 mg/L) while sulbactam was the most potent partner against *A. baumannii* (MIC_{90} = 4 mg/L). **Conclusions:** ETX2514 potently inhibits Class A, C, and a broad spectrum of Class D β-lactamases. Intrinsic antibacterial activity is likely due to PBP2 inhibition. *In vitro* susceptibility testing suggests sulbactam/ETX2514 could be an effective treatment for infections caused by MDR *A. baumannii*.

Weakening the Enemy: Novel Whole Cell Reporter Technology for Natural Product Screening

Author Block:

P. Premnath[1], M. Reck[1], B. Kunze[1], R. Jansen[1], S. Bhuyan[1], K. Wittstein[1], J. Niggemann[1], J. Herrmann[2], R. Müller[2], M. Stadler[1], I. Wagner-Döbler[1]; [1]Helmholtz Ctr. for Infection Res., Braunschweig, Germany, [2]Helmholtz Inst. for Pharmaceutical research, Saarland, Germany

Abstract Body:

The escalating problem of drug resistance calls for the development of novel screens targeting less studied pathogenic mechanisms in a microbe. We have designed a novel whole cell fluorescent screening system, incorporating three virulence mechanisms of *Streptococcus mutans* to find natural products from Myxobacteria and fungi specifically weakening the bug, rather than just killing it. Each screen employs a reporter strain where, a *gfp+* fluorophore preceded by the promoter of the target gene, is integrated into the native locus of the bacterial genome via single homologous recombination. Three primary screens individually consisting of promoters of (1) lytic transglycosylase, (2) a self-acting competence mediating murein hydrolase and (3) mutacin VI, a bacteriocin, have been constructed and validated in *S. mutans.* Screening of 310 myxobacterial and fungal compounds from different classes were performed. Of those, promising were selected which include seven compounds acting on the mutacin VI and tuscolid on murein hydrolase, all of them showing more than 50% effect and eighteen compounds stimulating the transglycosylase beyond 75%. Our study revealed that tuscolid and myxopyronin A which showed an activity on the murein hydrolase, simultaneously triggered the transglycosylase promoter indicating a dual target activity or that they acted on a common conserved mechanism. Sorangicin A, an RNA polymerase inhibitor from the myxobacterium *Sorangium cellulosum* and the glykenins 17 and 19, from the fungus *Dacrymyces stillatus*, stimulated strong induction (approx. 2-fold) of the transglycosylase promoter. A diterpene compound B5-1 erinacine, from the edible medicinal mushroom *Hericium erinaceus*, strongly suppressed mutacin VI induction (50% reduction). The system, thus, provides a suitable platform to discover drugs capable of modulating the bacteria's own mechanism to reduce it to a less pathogenic phenotype.

Rifampicin Resistant Leprosy in Southern India; analysis of efflux pump gene expressions and molecular modelling of rifampicin-RpoB interactions in <i>Mycobacterium leprae<i>

Author Block:

S. Vedithi, M. Das, L. Rajan; Schieffelin Inst. of Hlth.Res. and Leprosy Ctr., Vellore, India

Abstract Body:

Background: Mis-sense mutations within *rpoB* gene of *Mycobacterium leprae* were identified to be a possible reason for rifampicin resistance in leprosy. We investigated mutations within *rpoB* gene of *M. leprae* in relapsed leprosy cases from 4 tertiary care leprosy centres in south India. Further the differences in mRNA expression levels of 8 efflux pump genes in rifampicin resistant and sensitive strains were studied. In-silico modelling of rifampicin interaction with native and mutant RpoB protein models was also performed.
Methods: DNA and RNA were extracted from skin biopsies of 35 relapse/MDT non-respondent leprosy cases and PCR was performed to amplify 276bp rifampicin resistance determining region of *rpoB* gene of *M. leprae*. DNA Sequencing was performed to detect mutations. Homology models of mutant and native RpoB proteins were developed using iTasser Suite and docking experiments using Molecular Docking Server (AutoDock 4). mRNA expression levels of efflux pump genes (ML0556, ML1349, ML1388, ML1562, EMRB Efflux Pump and ML2350-2352) were analyzed in rifampicin resistant and sensitive strains.
Results: Mutations were detected in 5 out of the 35 relapse leprosy cases which included codon positions "Asp441Tyr" in two cases, "Leu436Ser", "Leu436Pro" and "His476Arg" in one case each. Molecular docking analysis revealed that native RpoB interacts with Rifampicin with two hydrogen bonds with estimated change in free energy of binding of -7.71 kcal/mol. This energy decreased in mutants with Asp441Tyr = -5.68 kcal/mol, Leu436Ser = -6.70 kcal/mol, Leu436Pro = -4.78 kcal/mol and His476Arg = -3.34 kcal/mol. Asp441Tyr mutation indicated complete loss in hydrogen bonding with rifampicin and rest of the mutations indicated only a single hydrogen bond. The estimated inhibition constant “Ki” has also increased in all mutants when compared to native RpoB. mRNA expression levels of ML1349-drrB family and ML1388-drug efflux membrane protein coding genes increased by 14.55 and 7.93 fold respectively in rifampicin resistant strains (normalized with 16SrRNA).
Conclusion: Structural variations induced by point mutations in RpoB protein can be a possible reason for loss in interaction with rifampicin and efflux pump gene expression is associated with rifampicin resistance in leprosy.

Translational Mouse Model of *Clostridium difficile* Infection

Author Block:

T. J. De Wolfe, M. N. Duster, J. L. Steele, B. J. Darien, N. Safdar; Univ. of Wisconsin - Madison, Madison, WI

Abstract Body:

Background: Current animal models to study *Clostridium difficile* infections (CDI) are beneficial to understand pathogenesis, however they contain several limitations when considering the effect of therapeutic intervention. The modifications made in our mouse model allow better approximation of clinical CDI for patients in healthcare settings and will allow researchers to study new treatment options, efficacy of supportive care, mechanisms of action, and CDI recurrence. **Methods:** Male 5-7 week old C57BL/6 wildtype mice obtained from Jackson Laboratories were housed with autoclaved food, bedding, and water. After 1 week of acclimation in the vivarium, mice were randomized and administered an antibiotic pre-treatment (0.25mg/ml cefoperazone) for 5 days in their drinking water. At the onset of antibiotic pre-treatment, mice were administered single strains (10^8 CFU/day) of *Lactobacillus casei* probiotics until the study endpoint. Two days after the last antibiotic pre-treatment, mice were gavaged with 10^2 *C. difficile* VPI 10463 spores and monitored for 48 hours. **Results:** Only 60% of mice survived the *C. difficile* challenge without probiotic administration while 80% of mice survived if administered *L. casei* M36 or *L. casei* BL23. Mice that were administered *L. casei* M36 and *L. casei* BL23 throughout the experimental timeline had significantly reduced weight loss and health scores compared to the *C. difficile* control. **Conclusions:** Modification of the antibiotic pre-treatment from a reputable mouse model has allowed us to establish reproducible CDI with moderate lethality. This lethality better approximates clinical CDI in humans. As a proof of concept, we have demonstrated probiotic efficacy for CDI prophylaxis. Moving forward this model will allow researchers to study alternative treatment options for CDI including mechanisms.

Dissecting the Microbiome in a Spatial Context

Author Block:

K. Duncan, S. Vaishnava; Brown Univ., Providence, RI

Abstract Body:

A dysregulated gut microbiome has been shown to contribute to gastrointestinal pathologies such as ulcerative colitis and Crohn's disease, but the mechanism is poorly understood. Traditional methods for studying the gut microbiome hint as to which organisms are present, but lack spatial context of the local environment. The microbiome contains a consortium of bacteria coming into close contact with the host (Fig A). Only by understanding the gut flora in its ecological framework can we begin to look into the host-microbe and microbe-microbe interactions that exist in this ecosystem. There is increasing evidence supporting the need for looking at the gut microbiome in a spatial context, but current methods have limited access to answering such questions.

We have developed a robust method that allows us to isolate distinct transverse regions to elucidate the biogeography of the microbiome. Specific fixation and sectioning techniques are employed that maintain the structural integrity of the gut flora, and by coupling laser-capture microdissection and 16s rRNA sequencing, the community composition of each layer is revealed.

By comparing the bacterial composition of 50um deep "layers" from the epithelium into the luminal space we are able to show that the specified regions do in fact vary in community composition (Fig B). A PCoA plot comparing consecutive 50um layers for small intestine and colon (Fig C) shows the layers from the same tissue cluster, but also that there is variation in each of the layers, showing that they are distinct.

Our approach of spatial microdissection of microbes *in situ* will be applied towards exploring the immune mechanisms that maintain biogeography of intestinal microbial communities. We anticipate that this will provide insight into the metabolic networks that govern the assembly of complex bacterial communities during health and disease.

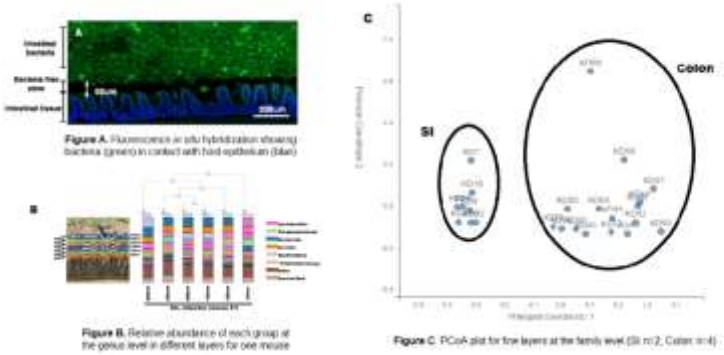

Figure A. Fluorescence in situ hybridization showing bacteria (green) in contact with host epithelium (blue)

Figure B. Relative abundance of each group at the genus level in different layers for one mouse

Investigation of Signaling Mechanisms that Control *Vibrio cholerae* Quorum Sensing Receptor VpsS

Author Block:

S. A. Jung, W-L. Ng; Tufts Univ., Boston, MA

Abstract Body:

Bacteria use quorum sensing (QS) for cell-cell communication to carry out group behaviors. This intercellular signaling process relies on cell density-dependent production and detection of chemical signals called autoinducers (AIs). *Vibrio cholerae*, the causative agent of cholera, uses four histidine kinases—CqsS, LuxQ, VpsS, and CqsR—to control virulence factor production through QS. At low cell density (LCD), these four signaling receptors function in parallel to activate the key regulator LuxO, while at high cell density (HCD), upon signal detection, the activity of these receptors is turned off, which leads to subsequent deactivation of LuxO and repression of virulence factor production. The CqsS and LuxQ systems have been well-studied: CAI-1 regulates the kinase activity of the CqsS system, while AI-2 controls LuxQ activity. However, little is known about the signals and their biosynthetic pathways that control receptors VpsS and CqsR. We have created transposon mutant libraries in a QS triple receptor mutant expressing only VpsS. Using a dual reporter system, we have identified a set of mutants with altered QS responses. Many of these transposon mutants carry insertions in genes responsible for generating key metabolites in the central metabolic pathway. Thus, our preliminary data suggest that certain intracellular signals could affect VpsS activity and could be key for modulating the QS response in *V. cholerae*.

Characterization of a Murine Model of ZIKV Infection

Author Block:

A. Muruato[1], S. Rossi[1], S. Weaver[1], R. Tesh[2]; [1]The Univ. of Texas Med. Branch, Galveston, TX, [2]UTMB, Galveston, TX

Abstract Body:

Background: Zika virus (ZIKV) is a rapidly emerging mosquito-borne flavivirus that is currently causing an explosive outbreak across Central and South America. ZIKV infection results in a disease known as Zika fever, which is typically characterized by a mild febrile illness, rash, and conjunctivitis in adults and may be linked a variety of severe neurological and congenital illnesses. Currently, no vaccine or antiviral exists to combat Zika disease. Here we describe a murine model to test the safety and efficacy of therapeutics.
Methods: To establish a murine model of ZIKV infection, we used groups of immunocompromised mice lacking either the interferon alpha/beta receptor (A129) or IFN alpha/beta/gamma receptors (AG129). Mice ranging in age from 3-11 weeks were infected with an intraperitoneal (i.p.) dose of 10^5 PFU of ZIKV (low passage contemporary Cambodian isolate) and monitored daily for signs of illness (ruffling, decreased mobility, etc) and weight loss. Blood was collected daily to evaluate viremia. Furthermore, mice were necropsied as various times post infection to quantify the viral load in key organs.
Results: Immunocompromised mice are susceptible to ZIKV infection. All A129 mice exhibited signs and symptoms of disease such as ruffled fur and hunched posture. ZIKV was detected in the brain of 3-week-old A129 mice by 3 days post infection (dpi) and caused observable signs of neurologic disease by 6 dpi. Virus was detected in all organs tested with the highest viral titers observed in the brain, spleen, and testes. All 3iweek-old mice became moribund and succumbed to illness by 7dpi. Meanwhile, 5- and 11-week-old A129 mice exhibited signs of illness, viremia, and weight loss, but did not naturally succumb to infection. This age-dependent mortality is not observed in AG129 mice. Three-week-old AG129 mice have a similar disease progression and reach similar titers in the blood and organs as same-aged A129 mice. However, the neurologic disease observed is more pronounced. A similar outcome was observed in 9-week-old AG129 mice, suggesting that mortality is not age-dependent in AG129 mice.
Conclusions: This is one of the first characterizations of a murine model for ZIKV infection and therefore further characterization of this model could provide valuable insight into disease pathogenesis and serve as an effective platform to test the efficacy of antivirals and vaccines in vivo for ZIKV.

The Structural Basis of Asymmetry in DNA Binding and Cleavage as Exhibited by the I-SmaMI LAGLIDADG Meganuclease

Author Block:

B. W. Shen[1], A. Lambert[1], B. C. Walker[2], B. L. Stoddard[1], **B. K. Kaiser**[2]; [1]Fred Hutchinson Cancer Res. Ctr., Seattle, WA, [2]Seattle U, Seattle, WA

Abstract Body:

• LAGLIDADG homing endonucleases ('meganucleases') are highly specific DNA cleaving enzymes that are considered selfish elements because they facilitate the spread of the gene that encodes them. Like other enzymes that act on DNA targets, meganucleases often display binding affinities and cleavage activities that are dominated by one protein domain.
• To decipher the underlying mechanism of asymmetric DNA recognition and catalysis, we identified and characterized a new meganuclease (I-SmaMI) that belongs to a superfamily of homologous enzymes that recognize divergent DNA sequences. I-SmaMI is a “monomeric” meganuclease that contains two LAGLIDADG domains on a single polypeptide.
• We solved a series of crystal structures of the enzyme-DNA complex representing a progression of sequential reaction states, and compared the structural rearrangements within each LAGLIDADG domain against their relative contribution to binding affinity. These results demonstrate that the N-terminal LAGLIDADG domain contributes the majority of DNA binding affinity, and that full binding involves significant conformational changes that position the C-terminal LAGLIDADG domain. We also tested how equivalent point mutations in each of the two actives sites affected DNA cleavage. These mutations generated partial nickase enzymes, with a point mutation in the N-terminal domain having a more significant effect on cleavage activity.
• Together, these results demonstrate the structural basis for 'dominance' by one protein domain over the other in a pseudodimeric DNA cleaving enzyme.

Phenotypic Analysis Of New Genes Appears To Be Responsible For Acid And Cold Resistance In *Bacillus Cereus* ATTC 14597

Author Block:

K. SENOUCI-REZKALLAH[1], M. P. JOBIN[2], P. SCHMITT[3]; [1]Mascara Univ., Mascara, Algeria, [2]UMR A408, INRA avignon, Avignon, France, [3]UMRA408, INRA Avignon, Avignon, France

Abstract Body:

Background: *Bacillus cereus* is a toxin producing bacterium responsible for food-borne toxi-infections. To monitor the ability of the food-borne opportunistic pathogen *Bacillus cereus* to survive during minimal processing of food products conditions were established which allowed the cells to adapt to heat and acid stresses.
Methods: To determine the relationship between the response to cold and acidity condition, we tried to see if certain genes involved in the adaptation to cold may occur in the acid stress response in B. cereus ATCC14579. The effect of acidity on the mutants that were identified in our laboratory as sensitive to cold: 109H2 (ydbR mutant RNA helicase ATPdépendante), 111D1 (RZC3747) 108C12 (porB mutant pyruvate synthase), 134G8 (mutS mutant / porB) and 110H1 (yqeC mutant, 6-phospho gluconate dehydrogenase) was studied. Growth in microculture at different pHe 7.0; 5.0; 4.8; 4.7; 4,6 and 4, 55 were conducted on the wild type and mutant sensitive to cold
Results: Results show that the cold 109H2 sensitive mutant is not affected by acidity and it is growing faster than the wild type, the other mutants are sensitive to acidity.
Conclusions: Our results Suggest that the mutated genes play an important role in the growth of B. cereus in acidic medium.

Outer Membrane Protein LptD/OstA (PA0595) Has a Novel Role in the Regulation of Alginate Synthesis in *Pseudomonas aeruginosa*

Author Block:

S. Pandey[1], C. Delgado[2], L. FLorez[1], H. Kumari[1], K. Mathee[1]; [1]Florida Intl. Univ., Miami, FL, [2]New York Univ., New York, NY

Abstract Body:

Pseudomonas aeruginosa, a Gram-negative bacterium, is a leading opportunistic pathogen in chronic cystic fibrosis (CF) and other lung diseases such as chronic obstructive pulmonary disease (COPD). The majority of *P. aeruginosa* isolates from the lungs of chronic CF patients are mucoid due to overproduction of an exopolysaccharide known as alginate. Alginate helps *P. aeruginosa* in immune invasion, antibiotic resistance, scavenging free oxygen radicals, and retention of water and nutrients. Sigma factor AlgT/U is the master regulator of alginate production in *P. aeruginosa*. An anti-sigma factor, MucA, sequesters AlgT/U and downregulates alginate production under normal conditions. It is well established that mutations in *mucA* lead to alginate overproduction. All the known proteins involved in alginate regulatory process reside in periplasm, innermembrane, or cytoplasm. To date, no outermembrane component involved in the regulation of alginate production has been identified. We hypothesized that novel components can be identified using nonmucoid variants of the constitutively alginate-overproducing strain PDO300 (PAO*mucA22*). Our analyses of a nonmucoid variant of PDO300, *sap27*, led to the identification of a cosmid, pMO012217, harboring 18 open reading frames (ORFs), to rescue the mucoid phenotype. Transposon mutagenesis of this cosmid revealed the insertion to be in a three-gene operon consisting of *lptD-surA-pdxA*. The *lptD* gene encodes an outer-membrane protein (OMP) involved in lipopolysaccharide transport. SurA is the cognate chaperone protein of LptD while PdxA is responsible for vitamin B_6 synthesis. We showed that expression of *lptD* alone restores the mucoid phenotype. Thus, we propose a novel role of LptD in alginate regulation in *P. aeruginosa* and this is the first report of an OMP involved in the process.

A Classroom Research Module to Assess Antibiotic-Resistant Microbes in the Environment

Author Block:

C. A. Bascom-Slack; Tufts Univ. Sch. of Med., Boston, MA

Abstract Body:

Providing discovery-based research opportunities to students at an early stage and establishing partnerships between different institution types are recommended strategies for retaining students in the sciences. Implementing authentic research in the classroom, however, can be challenging. The PARE (**P**revalence of **A**ntibiotic-**R**esistance in the **E**nvironment) program aims to improve the quality of undergraduate education in a transformative way by initiating a large-scale classroom project that is low cost and short in duration. The hypotheses of this study were that participating students would 1) report gains in items related to the process of science 2) increase in number each year 3) engage in partnerships with high school students and 4) contribute reliable environmental resistance data.

Currently, there are no systematic surveillance methods for reporting levels of antibiotic-resistant microbes at environmental sites, yet environmental exposure to antibiotics is high in certain areas. In the PARE program, students use systematic methods to assess and report prevalence of tetracycline-resistant (tet^R) microbes in soil samples. In the Undergraduate Research Student Self-Assessment (URSSA) survey, a majority of PARE students reported gains in confidence and attitudes relating to the process of science and that the experience prepared them for more advanced work. The project was disseminated to 18 instructors in the first year and to over 50 instructors across the nation this year; the number of students participating doubled to 1,000. 87% percent of students report feeling part of a scientific community, indicating that partnerships were created. Over 700 data points reporting the prevalence of tet^R microbes at various soil collection sites around the country have been reported by students. Ongoing formative assessment of the program using a student skills survey and monitoring of raw data entries has helped to identify factors contributing to data entry errors.

The PARE project has been transformative in providing an authentic research experience to hundreds of students who report gains in self-efficacy and attitudes about science. It has introduced instructors to classroom-accessible authentic research. Assessment measures are informing ongoing changes to protocols and instructional materials to improve reliability of student-entered data.

Tick-borne *Rickettsia* Pathogens in Southern Kazakhstan

Author Block:

T. Nurmakhanov[1], Y. Sansyzbayev[2], O. Yeskhodzhayev[1], A. Vilkova[1], A. Berdibekov[3], A. Matzhanova[4], R. Sailaubek[5], H. K. St. John[6], C. M. Farris[6], A. L. Richards[6]; [1]Kazakh Scientific Ctr. for Quarantine and Zoonotic Diseases, Almaty, Kazakhstan, Almaty, Kazakhstan, [2]Kazakh Scientific Ctr. for Quarantine and Zoonotic Diseases, Almaty, Kazakhstan, Amaty, Kazakhstan, [3]Taldykorgan Anti-plague Station, Taldykorgan, Kazakhstan, [4]Kyzylorda Anti-plague Station, Kyzylorda, Kazakhstan, [5]Shymkent Anti-plague Station, Shymkent, Kazakhstan, [6]Naval Med. Res. Ctr., Silver Spring, MD

Abstract Body:

Background: In Kazakhstan the distribution and prevalence of rickettsial pathogens is not well known. Thus, the focus of this study was to detect and identify rickettsiae in ticks from 3 southern Kazakhstan oblasts. **Methods:** Ticks collected from vegetation and farm animals (n=2,358) were identified by morphological methods and placed into pools of 10-20 individuals of the same species, homogenized and the DNA extracted. The nucleic acid preparations were assessed utilizing *Rickettsia* genus- and species-specific qPCR assays. **Results:** Ticks included: *Hyalomma asiaticum* (n=768/44 pools), *Hyalomma scupense* (n=660/44 pools), *Hyalomma anatolicum* (n=15/1 pool), *Haemaphysalis sulcata* (n=165/11 pools), *Haemaphysalis punctata* (n=30/2 pools), *Haemaphysalis* spp. (n=60/4 pools), *Dermacentor niveus* (n=30/2 pools), *Dermacentor* spp. (n=615/41 pools), and *Argas* spp. (n=15/1 pool). Of the 150 pooled tick samples rickettsiae were detected (n=27; 18%) and the agents identified as *R. slovaca* (n=6; 4%), *R. raoultii* (n=5; 3/3%), *R. aeschlimannii* (n=2; 1.3%), and *Rickettsia* spp. (n=14; 9.3%). **Conclusions:** The human pathogens *R. slovaca, R. raoultii,* and *R. aeschlimannii* were detected in tick pools from southern Kazakhstan.

Selective Signaling Response Inhibition Of A *Pseudomonas aeruginosa* Mucoid Variant Caused By Alginate Overproduction

Author Block:

J. Yang[1], M. Toyofuku[1], K. Tateda[2], N. Nomura[1]; [1]Univ. of Tsukuba, Tsukuba, Japan, [2]Toho Univ., Tokyo, Japan

Abstract Body:

Most microbes live in the environment in communities, called biofilms, rather than as solitary planktonic cells. Bacteria communicate with each other within their communities by releasing signaling molecules and by receiving them with specific signaling receptors. Bacteria use cell-cell communication to control the group behavior such as biofilm formation, virulence factors and respiration in their communities by regulating gene expression. In cell-cell communication, it is important that the signal reach the target cell and is received by its cognate receptor. Simultaneously, bacteria in biofilms produce an extracellular matrix (ECM) that consists of extracellular proteins and polysaccharides. The effect of the ECM on the signaling response of cell-cell communication is still not fully understood. The ubiquitous bacterium *Pseudomonas aeruginosa* produces various signaling molecules to communicate with one another. *P. aeruginosa* produce two acy-homoserine lactones (AHL), 3-oxo-C12-HSL and C4-HSL, and a quinolone signal, called *Pseudomonas* quinolone signal (PQS). In this study, we use a mucoid variant of *P. aeruginosa*, which overproduces the extracellular polysaccharide, alginate, to investigate the effect of ECM production on signaling response. We use a signaling molecule synthesis gene promoter fused to a plasmid to detect gene expression that is regulated by signaling molecules themselves. We find that the mucoid mutation causes a defect of the response to quinolone signal while the response to AHLs is partially inhibited. Next, we examine the effect of alginate production on the signaling response by deleting the alginate production gene of mucoid variant. Surprisingly, the deletion restores the PQS response but has no effect on the response to AHLs. These data indicate that alginate production interferes with only the quinolone signal response but has no effect upon AHL. We also confirm this phenomenon by measuring pyocyanin production, which is regulated by PQS. We show that the mucoid variant has low pyocyanin production while deletion of alginate restores production. Furthermore, the mucoid variant does not respond to the PQS from WT when cultured together. Our study implies that ECM production alters the signaling responses, which may result in varied behaviors within a group of bacteria.

