Comparative Genomics of *Vitreoscilla* sp. Strain C1 and Other Relatives from the *Neisseriaceae* Family

Author Block:

I. Veseli, B. C. Stark, D. A. Webster, J-F. Pombert; Illinois Inst. of Technology, Chicago, IL

Abstract Body:

Gram negative β-proteobacteria from the genus *Vitreoscilla* are closely related to *Neisseria* species. While the Neisseriaceae family is infamous for harboring the gonococcus *Neisseria gonorrhoeae* and meningococcus *Neisseria meningitidis*, these two human pathogens are the exception rather than the norm and species belonging to this group are usually commensal or neutral with limited pathogenic potential. Here we sequenced the complete genome of *Vitreoscilla* sp. strain C1 to help elucidate the evolution of pathogenicity in the Neisseriaceae but also to catalog this historically important bacterial strain. The *Vitreoscilla* sp. strain C1 sequenced in this report was originally obtained from R.G.E. Murray of Western Ontario University in 1962. This strain and several others furnished by him and R.Y. Stanier of the University of California at Berkeley were examined spectrally for cytochromes and strain C1 proved to be most suitable for extracting VHb, which was originally thought to be a soluble cytochrome o. It was only after its amino acid sequence was determined 20 years later that it was identified as a bacterial hemoglobin (VHb), the first prokaryotic hemoglobin to be discovered. VHb and its genes have been extensively studied as models of prokaryotic hemoglobins and used with success to improve many biotechnological processes. Despite its great historical and practical importance, there has been some confusion about its origin in *Vitreoscilla* strain C1. Specifically, it has sometimes been incorrectly assumed that VHb comes from *Vitreoscilla stercoraria*. In fact the hemoglobin from *V. stercoraria*, as well as the transcriptional promoter for its gene, are significantly different from those in strain C1. To formally establish the difference between these species the sequence of the complete genome of C1 has been determined, annotated, and compared with that of *V. stercoraria*. DNA sequencing was done with Pacific Biosciences technology, genome assembly with SMRT Portal and Geneious software, automatic annotation with Prokka software, and manual curation with NCBI BLAST and InterProScan 5 output. Other software used for data collection, comparison and mapping included PhyML, Circos and custom Perl and bash scripts. It was found that *Vitreoscilla* sp. C1 and *V. stercoraria* are genetically distinct. Further analysis of the C1 genome is ongoing.

First Genome Analysis of *Entamoeba marina*

Author Block:

A. K. Mukherjee, S. Izumyama, T. Nozaki; Natl. Inst. of Infectious Diseases, Tokyo, Japan

Abstract Body:

Background: In 2015, Shiratori *et al.* first described a new species named *Entamoeba marina* and was the first among the *Entamoeba* species described till date that have a marine habitat. The genome of rich and diverse group like Amoebozoa still remained unexplored and whole genome analysis of this species will greatly enhance our understanding of the adaptation of the amoebozoan group of organisms in such diverse environments and may also lead to better resolution of amoebozoan evolution from a free living to a parasitic form or vice versa. **Methods:** The genome sequencing was performed by the Illumina HiSeq sequencing platform using both 300bp short read and 8Kb long jump distance library. The processed and cleaned DNA reads were de novo assembled into contigs and potential ORFs were identified using CLC Genomics Workbench. The ORFs were BLAST search against the non-redundant database of gene and protein sequences with cutoff E-value of 0.001. Enzyme-code mapping was also performed to understand the metabolic pathways of this organism.**Results:** The genome dataset comprised around 4500 contigs with ~12600 ORFs and an overall GC contents about 25-30%. Blast search of the putative ORF s against public databases showed that most of the *E. marina* genes have maximum similarity with other *Entamoeba* species. The enzyme mapping and similarity BLAST search in KEGG database revealed both common shared genes by *Entamoeba* and *E. marina*-specific genes. Phylogenetic analysis of some *E. marina* specific ORFs that are not present in other *Entamoeba* sp. showed a possibility of lateral gene transfer from bacteria or eukaryotic organisms.**Conclusion:** *E. marina* possesses almost similar genome contents as compared to its relalted species. The presence of *E. marina*-specific unique genes by lateral gene transfer and modification of metabolic pathways as compared to other *Entamoeba* species have made this species a unique model to study diversification and evolution of the amoebazoa. Overall the complete genome analysis of this apparently free-living marine *Entamoeba* should help us to have a much deeper picture of genome evolution of the Amoebazoa group and its relation with its adaptation to parasitic or free-living habitat.