Application of Biochemical Antifouling Coating to Reduce Biocorrosion of Minnesota's Maritime Transportation Infrastructure

Author Block:

S. Huang; Univ. of Minnesota, Duluth, Duluth, MN

Abstract Body:

Background: Biocorrosion of steel structures in the Duluth-Superior Harbor (DSH) is a severe problem for Minnesota's maritime transportation industry. It is clear from previous research that corroding steel surfaces and tubercles in the DSH are covered by complex microbial biofilms that contain bacteria of the types responsible for corrosion of steel in other environments. Thus, it may be possible to reduce the rate of the corrosion by impeding microbial attachment and growth or modifying microbial communities that develop on the steel surfaces. **Methods:** We have conducted lab experiments testing anti-biofouling coatings by exposing steel coupons in harbor water environment. Steel coupons were surface coated with crosslinked silica coatings containing different non-toxic antifouling biochemical including surfactin, capsaicin, magnesium peroxide, gramicidin. After 2 months of exposure, coupons were retrieved and analyzed. Biocorrosion was evaluated by quantities and coverage of corrosion tubercle, and also by SEM imaging of the coupon surface. Microbial communities within tubercles that develop on the corroding coupons were sampled and DNA extracted. The extracted DNA was used to describe changes in the overall composition of bacterial communities with 16S rDNA-amplicon V4 region miseq 2x300 Illumina sequencing. **Results:** Corrosion tubercle analysis show that Surfactin and MgO_2 treated coupons have significant reduction in number (31%, 36%) and percent coverage (37%, 20%) of corrosion tubercles on steel coupons. NMDS Beta diversity analysis of 15M+ sequences data suggests the treatments have significantly changed the composition of bacteria communities. Burkholderiales (13%) and Rhizobiales (8%) are the dominated orders of bacteria found in all of the coupon samples. **Conclusions:** Result suggests the enzyme and biochemical treatment can change the composition of microbial communities and reduce the formation of corrosion tubercles on steel surface. Approaches to applying these antifouling enzymes and biochemical to steel structures will be further evaluated to provide reliable, cost-effective methods to treat steel structures in the DSH.

Degradation of Polyester Polyurethane by An Indigenously Developed Bacterial Consortium Isolated from Soil

Author Block:

A. A. Shah, M. Gulzar, Z. Shah, F. Hasan; Quaid-i-Azam Univ., Islamabad, Pakistan

Abstract Body:

Background: In the current study, a consortium of two polyester polyurethane degrading bacterial strains *Bacillus subtilis* MZA-75 and *Pseudomonas aeruginosa* MZA-85 was developed and its degradation rate was compared with that of individual strains.
Methods: The degradation was analyzed through measurement of weight loss and CO_2 evolved (Sturm test), as a result of breakdown of PU. The surface morphology of PU film was checked through scanning electron microscopy (SEM). Extracellular esterase activity was estimated using para-Nitrophenyl acetate (*p*NPA) as chromogenic substrate. The degradation products were detected through gas chromatography-mass spectrometry (GC-MS).
Results: More than 50% of weight loss was observed in PU film within 20 days of incubation. When plastic films pieces were subjected to consortium in Sturm test as a sole carbon source; the quantity of carbon dioxide released was much higher in comparison to control as well as to the individual strains. SEM micrographs showed surface changes in the treated PU film in the form of cracks originating from the point of bacterial attachment. A sharp increase in amount of extracellular esterase was observed in the presence of polyester PU with consortium as compared to pure culture. GC-MS results indicated that besides adipic acid and 1,4-butanediol, an additional peak for methylene bis di-isocyanate (MDI) was also detected in cell free supernatant of consortium samples that was not detected in pure cultures.
Conclusions: Hence, it is concluded that the consortium might be applied in polyurethane waste management and as a tool in the process of biochemical monomerization for purified monomers recycling.

Microbe Today: *Bordetella pseudohinzii* sp. nov. Infects C57BL/6 Mice

Author Block:

Y. V. Ivanov[1], B. Linz[1], K. B. Register[2], J. D. Newman[3], D. L. Taylor[1], K. R. Boschert[4], S. Le Guyon[5], E. F. Wilson[1], L. M. Brinkac[6], R. Sanka[6], S. C. Greco[4], P. M. Klender[4], L. Losada[6], E. T. Harvill[1]; [1]Pennsylvania State Univ., University Park, PA, [2]United States Dept. of Agriculture, Ames, IA, [3]Lycoming Coll., Williamsport, PA, [4]Washington Univ., St. Louis, MO, [5]Nanyang Technological Univ., Singapore, Singapore, [6]J. Craig Venter Inst., Rockville, MD

Abstract Body:

Background. Clinical studies rely heavily on mouse models of infection, making precise identification and control of contaminating pathogens in animal facilities an essential task. Over the past decade, there have been several reports documenting the isolation of *Bordetella* spp. from specific-pathogen-free C57BL/6 mice housed in various facilities in the United States, Europe and Asia.
Methods. To accurately speciate isolates of *Bordetella* from mice, we first sequenced the genomes of two from the United States and one from Germany and compared them with genome sequences of other *Bordetella*. We reconstructed whole-genome-based and 16S-rRNA-gene-based phylogenies for all *Bordetella* spp. sequenced to date. We then determined estimated DNA-DNA Hybridization (eDDH) values and Average Nucleotide Identity (ANI) scores. Metabolic profiles and antimicrobial sensitivities have been assayed with Biolog PM1 and PM2 tests, Biolog GENIII, API20 NE system, and Epsilometer tests. The ability of each isolate to colonize the lungs of mice was assessed using a previously described murine model of infection.
Results. Each of the two reconstructed phylogenies placed the three murine isolates into a distinct monophyletic cluster, most closely related to *B. hinzii*. Furthermore, distinctly different eDDH, ANI, gene content, metabolic profiles, and host specificity all provide compelling evidence for delineation of murine isolates from the *B. hinzii* group. Therefore, we designate these murine isolates as *B. pseudohinzii* spp. nov.
Conclusions. Our study provides means to precisely identify *B. pseudohinzii* sp. nov. and to assess its prevalence among laboratory-raised mice either based on the presence of *B. pseudohinzii*-specific genes such as the type II-C CRISPR-Cas genes, which are absent in all other bordetellae, or by a unique pattern of mutations observed in their 16S-rRNA sequence. Using the latter approach, we revealed that all *Bordetella* isolates, cultured from mice across Japan, most likely represent *B. pseudohinzii* sp. nov.

Revealing Conserved DNA Motifs in the 3' End of the Type IIA CRISPR Leader Region

Author Block:

P. Klein, F. Z. Najar, M. Van Orden, **R. Rajan**; Univ. of Oklahoma, Norman, OK

Abstract Body:

The Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) and CRISPR-associated (Cas) proteins consist of RNA-protein complexes that provide bacteria and archaea sequence-specific immunity against bacteriophages and conjugative plasmids. The bacteria or archaea become immune to phage or plasmid infections by inserting short pieces of the intruder DNA site-specifically into the leader-repeat (repetitive units of CRISPR RNA gene) junction, in a process called adaptation. The hypothesis for the present research is that sequence/structural motifs present in the leader-repeat junction recruits type-specific Cas proteins for successful adaptation. As part of our ongoing investigation on adaptation, we analyzed type IIA CRISPR loci belonging to 55 *Streptococcal* and 74 other bacterial genera. Our dataset consisted of 150 nucleotides of the CRISPR leader, the first repeat, and the protein sequences of Cas1, Cas2, Cas9, and Csn2. After performing multiple sequence alignments using MUSCLE, phylogenetic trees were generated in UGENE. Our results showed an over-representation of two distinct 3' leader ends in all the 129 loci analyzed, i) 5'-ATTTGAG-3' and ii) 5'- CYACGAG-3'. Interestingly *Streptococcus thermophilus* DGCC7710, a model bacterium used for adaptation studies, possesses two type IIA CRISPR loci of which locus 1 (Sth-CR1) has the ATTTGAG sequence motif and locus 3 (Sth-CR3) has the CYACGAG motif. A phylogenetic analysis of the repeat and the Cas proteins revealed segregation reflecting the 3' leader end conservation and pointed to the coevolution of the leader region and the CRISPR components. Based on previous studies (1) which experimentally demonstrated that the 3' end of the leader is essential for adaptation in Sth-CR1 locus and due to certain bacteria only carrying Sth-CR3 locus, we hypothesize that the two DNA motifs are essential for type IIA adaptation. We currently are investigating the importance of the two DNA motifs and its co-relation to locus-specific Cas proteins by *in vitro* assays. Similar studies can be used to identify conserved leader sequences in other CRISPR systems.

Rapid Detection of Polymyxin-resistant *Enterobacteriaceae* from Blood Cultures

Author Block:

A. Jayol[1], V. Dubois[1], L. Poirel[2], **P. Nordmann**[2]; [1]Univ. of Bordeaux, Bordeaux, France, [2]Univ. of Fribourg, Fribourg, Switzerland

Abstract Body:

Enterobacterial strains resistant to polymyxins are increasingly reported worldwide. MIC testing by broth microdilution (reference technique) for determining colistin susceptibility remains time-consuming (24 to 48 h) and many other techniques such as disk diffusion are not reliable. Therefore, the Rapid Polymyxin NP (Nordmann/Poirel) test was developed for a rapid identification of colistin-resistant *Enterobacteriaceae*. This test is based on the detection of the glucose metabolization related to bacterial growth in liquid medium in presence of a defined concentration of colistin (3.75 mg/L) (or polymyxin B) indicating colistin resistance. Formation of acid metabolites consecutive to the glucose metabolization was evidenced by a color change (orange to yellow) of a pH indicator (red phenol). The Rapid Polymyxin NP test has been evaluated to detect colistin-resistant *Enterobacteriaceae* directly from spiked blood cultures and from clinical positive blood cultures. It was evaluated with 80 blood culture sets positive with *Enterobacteriaceae* isolates belonging to various genera (*Escherichia, Klebsiella, Enterobacter, Citrobacter, Hafnia, Proteus, Providencia, Serratia, Morganella*). The test showed excellent performances to discriminate colistin-resistant and -susceptible enterobacterial isolates and results were rapidly obtained within 2-4 hours. The method was easy-to-perform, requiring neither subculture nor centrifugation of the blood culture (only a ten-fold dilution). This rapid test is well adapted for an early identification of polymyxin-resistant *Enterobacteriaceae* directly from blood cultures. It may be useful for the management of septic patients, especially in countries where carbapenemase producers are highly prevalent and where polymyxins are last resort antibiotics.

***H. pylori* PCR Test can Predict Presence of Clarithromycin Resistance-associated Mutations from Stool with High Correlation to Patient Eradication**

Author Block:

E. Beckman[1], G. Fiorini[2], I. Saracino[2], C. Clark[1], V. Slepnev[1], D. Patel[1], C. Gomez[1], R. Ponaka[1], S. Elagin[1], B. Vaira[2]; [1]Meridian BioSci., Cincinnati, OH, [2]Univ. of Bologna, Bologna, Italy

Abstract Body:

Background: *Helicobacter pylori* is associated with gastric illness including gastric cancer and peptic ulcers. *H. pylori* can be detected using samples obtained from both invasive and non-invasive methods. The prevalence of clarithromycin resistance among *H. pylori* infected population is increasing and there is a need to identify the resistance preferably with non-invasive methods. This PCR method can be used to detect *H. pylori* in stool as well as predict presence of mutations associated with resistance to clarithromycin.**Methods:** A total of 244 frozen stool samples predominantly positive according to the gold standard (culture and/or histology plus rapid urease test and ^{13}C-urea breath test) were tested. Genomic DNA was extracted from the stool using QIAamp FAST Stool DNA Kit (QIAGEN). A qPCR Exogenous Control (Bioline, UK) was added to samples prior to the extraction. Real-time PCR amplification was performed using *H. pylori* Analyte Specific Reagents (ASR) primers and probes (Meridian Bioscience, Cincinnati) and exogenous control specific primers and probes. The Real-time PCR reaction was prepared with SensiPLUS master mix (Bioline) and ran on RotorGene (QIAGEN). Presence of resistance-associated mutations to clarithromycin was determined by signal difference between two test fluorophores or DNA melt analysis. PCR results were compared to final outcome of the patient after combination therapy including clarithromycin. **Results:** The sensitivity of the assessement above mentioned was 90% according to the gold standard. Out of the 176 true positives tested, a total of 61 samples or 34.7% showed point mutations associated with clarithromycin resistance based on the PCR analysis. The resistance samples contain mutations that includes A2143G, A2412G and A2142C which were confirmed by DNA bidirectional sequencing. Eradication results from clarithromycin therapy showed 86% correlation to the PCR results from stool samples.
Conclusions: The Real-time PCR method is capable of detecting *H. pylori* in stool and detecting the point mutations associated with clarithromycin resistance. This assay may present a useful option for patient management in areas with high prevalence of resistance to clarithromycin.

Colistin Resistance of Gram-negative Clinical Bacterial Isolates

Author Block:

Q. Luo, W. Yu, Y. Xiao, L. Li; The First Affiliated Hosp., Coll. of Med., Zhejiang Univ., Hangzhou, Zhejiang, China, Hangzhou, China

Abstract Body:

Recently, researchers have discovered that bacteria worldwide are sharing *mcr-1*-a plasmid mediated gene that confers resistance to colistin, a 'last resort' antibiotic. The plasmid-mediated colistin resistant gene *mcr-1* has mainly been identified in bacterial species from livestock animals. However, it was also detected in humans from patients and asymptomatic people.
We used agar dilution method to measure MIC of 2866 non-duplicate Gram-negative clinical bacterial isolates collected from a tertiary hospital during 2014-2015. We screened out 40 *Escherichia coli* (3.15%; 40/1270), 8 *Klebsiella pneumoniae* (0.87%; 8/915), 4 *Acinetobacter baumannii* (0.67%; 4/600), 0 *Pseudomonas aeruginosa* (0/81) colistin resistant strains (MIC>2 μg/mL). Of note, *A. baumannii* and *P. aeruginosa* has much lower colistin resistant ration than *E. coli*.
PCR and DNA sequencing were employed to screen for the presence of *mcr-1* in the colistin resistant strains. Results indicated that *mcr-1* was only present in *E. coli*.
MLST according to warwick database indicated that these colistin resistant *E. coli* strains belonged to multiple sequence type are dispersedly distributed. S1-PFGE and Southern hydridization showed that *mcr-1* were located on plasmids of different sizes. These plasmids were successfully transferred to J53. In the clinical isolate *E. coli*, colistin resistant levels conferred by *mcr-1* are relatively lower than non-*mcr-1* colistin resistant strains. The mechanism of this phenotype is still unknown. We have discovered that lipid A structure was different between *mcr-1* containing and non-*mcr-1* colistin resistant strains through MALDI-TOF measurement.
Colistin resistance of gram-negative clinical bacterial isolates is definitely worth further study, including epidemiologic study and resistance mechanism research.

Targeted Amplicon Sequencing versus Standard Culture Methods for Detection of Cystic Fibrosis Pathogens

Author Block:

R. M. Davidson, E. Epperson, K. C. Malcolm, J. A. Nick, M. Strong; Natl. Jewish Hlth., Denver, CO

Abstract Body:

Individuals with cystic fibrosis (CF) often acquire chronic, polymicrobial lung infections due to excessive mucus production and defective airway clearance of bacteria. Diagnostic tests capable of detecting a range of pathogenic bacteria are essential for determining effective treatment regimens. Rapid and accurate detection is especially important for nontuberculous mycobacteria (NTM), which are emerging CF pathogens that currently take days to weeks to identify using laboratory culture techniques. Microbiome profiling using targeted amplicon sequencing is a promising approach for clinical diagnostics given the rapid turn around time and potential to detect most bacterial genera in a human sample. The method uses PCR to amplify target DNA directly from complex samples followed by high throughput sequencing. Our goal is to compare amplicon sequencing to gold standard culture methods for three CF pathogens: *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Mycobacterium* species (NTM). We hypothesize that molecular methods will recapitulate culture results. First, we performed 16s rRNA amplicon sequencing on sputa samples from 32 adult CF patients and evaluated the presence of 16s reads compared to positive microbiologic culture results. We observed the highest sensitivity and specificity for *P. aeruginosa* (sens:spec; 0.94: 1.0), lower accuracy for *S. aureus*; (0.85: 0.89) and the least precision for *Mycobacterium* species (0.60: 0.64). To improve upon the low predictive power of the 16s target for NTM, we sequenced a gene target designed to specifically detect mycobacterial pathogens, and significantly improved our NTM detection accuracy. Our results suggest that the choice of sequencing target is an important consideration for detection of desired pathogens, and rapid molecular methods may be feasible tools for diagnostic laboratories.

Rapid Detection of *Pseudomonas aeruginosa* in Wound Exudate from Patients with Chronic Wounds

Author Block:

H. J. Sismaet[1], A. Banerjee[2], S. McNish[2], Y. Choi[3], M. Torralba[3], S. Lucas[3], A. Chan[3], V. K. Shanmugam[2], E. D. Goluch[1]; [1]Northeastern Univ., Boston, MA, [2]George Washington Univ., Washington, DC, [3]J. Craig Venter Inst., Rockville, MD

Abstract Body:

A significant limitation to antibiotic stewardship and improved patient care is the delay between the obtainment of a biological sample and its bacterial identification from culture results. In the field of wound care in clinical practice, the use of plate cultures inoculated from swab samples is the standard practice for positive identification, taking anywhere from 24 to 48 hours before a positive result is produced. In the clinical setting, *Pseudomonas aeruginosa* is one of the leading causes for bacterial infection and is an important bacterium to study given its impact on people with chronic wounds and compromised immune systems. Because *Pseudomonas aeruginosa* infections are currently identified using plate cultures, a rapid detection for this bacterium would allow a doctor to switch from broad-spectrum antibiotics to more direct targeted therapy, lowering antibiotic resistance and improving patient care outcomes. Here we report the use of an inexpensive, disposable electrochemical sensor to detect pyocyanin, a unique, redox-active quorum sensing molecule released by *Pseudomonas aeruginosa*, in wound exudate from patients with chronic wounds. This electrochemical detection strategy eliminates sample preparation and takes less than a minute to complete analysis. The electrochemical results were compared against 16S rRNA profiling where blind identification yielded 9 correct matches, 2 false negatives, and 3 false positives giving a sensitivity of 71% and specificity of 57% for detection of *Pseudomonas aeruginosa*. The results from this study will help in improving the sensor for point-of-care diagnostics.

Detection of *Clostridium difficile* Binary Toxin Genes, *cdtA* and *cdtB,* in Buenos Aires, Argentina

Author Block:

N. Rios Osorio[1], D. Cejas[1], R. Quirós[2], M. A. Berger[3], R. Sadorin[2], **G. Gutkind**[1], L. Fernández Canigia[3], M. Radice[1]; [1]Univ. de Buenos Aires, Buenos Aires, Argentina, [2]Hosp. Austral, Buenos Aires, Argentina, [3]Hosp. Alemán, Buenos Aires, Argentina

Abstract Body:

Background: Hypervirulent *Clostridium difficile* strains are characterized by the presence of two large toxins, toxins A (TcdA) and B (TcdB), and the binary toxin (CDT), encoded by *cdtA* and *cdtB*. During the last decades, *C. difficile* BI/NAP1/027 strain has been reported in North America and Europe. This binary toxin producing strain displayed high-level fluoroquinolone resistance and has been related to severe nosocomial outbreaks. Epidemiological studies on *C. difficile* are scarce in our country. The aim of this study was to investigate the presence of binary clostridial toxins in Buenos Aires **Methods:** 29 *C. difficile* isolates were recovered from diarrheal stool samples of hospitalized patients between March and November 2015 at 2 hospitals in Buenos Aires. All these samples rendered positive Glutamate Dehydrogenase (GDH) test. Both GDH and A/B toxins were investigated by Quick Check Complete enzyme immunoassay (EIA). Regardless of the toxin results, all samples were shocked in 95% alcohol for 30 min and appropriately inoculated for *C. difficile* isolation. Identification was confirmed by MALDI-TOF. Susceptibility to fluoroquinolones (levofloxacin (LEV), moxifloxacin (MXF) and gatifloxacin (GAT)), vancomycin (VAN) and metronidazole (MTZ) was determined according to CLSI. A multiplex PCR was carried out in order to detect *tcdA, tcdB, cdtA* and *cdtB,* according to *Persson et* al 2008, using genomic DNA obtained from *C. difficile* cultures as template. All amplicons were sequenced **Results:** 12/29 isolates were positive for toxin A/B by EIA. Both *tcdA* and *tcdB* were detected in 16 isolates. Many discrepancies were observed between phenotypic and genotypic approaches. No *tcdA*-/*tcdB*+ isolates were observed. Coding genes for CDT were identified in 4 *tcdA*+/*tcdB*+ isolates, 2 of them characterized as toxin- by EIA. MIC90 (μg/ml) of LEV, MXF, GAT, VAN and MTZ were 4, 16, 16, 0.5, 0.5 respectively **Conclusions:** To the best of our knowledge, binary toxin has been reported only once in our country in stool samples using GeneXpert. CDT positive isolates were susceptible to the fluoroquinolones studied, suggesting that these isolates would correspond to other clone different from BI/NAP1/027

Transferable Resistance Gene *optrA* in *Enterococcus faecalis* Isolated from Swine in Brazil

Author Block:

L. M. Almeida[1], F. Lebreton[2], P. Bispo[2], J. T. Saavedra[2], J. Wurster[2], C. Pires[1], M. R. Fernandes[1], L. T. Cerdeira[1], N. Lincopan[1], A. M. Moreno[1], E. M. Mamizuka[1], M. S. Gilmore[2]; [1]Univ. of São Paulo, São Paulo, Brazil, [2]Harvard Med. Sch., Boston, MA

Abstract Body:

Background: The ABC transporter gene *optrA* is a transferable phenicol/oxazolidinone resistance gene identified very recently in staphylococci and enterococci isolates of human and animal origins in China and Italy. Here we investigate *Enterococcus faecalis* strains, isolated from swine in Brazil and carrying *optrA* on a previously uncharacterized genetic element. **Methods:** A total of 15 *E. faecalis* strains isolated from porcine fecal swabs exhibited high chloramphenicol and linezolid MIC levels. All strains were screened by PCR for the presence of the *optrA* gene. The multilocus sequence types (ST) were determined according to the MLST database. Finally, whole genome sequencing (Illumina Hiseq), de novo assemblies (CLC Genomics Workbench 8.0.3) and annotations (Rapid Annotation Server - RAST) were performed to investigate the genetic environment of *optrA*. **Results:** A conserved *optrA*-carrying DNA segment of 4439 bp was identified in all 15 *E. faecalis* strains, which grouped into genetically distant STs (ST29, ST330, ST590, ST591, ST592). Upstream of *optrA*, genes coding for a hypothetical protein and an AraC family transcriptional regulator were detected. Downstream of *optrA*, a gene coding for a protein of unknown function was found to display 100% DNA identity with the *optrA* genetic element previously reported in *E. faecalis* and *Staphylococcus sciuri*. Further downstream, a partially disrupted ISSep1-like transposase and a protein coding for DNA repair RadC were present. While in most of the *E. faecalis* strains, the *optrA*-carrying segment was inserted downstream of a complete copy of the site-specific transposable element Tn554, in one of them the 4439 bp *optrA* region inserted inside the *tnpC* gene of Tn554. **Conclusions:** The flanking regions of the *optrA*-carrying segment in the epidemiologically unrelated *E. faecalis* strains of this study differed from the elements described in other strains and species so far. The analysis of these segments suggests that the transposon Tn554 might be involved in the integration and transfer of *optrA*. Finally, our data suggest that *optrA* acquisition result from both vertical inheritance and horizontal transfer, possibly transposon mediated, in enterococci.

Combinations of Daptomycin Plus Gentamicin Exert Early Synergistic Killing of Streptococcus mitis In Vitro

Author Block:

B. Zapata[1], D. N. Alvarez[2], T. T. Tran[3], C. Garcia-de-la-Maria[4], J. M. Miro[4], C. A. Arias[3], M. J. Rybak[5], P. Sullam[6], A. S. Bayer[2], **N. N. Mishra**[2]; [1]Cal. St. Univ. Dominguez Hills, Carson, CA, [2]LA Biomed at H. UCLA Med. Ctr., Torrance, CA, [3]Univ. Texas Med. Sch., Houston, TX, [4]Hosp. Clinic-IDIBAPS, Univ. Barcelona, Barcelona, Spain, [5]Wayne State Univ., Detroit, MI, [6]VA Med. Ctr., San Francisco, CA

Abstract Body:

Background. Among viridans group streptococci, *S. mitis* has emerged as the most common cause of endocarditis and the toxic strep syndrome in immunocompromised hosts. *S. mitis* isolates are frequently β-lactam-resistant, rendering daptomycin (DAP) as a potential option for treatment of invasive infections with these strains. Of note, many clinically-derived *S. mitis strains* **rapidly develop high-level DAP-resistance (DAP-R) both *in vitro* and *in vivo* (≤ 48 hr exposure to DAP; AAC 2013)**. The objective of this study was to investigate the ability of DAP in combination with 'old' gentamicin (GEN) or 'new' antibiotics [tedizolid (TED), linezolid (LNZ) and ceftaroline (CPT)] to kill a prototypical *S. mitis* endocarditis isolate (SF100). We focused on early 'cidal effects of such combinations in time-kill assays.

Methods.

MICs. Determined both by Etest and broth microdilution assay (CLSI recommendations for *S. mitis*).

***In vitro* time-kill curves.** Time-kill curves (0, 2, 4, and 6 hr) were performed at an initial inoculum of 10^5 CFU/ml in the presence of a range of sub-inhibitory-to-inhibitory concentrations of all study antibiotics.

Results.

Although most combinations yielded enhanced early killing, only DAP + GEN combinations demonstrated significant early synergistic killing vs DAP or GEN alone (see **Table below**; data given as $\log_{10}$ CFU/ml ± SD; means of two separate runs)**.**

Time (hr)	**Control**	**DAP 1X**	**GEN 1X**	**DAP 1X + GEN 1X**
0	5.0±0.2	5.0±0.1	4.9±0.3	4.9±0.3
2	5.4±0.2	5.1±0.0	4.9±0.1	3.3±1.0
4	6.3±0.0	4.1±0.1	5.0±0.2	1.6±0.2*°¨

6	7.8±0.4	4.0±0.4	4.9±1.0	1.9±0.1*
DAP MIC =0.75µg/ml; GEN MIC=6 µg/ml ; *p-value <0.05 vs Control; p-value <0.05 vs DAP 1X; ¨ p-value <0.05 vs GEN 1X				

Conclusions.
Combinations of DAP + GEN are a promising therapeutic option for the treatment of invasive *S. mitis* syndromes. Current studies in our lab are examining additional DAP combination regimens (e.g. DAP + rifampin, trimethoprim-sulfa, imipenem or ampicillin) for ability to not only evoke early synergistic killing, but also to prevent the emergence of DAP-R upon longer *in vitro* exposures to DAP.

The Prp8 Intein as a Target for Inhibition of Pathogenic Fungi

Author Block:

Z. Li[1], J. Zhang[1], S. Chaturvedi[1], C. Green[2], M. Belfort[2], **H. Li**[1]; [1]Wadsworth Ctr., Albany, NY, [2]Univ. at Albany, Albany, NY

Abstract Body:

Abstract: Invasive fungal infections (IFIs) remain a major public health challenge. Globally, over 300 million people are affected by IFIs, with estimated deaths of over 1 million people every year. IFIs are largely caused by *Candida, Cryptococcus, and Aspergillus* species. Among the IFI pathogens, *Cryptococcus neoformans (Cne), C. gattii* (Cga), and *Aspergillus fumigatus (Afu)* cause significant human disease, and are difficult to treat. Currently, IFI treatment is usually achieved with combination therapy for a lengthy period of time. Despite the availability of anti-fungal drugs, mortality rates associated with these infections often exceed 50%. In addition, drug resistance is a significant problem. The *Prp8* intein is one of the most widespread eukaryotic inteins, occurring in important pathogenic fungi including *Cryptococcus* and *Aspergillus* species. Because the processed Prp8 carries out essential and non-redundant cellular functions in pathogenic fungi, a Prp8 intein inhibitor could be a mechanistically novel anti-fungal agent. Here, we developed high throughput screening assays to monitor Prp8 splicing. Using the assays, we demonstrated that cisplatin, a broad spectrum cancer drug, not only inhibited the Prp8 splicing *in vitro*, but also inhibited the growth of *Cne*, *Cga*, and *Afu*. In contrast, *Candida* species that do not harbor the Prp8 intein were only poorly inhibited by cisplatin, suggesting that cisplatin inhibition is through specific targeting of the Prp8 inteins. Furthermore, the inhibitions were found as fungicidal. We also investigated the binding of cisplatin to Prp8, using mass spectrometry and mutagenesis approaches. Overall these results indicated that the Prp8 intein is a novel anti-fungal target.

Publishing Title:

PK-PD Driver of Efficacy for CF-301, a Novel Anti-Staphylococcal Lysin: Implications for Human Target Dose

Author Block:

J. A. Rotolo[1], R. A. Ramirez[1], R. Schuch[1], M. Machacek[2], T. Khariton[3], P. Ghahramani[3], M. Wittekind[1]; [1]ContraFect, Yonkers, NY, [2]Lyo-X, Allschwil, Switzerland, [3]Inncelerex, Jersey City, NJ

Abstract Body:

Lysins are a new class of antimicrobials consisting of bacteriophage-derived cell-wall hydrolases. CF-301, the first lysin to enter US clinical trials, has concluded a First-in-Man Phase 1 trial (0.04-0.4 mg/kg in healthy volunteers) and is being developed for the treatment of *S. aureus* bacteremia. CF-301 exhibits rapid *S. aureus*-specific bacteriolysis, potent anti-biofilm activity, low propensity for resistance and pronounced synergy with antibiotics. Here, the PK-PD of CF-301 against *S. aureus* was characterized using the traditional murine thigh-infection (MTI) model.

Mice infected with $1x10^6$ CFU *S. aureus* were administered CF-301 divided into 1, 2, 3, or 4 doses over 24 h. Change in $\log_{10}$ CFU at 24 hours post infection was used as the dependent variable in a regression analysis to examine the predictive value of AUC:MIC ratio, Cmax:MIC ratio, %T>MIC, or a combination of these indices, using 20 different models ranging from linear to nonlinear, with model fit to the data assessed by comparing the residual standard errors. Efficacy of CF-301 (1 to 60 mg/kg in 4 divided doses) was evaluated against 10 clinical *S. aureus* isolates (MIC range: 4-64 ug/mL) and a subset in the presence of sub-therapeutic 0.5-5 mg/kg Daptomycin (DAP), and various models were fit to the data.

While all indices and index combinations displayed an association with CF-301 efficacy, the AUC:MIC index alone had the best predictive value. AUC:MIC ratios of $\geq$1.5 (single-agent) and $\geq$0.5 (DAP combo) are associated with maximal bacteriolytic activity (3 $\log_{10}$ CFU reduction from controls). Based on the CF-301 MIC_{90} value in human serum of 1 µg/mL, the AUC:MIC ratio target values, and estimated AUCs from a Phase 1 study in humans (in press), it is projected that CF-301 doses between 0.1-0.2 (single agent) and 0.03-0.1 (DAP combo) mg/kg will be efficacious in humans.

Data demonstrate that the AUC:MIC ratio is the PK-PD index most predictive of CF-301 efficacy against *S. aureus.* AUC:MIC ratio targets of approximately 1.5 and 0.5 are expected to be achieved in humans at CF-301 doses in the ranges of 0.1-0.2 (single agent) and 0.03-0.1 mg/kg (DAP combo). Additional studies incorporating population PK analyses and simulation will further refine the targets and evaluate optimal dosing regimens for CF-301.

Small Molecule Library Screening for *Pseudomonas aeruginosa* AmpR Inhibitors

Author Block:

H. Kumari[1], M. Giulianotti[2], S. Dhar[1], C. Bernard[1], K. Morales[1], K. Mathee[1]; [1]Florida Intl. Univ., Miami, FL, [2]Torrey Pines Inst. for Molecular Studies, Port St Lucie, FL

Abstract Body:

Failure of current antibiotic therapy to treat *Pseudomonas aeruginosa* infections is predominantly responsible for many life threatening acute and chronic human infections. This study aims to identify novel therapeutic agents against *P. aeruginosa* that can target its virulence and antibiotic resistance at the same time. For this, a high throughput screening approach is undertaken to identify inhibitors of a global regulator, AmpR, which is critical for its antibiotic resistance and acute virulence. Previous studies have shown that besides positively regulating ß-lactam resistance through AmpC ß-lactamase, AmpR regulon includes an extensive list of genes involved in non-ß-lactam resistance, quorum sensing associated virulence, T6SS protein, biofilm formation, regulation of cycling di-GMP, protein phosphorylation, and physiological processes. The objective of this study is to screen for non-bactericidal compound(s) that interfere with the AmpR function, with two specific aims: 1) Screening a chemical library for AmpR inhibitors, and 2) Verification of AmpR inhibitors. With a P_{ampC}-luxCDABE reporter system introduced in *P. aeruginosa* PAO1, a unique scaffold based combinatorial library was screened to identify potential AmpR inhibitors by screening millions of compounds using just 79 samples. Nine positive hits, showing more than 20% reduction in luciferase activity, were identified from the primary screening. The compounds identified in the primary screening contained one of the two core structures: pyrrolidine-based or guanidine-based molecules. Further, these hits will be used for counter selection using other AmpR regulated reporters, such as P_{phzA} and P_{mexE} to confirm specificity of AmpR inhibition. Positional scanning based secondary screening will be used to identify individual target compounds. The best hits from Aim 1 will be tested for human cell-cytotoxicity and their ability to affect *P. aeruginosa* virulence and antibiotic resistance using various *in-vitro* and *in-vivo* assays. The compounds identified in this study will hold promise to be developed as novel drugs that would prevent acute to chronic progression as well as greatly improve current antibiotic treatments against *P. aeruginosa* and other pathogens harboring AmpR homologues.

Gram-negative Sepsis During Alemtuzumab Conditioning for Hematopoietic Stem Cell Transplantation (HSCT) in Chronic Granulomatous Disease (CGD)

Author Block:

M. PARTA[1], D. Hilligoss[2], M. Marquesen[2], C. Kelly[2], N. Kwatemaa[2], H. Malech[2], E. M. Kang[2]; [1]Leidos BioMed. Res., Inc., Bethesda, MD, [2]Natl. Inst. of Allergy and Infectious Diseases/NIH, Bethesda, MD

Abstract Body:

Neutropenia with an absolute neutrophil count (ANC) <500/mm^3 is the dominant risk for bacterial infection in the early phase of HSCT. Four patients with CGD undergoing HSCT had bacteremia prior to neutropenia with bacteria that often cause disease in CGD without neutropenia.Four male patients, age 3-24 years, underwent HSCT for X-linked CGD. Three donors were matched/unrelated, one matched-related. All received alemtuzumab, day -8 to -4, dose-adjusted busulfan days -3 and -2. Total body irradiation of 300 cGy was used for recipients from unrelated donors.All patients had fever with alemtuzumab. Fever after completion of alemtuzumab was recurrent (3 cases) or persistent. *K. pneumoniae* (2 cases), *Serratia* sp. and *Burkholderia cepacia* complex bacteremias occurred on days -4 to 4. Average absolute lymphocyte count (ALC) and ANC on the days of bacteremia were 37/mm^3 and 2.89/mm^3. The interval from bacteremia to neutropenia was 5.5 days (range 1-10). Prolonged *Burkholderia* bacteremia and hypotension required intensive care unit support for 3 days. Engraftment occurred at an average of 23 days (range 16-39) in all.In conclusion, 4 patients with X-linked CGD undergoing HSCT had Gram-negative bacteremias during immunosuppressive conditioning prior to neutropenia. These events have led us to institute antibacterial prophylaxis at the start of conditioning. Funded by the NCI Contract No. HHSN261200800001E.

Non-hydroxamic Acid Lpxc Inhibitors, Their In Vitro And In Vivo Antimicrobial Activities

Author Block:

m. teng, D. Puerta, K. taganov; Forge Therapeutics, San Diego, CA

Abstract Body:

Background: Gram-negative infections continue to present threats to public health. With increasing resistance to the existing antibiotics, antibiotics with new mechanism of actions or through new targets are needed. LpxC is a zinc-dependent UDP-3-*O*-(*R*-3-hydroxymyristol)-*N*-acetylglucosamine deacetylase. It is responsible for the biosynthesis of lipid A which provides an anchor for lipopolysaccharide of the outer membrane of Gram-negative bacteria. LpxC inhibitors inhibit the biosynthesis of lipid A, disable the outer membrane assembly, and render the antibacterial activity. Though LpxC has attracted attention from drug hunters, no inhibitor had advanced to clinic. Nearly all known potent LpxC inhibitors contain hydroxamates as war-heads to coordinate the Zn(II) metal ion in the enzyme. Researches have suggested that part of the failures of these compounds are due to the liability of hydroxamate group, including high clearance, known toxicities (Ames, micronucleus) and poor target selectivity. We set out to discover non-hydroxamate LpxC inhibitors using fragment based design strategy starting out from the Zn-binding fragments. **Methods:** Through a screening of our metal binding fragment library against *E. coli* LpxC at 200 μM, we identified a handful of fragments. These were modeled into the LpxC. Those that provided the right trajectory into the hydrophobic tunnel were selected for further structural elaborations.
Results: Compounds were tested against *E. coli*, *P. aeruginosa* , *K. pneumoniae* and selected biodefense microbes. The most potent non-hydroxamate compounds possess MIC of 0.25 ug/mL against wild type *E. coli*. and 4 ug/mL against pump knock-out *P. aeruginosa* and showed no activity towards *S. aureus*. These compounds displayed potent IC_{50} against both Kpn and Pae enzymes. Cross screen against MMPs, HDACs, lysine demethylases, and carbonic anhydrase showed these inhibitors are highly selective for LpxC. A few compounds were evaluated in the murine thigh model against wild type E. coli infection and showed efficacy.
Conclusions: We have identified potent and selective non-hydroxamate inhibitors. These compounds showed good potency against broad panel GN bacteria with superb target selectivity. In vivo efficacy has been demonstrated in murine thigh infection model. Further effort will be focused on improving Pae activity, overcoming efflux pump and membrane permeability.

Publishing Title:

Safety and Pharmacokinetics of Multiple Doses of CD101 Injection: Results from a Phase 1, Dose-escalation Study

Author Block:

T. Sandison[1], D. Armas[2], V. Ong[1], J. Lee[1], **D. Thye**[1]; [1]Cidara Therapeutics, Inc., San Diego, CA, [2]Celerion, Tempe, AZ

Abstract Body:

CD101 Injection is a novel echinocandin being developed as a high-exposure, once-weekly agent for the treatment and prevention of invasive fungal infections. CD101 has potent in vitro and in vivo activity against a broad range of *Candida* and *Aspergillus* spp. CD101 Injection was evaluated in a randomized, double-blind, placebo-controlled, dose-escalation study to establish the safety, tolerability, and pharmacokinetics (PK) of multiple intravenous doses. In 3 sequential cohorts of 8 healthy subjects (n=6, active; n=2, placebo), CD101 Injection was infused over 1 h, once weekly (100 mg × 2 doses [Cohort 1], 200 mg × 2 doses [Cohort 2], 400 mg × 3 doses [Cohort 3]), with dose escalation by predefined safety criteria. Extensive plasma and urine sampling over 28 (Cohorts 1 and 2) or 35 days (Cohort 3) was performed for PK analysis. Safety and tolerability was assessed by adverse events (AEs), vital signs, physical exams, electrocardiograms (ECGs), and hematology and clinical chemistry laboratories up to 21 days after dosing. Subjects (N=24, randomized and completed all assessments) were primarily White (88%), Hispanic or Latino (75%); males and females were equally represented. There were no serious or severe AEs. The majority of AEs were mild; all AEs completely resolved by study completion. There was a higher incidence of AEs and mild, transient infusion reactions in Cohort 3. There were no clinically significant hematology or clinical chemistry laboratory abnormalities at any dose. Additionally, there were no safety issues related to ECGs, vital signs, or physical exam findings. CD101 plasma exposures were dose-proportional. The average C_{max} ranged from 6.49 (Cohort 1, Day 8) to 30.5 µg/mL (Cohort 3, Day 15); corresponding area under the curve ($AUC_{0\text{-}168h}$) values were 390 to 1840 µg·h/mL. Accumulation was minor (30% to 55%, $AUC_{0\text{-}168h}$ ratio of last/first dose). Apparent clearance of CD101 was low (<0.28 L/hour), and its half-life was long ($t_{1/2}$ >80 h). Excretion in urine was minimal (<1%). CD101 Injection was safe and well tolerated at multiple doses up to 400 mg once weekly for 3 weeks, exhibited long plasma $t_{1/2}$, and maintained plasma exposures that support once-weekly dosing. The overall safety, tolerability, and PK profile of CD101 support continued development as a once-weekly therapy for invasive fungal infections.

Multiple Active Site Substitutions in the Native Class D β-lactamase of *Acinetobacter baumannii*, OXA-51/66, Result in Increased Hydrolytic Activity Toward Carbapenems

Author Block:

E. C. Schroder[1], Z. Klamer[1], A. Saral[1], K. A. Sugg[1], C. M. June[1], R. A. Bonomo[2], A. Szarecka[1], D. A. Leonard[1]; [1]Grand Valley State Univ., Allendale, MI, [2]Cleveland VA, Cleveland, OH

Abstract Body:

Background Class D β-lactamases confer carbapenem resistance in *Ab*. Until recently, the chromosomally-encoded carbapenemase of *Ab* (OXA-51/66) was considered of little threat because of its inherent low affinity and turnover rate for carbapenems. Notably, several hundred clinical variants of OXA-51/66 have been reported, many with substitutions of active site residues. Herein, we investigated the kinetic properties of OXA-66 and clinical variants toward β-lactam antibiotics.
Methods OXA-66 and five clinical variants of OXA-66 were studied. Kinetic constants for imipenem, doripenem (Dori) and a variety of penicillins, cephalosporins and monobactam substrates were determined for all 5 variants. To explain the kinetic results, both OXA-66 and OXA-66 P130Q (OXA-109) were simulated for 200 nsec using CHARMM Molecular Dynamics (MD) package and force-field.
Results The presence of a P130Q mutation in OXA-66 results in a 15-40 fold increase in carbapenem hydrolysis efficiency (e.g. Dori k_{cat}/K_M 0.010 → 0.360 μM^{-1} s^{-1}), with modest or no gain in activity toward a variety of penicillins and cephalosporins. Compared to OXA-66, an OXA-66 triple-substitution clinical variant (I129V/W222L/P226S) displayed 20-70 fold increases against penicillin and carbapenems (Dori k_{cat}/K_M 0.010 → 0.710 μM^{-1} s^{-1}). Interestingly, while OXA-66 does not hydrolyze cephalosporins or monobactams, the triple-variant also showed increased hydrolytic activity toward cefotaxime, ceftriaxone, ceftazidime, cefepime and aztreonam (Azt $k_{cat} < 0.05$ → 0.340 s^{-1}). MD simulations show that in OXA-66, P130 inhibits side-chain rotation of I129 leading to steric prevention of Dori binding. A Gln substitution at position 130 greatly enhances I129 mobility, lessening this steric clash.
Conclusions Analysis of several clinical variants of the OXA-66 carbapenemase of *Ab* show that active site substitutions are emerging that lead to increased hydrolytic activity toward carbapenems and many other classes of β-lactam antibiotics. This evolution of substrate specificity represents a very worrisome development for the use of β-lactams against this troublesome pathogen.

Alterations in Membrane Fluidity Appears to Influence Drug Resistance in Opportunistic Pathogen, *Candida albicans*

Author Block:

T. Prasad[1], V. S. Radhakrishnan[1], A. Kumar[1], R. Singh[1], M. Kumar[1], N. N. Mishra[2];
[1]Jawaharlal Nehru Univ., New Delhi, India, [2]LABiomed, Harbor- UCLA Med. Ctr., Torrance, CA

Abstract Body:

Cell membrane serves as a permeability barrier for the entry of biomolecules. Physical properties of membrane strongly influence their biological functions. This study is an effort to characterize and correlate the membrane fluidity with observed fluconazole resistance in a pair of isogenic clinical isolates (F1-sensitive and F5-resistant) of *Candida albicans* isolated from AIDS patient with recurrent oropharyngeal candidiasis (OPC). Microviscosity is the reciprocal of fluidity and gives measure of fractional resistance to rotational and translational motion of the molecule. The fluorescent probe, 1,6-Diphenyl-1,3,5-hexatriene (DPH) has been used to determine the fluidity and microviscosity. The resistant isolate F5 was found to attain a more rigid membrane than the sensitive isolate F1. Increased membrane rigidity may be responsible for reduced drug entry by passive diffusion in the resistant isolate. Classical MDR is mostly attributed to the overexpression of the drug efflux pump proteins. High expression levels were previously reported in the resistant isolate F5 for *MDR1* gene, encoding MFS superfamily transporter and *ERG11* gene, encoding the azole target sterol 14α-demethylase. In view of the multitude of factors responsible for MDR, it was pertinent to characterize the changes in structure and function of cell membrane between resistant and sensitive clinical isolates for complete elucidation of the MDR mechanism and to design better therapeutic strategies for MDR reversal. Changes in membrane fluidity, a parameter of physical state of the membrane may also affect MDR by influencing entry or efflux of drugs. Observed drug resistance also appeared to be influenced by host factors, prior drug treatment and efflux pump overexpression. With the change in growth phase of cells, there was an observed change in membrane fluidity and the *Candida* cells appeared to adapt to environmental changes through modulation of their membrane properties and lipid composition leading to altered membrane fluidity.

Microbiome Antagonism of *Pseudomonas aeruginosa* Gastrointestinal Colonization

Author Block:

K. E. R. Bachta[1], W. Zheng[2], J. E. Hudak[2], S. Oh[2], D. L. Kasper[2], J. J. Mekalanos[2];
[1]Massachusetts Gen. Hosp., Boston, MA, [2]Harvard Med. Sch., Boston, MA

Abstract Body:

P. aeruginosa is found as a prominent member of the human gut microbiome, but the oral dose required to establish measurable colonization in a healthy subject is high. We hypothesized that there is a role for resident host microbiota in preventing gastrointestinal (GI) colonization and dissemination by *P. aeruginosa*. Germ-free and conventional BL-6 mice treated with antibiotics were challenged with *P. aeruginosa*. Twenty-four hours post-gavage, intestines were harvested and the CFU of surviving *P. aeruginosa* measured. Germ-free mice mono-colonized with *Bacteroides fragilis,* a dominant member of the human GI microbiome, were challenged similarly with *P. aeruginosa*. We found that a significant reduction in the presence of culturable microbiota was a prerequisite for mouse GI tract colonization. Mice colonized by *B. fragilis* showed more resistance to dissemination by *P. aeruginosa* compared to germ-free mice. We identified a transposon insertion mutant of *P. aeruginosa* that colonizes the intestines of both conventional antibiotic treated mice as well as *B. fragilis* mono-colonized mice at levels approximately 1,000-fold higher than that observed for the wild-type parental strain. The transposon insertion carried by this mutant causes a 300-fold increase in transcription of a *P. aeruginosa* efflux pump. Inactivation of the same efflux pump also significantly reduced intestinal colonization relative to the parental strain. The human GI microbiota act as protectors in the GI tract by preventing the dissemination of pathogenic bacteria throughly largely unknown mechanisms. Utilizing *P. aeruginosa* (pathogen) and *B. fragilis* (host commensal) as model organisms, we showed that *B. fragilis* alone restricts dissemination of *P. aeruginosa*. The level of expression of a *P. aeruginosa* efflux pump system correlated with the level of intestinal colonization. This result suggests that the host commensal microbiome restricts pathogen colonization and dissemination through the production of antagonistic small molecules that are transported by the efflux systems of pathogens. Together with mounting evidence that the host microbiome can modulate immune and metabolic homeostasis, commensal microorganisms may protect against invading bacterial pathogens by producing antibacterial compounds that are active *in vivo*.

Quorum Sensing Regulation of the CRISPR-Cas Adaptive Immune System in Pseudomonas aeruginosa

Author Block:

N. M. Hoeyland-Kroghsbo[1], J. E. Paczkowski[1], S. Mukherjee[1], E. R. Westra[2], J. Bondy-Denomy[3], B. L. Bassler[4]; [1]Princeton Univ., Princeton, NJ, [2]Univ. of Exeter, Penryn, United Kingdom, [3]The Univ. of California, San Francisco, San Francisco, CA, [4]Howard Hughes Med. Inst., Bethesda, MD

Abstract Body:

In a process called quorum sensing (QS), bacteria communicate, monitor population density, and control collective behaviors including virulence. QS relies on the production, release, and detection of diffusible signaling molecules called autoinducers (AI). Bacteria at high cell density maximally engage in QS. These cells are particularly vulnerable to bacteriophage infections. QS control of antiphage activities could enable bacteria to activate phage defense mechanisms specifically when they are at the highest risk of infection. CRISPR-Cas systems provide bacteria and archaea with acquired and heritable sequence-specific immunity against their parasites, such as phages and plasmids. CRISPR transcripts guide Cas proteins to cleave complementary parasite genomes, which provides immunity. There is little understanding of the regulation of these immune systems. In *Pseudomonas aeruginosa* PA14, we used qRT-PCR to measure the effect of QS on *cas* gene expression. We assayed the effect of QS on the activity of the PA14 CRISPR-Cas system to successfully eliminate a CRISPR-targeted plasmid containing a protospacer sequence (Fig. 1). We find that PA14 uses QS through the Las and Rhl systems to increase the relative transcript levels of the *cas* genes, which in turn leads to a potent increase in CRISPR-Cas activity. QS control of the CRISPR-Cas adaptive immune system has a profound influence on the success of CRISPR-mediated defense. Our discovery may prove particularly important for the development of QS-inhibitors and phage therapies as alternatives to traditional antibiotics.