Comparative Genomics of *Streptococcus suis* 90-1330 (Serotype 2; Sequence Type 28), a Low Virulence Strain from an Important Swine and Human-emerging Pathogenic Species

Author Block:

Y. Sun[1], K. Vaillancourt[2], M. Frenette[2], D. Grenier[2], J-F. Pombert[1]; [1]Illinois Inst. of Technology, Chicago, IL, [2]Université Laval, Québec, QC, Canada

Abstract Body:

The Gram-positive α-hemolytic bacterial opportunistic pathogen *Streptococcus suis* is a major cause of concern in the swine industry and an emerging zoonotic agent that can cause sepsis, meningitis, endocarditis and other systemic issues in both pigs and humans. A total of 35 distinct *S. suis* serotypes (1 to 34 and 1/2) have been identified so far based on biochemical capsular antigen antisera assays, with strains from serotype 2 being the most dangerous for zoonotic infections. However, strain virulence can vary substantially within the same serotype and each *S. suis* serotype has been further subcategorized into sequence types (ST) based on multilocus sequence typing (MLST) analyses. Within serotype 2 strains, European ST1 isolates are known as the most virulent of all *S. suis* isolates. Closer to home, North American ST25 and ST28 strains display moderate to low virulence phenotypes, respectively. We sequenced the complete genome of *S. suis* 90-1330, a Canadian serotype 2 (SS2) - ST28 isolate producing a rare lantibiotic bacteriocin with potential therapeutic and prophylactic applications, using the Illumina and PacBio platforms. We compared it to other available complete genomes, including distinct SS2-ST28 strains from Canada and China. Using maximum likelihood phylogenomic inferences derived from 1,201 shared orthologs and genome-wide single nucleotide polymorphism (SNP) analyses, we found that all three SS2-ST28 strains of *S. suis* are genetically distinct and more closely related to representatives of serotype 3 than to other sequenced serotype 2 genomes.

Comparative Genomics and Epigenetics of *Sporosarcina ureae*

Author Block:

A. S. Oliver, T. Kurbessoian, M. C. Kay, K. K. Cooper; California State Univ. Northridge, Northridge, CA

Abstract Body:

Sporosarcina ureae is an aerobic, motile, spore-forming Gram-positive cocci that was originally isolated in the early 20th century from soil enrichments with elevated levels of urea. The species is unique in that it is the only known spore-forming cocci, and is currently placed in a genus exclusively composed of bacilli. Current research has been focused on the biotech potential of the unique outer cell surface layer (S-layer), and the ability to efficiently convert urea into ammonia. Specifically, researchers are using organisms that hydrolyze urea in applications such as self-healing concrete, biofuel production, and more efficient means to make fertilizer. The goal of this study is to utilize Pacific Biosciences (PacBio) DNA sequencing technology to generate complete genome sequences and to investigate genetic and epigenetic variations between strains of *S. ureae* that differ in their spatial and temporal isolation. We have sequenced the first six complete genomes and methylomes of *S. ureae*. Genomes were assembled using PacBio SMRT Analysis (v2.3.0) and Geneious (Biomatters; v9.0.4) software programs, and annotated using Rapid Annotation using Subsystem Technology (RAST; rast.nmpdr.org). The average *S. ureae* genome is 3.3 Mb in size, and contains an average 3144 CDS, 67 tRNAs and 8 rRNAs, while only one of the strains contains a plasmid (64 kb). Epigenetic analysis, using SMRT Analysis and REBASE (New England Biolabs), of the strains demonstrated evidence of several novel adenine and cytosine methylases present in *S. ureae*. Examination of the species requirement of 97% sequence identity across the 16S rRNA gene was met by all six strains. However, further analysis using *in silico* DNA-DNA hybridization (DDH), average nucleotide identity (ANI), and additional core- and pan-genome analysis demonstrated a highly divergent species or possibly some of the strains were a subspecies or new species. Further genetic analysis of the entire genus is needed to determine exactly how *S. ureae*, a spore-forming cocci, relates to the other spore-forming bacillus species in the genus *Sporosarcina*. Utilizing genomics, our analysis has begun to clarify the make up of the genus, and also found that there may be additional species of spore-forming cocci other than just *S. ureae*.

Genomic Analysis of the Human Gut Microbiome Reveals Novel Enzymes in Energy Metabolism

Author Block:

D. A. Ravcheev, I. Thiele; Univ. of Luxembourg, Esch-sur-Alzette, Luxembourg

Abstract Body:

Background: Human intestine is an organ with a unique anatomy and physiology. This organ also is an environment for about 10 to 100 trillion of microbial cells. The human gut microbiome (HGM) has been intensively studied during last years; however, respiratory capacities of the gut microbiota have been investigated for only a limited number of model. Here, we present a systematic analysis of respiration genes for ATP synthases, respiratory reductases for electron acceptors, and quinone biosynthesis encoded by the genomes of the HGM.**Methods:** We applied our genomic analysis to 254 microorganisms commonly found in the human gut. The investigated genomes belonged mostly to Firmicutes, Bacteroides, Proteobacteria, Actinobacteria, and Fusobacteria phyla of Bacteria. For the annotation of gene functions, the PubSEED platform (http://pubseed.theseed.org) was used. The gene functions annotations was done using available literature data, protein sequence similarity, protein domain structure, specificity determining positions (SDPs, http://bioinf.fbb.msu.ru/SDPfoxWeb), and genome-context based approaches, including gene chromosomal clustering and phyletic patterns.**Results:** The ATP synthases of F- and/or V-type were found in all analyzed genomes, whereas in the distribution of respiratory reductases and quinone biosynthesis variations were observed. The analysis of studied genomes revealed aerobic and anaerobic reductases for tetrathionate, thiosulfate, polysulfide, sulfite, adenylyl sulfate, heterodisulfides, fumarate, trimethylamine N-oxide, dimethyl sulfoxide, nitrate, nitrate, nitrogen oxide, nitrous oxide, selenate, and arsenate, whereas no reductases for chlorate, perchlorate, or metals were found. In addition to previously known terminal reductases, two novel reductases were predicted, being a flavin- and thiol-dependent microaerobic reductase and an anaerobic thiosulfate reductase. Three pathways for a quinone biosynthesis were found in the analyzed genomes, one for the ubiquinone (Ubi) and two for the menaquinone (Men and Mqn). During the analysis of the quinone biosynthesis pathways, four alternative forms of previously known enzymes and four novel enzymes for the Mqn pathway were predicted.**Conclusions:** This work substantially expands our knowledge on both respiratory pathways in bacteria and physiology of the HGM.

Phylogenomic and Phenotypic Characterizations of *Tsukamurella* Species: Reclassification of *Tsukamurella pseudospumae* as a Later Synonym of *Tsukamurella sunchonensis*

Author Block:

Y. TANG, J. L. L. Teng, S. K. P. Lau, P. C. Y. Woo; The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Tsukamurella was first proposed as a genus in 1988 and currently comprised 11 species with validly published names. Among these, 5 species are known to be associated with human infections and 6 have been found in different environmental sources.During the characterization of *Tsukamurella* species, similar phenotypic profiles were observed between *T. sunchonensis* SCNU5^T, which was isolated from extensive foam in the aeration basin of an activated sludge process in South Korea in 2003 and *T. pseudospumae* N1176^T, which was also from foam on the surface of aeration tanks in an activated-sludge-treatment plant in UK in 2004. DNA-DNA hybridization assays proved their high relatedness (95.1±4.9% DNA-DNA relatedness, mean±SD, n=3), which was above the 70% DNA-DNA hybridization value as a gold standard criterion for delineating bacterial species. We hypothesized that these two *Tsukamurella* species be united under the same name.To test this hypothesis, we performed whole genome sequencing of the two ambiguous *Tsukamurella* species with Illumina Hi-Seq platform and used a phylogenomic approach to determine their exact taxonomic positions.After *de novo* assembly, the draft genome of *T. sunchonensis* SCNU5^T and *T. pseudospumae* N1176^T were 5.2 Mb and 5.0 Mb with G+C contents of 70.5% and 70.6% respectively. Phylogenomic analysis using the draft genome sequences was concordant to the phenotypic result. Comparative genomic analyses revealed only minor differences between the two strains, with a Genome-To-Genome Distance Calculator (GGDC) and an Average Nucleotide Identity (ANI) of 82.3% and 98.1% respectively, which was well above the recommended 70% and 95% threshold respectively for species differentiation. Sequence based comparisons exhibited high protein sequence identities of each orthologous gene present between the two genomes. We therefore proposed that the species *T. pseudospumae* should be reclassified as a later synonym of *T. sunchonensis*.This study represents the first two genomes of *T. sunchonensis* SCNU5^T and N1176 (reclassified as *T. sunchonensis* in this study). The findings also illustrate the power of phylogenomic analyses to classify bacterial strains with ambiguous taxonomic positions.