Antibiotic Resistance is Induced by a Bacterial Starvation Signal in Vibrio cholerae

Author Block:

H. Kim, Y. Oh, S. Yoon; Yonsei Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

When bacteria encounters variety of growth-inhibitory stresses, the stringent response (SR) is activated by accumulation of (p)ppGpp, a small nucleotide regulator known as a stress alarmone. Accumulation of (p)ppGpp results in a profound reprogramming of global gene expression. The genes *relA* and *relV* are involved in the production of (p)ppGpp, whereas the *spoT* gene encodes an enzyme that hydrolyzes it in *Vibrio cholerae*. Here, we show that the bacterial capability to produce (p)ppGpp is deeply involved in regulating antibiotic resistance in *V. cholerae*. N16961, a 7th pandemic *V. cholerae* strain, became resistant to tetracycline, when (p)ppGpp accumulation was induced. N16961 and *ΔrelAΔspoT*, a (p)ppGpp-overproducing mutant strain, were more resistant to the treatment of lethal concentration of tetracycline, when compared with (p)ppGpp^0 (i.e.*ΔrelAΔrelVΔspoT* mutants) and *ΔdksA* mutants, which cannot synthesize nor utilize (p)ppGpp for transcription, respectively. Similar effects were also induced, in response to the treatment with other antibiotics, such as erythromycin and chloramphenicol. No remarkable differences, however, were observed when bacterial strains were treated with aminoglycosides. Furthermore, the *ΔrelAΔspoT* mutant, which mounted resistance, lost typical curved-rod shape morphology and looked smaller in size based on our scanning electron microscope image analysis. N16961, when harvested at stationary phase, also exhibited similar cell shape change, while (p)ppGpp^0 and *ΔdksA* mutants maintained their normal cell shape. We also found that N16961 gained smaller cell shape phenotype, when (p)ppGpp accumulation was induced by serine hydroxamate at exponential phase. Together, our results demonstrate that the alteration of bacterial cell phenotype by accumulation of intracellular (p)ppGpp is associated with antibiotic resistance in *V. cholerae*. Future research will clearly reveal a previously unexplored role of the bacterial starvation signal in regulating bacterial resistance phenotype.

Understanding Intragenic Transcription and its Regulation

Author Block:

L. E. Lamberte, B15 2TT, S. S. Singh, B15 2TT, D. C. Grainger; Univ. of Birmingham, Birmingham, United Kingdom

Abstract Body:

Horizontally acquired DNA, which is AT-rich in nature, is known to be toxic to bacterial cells. Furthermore, the nucleoid-associated protein H-NS counteracts this toxicity. Despite its central role in shaping the evolution of bacterial genomes, molecular explanations on the mechanisms behind the toxicity of AT-rich DNA and regulation of AT-rich DNA by H-NS are lacking. It was previously thought that AT-rich genes are subject to canonical regulation by H-NS (i.e. H-NS silences activity coming from the genuine promoter). However, this work demonstrates the phenomenon of "pseudo-regulation". Using an array of biochemical, genetic, and bioinformatic approaches, we show that H-NS silences activity coming from internal promoters within the coding sequence of an AT-rich gene, rather than the genuine promoter. In addition, we also show that the toxicity of this gene is due to the presence of these internal promoters. This phenomenon is likely widespread, and is demonstrated by this study in a number of AT-rich genes. In addition, the transcription terminator Rho provides an additional mechanism for regulation by terminating intragenic transcripts coming from the H-NS-targeted AT-rich genes. We predict that all AT-rich genes are likely to be enriched for internal promoters. This study therefore provides a molecular explanation for the toxicity of AT-rich DNA that may extend to all domains of life.

Cross-membranes Orchestrate Compartmentalization and Morphogenesis in Streptomyces

Author Block:

Abstract Body:

Bacteria have complex social behaviour and organization, some living as coherent, multicellular entities. The filamentous streptomycetes grow as a multicellular syncytial mycelium with physiologically distinct hyphal compartments separated by cross-walls. The viability of mutants devoid of cell division, which can be propagated from fragments, suggests a different form of compartmentalization. We have discovered that complex membrane structures, visualized by cryo-correlative light microscopy and electron tomography, fulfil this role. Membranes form small assemblies between the cell wall and cytoplasmic membrane, or, as evidenced by FRAP, large protein-impermeable cross-membrane structures, which compartmentalize the multinucleoid mycelium. All areas containing cross-membrane structures are nucleoid-restricted zones, suggesting that the membrane assemblies also act to protect nucleoids from cell-wall restructuring events. Our work reveals an entirely novel mechanism of controlling compartmentalization and chromosome segregation in multicellular bacteria. A model for the role of cross-membranes in compartmentalization and multicellular growth will be presented.

Understanding Copper Uptake in Gram Negative Bacteria

Author Block:

A. González Sánchez, C. A. Ramirez Cubillas, A. Dávalos, A. García-de-los-Santos; Ctr. for Genomics Sci., UNAM, Cuernavaca, Morelos, Mexico

Abstract Body:

Copper (Cu^{2+}) is an essential micronutrient for all forms of life. Oxidation states (Cu^{+}/Cu^{2+}) this metal is ideal cofactor of enzymes catalyzing redox reactions in vital biological process as respiration and others. Uptake of Cu^{2+} is the unknowing part of a fine regulated Cu-trafficking network mediated by protein-protein interactions that deliver Cu^{2+} to target proteins and efflux excess of metal to avoid toxicity. To date, inner and outer membrane proteins (OMP) involved with import of copper has not been characterized in Gram negative bacteria.
In this study we report the identification and partial characterization of a putative OMP involved with Cu^{2+} uptake in *Rhizobium etli* CFN42, a facultative symbiotic diazotroph that must ensure appropriate Cu^{2+} supply for living either free in the soil or as intracellular symbiont of leguminous plants. The putative Cu^{2+}-uptake OMP described in this study was identified in an isogenic mutant, more tolerant to Cu^{2+} than the parental strain, which spontaneously lost 200 kb of plasmid p42e. This Cu^{2+}-resistance phenotype suggested that a putative Cu^{2+}-uptake protein may be encoded in such region. Copper tolerant mutants with smaller deletions of plasmid p42e shared the absence of different putative transporters including an OMP annotated as RopAe. Disruption of *ropAe* gene was the only mutation that increased copper tolerance to *R. etli.* Bioinformatic predictions, genetic experiments and RT-qPCR analyses supported the hypothesis that *ropAe* gene maintain a basal transcription level that facilitates copper uptake. Under copper limitations, the transcription of *ropAe* increases and the putative OMP worked as a high-affinity copper β-barrel channel that permits the copper uptake across outer membrane.

Increased Expression of Genes Involved in Uptake and Degradation of Murein Tripeptide under Nitrogen Starvation in Escherichia coli

Author Block:

U. Choi[1], Y-J. Seok[2], C-R. Lee[1]; [1]Myongji Univ., Yongin, Korea, Republic of, [2]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Peptidoglycan (also known as murein) is an important envelope component of bacteria, and its turnover usually takes place at low levels during normal growth and at considerable levels under stress conditions. Degraded amino sugars and murein tripeptide are used for re-synthesis of peptidoglycan or as self-generated nutrients or energy sources for cell growth. PgrR (regulator of peptide glycan recycling; formerly YcjZ) was recently identified as a repressor of several genes participating in uptake and degradation of murein tripeptide. **Methods:** To identify genes regulated by PgrR, the genome-wide transcription profile in the *pgrR* mutant was carried out by RNA sequencing. These transcriptome data were confirmed by quantitative RT-PCR (qRT-PCR) analysis. To determine whether transcriptions of identified genes are directly regulated by PgrR, an electrophoretic mobility shift assay (EMSA) using DNA fragments upstream of the identified genes as a probe was also performed. Eenvironmental conditions that induce the expression of PgrR-regulated genes were determined using several *lacZ* fusion constructs, such as *ycjY-lacZ*, *mpaA-lacZ*, and *mppA-lacZ* fusion constructs. We also examined the phenotype of the *pgrR* mutant strain. **Results:** The *ycjG* gene involved in murein tripeptide degradation as a new direct target of PgrR. The expression of these PgrR-regulated genes was repressed in the presence of a good nitrogen source, but their expression increased under poor nitrogen conditions because of a nitrogen starvation-induced decrease in the PgrR protein level. Under nitrogen starvation, the *pgrR* mutant cells exhibited faster growth than wild-type cells, implying that derepression of genes under the control of PgrR may help cells overcome nitrogen limitation. **Conclusions:** Nitrogen starvation induces PgrR-mediated derepression of genes involved in uptake and degradation of murein tripeptide, and this may stimulate the utilization of murein tripeptide as a nitrogen source.

Structure-based Engineering of Type II Acyl Carrier Protein Interactions

Author Block:

J. C. Milligan, D. R. Jackson, A. J. Schaub, S. Tsai; Univ. of California, Irvine, Irvine, CA

Abstract Body:

Background: The *E. coli* type II fatty acid synthase (FAS) has long been a target for biofuel production given its ability to efficiently produce hydrocarbon chains. Though the individual enzymes in the pathway have been structurally and functionally characterized, uncovering the key protein-protein interactions, particularly between the acyl carrier protein (ACP) and its partner enzymes, has remained elusive due to the transient nature of the interactions. Without this structural information, engineering efforts and combinatorial biosynthesis have proved unsuccessful.
Methods: Here, we present the application of a mechanism-based crosslinker to trap an ACP-ketosynthase (KS) complex and solve its crystal structure.
Results: The structure of this ACP-KS complex dimer reveals the key interactions between the ACP (AcpP) and one of the KS enzymes in the pathway (FabB). Structural analysis suggests that allosteric mechanisms exist to facilitate enzyme turnover by forcing the dissociation of one AcpP upon docking of a second AcpP to the opposite FabB monomer. This hypothesis was tested using molecular dynamics simulations which predict that a network of interactions exists from one AcpP across the FabB dimer to the second AcpP, forcing its dissociation. Using this structural and dynamics data, several surface mutants of AcpP and FabB were generated and overexpressed in *E. coli* BL21 cells. As hypothesized, the lipid profile of the cultures was altered due to the disruption of this key protein-protein complex that is known to affect chain length and saturation.
Conclusions: This work represents the first crystal structure of an ACP-KS complex as well as the first successful attempt to alter the product profile of this metabolic pathway by specifically targeting protein-protein interactions.

Acquisition of Non-transferable Plasmid and its Deleterious Effect upon UV Exposure

Author Block:

M. shahnaij; icddr,b, Dhaka, Bangladesh

Abstract Body:

Background: Serendipitily an *E. coli* strain (ID SK-13) which can acquire non-transferable plasmid via conjugation in considerably high rate has been isolated from stool sample. Non-conjugable plasmids of Shigella flexneri 2a, 2b, 3a, 3b and X variant were transferred to this recipient *E. coli* strain SK-13 (Lac+, Ara+ and F-). UV light susceptibility test were performed on exconjugant and their cured counterpart to analyze the effect of UV light on non-transferable plasmid.
Methods: Host range was determined using different serotypes of *Shigella* spp.(n=50), *E. coli* (n=20) and *Salmonella* (n=20). Broth mating technique was performed to prepare ex-conjugants, acridine orange facilitated curing of transferable plasmid (20-100Mda) and confirmed by plasmid profile analysis. Exconjugants and its cured strains having different plasmid profile were subjected to varying doses of UV light to elucidate the effect of acquired non-transferable on survival after UV irradiation.
Result: Donor *S. flexneri* 2a, 2b, 3a, 3b and X variant transferred non-transferable plasmid along with conjugative plasmid to recipient *E. coli* strain SK-13. On the other hand, other tested donor strains, different serotype of *Shigella* spp. except above mentioned 5 sub-serotypes of *S. flexneri*, *E. coli* and *Salmonella* spp., did not mobilize non-transferable plasmid but rather transfer only conjugative plasmid. Plasmid transfer rate of conjugative plasmid in SK-13 was 5×10^{-4} (median) and in which 5-30% ex-conjugants was harbor non-transferable plasmid/s in ascending order of molecular weight and in cumulative manner. Comparison of UV light susceptibility test on different plasmid pattern of ex-conjugant and their respective cured counterparts indicated that upon UV exposure, acquisition of non-transferable plasmid/s might be increased DNA breakage, thus reduced number of UV induced bacteria were survived by DNA repair system. In summary, this study explained the natural phenomenon, why mobilization of non-transferable plasmid is rare and low.

Survey of Antibiotic Resistance Genes in Soil Near Two Antarctic Research Stations in Terra Nova Bay

Author Block:

F. Wang[1], **R. D. Stedtfeld**[2], O-S. Kim[3], S. Hashsham[2], J. M. Tiedje[2], W. Sul[4]; [1]Inst. of Soil Sci., Chinese Academy of Sci., Nanjing, China, [2]Michigan State Univ., E. Lansing, MI, [3]Korea Polar Res. Inst., Incheon, Korea, Republic of, [4]Chung-Ang Univ., Anseong, Korea, Republic of

Abstract Body:

Soil is one of the most important environmental carriers of antibiotic resistance genes, which are increasingly perceived as environmental contaminants. Methods to assess the risks associated with the acquisition or transfer of resistance mechanisms are still underdeveloped. Assessment of this risk requires quantification of background levels of antibiotic resistance genes in different matrices. Towards this goal, samples were collected from soils near the 30-year old Gondwana Research Station and before and during newly developed Jangbogo Research Station from the Terra Nova Bay in Antarctica. A qPCR array with 384 primer sets targeting antibiotic resistance genes and mobile genetic elements was used to detect and quantify these genes. A total of 74 antibiotic resistance genes and mobile genetic elements encompassing eight major antibiotic resistance gene categories were detected. Seven antibiotic resistance genes were present in most samples, potentially indicating natural existence in Antarctica soil. In addition, samples significantly grouped based on spatial proximity to research stations.These results suggest that certain types of antibiotic resistance genes may occur in pristine environmental soils regardless of anthropogenic activity.

CSA-131 and CSA-138, Cationic Steroid Antibiotics, Inhibit Pseudomonas aeruginosa Biofilm Formation

Author Block:

C. Bozkurt Güzel[1], M. Tuysuz[1], G. Inci[1], P. B. Savage[2]; [1]Istanbul Univ., Istanbul, Turkey, [2]Brigham Young Univ., PROVO, UT

Abstract Body:

Background: *Pseudomonas aeruginosa* can cause hard to treat life-threatening infections due to its high resistance to antibiotics and to the ability to form antibiotic tolerant biofilms. The biofilm-forming capability of *P. aeruginosa* is a crucial virulence attribute that is responsible for its increased resistance to different classes of antibiotics and disinfectants. As chronic infections are difficult to treat, attempts have been made to discover new therapeutics targeting novel sites. The ceragenins, designed to mimic the activities of antimicrobial peptides, represent a new promising group of agent that revealed a potent *anti-P. aeruginosa* action.
Methods: A total of 25 *P. aeruginosa* isolates and control strain were used. Firstly, biofilm formation and determination of MIC values of CSA 13, CSA 44, CSA 131, CSA 138, ciprofloxacin and colistin were evaluated with crystal violet staining method and microbroth dilution technique, respectively. Among these strains four good biofilm producing strains and the control strain were chosen for biofilm studies. Sessile MICs and inhibition of cells adhesion and biofilm formations were evaluated.
Results: Susceptibility testing demonstrated that the MIC_{50} (µg/ml) values of CSA 13, CSA 44, CSA 131, CSA 138, ciprofloxacin and colistin were 8, 8, 8, 16, 1 and 2, respectively. The SMICs were found greater than MICs. Inhibition of adhesion rates depended on time. CSA 13, CSA 44 and CSA 131 were found more efficient after 4 hour incubation although CSA 138, ciprofloxacin and colistin after 1 hour incubation. The most efficient agent for inhibition of adhesion was found colistin (up to %45). Although inhibition of biofilm formation rates depended at concentration, the highest inhibition rates were shown at MICs for all agents, as expected. CSA 131, CSA 138 and colistin were found most efficient agents for inhibition of biofilm formation (up to %90).
Conclusion:
Overall, our study highlighted the potential of CSA-131 and CSA-138 to be used as effective alternatives to the conventional antibiotics against biofilms of *P. aeruginosa*. Future studies should be performed to correlate safety, efficacy and pharmacokinetic parameters of these molecules.

High-yield production of 3-Hydroxybutyric Acid in the acetogen C. ljungdahlii

Author Block:

B. M. Woolston, **D. H. Currie**, G. N. Stephanopoulos; Massachusetts Inst. of Technology, Cambridge, MA

Abstract Body:

Clostridium ljungdahlii has recently emerged as an attractive candidate for the bioconversion of synthesis gas (CO, CO_2, H_2) to a variety of fuels and chemicals through the Wood-Ljungdahl (WL) pathway. Here we examine another use of the WL pathway; namely the augmentation of fermentation yields on heterotrophic substrates by using reducing equivalents produced in glycolysis to fix the CO_2 released, thus resulting in complete carbon conversion. As a proof of concept, we focused on 3-hydroxybutyric acid (3HB), a chiral compound that serves as feedstock in a variety of applications. First, we varied promoters, codon usage, and ribosome binding site spacing to optimize 3HB production, achieving titers of 1 g/L. Second, we implemented a CRISPRi approach to reduce flux to unwanted byproducts. Finally, we quantified the activity of the WL pathway during fermentation using isotopic tracers. The results demonstrate the ability to significantly enhance fermentation yields above those that can be achieved in typical engineering hosts such as *E. coli* or *S. cerevisiae*.

Abstract Body:

Methane emissions from ruminants are widely recognized as one of the significant factors contributing to global climate change. Methane stemming from the fermentation process in the rumen is produced by methanogenic archaea that are typically only a small proportion of the total microbial community (1-4%). One strategy for mitigating these emissions is to develop inhibitory compounds that specifically target rumen methanogens. To accelerate inhibitor discovery, high-throughput screening techniques were developed that simultaneously target the specialized biochemical pathways of methanogens (including methanogenesis, cofactor biosynthesis and archaeal lipid synthesis). Large chemical compound libraries (representing a variety of well-known chemotypes) and natural product libraries (representing unique and diverse chemistry) were sourced from commercial distributors. These were screened for their effects against methanogens using a newly-developed cell-based assay measuring the optical density of pure cultures of methanogens in 96-well plates and a new high-throughput rumen fluid-based assay where methane production is monitored. Several novel methanogen-specific compounds with potential for mitigating methane emissions have been discovered using these methods.

Co-Detection and Association of O Antigen-specific Genes with Major Virulence Genes of Shiga Toxigenic *Escherichia Coli* Using Digital PCR Technology

Author Block:

X. Liu[1], L. Noll[1], X. Shi[1], A. O'Guin[2], J. Mitchell[3], B. Dalke[3], T. Nagaraja[1], G. Anderson[1], **J. Bai**[1]; [1]Kansas State Univ., Manhattan, KS, [2]Fluidigm Corp., South San Francisco, CA, [3]Thermo Fisher Scientific, Cambridge, MA

Abstract Body:

Shiga toxin-producing *E. coli* (STEC) are major foodborne pathogens and seven major serogroups, O157, O26, O45, O103, O111, O121, and O145 that carry *stx*1 and/or *stx*2 and *eae* genes have been declared as adulterants in ground beef by the USDA-FSIS. The USDA-FSIS recommended culture-based method takes at least a week, and it does not fit high throughput settings. A number of PCR detection assays have been developed; none is capable of associating virulence genes with the STEC O-groups. Some multi-channel digital PCR systems disseminate a PCR reaction into hundreds or thousands of tiny reactions. Each reaction chamber can only hold a single to a couple of templates, providing the opportunity to differentiate if 2 or 3 genes are from a single genome or multiple genomes. Using Thermo Fisher QuantStudio 3D system (20K chambers/chip), we demonstrated, with both pure culture and culture-spiked cattle feces, that the gene association rates of *rfb*E-O157 and *stx*2 from the same genome was significantly higher than that from two separate genomes. The Fluidigm Biomark 37K chip (48 samples/chip, 770 chambers/sample) allowed us to associate each of the seven major O-groups with one of the *stx* genes. Gene association rates for strains that carry two genes were 67.3 to 90.5, with an average of 77.3 for culture and 74.6 to 88.0 with an average of 81.1 for culture-spiked fecal samples. The rates for the two genes carried by separate genomes were 8.7 to 28.8, with an average of 21.4 for culture, and 8.3 to 30.9, with an average of 13.9 for culture-spiked fecal samples. In addition, we were able to associate three genes, *rfb*E-O157, *stx*2 and *eae* from the same *E. coli* genome. We identified three O103 strains that carried *eae*, and three O45 strains that carried *stx*1 from cattle feces, and the whole process took two days. These results were confirmed by the traditional IMS-based isolation, followed by PCR confirmation. To our knowledge, this is the first report of the application of digital PCR system to detect and to associate major virulence genes with O-groups of STEC.

Photoarsenotrophy in Action

Author Block:

J. Hernandez, 95064[1], B. Stoneburner[1], M. Rosen[2], L. Miller[3], R. Ronald Oremland[3], C. Saltikov[1]; [1]Univ. of California Santa Cruz, Santa Cruz, CA, [2]United States Geological Survey, Carson City, NV, [3]United States Geological Survey, Menlo Park, CA

Abstract Body:

Anoxygenic photosynthetic arsenite oxidation "photoarsenotrophy" is a recently identified arsenic metabolism involving the inter-conversion of arsenite to arsenate and coupling to cellular energy production. Because arsenate is less toxic than arsenite, these microbes mediate the attenuation of arsenic toxicity in the environment. Little is known about the impact of photoarsenotrophic bacteria on arsenic biogeochemical cycling. Photoarsenotropy was first identified in *Ectothiorhodospira sp.* Str. PHS-1, cultured from a hot spring on Paoha Island Mono Lake, California. Big Soda Lake (Nevada), a hypersaline alkaline arsenic rich lake (similar to Mono Lake) is also known to have seasonal blooms of similar purple sulfur bacteria (PSB) (e.g. *Ectothiorhodospira* and *Chromatium*). The activities of photosynthetic arsenite oxidizing bacteria were investigated using anaerobic microcosm experiments with Big Soda Lake water collected within the PSB layer. High performance liquid chromatography-inductive coupled plasma-mass spectroscopy was used to detect and quantify arsenite and arsenate. Arsenite oxidation was observed initially in light incubated microcosms containing 50 µM arsenite. Cyclic arsenite oxidation/arsenate reduction was observed when shifting microcosms between light and dark conditions. However arsenate reduction occurred only in the dark. Neither reduction nor oxidation of arsenic was observed in autoclaved water samples, indicating that oxidation and reduction reactions were biologically mediated. The anaerobic arsenite oxidase gene, *arxA,* was detected in light-incubated samples, which was most similar to those within *Ectothiorhodospira* spp. The *arrA* gene for arsenate respiratory reductase was also detected in microcosms incubated in the dark, indicating that *arxA* and *arrA* might be mediating arsenic redox reactions. Big Soda Lake microcosm results support the potential occurrence of light dependent arsenite oxidation and coupling to arsenate reduction in the dark. These results suggest that light-dependent arsenic redox cycling could occur in other arsenic-impacted aquatic systems irrigated with arsenic rich groundwater, such as rice paddies in Bangladesh.

Parallel Uniform Sequencing of Microbial Aggregates by Barcode Droplet MDA

Author Block:

Y. K. LIght[1], M. Rhee[2], R. J. Meagher[1], A. P. Arkin[3], A. K. Singh[1]; [1]Sandia Natl. Lab., Livermore, CA, [2]Illumina Inc., San Diego, CA, [3]Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

Microbial aggregates naturally occurring in an environmental niche are representative of direct microbial interactions, thus understanding this scale of interactions allows us to predict relationships between species and environmental traits with high resolution. To be able to study microbial aggregates at the micron scale, genomic amplification prior to sequencing is required, owing to limited amount of genomic content from microbial aggregates. Multiple displacement amplification (MDA) is robust but it has shown amplification bias that results in uneven sequence coverage. Here, we have developed a platform for unbiased genomic amplification and high-throughput sequencing library preparation to process large number of microbial aggregates in parallel utilizing barcode MDA emulsion droplets. Initially, we used *Ecoli* K-12 MG1655 to perform droplet MDA and compare the evenness of sequencing coverage to that of conventional tube MDA. *E.coli* genomic DNA was denatured and fragmented after heat lysis of cells and each fragmented DNA was partitioned in an emulsion droplet containing MDA reaction mixture and hexamer primer. MDA DNA was pulled together and sequenced. The coverage of genomic DNA was determined by mapping contigs to the reference sequence after *de novo* assembly. For microbial aggregate study, hexamer primer with specific barcode was assigned to each aggregate to handle many aggregates in parallel and whole genome assemblies of members of each microbial aggregate and network analysis of microbial aggregates were performed from the multi-flexed sequence reads. For a sample containing 0.1 pg/µL of *E. coli* DNA (equivalent of ~3/1000 of an *E. coli* genome per droplet), droplet MDA achieved a 65-fold increase in coverage in de novo assembly compared to conventional tube MDA. Indexing of each microbial aggregate together with unbiased amplification utilizing droplet MDA enables us to sequence microbial aggregates with high-throughput and to provide improved sequence coverage of aggregate members. The promise, accordingly, is the ability to link phylogenetics to functional genetics of the members of the community.

Determination of Vancomycin Susceptibility for *Staphylococcus aureus* by Flow Cytometry

Author Block:

A. P. Silva, A. Silva-Dias, R. Teixeira-Santos, **S. Costa-de-Oliveira**, A. G. Rodrigues, C. Pina-Vaz; Faculty of Med., Univ. of Porto, Porto, Portugal

Abstract Body:

Background: Vancomycin MIC determination is recommended whenever considering its use in case of a severe *S. aureus* infection. Moreover, whenever therapeutic failure is suspected, testing for heteroresistant vancomycin intermediate *S. aureus* (hVISA) is also recommended. The methods available for detection of susceptibility to vancomycin are based on MIC determination by broth microdilution, by E-test or automated systems. The main disadvantage of such procedures, is that they require a long incubation period, needing a time to result (TTR) of at least 24h since they are based on growth. Flow cytometry (FC) is an accurate and fast approach for the analysis of cell architecture and its functional parameters. Herein, we propose a FC based approach to determine vancomycin MIC and hVISA strains. **Methods:** Thirty-five *S. aureus* isolates with vancomycin MICs ranging between 0.125 to 2 µg/mL; the Mu50 strain, a vancomycin intermediate *S. aureus* (VISA) strain, with MIC 8 µg/mL, and the Mu3 (hVISA) strain, with MIC 2 µg/mL, both kindly provided by Rafael Canton (Hospital Ramon y Cajal, Madrid), were studied. The vancomycin MIC values were determined by broth microdilution method. *S. aureus* cells were exposed to serial concentrations of vancomycin (from 0.03 to 16 µg/mL) during 1 h/37ºC and stained with a fluorescence probe for assessing membrane depolarization. Non-treated cells were used as control. Afterwards, cells were analyzed in a flow cytometer (BD Accuri™ C6 Cytometer) and a dedicated software. The percentage of depolarized cells exposed to each vancomycin concentration was compared to control cells. Regarding hVISA detection, the Mu3 strain was incubated with 4 µg/mL of vancomycin for 2 h/37ºC and the MIC value re-determined by FC. **Results:** The percentage of depolarized cells significantly increased comparing to control at MIC value plus/minus one dilution. For lower concentrations no significant changes were observed. The test revealed an excellent correlation with the microdilution method. Using FC test we were able to detect the heteroresistant strain; the MIC value increased after pre-incubation with vancomycin. **Conclusions:** We propose a new method for vancomycin MIC determination. The method is fast (TTR of 2h) and easy to perform; its high sensitivity can also be useful for detection of hVISA.

Improved Efficiency with Kiestra Total Laboratory Automation

Author Block:

D. R. Shibib, I. K. Dusich, R. B. Thomson, Jr.; NorthShore Univ. Hlth.System, Evanston, IL

Abstract Body:

Background:
Total laboratory automation (TLA) in Microbiology includes automated specimen processing, incubation, plate imaging, reading of high resolution plate images, and plate discard when results are finaled. We were first in the USA to install the Kiestra TLA System (BD, Sparks, MD) in December, 2014. As of February, 2016, all bacteriology specimen types have been validated and added to the TLA system. To assess the relative efficiencies of TLA compared to manual methods, all bacteriology tasks common to both systems were compared for similar lengths of time pre- and post-TLA installation.
Methods:
The number of bacteriology tests performed, hours worked, and FTEs used for a two week period pre-TLA (2014) and a corresponding two week period post-TLA (2016) were determined by reviewing laboratory records. Time and personnel required for all tasks, including specimen processing and inoculation, incubation, plate reading, identification of all isolates, antimicrobial testing of all pathogens, results reporting and discard of culture plates were counted. Time periods with full laboratory staffing were selected. A comparison of the data was performed.
Results:
During a two week period before TLA, when manual methods were used, 4,534 bacteriology tests were performed with 2,062.5 hours worked, amounting to 25.78 FTEs. During a two week period after TLA installation and validation of all bacteriology specimens, 5,032 bacteriology tests were performed with 1,828.25 hours worked, amounting to 22.85 FTEs. There was an 11.0% increase in bacteriology tests performed (498 tests) and an 11.4% reduction in FTEs required (2.93 FTEs) after the introduction of TLA. Manual methods resulted in 176 tests performed/FTE, while Kiestra TLA resulted in 220 tests/FTE, a 25% increase.
Conclusion:
Data from our first year of use indicate that Kiestra TLA, compared to manual methods, reduces the number of FTEs required to perform all bacteriology tasks resulting in a 25% increase in the number of tests performed/FTE. Ongoing development of automated MALDI-TOF target spotting and antimicrobial testing may further improve efficiency.

Performance of Ten Phenotypic Assays for the Detection of Carbapenemase-producing *Enterobacteriaceae*

Author Block:

P. D. Tamma, B. N. A. Opene, **P. J. Simner**; Johns Hopkins Hosp., Baltimore, MD

Abstract Body:

Background: The objective of this study was to compare the accuracy of 10 phenotypic assays for the detection of carbapenemase-producing Enterobacteriaceae (CPE).
Methods: A collection of 184 isolates including 112 isolates producing a variety of carbapenemases (CP) and 72 non-CP-producing (ESBL or AmpC producers +/- porin mutations) isolates were included in this study. All tests were set up on the same day from a common blood culture plate containing a pure culture of the isolate. The testers were blinded to the expected results. The sensitivity and specificity of each test was determined, with the molecular genotype serving as the gold standard.
Results: Table 1: Performance of ten phenotypic assays for the detection of CPE.

Predictors for Mortality in MERS (Middle East Respiratory Syndrome)-Infected Patients: Emphasis on Viral Load, Antibody Response and Clinical Manifestations

Author Block:

S. Park[1], K-H. Hong[2], J-Y. Lee[3], B-N. Kim[4], H. Pai[5], S-H. Park[6], E-C. Shin[6], J-P. Choi[2], S-H. Kim[1]; [1]Asan Med. Ctr., Seoul, Korea, Republic of, [2]Seoul Med. Ctr., Seoul, Korea, Republic of, [3]Dankook Univ. Hosp., Cheonan, Korea, Republic of, [4]Sanggye-Paik Hosp., Seoul, Korea, Republic of, [5]Han Yang Univ. Hosp., Seoul, Korea, Republic of, [6]KAIST, Daejeon, Korea, Republic of

Abstract Body:

Background: The combined interpretation of clinical manifestations with viral load and immune response help us understand the pathogenesis of viral infection. We thus analyzed the clinical manifestations with detailed viral shedding and antibody kinetics in MERS patients. **Methods:** We enrolled all patients admitted into 3 MERS-designated hospitals and obtained sputum and sera over the course of disease. The samples were tested by reverse-transcriptase polymerase chain reaction (RT-PCR) and the whole-virus indirect immunofluorescence antibody (IFA) test. **Results:** Of 30 patients with MERS, 6 (20%) died. The median time (IQR) to death from the symptom onset was 23 days (13-28). The median times (IQR) to the negative conversion of RT-PCR for MERS-CoV and the positive conversion of IFA titer (≥ 1:640) for MERS-CoV from the symptom onset were 19 days (15-21) and 18 days (17-23), respectively. Risk factors for mortality are shown in Table 1. Old age, low albumin, altered mentality, and high pneumonia severity index (PSI) score at admission were identified as risk factors for mortality. High viral loads in respiratory samples on 2 weeks (median Ct value 30.2 [survivor] vs. 27.1 [non-survivor], *P*=0.02) and low antibody titer (< 1:640) on 3 weeks (33% [3/9, survivor] vs. 100% [4/4, non-survivor], *P*=0.03) from the symptom onset during the course of disease were found as risk factors for mortality. **Conclusions:** These data suggest that patients with old age as well as those who neither control viral control nor mount adequate immune responses are associated with mortality in MERS-infected patients.

Table 1. Univariate analysis for predictors of mortality in MERS patients.

Value	**Total (n=30)**	**Survivor (n=24)**	**Death (n=6)**	***P***
At admission

Emergence of KPC-producing Urease-negative *Klebsiella pneumonia* in Corrientes, Argentina

Author Block:

J. Di Conza[1], M. E. Badaracco[2], Y. Calza[2], P. Chavez[2], R. Goyechea[2], M. Almuzara[1], C. Vay[1], M. Bangher[2], L. Soler[2], **G. Gutkind**[1], L. Peña[2]; [1]UBA, CABA, Argentina, [2]ICC, Corrientes, Argentina

Abstract Body:

Background: KPC-producing *K. pneumoniae* (KPC-Kpn) are severe nosocomial pathogens. To our knowledge, Corrientes has been free of KPC-Kpn outbreaks. This province limits and is a key for regional transit with Paraguay and Brazil. Dissemination of the hiperendemic ST 258 clone as well as ST11 and ST23 have been already reported. Our aim was to describe the molecular and clinical epidemiology of an atypical urease-negative KPC-Kpn clone. **Methods:** We conducted a prospective descriptive analysis of all patients with KPN-KPC infection (August 2015 to January 2016) in Corrientes, Argentina. Identification included conventional, semiautomated panels and MALDI-TOF. Antimicrobial susceptibility was performed by disk diffusion according to CLSI. Screening for carbapenemases (KPC) was performed by using APB disks, a modified Hodge and blue-Carba tests. bla_{KPC} was confirmed by PCR and sequencing. The clonal relatedness was investigated by ERIC-PCR and MLST. **Results:** A patient derived in August 2015 from a limiting province rendered a KPC-producing isolate (characterized as *Klebsiella* (*Raultella*) *terrigena* by API 20E (98%)) from an urine colonization. As the resistance profile made was unlikely, it was submitted for MALDI-TOF confirmation, which placed it as *K. pneumoniae*; urease production was negative. Since then, other 12 microorganisms with the same profile were recovered in two hospitals, 4 from rectal swabs, and 8 from clinically relevant samples (3 UTIs, 1 from an hepatic abscess, 2 from respiratory syndrome, a pancreatic abscess and a mediastinitis; the last 4 died). All isolates presented the same biotype with an antibiotic multiresistance profile, being only fully susceptible to amikacin. Further, all of them displayed identical ERIC-PCR electropherotype belonging to a single clonal type ST340. **Conclusions:** Our findings report a KPC-producing clone with an atypical urease reaction associated with nosocomial outbreaks. It also constitutes the first description of ST340 in Argentina alerting for the emergence of a non-ST258 clone, especially considering that urease-negative BLEE-producing *K. pneumoniae* have already been reported in Brazil.

Publishing Title:

Impact of Implementing Direct Stool Pathogen Detection on Test Volume and Results Delivery in a Patient-Centered Microbiology Laboratory Serving a Pediatric Population

Author Block:

S. Holt[1], M. V. Powers-Fletcher[2], A. Phillips[1], R. Grand-Pre[1], M. Dickey[1], A. Pavia[2], C. Stockmann[2], A. Blaschke[2], J. Daly[1]; [1]Primary Children's Hosp., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Diagnosis of infectious gastroenteritis (IGE) is complicated by the variety of potential causative pathogens with similar disease presentations. Laboratory detection of these pathogens often requires a combination of individual tests, including culture and molecular assays, which can delay diagnosis. Multiplex PCR panels, which test for multiple pathogens at once, have the potential to reduce turnaround time (TAT) and improve patient care. The purpose of this study was to determine the impact of implementation of the FilmArray (FA) GI panel (BioFire Diagnostics, Salt Lake City, UT) on ordering practices and results delivery in a pediatric patient-centered laboratory.

The FA GI panel assay, which contains 22 bacterial, parasitic, and viral targets, was available for clinical use at Primary Children's Hospital (PCH) during a 5 month study period (October 2015 - February 2016). All other stool tests for IGE remained orderable and included stool culture, viral antigen and molecular tests, and microscopy for ova/parasites. FA GI testing was performed on-demand, as soon as specimens were received by the laboratory and an instrument was available. Ordering practices, laboratory test volumes, and TAT were analyzed.

From the beginning to the end of the study period, the volume of FA GI tests ordered increased by 87.5%, while the volume of other stool testing decreased by half. The most striking declines were in adenovirus and rotavirus testing, followed by stool culture, with a 97.4%, 78.5% and 51.2% decrease, respectively. FA GI results were available within an average of 3.0 hrs from the time of specimen receipt, which was faster than the average time of 33 hrs ($p < 0.05$ using Student's t-test) required to obtain results for all of the same targets using traditional methods.

The results of this study suggest that physicians are willing to utilize direct molecular detection assays to assist with the diagnosis of IGE in a pediatric patient population. Implementation of this assay correlated with a reduction in traditional stool tests ordered and decreased results TAT; future studies to determine the impact on clinical outcomes and healthcare costs are required.

Metagenomic Evaluation of Sink Trap Biofilms as a Nosocomial Reservoir for Carbapenemase Producing Gammaproteobacteria

Author Block:

P. Subramanian[1], N. A. Hasan[1], C. Grim[2], A. Mathers[3], R. Colwell[1]; [1]CosmosID, Inc., Rockville, MD, [2]CFSAN U.S. FDA, Laurel, MD, [3]Univ of Virginia Sch of Med, Charlottesville, VA

Abstract Body:

Background: Carbapenemase producing bacteria are an increasing threat to hospitalized patients and a full understanding of nosocomial transmission has yet to be realized. The biofilm in sink traps has long been recognized as a biologically active community but little is known about how to evaluate the presence of highly resistant organisms or the risk they could pose to patients. We adapted a novel genomic approach to evaluate a sink trap as a hospital reservoir for carbapenemase organisms. **Method:** 15 *Klebsiella pneumoniae* carbapenemase (bla_{KPC}) *Aeromonas* sp. and Enterobacteriaceae clinical isolates collected between 2/2012-5/2013 paired with 9 sink trap biofilm samples from the same hospital (3/2014) underwent whole genome shotgun sequencing using an Illumina MiSeq and metagenomic analysis using CosmosID's MetaGenID software. To determine if patient isolates were present in the biofilm, their genomes were added to the MetaGenID bacterial database. The biofilm metagenomes were examined using this supplemented database. Both biofilm samples and patient isolates were also profiled using the MetaGenID antimicrobial resistance and virulence gene database. Genes with partial match to a biofilm sample at >50% coverage and > 80% isolate coverage were aligned, using BLAST, to a characterized bla_{KPC} plasmid. **Result:** 7 patient isolates were identified as present in the sink biofilms indicating that the sink trap biofilm can act as a sustained reservoir over time. Of 303 antibiotic resistance and virulence associated genes found in the biofilm samples and patient isolates, the majority (n=190) were plasmid associated. The remaining genes not on the plasmid, with the exception of a single virulence factor, were found only in the biofilms. All genes present and common to multiple biofilm samples and patient isolates (including those isolates not identified in the biofilms) were plasmid associated. **Conclusion:** We have applied a novel approach to understand a nosocomial reservoir of drug resistance which can sustain plasmid based genes of resistance shared between environmental and patient isolates. Based on these results, we conclude that biofilms can create a niche for sustaining clinically relevant multidrug resistance organisms (MDROs) in a hospital.

Creation GARD (Genotype-linked Antibiotic Resistance Database)

Author Block:

J. W. Kim, 95060[1], P. Chan[2], T. M. Lowe[2], M. Barlow[3], M. Camps[1]; [1]Univ. of California, Santa Cruz, Santa Cruz, CA, [2]Maverix Biomics, Inc, San Mateo, CA, [3]Univ. of California, Merced, Merced, CA

Abstract Body:

We are establishing a cloud-based data-sharing and sequence analysis platform called GARD (Genome-Linked Antibiotic Resistance Database), which is decentralized by design and has data-sharing protocols that are compatible to the exchange standards for broad sharing of clinical human genomic data.
We are populating this platform by sequencing strains of extraintestinal pathogenic *E. coli* exhibiting unique profiles of extended-spectrum β-lactam resistance (ESBL), as measured using MIC assays for a panel of nine β-lactam antibiotics. These isolates were obtained through a collaboration with Mercy Hospital in Merced, California.
Here, we present the results of sequencing 22 of these strains using MiSeq technology. Based on MLST typing and phylogenetic analysis across all protein-coding SNPs, our samples are largely comprised of ST131 (13 of 22 strains), with the remaining 9 strains distributed across 7 sequence types.
We detected four classes of β-lactamase genes: plasmid-borne TEM (10), CTX-M (16) and OXA (13), and chromosomal AmpC. Nine of the TEM genes and all the OXA and AmpC genes lacked the mutations associated with ESBL activity. Genes encoding four CTX-M variants were found: CTX-M-14, 15, 65 and 27. The presence of CTX-M genes showed a high correlation with resistance to 3rd generation (and to a lesser degree 4th generation) cephalosporins, particularly ceftriaxone ($r = 0.99$ with 22 samples, $p = 0.0$). Our clinical data also suggests that TEM-1 can be sufficient for conferring resistance against cefazolin (2nd generation), consistent with prior experimental reports.
Overall, our initial results suggest that β-lactamase sequences can be used to classify ESBL phenotypes more accurately than previously reported, although additional mechanisms of resistance still appear to be at play. As it develops further, GARD should serve as a knowledge base for monitoring the spread of resistance to ESBLs and other classes of antibiotics, for identifying mobile genetic elements facilitating its spread, and for diagnosis of antibiotic resistance.

Genotyping and Phenotypic Analysis of Hybrid Strains of *Escherichia coli* (EAEC/UPEC) Isolated From Urinary Tract Infections

Author Block:

F. B. M. Lara[1], D. R. Nery[1], P. M. d. Oliveira[1], M. L. Araujo[1], L. B. Ferreira[2], A. L. Pereira[1]; [1]Univ.e de Brasília, Brasília, Brazil, [2]Hosp. Reginal de Ceilândia, Brasília, Brazil

Abstract Body:

Background: The diversity of behaviors showed by *E. coli* strains is supported by a high genetic plasticity that allows the transfer and maintenance of a diversity of virulence genes among *E. coli* strains. The aim of this study was caried out the genotyping and the phylogenetic analysis of *E. coli* strains isolated from urinary tract infections treated in a hospital of Brasília-DF, Brazil. **Methods:** Strains were tested for the presence of 6 virulence genes of UPEC (*focA*, *pap*, *vat*, *fyuA*, *chuA* and *yfcV*), 2 of MNEC (*cnf* and *sfa*), 2 of EAEC besides *csgA* (curli fimbriae) and *ag43*. Amplification and sequencing of the genes *dinB* (DNA polymerase) and *icdA* (isocitrate dehydrogenase) were employing in the phylogenetic analysis. *dinB-icdA* concatenated sequences (966 base-long sequences) were used in bootstrap analysis (with 1000 replications) in order to infer phylogenetic relationship among strains. **Results:** The most frequently detected genes were *chuA* (78% - 62/78), *csgA* (76% - 61/78) and *fyuA* (69% - 54/78). EAEC genes (*p*CVD432 and *agg*R) were detected in 3,8% (3/78) of UPEC strains. Forty different genotypes were detected among tested strains. Hybrid genotypes (EAEC/UPEC) were identified in 3 strains as follows: *fyuA+ chuA+ pap+ csgA+ ag43+ pCVD+ aggR+* in EAEC strain 1.1; *fyuA+ vat+ focA+ pap+ csgA+ ag43+ pCVD+ aggR+* in EAEC strain 1.2; and *fyuA+ chuA+ pap+ csgA+ pCVD+ aggR+* in EAEC strain 1.3. Twenty one strains with the most common genotypes and the hybrid strains EAEC/UPEC were selected for the phylogenetic analysis. In phylogenetic tree, EAEC/UPEC strains 1.1 and 1.3 compose a large cluster along with 7 UPEC strains. Branching of this cluster was supported by a bootstrap value of 98. In this cluster, 6 of out 7 strains displayed the combination *fyuA+ chuA+ pap+ csgA+* as shared gene set. **Conclusions:** Our data showed that heteropathogenic EAEC/UPEC strains can cause extraintestinal infections. Additionally, the data raise the possibility that typical genes of EAEC strains can be transferred to and stably maintained by UPEC strains, what can lead to the emergency of heteropathogenic categories.

Intradermal Accumulation of Doxycycline Could Explain its Anti-Inflammatory Action on Rosacea

Author Block:

P. Matzneller, E. Lackner, M. Zeitlinger; MUV, Vienna, Austria

Abstract Body:

Background: Doxycycline (DOX) is approved for the treatment of rosacea. The drug's therapeutic efficacy is believed to be based on its anti-inflammatory properties rather than on a direct antibacterial effect. However, DOX pharmacokinetics (PK) in human skin, i.e. the target site for this indication, has to date not been described. This study was designed to measure single (SD) and repeated dose (RD) PK of DOX in plasma and skin of healthy volunteers (HV) during oral therapy with DOX. **Methods**: 6 HV received 40 mg DOX delayed release capsules orally once daily for 7 days. After dosing on days 1 and 7, DOX levels were assessed in plasma and skin of HV. Skin measurements were done with microdialysis. **Results:** Concentration-time profiles of DOX in plasma and skin of HV are shown in figure 1. Mean ± SD C_{max} and $AUC_{0\text{-}24h}$ as well as median (min-max) t_{max} of total DOX in plasma were 409.5 ± 145.9 µg/L, 4051.2 ± 985.3 µg·h/L and 1.5 (1.5-2.5) h after SD and 529.8 ± 80 µg/L, 6432.6 ± 853.6 µg·h/L and 1.5 (1.5-2.5) h after RD, respectively. Mean ± SD C_{max} and $AUC_{0\text{-}24h}$ as well as median (min-max) t_{max} of unbound drug in skin of HV were 90.7 ± 35.2 µg/L, 1036 ± 519.7 µg·h/L and 2.8 (2.3-6.5) h after SD and 255.4 ± 82.6 µg/L, 3232.2 ± 1130.6 µg·h/L and 3.8 (1.3-8.5) h after RD, respectively. Assuming 90% plasma protein binding, skin to plasma ratios of C_{max} and $AUC_{0\text{-}24h}$ of unbound DOX were 2.4 and 2.1 on day 1. They increased to 4.1 and 4.8, respectively, after 7 days of therapy. Interestingly, post-dose C_{min} to pre-dose C_{min} ratios of > 1 for both compartments indicate incomplete achievement of steady-state. **Conclusions:** Pronounced accumulation in the interstitium of human skin may help explaining the activity of DOX against inflammatory skin diseases such as rosacea. This accumulation might be enhanced at steady-state and in intracellular compartments.

Publishing Title:

Robust Potentiation of Known Antimycotic Agents with Molecular Replacement Therapy for the Topical Treatment of Tinea Infections

Author Block:

S. Ghosh[1], R. S. Patel[1], S. P. Kaur[1], S. Sadhasivam[1], K. K. Aavula[1], M. Sinha[1], A. Bhattacharyya[1], D. Kumar[1], A. Jain[1], S. Ghosh[1], S. Sengupta[2]; [1]Vyome BioSci.s Pvt. Ltd, Delhi, India, [2]Brigham & Women's Hosp., Cambridge, MA

Abstract Body:

Dermatophytoses, also known as tinea, are fungal infections of the skin rampant among the human population. *Trichophyton* spp. are dermatophyte fungi that invade and grow in the keratin of skin, hair and nails and are responsible for causing these infections. Depending on the site of infection, various topical anti-mycotics show efficacious therapeutic benefits in the treatment of tinea while many fail to achieve the desired therapeutic outcome. In recent years there have also been reports of drug resistance in dermatophytes that further aggravate the clinical scenario. Potentiation of known agents and achieving their effective concentrations in skin thus remains an area of active research for the development of anti-tinea products. In this study we report that our proprietary Molecular Replacement Therapy (MRT) platform potentiates the *in vitro* antifungal activity of different classes of antimycotics including azoles and allylamines against *Trichophyton* spp. as demonstrated through time kill assays. Our data suggest a synergistic action of the MRT agent with various antifungals against *T. rubrum*. We further show that clinical isolates of *Trichophyton* spp. resistant to fluconazole and terbinafine are efficiently inhibited by topical formulation(s) of certain azoles or terbinafine with MRT. This platform technology not only imparts enhanced *in vitro* fungal killing but also causes enhanced skin penetration and allows higher deposition of the active anti-mycotic agent in rat skin as observed in an *in vivo* dermal PK study. Therefore a two-pronged effect comprising an immediate impact of the formulation on fungus residing in the upper layers of the skin followed by a long term sustained effect of higher retained amount of actives on fungus residing in deeper layers of the skin becomes evident.