Comparative Genomics for Inferring Bacterial Chromosome Topologies and Their Selective Value

Author Block:

S. Khedkar, A. Seshasayee; Natl. Ctr. for Biological Sci., Bangalore, India

Abstract Body:

Genomes evolve not only in base sequence, but also in terms of their genome architecture (defined by gene organization and topology). Changes at both these levels are crucial for adaptation to stress and changing environmental conditions. While extensive genome sequence data informs us about changes in base sequences, the study of genome architecture is restricted to a few model organisms. Further, the role of genome architecture in regulation of gene expression and bacterial response to antibiotics[1] and stress[2] has made it essential to study genome architecture across a wide range of bacteria. Towards this we exploit whole genome sequence data for a range of free-living, pathogenic and non-pathogenic bacteria to study link between gene organization and chromosome topology. Using comparative genomics across ~250 pairs of closely related bacteria we show (a) many organisms show a high degree of inter-replichore translocations, which are not limited to the inversion-prone terminus (*ter*) or the *oriC* regions; (b) translocation maps may reflect chromosome topologies, and (c) inter- replichore contacts equidistant from *oriC* may serve to divert recombination events towards maintaining gene dosage gradient down the *oriC-ter* axis. In summary, we suggest that translocation maps might be a first line in defining a gross chromosome topology given a pair of closely related genome sequences, and argue that chromosome topology might help maintain gene order. Finally we think our analysis could act as a useful resource to study genome architecture across a range of bacteria, just given their genome sequence.

Comparative Genomics and Transcriptomics of *Escherichia coli* Carrying Virulence Factors of Both Epec and Etec

Author Block:

T. H. Hazen[1], S. Daugherty[1], A. C. Shetty[1], J. P. Nataro[2], D. A. Rasko[1]; [1]Inst. for Genome Sci., Baltimore, MD, [2]Univ. of Virginia, Charlottesville, VA

Abstract Body:

Escherichia coli that are capable of causing human disease are typically classified into pathovars or pathotypes based on the illness they cause and their virulence gene content. Recent comparative genomics studies have demonstrated that both EPEC and ETEC are genomically diverse pathovars consisting of isolates in many different genomic lineages of *E. coli*. Both EPEC and ETEC are characterized by the presence of virulence factors encoded by mobile genetic elements including plasmids, phage and pathogenicity islands. In the current study we used comparative genomics and transcriptomics to characterize four *E. coli* isolates that contained virulence factors of both EPEC and ETEC. Three of the isolates contained a complete locus of enterocyte effacement (LEE) region that is usually found in EPEC, as well as the heat-labile enterotoxin (LT) that is one of the canonical virulence factors of ETEC. These isolates did not contain the bundle-forming pilus that is characteristic of typical EPEC, nor did they contain the Shiga-toxin of EHEC, thus they would be classified as atypical EPEC based only on virulence factor profiling. Phylogenomic analysis demonstrated these *E. coli* isolates were most related to a recently designated lineage of EPEC that contained both typical and atypical EPEC. A fourth *E. coli* isolate that was atypical EPEC (LEE+/BFP-) contained an autotransporter, *eatA*, which is more frequently identified in ETEC. RNA sequencing (RNA-Seq) analysis of the EPEC/ETEC isolates during growth in laboratory conditions that promote virulence factor expression of EPEC and ETEC prototype isolates demonstrated that some but not all of the virulence factors were expressed, suggesting that a coordinated regulation of chromosomal and mobile elements are required for full virulence. Genes in the LEE region exhibited increased expression under these conditions in the EPEC prototype isolate and the EPEC/ETEC isolates. The autotransporter *eatA* also exhibited increased expression under these conditions; however, the genes encoding LT did not exhibit increased expression. The findings of this study provide insight into the function of horizontally-acquired virulence factors in *E. coli* isolates that blur the designation of the *E. coli* pathovars EPEC and ETEC.