Publishing Title:

Superior Efficacy and Improved Renal and Bone Safety After Switching from a Tenofovir Disoproxil Fumarate (TDF) Regimen to a Tenofovir Alafenamide (TAF) Based Regimen Through 96 Weeks (W96) of Treatment

Author Block:

E. DeJesus[1], B. Haas[2], S. Segal-Maurer[3], M. Ramgopal[4], A. Mills[5], Y. Liu[6], S. McCallister[6]; [1]Orlando Immunology Ctr., Orlando, FL, [2]Medizinische Univ.t Graz, Graz, Austria, [3]NY Hosp., Flushing, NY, [4]Midway Immunology Ctr., Ft. Pierce, FL, [5]So. CA Men's Hlth.Group, Los Angeles, CA, [6]Gilead Sci. Inc., Foster City, CA

Abstract Body:

Background: TAF is a tenofovir (TFV) prodrug with a 90% reduction in free TFV plasma levels compared to TDF. Week 48 (W48) data from this large switch study demonstrated a significantly higher rate of virologic suppression and statistically significant improvements in renal function and bone density. Data from W96 comparing those maintaining their prior TDF-based regimen to those switching to elvitegravir 150 mg, cobicistat 150 mg, emtricitabine 200 mg, & TAF 10 mg (E/C/F/TAF) are presented.
Methods: GS-US-292-0109 is an ongoing, active controlled, open-label international study in which virologically suppressed subjects on one of three TDF-based regimens (E/C/F/TDF, EFV/FTC/TDF, or boosted ATV + FTC/TDF) were randomized 2:1 to switch to E/C/F/TAF or to maintain their prior regimen. Efficacy and safety data through W96 following the switch are summarized.
Results: 910/959 (95%) of subjects randomized to E/C/F/TAF and 434/477 (91%) of those who continued on a TDF-based regimens completed W96 in this study. Virologic success rates (HIV-1 RNA less than 50 copies/mL): E/C/F/TAF 93%; TDF-based regimen 89% (p=0.017; difference 3.7%; 95% CI 0.4-7.0%). AE-related discontinuations occurred in 0.9% of those on E/C/F/TAF and in 2.5% of those who maintained their TDF-based regimen. Key safety data at W48 and W96 are shown in the table below. **Conclusions:** Switching to E/C/F/TAF from a TDF-based regimen resulted in superior virologic control and in significant improvements in both renal function and in bone density through W96. For those switching to E/C/F/TAF, these differences persisted from W48 to W96.

Safety data, W48 & W96

		E/C/F/TAF		TDF-based regimen		p value
		W48	W96	W48	W96

Efficacy of a Human Monoclonal Antibody with Biofilm Disrupting Activity in a Rat Infective Endocarditis Model due to Methicillin-Resistant *Staphylococcus aureus* (MRSA)

Author Block:

Y. Q. Xiong[1], A. Bayer[1], A. Estelles[2], E. Tenorio[2], **A. Leighton**[2], S. Ellsworth[2], S. Ryser[2], L. Kauvar[2]; [1]David Geffen Sch. of Med. at UCLA, Torrance, CA, [2]Trellis BioSci., Menlo Park, CA

Abstract Body:

Background: Many serious bacterial infections are associated with biofilm formation. TRL1068 is a high affinity native human antibody against a biofilm epitope conserved across both Gram-positive and Gram-negative bacterial species. **Methods:** TRL1068 was evaluated in a catheter-induced aortic valve IE rat model (Xiong et al., 2005, *AAC)*. Rats were infected with a clinical isolate (MRSA strain 300-169; associated with persistent bacteremia). Animals were treated with 6 days of vancomycin (n=8; VAN: 120 mg/kg, SC, bid) alone or in combination with TRL1068 (n=10) or isotype control antibody (n=8); each at 15 mg/kg, iv, QD on days 1 and 4. MRSA burden was quantified at day 7 sacrifice (mean $\log_{10}$CFU/g tissue ± SD) (cardiac vegetations, intracardiac catheter, kidney, spleen and liver). **Results:** MRSA densities in vegetations showed ≥ 1.75 log reduction in the TRL1068 + VAN arm vs. isotype control + VAN arm ($P<0.001$). Significant reductions in CFUs was also observed for intracardiac catheters, kidneys, spleens and livers ($P<0.05$) for the VAN + TRL1068 arm vs both VAN + isotype and isotype alone arms. A trend towards mortality reduction in the VAN + TRL1068 arm was also observed ($P=0.09$). **Conclusions:** The reduced bacterial burden and mortality following combination therapy with TRL1068 + VAN supports further development of TRL1068 for the treatment of endovascular and other serious infections associated with biofilm formation.

Publishing Title:

Cytotoxic Properties of 50kDa Protein Isolated from *Streptomyces A13* Against A549 Human Lung Cancer Cells and AA8 Healthy Hamster Cells

Author Block:

M. L. Delos Santos[1], H. Banocnoc[1], M. Badong[1], J. Nacional[1], T. Zulaybar[2]; [1]Dept. of Ed., Makati City, Philippines, [2]Inst. of Molecular Biology & Biotechnology UP Los Banos, Laguna, Philippines

Abstract Body:

Background: *Streptomyces* are known to produce anticancer compounds that are effective inhibitors of some cancer cells. As such, we would like to determine if 50 kDa protein from *Streptomyces* A13 have cytotoxic properties against A549 lung cancer cells and AA8 Healthy Hamster Cells. **Methods:** A13 were grown on Croatian Vegetative Medium. Cells were separated by centrifugation at 3,000 rpm. Extraction of the proteins from the cells was performed through ammonium-sulfate precipitation. Protein content was measured by the Bradford Method with bovine serum albumin as the reference protein. The precipitated proteins were analysized for size by denaturing PAGE using standard procedures. The ammonium sulfate-precipitated broth (B1) sample and cell extract were used for the MTT assay. Identification of A13 was done using the 16s rRNA full gene sequence. **Results:**The protein concentration was highest with the B1 (446.323ug/mL) followed by the spent medium (215.700 ug/mL), cell extract (96.158ug/mL) and least in the PEI pellet (65.166ug/mL).This high protein concentration in B1 as compared to the cell extract may be explained by their extrusion from the cell. A13 cell extract and B1 were found cytotoxic against the A549 lung cancer cells having mean IC_{50} values of 4.37013 µg/ml and 4.54037 µg/ml respectively while the positive control had a mean IC_{50} value of 2.27627 µg/ml. It was also found that the crude extract of A13 was less cytotoxic against AA8 healthy hamster cells having an IC_{50} value of 3.6794 µg/ml compared to the IC50 value of the positive control which was 1.8370. BLAST result of the 16s rRNA for A13 yielded 99% homology to *Streptomyces costaricanus, Streptomyces padanus* and other 15 Stre*ptomyces sp*. isolates. **Conclusions:** We conclude that the 50kDa protein from *Streptomyces* A13 is a potential source of chemotherapeutic agent against A549 and its less toxic compared to the positive control.

Novel Compound from *Variovorax paradaxux S110* Kills *Mycobacterium tuberculosis*

Author Block:

M. Espinoza-Moraga, H. I. Boshoff, C. E. Barry, III; NIH, Bethesda, MD

Abstract Body:

Bacterial natural products are a varied and rich source of undiscovered anti-tuberculosis (TB) drugs with unique scaffolds and/or novel mechanisms of action. Due to the threats of anti-TB drug resistance keep growing, we are in urgent need of new drugs to treat the disease. Sphagnum peat bogs are acidic and hypoxic environments, with similar conditions to those encountered in tuberculous granulomas. Moreover, these habitats are also major natural reservoirs of mycobacterial and competing species. These factors support sphagnum peat bogs as ideal sources of novel anti-mycobacterial compounds. Here we reported a novel compound from a bog bacteria capable to inhibit selectively *M. tuberculosis.*

Sphagnum bog samples were collected across Northeastern US. Bog bacteria producing inhibitory activity against *M. tuberculosis* (MIC ≤50 μg/ml) were isolated and genotyped by their 16S rRNA gene sequence. PacBio was used to sequence the whole bacterial genome, and biosynthetic gene clusters were identified using automated bioinformatics software PRISM and anti-SMASH 3.0. Active metabolites were purified from bacterial biomass samples using gel filtration chromatography and further characterized by LC-MS and NMR. Subsequent transcriptional profiling of *M. tuberculosis* treated with the most active metabolite yielded signatures indicating novel mechanisms of action.

Bog bacteria, including *Pedobacter*, *Pantoea*, *Pseudomonas*, *Chryseobacterium*, *Streptomyces*, and *Variovorax* were found to produce secondary metabolites against *M. tuberculosis.* One positive hit, identified as *Variovorax paradaxus strain S110*, was selected for whole genome sequencing based on scarce prior reports of associated natural products and exclusive and potent activity of the active agent against *M. tuberculosis* (MIC <0.39 μg/ml; other species MICs >200 μg/ml). Three novel non-ribosomal peptide (NRP) or hybrid NRP/polyketide (PK) biosynthetic gene clusters were identified. Based on the *in silico* predict structure, bioactivity-guided fractionation and spectrometric tools, a novel peptide was identified.

Our findings indicate that a novel compound with unique scaffolds and/or novel mechanism of action can be fully isolated and characterized from *V. paradaxus S110*. This new compound has the potential to form a basis for new anti-TB classes addressing bacterial targets that are currently underexploited.

Treatment of Adenovirus Infection in Solid Organ Transplant with Brincidofovir

Author Block:

M. Grimley[1], D. Florescu[2], E. Vainorius[3], T. Brundage[3], G. Nichols[3]; [1]Cincinnati Children's Hosp., Cincinnati, OH, [2]Univ. of Nebraska Med. Ctr., Omaha, NE, [3]Chimerix, Inc, Durham, NC

Abstract Body:

Background: Disseminated adenovirus (AdV) infection is increasingly described in solid organ transplant (SOT) recipients, particularly in pediatric patients, in whom the infection can be rapidly fatal following diagnosis. The investigational antiviral, Brincidofovir (BCV), has been administered through an expanded access trial (Study CMX001-350) and an open-label trial of serious AdV infection (Study CMX001-304) to patients who are immunosuppressed following SOT. Herein we describe the characteristics and outcomes of 26 SOT recipients who received BCV for serious AdV infection. **Methods:** Pediatric and adult patients who had undergone solid organ transplantation and who were diagnosed with serious AdV infection were treated with BCV 100 mg twice weekly (BIW) or, for children <50 kg, 2 mg/kg BIW. Descriptive statistics are presented for categorical variables, and medians (range) for continuous variables. **Results:** 26 pediatric and adult patients were treated with BCV. 73% of patients were pediatric (n=19; <18y), with a median age 8y (range 8m to 58y) and received BCV for a median of 8.5 wks. The most prevalent transplant type was liver (n=12; 11 pediatric subjects), although in adults lung (n=3) and kidney or kidney/pancreas (n=3) were predominant. 54% (n=14) of AdV infections were disseminated disease. 69% (n=18) subjects presented with median 3.7 $\log_{10}$ c/mL, baseline viremia (range <LLOQ to >ULOQ). Of these, 89% (n=16) were not quantifiable (<190 c/mL) at some point on treatment and 83% (n=15) were not quantifiable at end of treatment. 19% (n=5) of subjects died while in the study, with a median follow-up to 22 wks (range 1 week to 39 weeks). **Conclusions:** In this limited cohort of predominantly pediatric patients who had undergone SOT, a significant, and sustained adenoviral suppression was noted that might be attributed to treatment with BCV. BCV continues in development as the first potential treatment for serious AdV infection in immunocompromised patients. Additional study of BCV in treatment of AdV infections in SOT recipients is needed to address the clinical improvement associated with viral suppression of AdV viremia.

Daptomycin Resistance Associated with Loss of Function Mutation in Staphylococcus aureus

Author Block:

E. M. Barros[1], M. J. Martin[2], E. M. Selleck[2], J. L. M. Sampaio[1], M. S. Gilmore[2]; [1]Faculdade de Ciencias Farmaceuticas, Univ.e de Sao Paulo, Sao Paulo, Brazil, [2]Harvard Med. Sch., Massachusetts Eye and Ear Infirmary, Boston, MA

Abstract Body:

Antibiotic resistance is increasing among *Staphylococcus aureus,* and often spreads throughout the bacterial population rapidly. Recently introduced drugs, such as daptomycin, represent the last line treatment options. However, resistance to daptomycin is also beginning to emerge. The mechanisms of daptomycin resistance (DAP-R) in *S. aureus* are diverse and complex, and remain to be fully elucidated. To identify genetic changes that can confer DAP-R in *S. aureus,* we used a highly saturating library of transposon insertions in the genome of *S. aureus* HG003 to screen for resistant mutants with enhanced survival in presence of daptomycin. Sixteen colonies were selected for further characterization. In this collection, transposon insertions were observed in two genes and they were further identified by arbitrarily primed PCR and sequence analysis. One gene encodes a hypothetical lipoprotein (*362*) and the other an alkaline shock protein (Asp23). Targeted deletions constructed by homologous recombination were generated for each of the two genes, followed by phenotypic analysis. Mutants *Δ362* and *Δasp23* exhibited a slightly higher MIC (2 μg/ml) to daptomycin than wild type. Mutant 362 also showed a slightly higher MIC (2 μg/ml) to vancomycin. Importantly, when the MBC was examined, a much higher tolerance for vancomycin was noted for both mutants (32 μg/ml for *Δ362*; 64 μg/ml for *Δasp23* and 2 μg/ml for wild type strain). By killing curve assay the mutant strains showed reduced bacterial mortality in presence of high antibiotic concentration (5X MIC) compared to the wild type strain. Neither mutation was associated with a fitness cost. Both mutants were able to grow in the presence of 1ug/mL daptomycin. These findings identified novel genes that contribute to the tolerance of *S. aureus* to daptomycin and vancomycin. Reduced susceptibility associated with loss of function mutations that has not previously been observed.

Development and Application of Microfluidic Devices in Time Course Studies of Microbial Symbiosis in Individual, Living *Steinernema* Nematodes

Author Block:

M. D. Stilwell, M. Cao, D. B. Weibel, H. Goodrich-Blair; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Background: Animal-microbe symbioses are ubiquitous phenomena with great importance in medical and agricultural sciences. *Steinernema* nematodes and *Xenorhabdus* bacteria have been established as a successful model system to investigate microbial pathogenesis and mutualism, the two extremes of symbiotic relationships. The bacterium *Xenorhabdus nematophila* forms a mutualistic relationship with *Steinernema carpocapsae* nematodes, colonizing a specialized intestinal pocket of the nematode host in a species-specific manner, and together they infect a wide range of insects. During their lifecycle, certain networks of bacterial genes are regulated to confer either pathogenic or mutualistic states depending on the environment and host. The *X. nematophila* global transcription regulator, leucine-responsive regulatory protein (Lrp), is crucial for controlling gene expression necessary for both pathogenesis and mutualism. However, current understanding of Lrp-regulated bacteria-nematode interactions is based solely on population level, single time point studies, since investigating *in vivo* temporal dynamics of these interactions is impeded by the difficulty of isolating and maintaining individual living nematodes in which bacteria can be observed over time. **Methods:** To overcome this challenge, we developed a microfluidic device that enables us to isolate and microscopically observe individual, living *Steinernema* nematodes. We characterized both wild type and *lrp* null mutant *X. nematophila* bacterial populations within these nematodes over 5 days. **Results:** Our data are consistent with population level studies of Lrp-dependent bacteria-nematode symbiosis. We also find that compared to wild type, nematodes co-cultured with *lrp* mutant carry a more loosely packed symbiont population and display higher mortality. **Conclusions:** We present our current progress in this research, which provides new perspectives into animal-bacterial symbioses with, to the best of our knowledge, the first direct time course study of individual living animal hosts and their bacterial symbionts.

Iron Sensing via a Catalytically Divergent Rhomboid Protease

Author Block:

S. Nambi; Univ. of Massachusetts Med. Sch., worcester, MA

Abstract Body:

Environmental sensing in prokaryotes can be accomplished by the release of regulatory proteins from the membrane following two sequential proteolytic events. In *Mycobacterium tuberculosis* (Mtb), final release of anti-sigma factors is mediated by Rip1, a zinc metalloprotease similar to other described site-2 proteases. However, orthologs of known periplasmic site-1 proteases that sense environmental signals and initiate the cascade in Mtb were shown to be inactive. We report here, a previously un-annotated and highly divergent member of the rhomboid family of intramembrane proteases, which we term, catalytically divergent 'cdRhom', performs this activity. Despite lacking a canonical rhomboid active site, Rv3193c (RomA) uses distinct catalytic residues to perform the site 1 cleavage of the anti-sigma factor (RsmA), priming it for processing by Rip1. A physical interaction between the PDZ domain of Rip1 and a proline-rich region in extracytoplasmic domain of RomA facilitate the signaling cascade. Structural analysis of the extracytoplasmic domain revealed a conserved iron coordination site, indicating a likely environmental trigger for this system. Indeed, we found that RsmA processing was altered by iron concentration, and RomA-deficient bacteria were unable to replicate in low iron conditions due to altered levels of iron homeostatic genes. The substrate topology, active site, and sensory domains of cdRhom impart an environmental sensing function that is unprecedented for this family of proteins.

The ArlRS-MgrA Regulatory Cascade Modulates Clumping and Virulence in Staphylococcus aureus

Author Block:

H. A. Crosby, P. M. Schlievert, A. R. Horswill; Univ. of Iowa, Iowa City, IA

Abstract Body:

Staphylococcus aureus causes a wide variety of superficial and invasive infections, including septicemia, osteomyelitis, and endocarditis. Its pathogenicity is dependent on expression of virulence factors such as toxins, secreted enzymes, and adhesins. Several *S. aureus* adhesins bind to fibrinogen, an abundant component of human plasma. When *S. aureus* interacts with fibrinogen or whole plasma it forms macroscopic clumps, a process termed clumping. This behavior is thought to aid in immune evasion, and it can also promote the formation of vegetations on heart valves, leading to endocarditis. Our laboratory recently demonstrated that clumping of *S. aureus* is regulated by the two-component system ArlRS. Little is known about ArlRS, although multiple studies have shown that *arlRS* mutants are less virulent. An *arlRS* mutant fails to form clumps in the presence of human plasma or fibrinogen, and the mutant is attenuated in a rabbit model of infective endocarditis. How ArlRS affects clumping and virulence was not well understood, though. We demonstrate here that ArlRS activates expression of the global regulator MgrA. Like *arlRS* mutants, *mgrA* mutants are also unable to clump, and are attenuated in infective endocarditis. RNA-seq analysis of an *mgrA* mutant showed that MgrA represses expression of up to eight putative and known adhesins, including Ebh, a giant ~1.1 MDa membrane-anchored surface protein, and SraP, a large cell wall attached protein. EMSA analysis, combined with transcriptional reporters and qRT-PCR, confirmed that MgrA directly represses *ebh* and *sraP*. We found that clumping could be restored to an *mgrA* mutant by deleting the genes for Ebh and SraP, suggesting that overexpression of these large surface proteins blocks clumping through steric hindrance. Deletion of *ebh* and *sraP* also partially restores virulence to an *mgrA* mutant. Taken together, these results demonstrate that ArlRS and MgrA constitute a regulatory cascade that controls expression of many genes, including the genes for eight large surface proteins. Regulation of these surface proteins has broad effects on the behavior of *S. aureus* in the presence of host proteins and inside a host.

Virulence Factor Regulators Control CRISPR-Cas Gene Expression in *Pseudomonas aeruginosa*

Author Block:

B. Castro, **J. Bondy-Denomy**; Univ. of California, San Francisco, San Francisco, CA

Abstract Body:

CRISPR-Cas systems are bacterial immune systems that present a formidable barrier to bacteriophage (phage) infection. Although many aspects of CRISPR-Cas function and mechanism have been well characterized *in vitro* and *in vivo*, the regulatory cues that control these processes are poorly understood in most microbes. This is the case in *Pseudomonas aeruginosa*, an organism that has become a widely used model system for studying all aspects of CRISPR-Cas function. Here, we describe a genetic screen to identify regulators of CRISPR-Cas expression and efforts to map the regulatory components for CRISPR-Cas operons in this organism. We have detected *kinB* as a sensor kinase/phosphatase that is required for optimal CRISPR-Cas expression. Through *in vivo* mutant analysis, we show that the important activity of KinB is not its kinase function but its ability to dephosphorylate its cognate response regulator, AlgB. In the absence of KinB, phosphorylated AlgB activates previously identified global virulence regulators AlgR and AlgU, which we show leads to CRISPR-Cas repression. Why do virulence regulators in *P. aeruginosa* control CRISPR-Cas expression? We speculate that this could be optimized to reflect phage infection risk, and/or that this CRISPR-Cas system may possess alternative gene regulatory functions. Further, through crRNA engineering, we have shown that the Type I CRISPR system in *P. aeruginosa* is able to repress and activate gene expression through base pairing in the absence of cleavage. Therefore, this work provides novel insight into the regulatory inputs for CRISPR-Cas function and also suggests regulatory outputs for CRISPR-Cas-dependent gene regulation through base pairing. Finally, the ability to design crRNAs rationally provides a facile and exciting new technology for gene regulation manipulation in this and other microbes.

A Novel Type of Mobile DNA: How the *qacC* Gene Has Recently Spread Between Rolling Circle Plasmids of *Staphylococcus*

Author Block:

T. M. Wassenaar[1], H. Ingmar[2], D. W. Ussery[3]; [1]MMGC, Zotzenheim, Germany, [2]Univ. of Copenhagen, Frederiksberg C, Denmark, [3]Oak Ridge Natl. Lab., Oak Ridge, TN

Abstract Body:

Background: Resistance of *Staphylococcus* species to quaternary amonium compounds, frequently used as desinfectants and biocides, is due to presence of various Qac genes. Various Qac genes belong to the Small Multidrug Resistant protein family; these are mostly, though not exclusively, found on rolling-circle replicating (RC-) plasmids. Four classes of Qac genes are found in *Staphylococcus* species: QacC, QacG, QacJ and QacH. Within their class these genes are conserved, but QacC is extremely conserved, while present in variable plasmid backgrounds. The lower degree of sequence identity of these plasmids compared to the strict nucleotide conservation of their QacC gene suggests that this gene is a recent addition to these plasmids. **Methods:** By sequence comparison, we searched for an explanation how this gene was mobilized in absence of insertion sequences or other mobile elements. Publically available sequences of *qacC*, their flanking sequences and the replication gene that is invariably present in RC-plasmids were compared, to reconstruct the evolutionary history of these plasmids and the recent spread of QacC. **Results:** A new model of gene mobility is proposed that explains how *qacC* can be transfered to recipient RC-plasmids without assistance of other genes, by means of its location in between the double strand replication origin DSO and the single-strand replication origin SSO. **Conclusions:** The proposed mobilization model explains all sequence conservation observations. It represents a novel mechanism of gene mobilization in RC-plasmids, by which other genes, such as *lnuA* (conferring lincomycin resistance) is likely to be transferred as well.

Expression of Active Human Akt Protein Kinase in *Saccharomyces cerevisiae* Overruns PtdIns4,5P_2 Signaling Pathways

Author Block:

I. Rodriguez-Escudero, T. Fernandez-Acero, M. Molina, **V. J. Cid**; Univ. Complutense de Madrid, Madrid, Spain

Abstract Body:

The Akt protein kinase acts in mammalian cells as the core transducer of phosphatidylinositol-3,4,5-*tris*phosphate (PtdIns3,4,5P_3)-dependent signaling, thus controlling cell growth, proliferation and survival. The yeast *S. cerevisiae*, an eukaryotic model organism, lacks this phosphoinositide. However, co-expression of Akt with its upstream activator, mammalian class I phosphatidylinositol 3-kinase (PI3K), allows the heterologous reconstitution of this signaling module. Simultaneous expression of PI3K and Akt inhibited yeast growth, an effect that relied on the activity of both kinases. Both fluorescence and transmission electron microscopy revealed large plasma membrane (PM) intracellular invaginations in PI3K/Akt-expressing yeast cells. Actin patches supported the development of such altered membranes, which were also associated to the peripheric endoplasmic reticulum. Occasionally, invaginated PM promoted abnormal intracellular deposits of cell wall material, showing concomitant markers of activation of the cell wall integrity (CWI) signaling pathway, such as local recruitment of the Pkc1 protein kinase and general activation of the downstream MAPK pathway. Moreover, phosphatidylserine (PS) and, paradoxically, the PI3K substrate, phosphatidylinositol-4,5-*bis*phosphate (PtdIns4,5P_2) were enriched in such invaginations. Overproduction of the PtdIns4,5P_2-effector Slm1 largely mimicked the effects of PI3K-Akt. Furthermore, we found that Slm1 was hyperphosphorylated in PI3K-Akt expressing cells. We hypothesize that mammalian Akt is able to take over substrates of endogenous yeast AGC kinases, leading to hyperactivation of PtdIns4,5P_2-dependent pathways. These observations underscore that phosphorylation by PtdIns4,5P_2-dependent AGC kinases regulates PtdIns4,5P_2, and that such mechanisms are key actors in maintaining the homeostasis of the yeast PM.

The Heterogeneity Of Primary And Alternative Ribosome Proteins During Drug Tolerance In Mycobacterium

Author Block:

y. li, 12208, a. ojha; Wadsworth Ctr., New York State Dept. of Hlth., Albany, NY

Abstract Body:

Background
Ribosomes, made of 23S, 16S, 5S RNA and 54 ribosomal proteins in Mycobacterium , are molecular machine for protein biosynthesis. .Generally, most prokaryotic genomes have only one gene for each ribosomal protein, but several species have additional copy of one or several ribosomal proteins. Cys-rich (CXXC) zinc binding motif is contained in the primary ribosomal proteins (C^+) but not in alternative ribosomal proteins (C^-). And there are five (L28, S14, L33, L28, L31) or four (L28, S14, L33, L28) alternative ribosomal proteins (C^-) encoded by genomes in Mycobacterium smegmatis and Mycobacterium tuberculosis respectively. C^- ribosome proteins are strongly induced in the low-zinc condition in Mycobacterium. The role of these alternative ribosomal proteins in ribosomal functionality, however, remains unclear.
Methods
In this study, we are focusing on the role of C^- ribosomal proteins in Mycobacterium by the Fluorescence microscope observations, RT-PCR, Survive experiment, iTRAQ analysis, in vitro translation assay and other methods.
Results
In this study, we showed that C- ribosomal proteins are required for the zinc homeostasis in Mycobacterium. Furthermore, we discovered that C^- ribosome is more resistant to aminoglycoside (Kanamycin, Streptomycin, Tetracycline and Hygromycin) than the C^+ ribosome, using Mycobacterium as the working model. Moreover, we can increase the sensitivity Mycobacterium smegmatis to Kanamycin and Streptomycin by repressing the expression of C^- ribosome protein through adding the zinc. Similar results are also found in Mycobacterium tuberculosis. And the proteomics iTRAQ analysis shows that zinc could regulate a switch C^+ and C^- ribosomal proteins and result in the changes of non-ribosomal proteins in Mycobacterium smegmatis. It may indicate the differences in the structure and functionality between C^- and C^+ ribosome. Furthermore, we found that the translation rate of C^- ribosome is slower than the C^+ ribosome but more resistant to Kanamycin inhibition in vitro translation assay.
Conclusions
Overall, our results suggest that C^- ribosomal proteins of Mycobacterium play an important role in the drug tolerance and the heterogeneity of primary and alternative ribosomal proteins.

MIC Distribution of MGIT 960 Susceptible and Resistant Strains of *Mycobacterium tuberculosis* and Correlation with Established Critical Concentrations

Author Block:

I. Martin, K. Dionne, K. Carroll, N. Parrish; Johns Hopkins Med. Inst., Baltimore, MD

Abstract Body:

Antimicrobial susceptibility testing (AST) of *M. tuberculosis* (MTB) has been based on established critical concentrations (CCs) of drugs rather than minimum inhibitory concentrations (MICs). A microbroth dilution method (TREK MYCOTB plate) allows determination of MICs for 12 drugs. We used the MYCOTB plate to determine the MIC distribution of MTB strains identified as susceptible or resistant to isoniazid (INH), rifampin (RIF), and ethambutol (EMB) in the Mycobacterial Growth Indicator Tube (MGIT)-960 system. A total of 193 unique clinical and control strains of MTB were subjected to AST using both the MGIT and the MYCOTB plate. Susceptibility/resistance in the MGIT was dependent upon growth relative to a static CC for the following drugs: INH (0.1 µg/ml), RIF (1µg/ml) and EMB (5µg/ml). For the MYCOTB plate, MICs were determined for the same drugs after 14 days of incubation. MICs were compared to established CC or the next nearest concentration represented in the MYCOTB plate. For INH, RIF, and EMB, the MYCOTB concentrations used for susceptible/resistant breakpoints were 0.06µg/ml, 1µg/ml and 4µg/ml, respectively (≤ concentration = susceptible; > concentration = resistant). Categorical agreement was calculated for all strain/drug combinations. Categorical agreement for all strains/antibiotics considered together was 98% between the 2 methods. This included a total of 424 susceptibility data points (n: RIF=137, EMB=145, INH=142). MIC distributions relative to established CC varied between antibiotics. For RIF, 100% (109/109) of MGIT susceptible strains had MICs < the CC of 1µg/ml; 100% of resistant isolates had MICs > 1µg/ml. For INH, 98% (97/99) of MGIT susceptible strains had MICs ≤0.06 µg/ml, whereas 100% of MGIT resistant strains (43/43) had MICs > 0.06 µg/ml. For EMB, 100% of MGIT susceptible strains (128/128) had MICs <4 µg/ml. However, only 53% (9/17) MGIT resistant strains had MICs >4; 8 strains identified as EMB resistant in the MGIT had MICs of 4µg/ml. Perfect categorical agreement and dichotomous MIC distribution was observed between methods for RIF, whereas for EMB and INH results were less concordant with MICs within one 2-fold dilution of the MGIT-based CC. These results demonstrate that categorical agreement decreases when the MGIT-based CC is not included in the MYCOTB plate.

Abstract Body:

Carbapenem-resistant *Enterobacteriaceae* (CRE) are an emerging threat to patients and are often resistant to all primary therapies. One aim of this study was to determine how well US laboratories identify CRE using standard methods. Targeted clinical isolates of CRE and carbapenem-susceptible *Enterobacteriaceae* (CSE) were collected from 9 US clinical laboratories between Oct. 2013-Sept. 2015 and sent to the CDC. MICs were determined using reference broth microdilution and confirmed CRE were tested by PCR for KPC, NDM, OXA-48, and other carbapenemases. 392 CRE isolates were evaluated. Of these, 339 (86.5%) were confirmed as CRE, the majority were *Klebsiella pneumoniae* (73%), *Escherichia coli* (7.4%), *Enterobacter cloacae* (8.8%) and other *Enterobacter* species (7.1%). The most common CRE not confirmed by reference testing were *E. coli* (29%), *K. pneumoniae* (27%), *E. aerogenes* and *E. cloacae* (17% each). Among 752 CSE evaluated, 12 were determined to be CRE, including 3 *E. cloacae*, 3 *E. coli*, 3 *K. pneumoniae*, and a *Proteus mirabilis*, *P. vulgaris*, and *Serratia marcescens.* The majority of confirmed CRE (n=351) were carbapenemase producers (CP), including KPC (75%), OXA-48 (1.1%) or NDM (0.6%). Non-CP CRE were resistant to ertapenem (99%), and 52% were also resistant to at least one other carbapenem; one was resistant only to doripenem. The most common non-CP CRE included *K. pneumoniae* (34%), *E. coli* and *E. cloacae* (16% each), and *E. aerogenes* (12%). Although most CP tested as CRE, 7 KPC isolates were not resistant to any of the carbapenems; these included 4 *K. pneumoniae*, and an *E. coli*, *E. cloacae*, and *E. aerogenes*. In conclusion, primary testing at clinical laboratories over-called carbapenem resistance in 14% of suspected CRE compared to reference methods. Most CP were phenotypically resistant to at least one carbapenem, but 2.5% were not resistant to any carbapenem. Discrepancies occurred among multiple species of *Enterobacteriaceae* and among both CP and non-CP CRE.

Emergence of Colistin Resistant *Klebsiella pneumoniae* in an Oncology Center in Eastern India

Author Block:

G. Goel, M. Chandy, S. Banerjee, S. Gupta, S. Mullick, K. Sengupta, S. Bhattacharya; Tata Med. Ctr., Kolkata, India

Abstract Body:

Colistin is one of the last antibiotic resorts in the armamentarium in treatment of multi—drug resistant Gram negative bacilli (MDR-GNB) like carbapenem resistant enterobacteriaceae (CRE), which comprise up-to 30% of all the GNB isolated from blood cultures in developing nations. This has caused increasing dependence on colistin and thereby emerging colistin resistance in GNB is becoming a real challenge in successful treatment. There are hardly any new antibiotics in pipeline for GNB. There is dearth of epidemiologic data about colistin resistance. In this observational study we analyzed the epidemiology and outcome of patients with colistin resistant *Klebsiella*. Data was collected retrospectively from February 2014 to September 2015. A total of 12,957 cultures were processed including 6290 blood cultures. Predominant MDR-GNB were *Escherichia coli* (482), *Klebsiella pneumoniae* (343), *Pseudomonas aeruginosa* (56), *Enterobacter cloacae* (13), *Proteus* spp. (6) and *Citrobacter* spp. (4). Extended spectrum beta lactamase producers were 479 while 396 were CRE. Fifteen patients had colistin resistant *Klebsiella pneumoniae* (CRK) isolated from blood (3), respiratory samples (4), urine (3), pus (2) and 1 each from tissue, bile and stool surveillance culture. All CRK isolates were pan-resistant except fosfomycin (all 15 sensitive-S), tigecycline (8-S; 6 intermediate-I); doxycycline (1-S; 2-I); amikacin (1-S; 1-I); co-trimoxazole (3-S) and chloramphenicol (3-S). The patients were 10 males and 5 females (age range 12 to 80 years; median 44). Underlying malignancies were hematological (9), gastro-intestinal tract (3) and urinary bladder (3). Three patients have had bone marrow transplantation and 7 had neutropenia. Prior to isolation of CRK, 11 patients had infections with carbapenem resistant *Klebsiella pneumoniae* (73%), while 3 had it in stool surveillance cultures. Previous use of colistin was noted in 53% (8 patients). All cause mortality was 47% (7). The study highlights CRK is associated with high mortality. Colistin resistance can arise denovo due to selection pressure or horizontal spread as a breach in infection control practices. There is a need to optimize colistin use and dosing adjustments in deranged renal profile. Further molecular research is required to study predilection of *Klebsiella pneumoniae* for colistin resistance.

Evaluation of a New Rapid Multiplexed Molecular System for the Direct Detection of Bacterial Pathogens in Blood

Author Block:

T. Alavie[1], P. Lo[2], A. Khine[1], F. Mohammadzadeh[3], T. Mazzulli[2]; [1]Qvella Corp., Richmond Hill, ON, Canada, [2]Mount Sinai Hosp., Toronto, NT, Canada, [3]Qvella Corp., Richmond Hill, ON

Abstract Body:

Background: A key element to improve the treatment of sepsis is rapid identification of bloodstream pathogens and susceptibility testing. The objective of this study was to compare pathogen detection directly from blood samples using Qvella's FAST ID™ prototype to conventional blood culture results for samples collected from patients with suspected sepsis in the emergency department (ED).
Methods: An additional "test" blood culture bottle was collected from patients ≥18 years presenting to an academic hospital ED with suspected sepsis from Feb-Nov 2015. 800 microliters of blood from this test bottle was used for the FAST ID method prior to incubation, with the reminder of the sample subjected to routine incubation up to 6 days. Any positive results detected from the test bottle (either FAST ID or culture) were cross-referenced with routine bacterial identification by MALDI-TOF from the same patient.
Results: Among 589 test bottle samples from patients with suspected sepsis, 28 samples were positive using both FAST ID and standard culture techniques, 1 culture-negative sample was positive using FAST ID while 1 culture-positive sample was negative using FAST ID. This yielded a sensitivity for bloodstream infection detection of 96.6% and specificity of 99.8% using the FAST ID when compared to standard microbial detection. Pathogen identification results from FAST ID were compared with the identification obtained through routine microbiology according to the hospital's standard clinical workflow. For 26 out of 28 positive samples (92.5%), FAST ID results were in agreement with the identification results obtained employing the routine microbiology workflow.
Conclusions: This study demonstrated the automated, rapid and direct detection and identification of a panel of bacterial pathogens in clinical blood samples. Rapid identification of microorganisms in blood samples should allow clinicians to expedite and tailor initial antimicrobial therapy for patients with suspected sepsis, resulting in improved clinical outcomes and a reduction in the use of unnecessary antibiotics. Additional clinical studies are needed to determine the clinical impact of new technologies capable of detecting microorganisms directly in blood samples collected from patients with suspected sepsis.

Abstract Body:

Background: Environmental enteric dysfunction (EED) is an acquired subclinical infectious condition of the small intestine among residents of low-income countries. Insulin-like growth factor 1 (IGF-1) is the circulating mediator of growth hormone activity. Adequate concentrations of IGF-1 during infancy are crucial for promoting linear growth. The suppression of IGF-1 and IGF-BP-3 (principal binding protein of circulating IGF-1) may be a primary mechanism through which EED affects growth. We aimed to assess the association between IGF-1 & IGF-BP3 with child growth among young Tanzanian children at risk of EED.**Methods:** Blood samples were obtained from 590 children at age 6 wks & 6 mths. Measurement of serum IGF-1 and IGF-BP3 was by ELISA. Growth was measured monthly. Cox proportional hazards models were constructed to estimate hazard ratios (HRs) and corresponding 95%CIs of stunting (HAZ<-2), wasting (WHZ<-2), & underweight (WAZ<-2) across quartiles of IGF-1 and IGF-BP3.**Results:** In multivariate analyses, children with IGF-1 concentrations in the highest quartile had a 51% (HR 0.49, 95% CI: 0.3, 0.8; p for trend=0.05) decreased risk of stunting and a 57% (HR 0.43, 95% CI: 0.23, 0.78; p for trend=0.048) lower risk of underweight than children with concentrations in the lowest quartile after adjusting for covariates. Compared to infants with IGF-BP3 levels in the lowest quartile, those with values in the highest quartile had a 51% (HR 0.49, 95% CI: 0.27, 0.91; p for trend=0.049) lower risk of underweight compared to those in the lowest quartile. Neither biomarker was related to the risk of wasting.**Conclusions:** Serum levels of IGF-1 and IGF-BP3 in early infancy are associated with stunting and underweight. The relationship between these growth markers and their biological significance with regards to EED require further study.

Killing *Vibrio cholerae* by a Chemical Modulator for Glucose Metabolism

Author Block:

Y. Oh, H. Kim, S. Yoon; Yonsei Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Vibrio cholerae, a Gram-negative bacterium, causes pandemic cholera. An oral rehydration solution (ORS), which contains a large amount of glucose, has been used as the primary treatment for cholera. Meanwhile, it has also been speculated that continuous administration of ORS may create glucose-enriched microenvironments in favor of *V. cholerae* growth. Previous studies revealed that the capability of *V. cholerae* 7th pandemic strain N16961 to produce acetoin is essential to maintain the survival fitness under glucose-rich environment. Production of acetoin, a neutral fermentation end-product, allows *V. cholerae* metabolizing glucose without pH drop, which is mediated by organic acid production. This notion also suggests that inhibition of acetoin fermentation may end up with killing *V. cholerae* by acidic pH stress under glucose-rich conditions. Here, we developed a simple high-throughput screen to identify **i**nducers of **m**etabolism-mediated **ac**idification (termed as iMAC). Out of 8,364 compounds, we identified a chemical, 5-(4-chloro-2-nitrobenzoyl)-6-hydroxy-1,3-dimethylpyrimidine-2,4(1H,3H)-dione (iMAC17191) that killed glucose-metabolizing N16961 by pH drop. When N16961 was grown with extra glucose in the presence of 50 μM iMAC17191, acetoin production was completely suppressed and concomitant accumulation of lactate and acetate was observed. Beta-galactosidase activity assay using a single-copy P_{VC1589}::*lacZ* reporter fusion demonstrated that iMAC17191 likely inhibited acetoin production at the transcriptional level. Together, our results suggest that iMAC17191, acting as a metabolic switch, has a therapeutic potential to be developed as a novel antibacterial agent against cholera.

HCV Antigen Testing Instead of HCV Antibody Testing to Screen for HCV Infections

Author Block:

M. M. Konstantinovski, H. J. Gerritsen, J. J. C. de Vries; Leiden Univ. Med. Ctr., Leiden, Netherlands

Abstract Body:

Background: Anti-HCV serology is routinely used for screening for active and past HCV infections in the Netherlands. HCV core antigen (Ag) testing is not delayed by a window phase between infection and immune response as is the case with anti-HCV, also HCV Ag testing is inexpensive compared to PCR. This study investigated the diagnostic characteristics of HCV Ag testing in the setting of an academic center.
Methods: 4 types of clinical serum and plasma samples were selected and HCV Ag testing was performed conform the manufacturers manual. HCV RNA load was used as the golden standard. Group 1(N=23): Active HCV infection with a RNA load of <100 000 IU/mL ;Group 2 (N=18): Active HCV infection with a RNA load of >100 000 IU/mL; Group 3 (N=17): Cleared HCV infection with undetectable RNA load; Group 4 (N=2): Acute infections with positive PCR but negative HCV ab serologyOverall 11 samples were from HIV positive patients, 14 samples had an unknown HIV status and the rest of the samples was HIV negative.
Results: All 18/18 samples with high HCV RNA load tested positive for HCV Ag. Whereas 9/23 samples with a RNA load <100 000 IU/mL tested negative for HCV Ag. The positive HCV Ag samples from group 2 had a viral load of 7900-79000IU/mL and the negative samples of 54-25400 IU/mL, 4 negatives belonged to HIV positive patients. All 17 cleared HCV infection samples tested negative. The two acute infections tested positive for HCV Ag with a viral load at the time of diagnosis of 79000 IU/mL and > 1,000,000 IU/mL Another seroconversion was identified. This patient had a negative HCV Ag test along with a positive HCV Ab and a low viral load of 158 IU/mL.
Conclusions: From other studies it is known that the HCV Ag test performs less within the lower range of viral load, that has been confirmed in this study. We identified 2 patients who would have benefited from the HCV Ag test with a more timely diagnosis of HCV.
Discussion: We demonstrated that the HCV Ag test should be used in addition to HCV Ab testing due to possible missed cases if there is a low viral load, either in the acute phase or later on. HCV Ag testing may be a more appropriate choice if a recent infection is suspected.Our medical center decided to implement the HCV Ag testing as per march 2016 as a routine part of the periodical screening of HIV patients in addition to the HCV Ab test, being the first laboratory in Europe implementing this test.

Cobas HPV Assay; Suboptimal Reproducibility and Effect of Re-testing to Detect False Negative Results

Author Block:

H. Salimnia[1], P. Lephart[2], C. Rajan[3], D. Prebelich[2], E. Paulson[2], J. Howell[2], S. Hallock[2], K. Fabis[2], M. Fairfax[1]; [1]Wayne State Univ. Sch. of Med., Detroit, MI, [2]Detroit Med. Ctr. Univ. Lab., Detroit, MI, [3]Trilogy Diagnostics, Dallas, TX

Abstract Body:

The FDA-cleared, Cobas human papillomavirus (HPV) assay (Roche, Pleasenton, CA) detects 14 high risk (HR) HPVs and distinguishes HPV 16 and 18 from the other 12 HR viruses. It is a qualitative, multiplex, real time (RT) PCR. Cobas HPV results are reported as positive or negative for HPV 16, 18 or for the other 12 HR HPVs. Samples that have a crossing point (Cp) value less than the manufacturer's assigned cut-off value, are reported positive. Those with no Cp or a Cp greater than the cut-off value are reported negative. Upon retesting of clinical samples we found that 4 - 6% of results were not reproducible. The discrepancies occur in samples with Cp values near the cut off value. Minor variations in Cp in RT PCR assays are well known, but such small changes are usually inconsequential. However, near the cut-off value, these variations may change test result from negative to positive and vice versa. With the new proposed screening algorithm that uses HPV with genotype as the primary screening tool for cervical cancer, false negative HPV results can have significant impact on patient care. Following the discovery of suboptimal reproducibility of the Roche HPV assay, and to avoid false negative results, we started to test all HPV samples in duplicate. After testing 2200 clinical samples, we observed a 4% discrepancy between duplicate results. All discrepant results belonged to the samples with Cp values close to the cut-off value of the assay. Running all HPV samples in duplicate imposed additional costs to our lab. We discussed the issue with Roche and requested access to Cp value of those samples reported as negative. Our goal was to limit repeat testing to negative samples with Cp values near the cut off. Our request was temporarily approved by Roche for research and investigational purposes, but they feel that, since the test is not FDA approved in this format, it constitutes an off-label use. Physicians should be alerted to the possibility of false-negative results, so they can make appropriate clinical decisions about patient follow up.

Prevalence of *Trichomonas vaginales* in ThinPrep Specimens from Asymptomatic Patients of Various Age Groups to Improve Sexually Transmitted Disease Diagnosis and Management

Author Block:

M. Martinez, P. Rodriguez, C. Lanteri, J. Perez, L. Hamilton; San Antonio Military Med. Ctr., San Antonio, TX

Abstract Body:

Background: The Center for Disease Control states that the prevalence of *Trichomonas vaginales* infections increases with age. However, *Trichomonas vaginales* testing is not routinely in asymptomic patient populations, suggesting that the prevalence is underdiagnosed. The purpose of our study was two-fold: 1) to confirm CDC's age stratification observations and 2) determine the prevalence of *T. vaginales* in ThinPrep samples in asymptotic patients.
Methods: PANTHER nucleic acid amplication testing using Aptima *T. vaginales* primer and probe kit was used to detect *T. vaginales* in 1000 ThinPrep clinical specimens during an eight week month period. Results were tallied by age groups and prevalence determined.
Results: Of the 1000 samples tested, 400 samples were collected from patients >30, 300 from ages 25-30, and 300 from those less than 25-years of age. Overall, 2.8% of samples tested positive for *T. vaginales*. The highest prevalence was in those >30 years with a 3.75% (37/1000) positivity rate. Patients between the ages of 25-30 had a 2.3% (7/300) positive rate while those samples less than 25 years were positive in 2% (6/300) of the samples.
Conclusions: Our results confirm that the prevalence of *T. vaginales* is greater in older woman than younger cohorts. Furthermore, samples that otherwise would not have been tested for *Trichomonas vaginales* were found to be positive, suggesting that routine screening of asymptotic patients is warranted.

Decreasing Overall Turnaround Times for Targeted and Whole Genome Sequencing

Author Block:

C. Davidson[1], M. Landes[2], R. Qi[1], C. Parikh[1], D. Mandelman[2], H. Latif[2], W. Zhang[2], A. Harris[2], N. Hasan[3], S. Ghosh[1]; [1]Thermo Fisher Scientific, South San Francisco, CA, [2]Thermo Fisher Scientific, Carlsbad, CA, [3]CosmosID, Inc, Rockville, MD

Abstract Body:

Background: Currently next generation sequencing (NGS) is handicapped by slow and complex workflow processes. Reducing overall turnaround time is critical for the wide adoption of targeted and whole genome sequencing (WGS) for microbiological applications. Here we describe improvements to the four steps of the NGS workflow: i) library preparation; ii) template preparation, iii) sequencing; iv) and data analysis. Together, these improvements dramatically decrease the overall sequencing turnaround times. **Material/Methods:** The new rapid approach was applied to two different library preparation protocols: i) a highly-multiplexed PCR approach consisting of 1200 amplicons targeting the 16S rRNA gene as well as species and antimicrobial resistance determinants; ii) and a WGS approach using a MuA transposon-based library preparation method. To assess the accuracy of detection with the optimized workflow, nucleic acid from six bacterial cultures (*A. baumannii, E. cloacae, E. faecium, K. pneumoniae, P. aeruginosa,* and *S. aureus)* were extracted as input for targeted and WGS sequencing. Both targeted and WGS libraries were clonally amplified using an isothermal amplification approach that saves 3 hours over the standard methods. Sequencing times were improved by reducing flow times and the total number of flows. The implementation of On-Instrument Analysis (OIA) enabled near real-time base calling reducing the total primary analysis time. **Results:** Targeted and WGS libraries were generated, sequenced, and analyzed in 6.5 hours with sequencing and analysis taking 50 minutes compared to 2.5 hours and 1 hour for standard sequencing and analysis, respectively. Analysis of sequencing accuracy revealed a raw read accuracy >99.5%, comparable to data from the standard workflow. The read length distribution for the targeted libraries was similar to standard workflow with 100% specificity for species identification and antimicrobial resistance determinants for targeted and WGS libraries indicating rapid sequencing without compromising detection accuracy. **Conclusions:** For the targeted and WGS assays described, the total turnaround time could be completed in a standard workday.