Evaluation of Horizontal Gene Transfer in the Evolutionary History of Beta-Galactosidase

Author Block:

A. Wu, L. David; Duke Univ., Durham, NC

Abstract Body:

Eukaryote-to-prokaryote horizontal gene transfer (HGT) events are believed to be rare. Here, we investigate the possibility that select bacterial beta-galactosidase genes are inherited from an ancient eukaryote-to-prokaryote HGT event. We analyzed 433 beta-galactosidase eukaryotic and prokaryotic beta-galactosidase genes downloaded from the UniProt database. These sequences were then aligned and trimmed in order to build phylogenetic trees. Inspecting our phylogenies, we observe an association between select beta-galactosidase genes in animals and host-associated bacteria. This association may be explained by an ancient HGT event, or by a series of gene duplication and loss events. Independent of inheritance mechanisms, however, these findings point to a carbohydrate-driven association between ancient bacteria and eukaryotes. Experiments are underway to test the functional role of animal-associated beta-galactosidase genes in bacteria.

Comparative Genomics of *Salmonella enterica* Serovars Anatum and Typhimurium Isolated from Cattle and Humans

Author Block:

S. V. Nguyen, J. L. Bono, T. P. L. Smith, R. Wang, C. M. Kelley, G. P. Harhay, D. M. Brichta-Harhay; US Meat Animal Res. Ctr., Clay Center, NE

Abstract Body:

Salmonella enterica subsp. *enterica* is an important group of pathogens capable of inhabiting a range of niches and hosts with varying degrees of impact, from commensal colonization to invasive infection. Recent outbreaks of multi-drug resistant *S. enterica*, attributed to consumption of contaminated ground beef, have led to increased scrutiny of the presence of these pathogens in red meat. To date, there has been limited comparative genomics research examining the virulence determinants that exists among serotypes of *S. enterica* associated with cattle. Such comparisons are necessary to understand disease etiology in cattle and humans.For *S. enterica* genomic comparisons, we present the complete genome sequences of 24 *S. enterica* isolates of serotypes Anatum (BA, bovine n=7; HA, human n=5) and Typhimurium (BT, bovine; HT, human n=6 each), isolated from healthy cattle or clinically infected humans. For all isolates, genomes were sequenced with single molecule real time technology and subsequently closed (HGAP3 or Celera 7.3). All circularized genomes and plasmids were annotated using a local instance of Do-It-Yourself Annotator (DIYA). Using the EDGAR comparative genomics system, phylogenetic trees were constructed and core-genome and pan-genome analyses performed between the different serotypes. Core and pan-genome values for Anatum were 4302 and 4969 ORFs, while those for Typhimurium were 4362 and 5347 ORFs respectively. Comparisons of core genomes revealed that many of the non-orthologous gene sets observed are associated with the mobilome. Specifically, phages GIFSY-1 and GIFSY-2 were only found predominantly in Typhimurium, while transposon IS903 was found in several strains of Anatum only. Analysis of the BA and HT core genomes revealed that 4118 genes were shared while 213 and 304 were unique to BA and HT, respectively. Genes unique to the HT core and possibly important for virulence, include retrons, methyltransferases, fimbrial operons, secreted effectors, and phosphotransferase systems. The results of these analyses and implications for differences in virulence potential within these serovars will be discussed.

Comparative Whole Genome Sequence Analysis of Long-term Surviving *Vibrio cholerae* in Nutrient-poor Lake Water Microcosms

Author Block:

S. Sinha Ray; Univ. of Florida, Gainesville, FL

Abstract Body:

Vibrio cholerae, the causative agent of the water-borne disease cholera, can shift to Growth-advantage stationary phage (GASP) phenotype in a stationary growth condition. We have previously reported a "GASP" phenotype that survived in nutrient-poor "filter sterilized" lake water (FSLW) microcosms for up to 700-days. Furthermore, we observed that the GASP persisting cells in 700-day old microcosms produced biofilms unique to FSLW. Identifying the sustained mutations in *Vibrio cholerae* GASP *phenotype will enhance our understanding of how this phenotype is selected under stressful conditions that promote its environmental fitness and adaption*. Here we report whole genome comparative analysis of wild-type *V. cholerae* N16961 El tor strain N16961, together with the same strain from a 24-hour microcosm,190 day-old microcosm and a 700-day old microcosm. Single nucleotide polymorphisms (SNPs) and INDELs were identified by using both reference mapping and *de novo* assembly approaches, including a bioinformatic pipeline optimized for cholera genomic analysis implemented in Galaxy. In particular, Freebayes was used to detect the variants and the SnpEff tool for annotating the variants and predicting their effect, while de novo assembly of the sequence reads was obtained with multiple alignments of whole genomes using MAUVE. Our analysis shows that compared to the wild type *V.cholerae* N16961 El tor strain, all three GASP phenotypes exhibited a total of 191 high quality mutations, with 50 mutations identified in the coding regions in both N16961-24 and190 days-old strain and 51mutations in 700-day-old GASP genome, respectively; out of which 28 (55%), 24 (48%) and 28 (52%) were due to INDELs, causing frameshift in several open reading frames. Point mutations consisted of 20 non-synonymous and 3 synonymous changes in all three GASP phenotypes. Among the genes exhibiting these changes, important regulatory proteins are included such as the CsrD, Ribosome GTPase, GGDEF and (p) ppGpp synthetase. In conclusion, our comparative analysis sheds light on significant genomic changes occurring in the long-time surviving GASP phenotypes, some of which may be responsible for the adaptation of the bacteria to stressful and stationary growth conditions.