First Report of *E. coli* Isolates Harboring the *mcr-1* Gene in Brazil

Author Block:

S. A. M. Lentz[1], D. Lima-Morales[2], V. M. L. Cuppertino[1], A. S. Motta[1], A. L. Barth[2], **A. F. Martins**[1]; [1]Univ. Federal do Rio Grande do Sul - UFRGS, Porto Alegre, Brazil, [2]Hosp. de Clínicas de Porto Alegre, Porto Alegre, Brazil

Abstract Body:

Background: The recent identification of the plasmid-mediated transferable colistin resistance *mcr-1* gene is of great concern to public health as polymyxins are considered the last resource for treatment of infections caused by carbapenemase producing Enterobacteriaceae. The *mcr-1* gene, was first described in China, and was then reported in Europe, Asia, Canada and Africa. In view of the concerning spread of antibiotic resistance and the prevalence of *mcr-1* gene among ESBL producers, we screened ceftazidime resistant isolates collected in a poultry slaughterhouse. **Methods:** A total of 295 isolates obtained from poultry chicken rectal swab in 2015 in southern Brazil, were screened by PCR for the presence of the *mcr-1* gene. We were able to find the *mcr-1* gene in 3 out of the 295 isolates (1,0%). **Results:** The 3 amplicon fragments were sequenced using the CLR5-F (5′-CGGTCAGTCCGTTTGTTC-3′) and CLR5-R (5′-CTTGGTCGGTCTGTAGGG-3′) primers and showed a 100% identity with the *mcr-1* sequence (GeneBank Accession Number KP347127). According to 16S RNA analysis, all three isolates were identified as *Escherichia coli.* The minimum inhibitory concentration (MIC) of polymyxin, performed by broth microdilution, was 1, 2 and 8 mg/L. The isolates were susceptible to piperacillin-tazobactam, amikacin, cefepime, meropenem and gentamicin and non-susceptible to cefuroxime, amoxicilin-clavulanate, ampicillin, ampicillin-sulbactam, sulfametoxazol/trimetoprim, ciprofloxacin and ceftazidime by the disc diffusion method. Further studies are being carried out in order to evaluate the presence and type of plasmids and to establish the MLST of the *E. coli mcr-1* positive isolates. **Conclusions:** To the best of our knowledge, this is the first report of *mcr-1* in Brazil and, probably in Latin America, highlighting the worldwide spread of this novel resistance determinant.

Moxifloxacin Improves Treatment Outcomes in Patients with Ofloxacin-resistant Multidrug-resistant Tuberculosis

Author Block:

J-Y. Chien, C-J. Yu, P-R. Hsueh; Natl. Taiwan Univ., Taipei, Taiwan

Abstract Body:

Background: It is unclear whether the use of moxifloxacin (MFX), a fourth-generation synthetic fluoroquinolone, results in better outcomes in patients with ofloxacin (OFX)-resistant multidrug-resistant tuberculosis (MDR-TB). **Methods:** During the period April 2006 to December 2013, a total of 2511 patients with culture-confirmed tuberculosis (TB) were treated at a TB referral hospital in southern Taiwan. Of them, 325 (12.9%) had MDR-TB, and of those patients, 81 (24.9%) had OFX-resistant MDR-TB and were included in the study. **Results:** Among the 81 patients with OFX-resistant MDR-TB, 50 (61.7%) were successfully treated and 31 (38.3%) had unfavorable outcomes, including treatment failure (n=25; 30.9%), loss to follow-up (n=2; 2.5%) and death (n=4; 4.9%). Patients with MFX-susceptible and low-level MFX-resistant isolates who were treated with MFX had a significantly higher rate of treatment success (77.3% vs. 43.2%; odds ratio [OR]=4.46; 95% confidence interval [CI]=1.710-11.646; *P*=0.002) than without MFX. Multivariate logistic regression analysis showed that treatment with MFX (OR=3.46; 95% CI=1.18-10.15; *P*=0.024) and second-line injectable agents during the intensive phase (OR=3.29; 95% CI=1.11-9.74; *P*=0.031) were independent predictors of treatment success. Mutation at codon 94 in the *gyrA* gene was the most frequent mutation (68.0%) associated with high-level MFX resistance. Multivariate Cox proportional hazards regression analysis showed that treatment with MFX was an independent factor associated with early culture conversion (hazard ratio=2.02, 95% CI=1.14-3.56; *P*=0.016). **Conclusions:** Our results show that a significant proportion of OFX-resistant MDR-TB isolates were susceptible or had low-level resistance to MFX, indicating that patients with OFX-resistant MDR-TB benefit from treatment with MFX.

Pyrvinium Inhibits the Growth and the Biofilm Formation of *Candida albicans* by Affecting Yeast Casein Kinase 2

Author Block:

M. Macias, L. Yeo, J. Garcia, C. Truong, H. Park; California State Univ. Los Angeles, Los Angeles, CA

Abstract Body:

Background: As an opportunistic pathogen, *Candida albicans* cause serious infection in immunocompromised individuals. The pathogenicity of *C. albicans* can be attributed to its ability to form hyphae and biofilm on host cells. Our previous study discovered that yeast casein kinase 2 (*YCK2*), a member of Casein Kinase I (CK1) family of eukaryotic systems, negatively regulates hyphal transition and biofilm formation (Jung et al). Recently, an anthelmintic drug, pyrvinium pamoate, has been reemphasized as a potential anti-cancer drug as it targets Casein Kinase I (CKI), which governs cell cycle (Deng et al). Thus we hypothesized that pyrvinium also affects *YCK2* that shares a significant homology to CK1, thus may inhibit hyphal transition and biofilm formation in *C. albicans*.
Methods: *C. albicans* wild type and *yck2* mutant strains were tested for morphology, growth, and biofilm formation in various concentrations of pyrvinium. To determine the molecular mechanisms by which pyrvinium affects on *C. albicans* hyphal transition and biofilm formation, transcriptional analysis on *YCK2* and its homologs were conducted with pyrvinium compared to no drug control.
Results: The morphology of cells grown in pyrvinium, demonstrated signs of cell apoptosis for 2.5 μg/mL, with the most cell death in the 5 μg/mL. Growth curve analysis showed significant growth inhibition by pyrvinium as a dose dependent manner. The biofilm formation was also inhibited by pyrvinium as a dose dependent manner. It was also noted that the *yck2* mutant strain was less affected by pyrvinium compared to the wild type strain in biofilm inducing condition, still remains 30-40 % more biofilm than the wild type strain. Transcriptional analysis demonstrated the mRNA expression of all three CK1 homologs was not changed by pyrvinium, suggesting the inhibitory effect of pyrvinium to *C. albicans* growth and biofilm formation is likely by affecting *YCK2* at post translational level.
Conclusions: Pyrvinium has inhibitory effect on both growth and biofilm formation of *C. albicans.* In particular, the drug seems to function via manipulating the YCK2 signaling cascade. As pyrvinium is a FDA approved and safe to treat patients, we will further look into the possibility of utilizing pyrvinium as a new antifungal agent.

Computational Predictions of Substrate Specificity in Nonribosomal Peptide Synthetases through Comparative Adenylation Domain Trees

Author Block:

M. G. Chevrette[1], C. R. Currie[1], M. H. Medema[2]; [1]Univ. of Wisconsin-Madision, Madison, WI, [2]Wageningen Univ., Wageningen, Netherlands

Abstract Body:

Microbial nonribosomal peptide synthetases (NRPSs) are an important source of complex natural molecules of high therapeutic and biotechnological value. These modular protein-systems are found in a variety of microbes and produce structurally and functionally diverse peptide metabolites used in medicine as antibiotics, anticancers, and more. The order and identity of peptides incorporated by an NRPS are dictated by its assembly-line module and domain structure. Various methods have been developed to computationally predict NRPS adenylation domain (NRPS-AD) substrate specificity directly from genomes. The ability to deduce this information from sequence data has revolutionized natural product drug discovery by greatly increasing throughput, prioritizing novelty, and lowering the rate of costly rediscoveries. However, it is unclear how available algorithms compare in terms of accuracy. Here, we gathered 314 NRPS-AD sequences from recently experimentally characterized NRPSs from literature, and used these as a test set for systematic benchmarking. Algorithms based on active site motifs (using pattern matching or support-vector machines) performed better than whole-domain-based algorithms (using profile hidden Markov models; pHMMs), at 56% and 42% accuracy respectively. All algorithms were unable to reliably predict highly similar (>80% protein identity; PID) NRPS-ADs that had shifted or expanded substrate specificity due to recent evolutionary events. To address this, we describe a comparative genomics algorithm (Predictions through Comparative A-domain Trees; prediCAT) which constructs NRPS-AD trees and predicts query specificity by monophyly. PrediCAT increased precision to 65% accuracy within the test set. Incorporating the entire assembled dataset into a jackknife benchmarking scheme resulted in the correct substrate predictions for 86% of NRPS-ADs by prediCAT compared to 63% by pHMMs. At >80% PID, prediCAT was 86% accurate versus 72% in pHMMs. Queries at low similarity (<60% PID) to the training data had accuracies of 81% and 40% for prediCAT and pHMMs respectively. Our findings suggest that comparative genomics can be used as a powerful tool to predict NRPS scaffolds to assist investigations of chemical diversity and drug discovery efforts.

Systemic Delivery of Multiple siRNA Treatment for Prevention of Neuro-inflammation and Viral Encephalitis, Induced by Japanese Encephalitis Virus in BALB/c mice.

Author Block:

T. N. Dhole, D. Singh, A. Zia, P. Kumar, S. Saxena, R. Kapoor; Sanjay Gandhi Post Graduate Inst. of Med. Sci., Lucknow, UP, India

Abstract Body:

Background: Japanese Encephalitis Virus (JEV) is a member of the family Flaviviridae. JEV is transmitted by Culex mosquitoes between wild and domestic birds and pigs. Therapy for JE is supportive and no clearly effective antiviral agents exist. In recent years RNAi has been explored to inhibit viral diseases. However, the development of siRNA-based antiviral strategies hampered by a number of challenges related to the in vivo delivery. Rabies virus glycoprotein (RVG) is able to cross the blood brain barrier. Complexing or encapsulating siRNA with liposomes has been shown to protects RNAi from degradation and improve delivery through the vasculature.**Methods:** siRNA against structural proteins of JEV, designed in-silico, synthesized commercially. Cationic liposome prepared and physically characterized by Zeta sizing and electron microscopy. Mice were challenged with 3×10^5 PFU of GP-78. siRNA were given at 0 hour, 24 hour, day 3, and day 5. BALB/c mice sacrificed at 3d.p.i., 5d.p.i., 7 d.p.i., and 9 d.p.i. Virus was estimated in brain by plaques and rRT-PCR. CBA was done for cytokine levels. Brain histopathology and IHC was done for the JEV, MMPs (2, 7 and 9) and TIMP (1 and 3) for virus and CNS inflammations. Mice were observed for mortality for 30 days.
Results: Viral replication was inhibited in N2A by 100 pmole of siRNA. Decreased mean log pfu viral load has been observed (3.46 on 3dpi, 3.47 on 5dpi, 2.37 on 7dpi and 2.59 on 9dpi) as compared to infection control mice. Over expression of MMPs and TIMPs has been suppressed followed by reduced neuronal degradation. Mice were survived up to 30 days whereas controls died up to 9th day. Virus was cleared from brain suggested by histopathology and IHC examinations. **Conclusions:** Study could be used as effective clinical strategy in epidemic outbreak for JEV positive patients even after vaccination.

Extended Protection by DAV131 against Antibiotic-Induced *Clostridium difficile* Infection in Hamsters

Author Block:

N. Saint-Lu[1], S. Sayah-Jeanne[1], F. Sablier-Gallis[1], M. Pulse[2], C. Burdet[3], T. T. Nguyen[3], W. J. Weiss[2], F. Mentré[3], E. Chachaty[4], **A. Andremont**[3], J. de Gunzburg[1]; [1]Da Volterra, Paris, France, [2]Univ. of North Texas Hlth.Sci. Ctr., Fort Worth, TX, [3]Univ. Paris Diderot and INSERM, UMR 1137, IAME, Paris, France, [4]Inst. Gustave Roussy, Villejuif, France

Abstract Body:

Background: We previously showed that DAV131, an oral adsorbent-based product, could protect hamsters against *C. difficile* infection (CDI) induced by moxifloxacin. Besides fluoroquinolones, cephalosporins and clindamycin are major risk factors for the development of CDI. We investigated if DAV131 could also protect hamsters against CDI after treatment with these antibiotics.
Methods: Male Syrian hamsters were administered 90 mg/kg ceftriaxone subcutaneously oad for 5 days (D1 to D5), and infected orally at D3 with 10^4 *C. difficile* spores from a non-epidemic toxigenic strain. Alternatively, hamsters were infected orally at D1 with 10^4 *C. difficile* spores as above, and administered 10 mg/kg clindamycin subcutaneously at D2. Groups of 10 animals, in either experimental settings, were orally administered 100, 300, 600 or 900 mg/kg DAV131 twice per day, from D1 to D8. Survival was monitored up to D12, and feces were collected to determine free clindamycin concentrations by bioassay.
Results: When administered at 900 and 600 mg/kg doses, DAV131 protected 100 % of hamsters from mortality induced by clindamycin, whereas 30% and no protection were achieved with 300 and 100 mg/kg doses respectively. This was associated with a significant and dose-dependent reduction of clindamycin concentrations in feces. A similar dose-dependent protection from ceftriaxone-induced CDI was also achieved.
Conclusions: Oral DAV131 exhibited a dose-dependent protection of hamsters against ceftriaxone-, and clindamycin-induced lethal CDI, as it did with moxifloxacin. This study clearly shows that DAV131 constitutes the first preventive strategy that can potentially protect against CDI when applied concomitantly with diverse causative antibiotic treatments. The development of this promising strategy for the prevention of CDI in humans (named DAV132) is ongoing.

Ridinilazole Preserves Major Components of the Intestinal Microbiota During Treatment of *Clostridium difficile* Infection

Author Block:

J. Chang[1], A. Kane[1], L. McDermott[1], R. J. Vickers[2], D. R. Snydman[1], C. M. Thorpe[1]; [1]Tufts Med. Ctr., Boston, MA, [2]Summit Therapeutics, Abingdon, United Kingdom

Abstract Body:

Background: *Clostridium difficile* infection (CDI) and the subsequent high recurrence rates have been shown to be associated with perturbation of the native microbiota following the use of broad-spectrum antibiotics such as vancomycin to treat CDI. There is a need for *C. difficile* treatment that may have minimal impact on the normal protective microbiota. **Methods:** Stool samples were obtained from 82 patients enrolled in a phase II randomized, blinded clinical trial comparing vancomycin and ridinilazole. Real-time quantitative PCR was used to assess changes in 5 different bacterial groups (*Bacteroides, Prevotella, Enterbactericeae, C. coccoides* and *C. leptum*) as well as all bacteria present using universal 16S ribosomal DNA primers. Plasmid-based standard curves were utilized to interpolate copy numbers per sample. Patient samples were obtained at study entry, days 5 and 10 of treatment, day 25 and day 40 post-entry, as well as at the time of any recurrence. **Results:** Treatment with vancomycin significantly decreased ($P < 0.001$) levels of the groups *Bacteroides, Prevotella, C. coccoides* and *C. leptum* during treatment days 5 and 10, with an average drop of 3 logs for each of these groups. Vancomycin also resulted in significant decrease of all bacteria as detected by the 16S primers. Treatment with ridinilazole resulted in no significant decrease in these specific microbiota groups and total bacteria. Neither vancomycin nor ridinilazole resulted in any significant change in *Enterobacteriaceae* levels. **Conclusions:** These findings indicate that ridinilazole is superior to vancomycin in sparing these major components of the native microbiome during treatment of CDI, which may be responsible for the marked reduction in disease recurrence rates following ridinilazole therapy.

Publishing Title:

In Vitro* and *In Vivo* Efficacy of the Novel β-lactamase Inhibitor ETX2514 Combined with Sulbactam Against Multidrug Resistant *Acinetobacter baumannii

Author Block:

J. O'Donnell[1], J. Newman[2], A. Tanudra[1], A. Chen[1], B. De Jonge[2], H. Shankaran[2], J. Mueller[1], R. Tommasi[1]; [1]Entasis Therapeutics, Waltham, MA, [2]AstraZeneca, Waltham, MA

Abstract Body:

Background: The novel diazabicyclooctenone β-lactamase inhibitor ETX2514 is active against Class A, C and D serine β-lactamases and effectively restores the antibacterial activity of sulbactam against multidrug resistant (MDR) *A. baumannii*. To further evaluate the therapeutic potential of this combination, its activity against a large collection of clinical isolates and its PK/PD drivers *in vitro* and *in vivo* were assessed. **Methods:** The *in vitro* antibacterial activity of sulbactam with 4 mg/L of ETX2514 was determined at IHMA against a globally diverse collection of *A. baumannii* from 2011-2014 (n = 1223), by broth MIC using CLSI guidelines. The *in vitro* activity of ETX2514 / sulbactam was characterized using an *in vitro* hollow-fiber model. Dose range and dose fraction experiments varying concentration (C_{max}, AUC) and frequency of administration of ETX2514 and sulbactam (q3h, q6h, q12h, and q24h) were used to determine PK/PD endpoints against five clinical *A. baumannii* strains. The same strains were evaluated *in vivo* by bacterial burden reduction in a tissue-based abscess in neutropenic thigh and lung infection models to validate exposure targets established *in vitro*. **Results:** The MIC_{90} of sulbactam/ETX2514 was 4 mg/L across all years tested with no carbapenem cross-resistance observed. Initial results of *in vitro* and *in vivo* investigations with sulbactam alone vs. a sulbactam-sensitive *A. baumannii* isolate (MIC = 2 mg/L) suggested Time > MIC as the PK/PD driver with 21 to 38% Time > MIC associated with a 1-log kill *in vivo*. Against MDR strains (with sulbactam MICs > 8 mg/L), ETX2514 restored MIC potency to < 2 mg/L and demonstrated a PK/PD driver of Time > critical threshold (C_T) in the hollow-fiber model system. E_{max} modelling of *in vivo* data from lung and thigh models suggested ETX2514 effectively restores sulbactam activity, and > 1-log kill is realized with Time > MIC for the combination ranging from 26 to 58% of the dosing interval. **Conclusions:** The combination of ETX2514 and sulbactam was highly effective against clinical *A. baumannii* strains *in vitro* and *in vivo*. These results support further evaluation of this combination to treat MDR *A. baumannii* infections.

Publishing Title:

A Phase 1 Safety and Tolerability Study of Radavirsen (AVI-7100), an Anti-sense Oligonucleotide Targeting Influenza A M1/M2 Translation

Author Block:

J. Beigel[1], J. Voell[2], P. Munoz[2], P. Iversen[3], A. Heald[3], M. Wong[3], R. T. Davey[2]; [1]Leidos BioMed. Res., Inc., Bethesda, MD, [2]Natl. Inst. of Allergy and Infectious Diseases, Bethesda, MD, [3]Sarepta Therapeutics, Cambridge, MA

Abstract Body:

Background: Therapeutic agents with novel mechanisms of action are needed for treating influenza A viruses. Radavirsen, formerly AVI-7100, is an antisense oligomer (specifically a phosphorodiamidate morpholino oligomer with positive charge (PMOplus®)) that has been shown to inhibit the translation of M1 and M2 protein of influenza A and has demonstrated preclinical efficacy in mouse and ferret models. **Methods:** A Phase 1 safety, tolerability and pharmacokinetic study of Radavirsen was performed in healthy adult volunteers in the Clinical Trials Unit at the National Institutes of Allergy and Infectious Diseases, NIH. The study was divided into 2 parts. The first was a single-ascending dose study of 5 cohorts, 40 subjects total, randomized 6:2 to receive single intravenous doses of Radavirsen ranging from 0.5 mg/kg to 8 mg/kg or control, and followed for 28 days. The second part was a multiple dose study of 16 subjects randomized 12:4 to receive 8 mg/kg/day or control x 5 days and followed for 32 days. **Results:** A total of 66 subjects signed informed consent, and 56 subjects were dosed. All doses of Radavirsen were well tolerated. The most common AE in the single dose cohorts were headaches, hyperglycemia, hypomagnesemia, and hypoglycemia. Headaches, hypomagnesemia, and hypoglycemia were similar between the subjects receiving Radavirsen and controls. Transient grade 1 hyperglycemia occurred more frequently in subjects receiving Radavirsen, and was more common with the higher doses. There were no apparent dose related changes in other laboratory parameters or EKG measurements. Following a single dose, Radavirsen conforms to a linear and dose-proportional two-compartmental pharmacokinetic model, with a terminal half life of approximately 2.7-3.0 hours. The multi-dose cohort had an increase in reversible proteinuria in the AVI treated cohort. PK analysis of this cohort reveled an effective half life of 2-3 hours, though there was a third compartment with an extended half-life without drug accumulation. **Conclusions:** With the data available to date, Radavirsen appears to be well tolerated. Full safety and pharmacokinetic data from the single and multi-dose cohorts will be presented.

Identification of Genes Mediating Antibiotic Sensitivity in *Mycobacterium tuberculosis* Using Tn-seq

Author Block:

W. Xu[1], M. A. DeJesus[2], M. G. Wright[1], T. R. Ioerger[2], S. Ehrt[1]; [1]Weill Cornell Med. Coll., New York, NY, [2]Texas A&M Univ., College Station, TX

Abstract Body:

The treatment of tuberculosis (TB) is challenging - the standard HRZE (isoniazid, rifampicin, pyrazinamide and ethambutol) regimen for drug-sensitive TB needs at least 6 months, whereas more complicated cases of multidrug-resistant (MDR) and extensively-drug-resistant (XDR) TB require the additional use of second-line drugs for an extended duration of 18 months and beyond[1]. These lengthy treatment regimens result in toxic side-effects for many patients and often lead to patient non-compliance, which contributes to treatment failure and the development of drug-resistant TB. Consequently, there is a pressing need for the development of a shorter therapeutic regimen, as well as a better understanding of the factors limiting the effectiveness of current drugs.

We screened a saturated *Mycobacterium tuberculosis* (Mtb) transposon mutant library for mutants that exhibit altered fitness under partially-inhibitory concentrations of rifampicin, ethambutol, isoniazid, vancomycin and meropenem. By analyzing the change in frequency of the various transposon mutants using the TRANSIT[2] transposon insertion sequencing (Tn-seq) analysis platform, we were able to identify and rank genes mediating antibiotic sensitivity in Mtb. We verified the data by drug sensitivity assays with individual mutants and with information from existing literature. Multiple cell envelope mutants were predicted to be strongly sensitive to the drugs tested, whereas inactivation of individual efflux pumps did not appear to contribute majorly to drug sensitivity.

Protein acetylation is involved in *Salmonella enterica* serovar Typhimurium virulence

Author Block:

Y. Sang, J. Ren, Y-F. Yao; Shanghai Jiao Tong Univ. Sch. of Med., Shanghai, China

Abstract Body:

Salmonella causes a range of diseases in different hosts, including enterocolitis and systemic infection. Lysine acetylation regulates many eukaryotic cellular processes, but its function in bacteria is largely unexplored. The acetyltransferase Pat and nicotinamide adenine dinucleotide (NAD^+)-dependent deacetylase CobB are involved in the reversible protein acetylation in *Salmonella* Typhimurium. Here, we used cell and animal models to evaluate the virulence of *pat* and *cobB* deletion mutants in *S.* Typhimurium, and found that *pat* is critical for bacterial intestinal colonization and systemic infection. Next, to understand the underlying mechanism, genome-wide transcriptome was analyzed. RNA-seq data showed the expression of *Salmonella* pathogenicity islands 1 (SPI-1) is partially dependent on *pat*. In addition, we found that HilD, a key transcriptional regulator of SPI-1, is a substrate of Pat. The acetylation of HilD by Pat maintained HilD stability and was essential for the transcriptional activation of HilA. Taken together, these results suggest that protein acetylation system regulates SPI-1 expression by controlling HilD in a post-translational manner to mediate *S.* Typhimurium virulence.

Alpha-ketoglutatate Mediated Regulation of *Pseudomonas aeruginosa* Pathogenesis by MifS-MifR Two-Component System

Author Block:

G. D. Tatke, S. Mustafi, M. A. Barbieri, K. Mathee; Florida Intl. Univ., Miami, FL

Abstract Body:

Pseudomonas aeruginosa is a Gram-negative opportunistic pathogen that causes incapacitating infections in immunocompromised patients. Successful infection and disease progression extensively depends on any pathogen's ability to effectively utilize available nutrients that are essential for its growth and survival. *P. aeruginosa* preferentially utilizes tricarboxylic acid (TCA) cycle intermediates as carbon, nitrogen and energy sources. In *P. aeruginosa*, two-component system (TCS) signaling proteins have played an integral part in regulating the uptake of TCA cycle intermediates, specifically, C_4-dicarboxylates such as succinate, fumarate and malate. Recently, MifS and MifR TCS proteins were identified to regulate utilization of a key TCA cycle intermediate, the C_5-dicarboxylate α-ketoglutarate (α-KG). Importantly, in the recent years, α-KG has gained significant importance as a biological signaling molecule in bacteria, animals and plants. To date, very little is known of the physiology of *P. aeruginosa* when provided with α-KG as the sole carbon source and their role in virulence. We postulate that MifSR TCS is required to regulate *P. aeruginosa* pathogenesis in the presence of α-KG. Multiple virulence phenotypes were tested in the presence and absence of α-KG. Loss of *mifSR* had no effect on *P. aeruginosa* virulence in the presence of other TCA cycle intermediates, except α-KG. However, in comparison to the wild-type PAO1 strain, *mifSR* deletion strains exhibited differential regulation of pigment production, motility, phenazine production and cell cytotoxicity in the presence of α-KG. Thus, MifSR TCS regulates the expression of *P. aeruginosa*'s key virulence determinants in α-KG-dependent manner. Simultaneous regulation of multiple mechanisms involved in *P. aeruginosa* pathogenesis suggests a complex mechanism of MifSR action. Thus, understanding the physiological cues and regulation would provide a better stratagem to fight the often indomitable infections.