Isolation and Genomic Diversity of Bifidobacteria Occupying the Gastrointestinal Tract of Mammals

Author Block:

K. Albert, A. C. Kundmann, R. M. Levantovsky, D. A. Sela; Univ. of Massachusetts, Amherst, MA

Abstract Body:

The genus *Bifidobacterium* contains 39 species of anaerobic rod-shaped bacteria that exhibits a characteristic bifid morphology under certain conditions. Bifidobacteria are an early colonizer of the infant gastrointestinal tract (GIT) and are considered a beneficial member of the gut microbiome in adults, albeit at lower concentrations. The goal of this study was to isolate gut-colonizing bifidobacteria from mammals and infer the molecular evolution of these strains using comparative genomics. Our overarching hypothesis is that the sequence divergence and gene complement encoded within bifidobacterial genomes reflects mammalian host divergence and may enable colonization of the specific ecological niche (e.g. non-human primate) from which it was isolated. Accordingly, bifidobacteria were isolated from various mammals (i.e. humans and non-human animals) using selective media and confirmed by genotypic and phenotypic assays. Whole genomes of bifidobacterial isolates were sequenced, with resulting reads assembled, annotated, and subjected to various comparative analyses. As a result, bifidobacterial strains were isolated and identified as several taxa and further characterized. This includes subspecies belonging to *Bifidobacterium longum*, *Bifidobacterium pseudolongum*, among other taxa typically associated with gut microbiota. In addition, strains of *Alloscardovia* spp. were isolated from non-human primates. This genus belongs to the family *Bifidobacteriacea* and is phosphoketolase positive, which was once posited as the characteristic enzymatic activity of the genus *Bifidobacterium*. In addition to comparative genomics, several metabolic and nutritional phenotypes were characterized including carbohydrate utilization profiles and fermentative end product yields.

Population Genomics Traces the Evolution History of the Fungal Pathogen *Cryptococcus neoformans*

Author Block:

C. A. Desjardins[1], S. M. Sykes[1], J. Rhodes[2], Y. Chen[3], J. Perfect[3], A. Litvintseva[4], M. Fisher[2], C. A. Cuomo[1]; [1]Broad Inst., Cambridge, MA, [2]Imperial Coll. London, London, United Kingdom, [3]Duke Univ. Med. Ctr., Durham, NC, [4]CDC, Atlanta, GA

Abstract Body:

Cryptococcus neoformans causes approximately 1 million new infections resulting in 625,000 deaths per year worldwide. While global populations of *C. neoformans* are highly clonal, a unique subpopulation in sub-Saharan Africa is characterized by high genetic diversity, the presence of both mating types, and evidence of recombination. We have sequenced the genomes of roughly 400 isolates of *C. neoformans*, representing each of the three major population subdivisions: the global lineages VNI and VNII and the sub-Saharan African VNB. These include mainly clinical strains for VNI and the less commonly observed VNII, and a mix of clinical and environmental strains for VNB. Phylogenetic and linkage disequilbrium analysis revealed a deep split in the VNB group and a lack of recombination between the major lineages. Population genomic analysis highlighted patterns of recent hybridization and more ancient genetic exchange between and within subpopulations. The sub-Saharan VNB clade had substantially more diversity than the global VNI lineage. However, their genomes are also characterized by extensive regions of loss of diversity, suggesting recent selective sweeps through these populations, which could be linked to transitions between the environment and human host. These new insights highlight the evolutionary dynamics of this important fungal pathogen and a better understanding of the fundamental differences between the global and African subpopulations.

Reinstatement of the Genus *Kaistella* Within the *Flavobacteriaceae*

Author Block:

J. Newman, N. Pisani, D. Ciccarelli; Lycoming Coll., Williamsport, PA

Abstract Body:

The identification of a novel strain belonging to the *Flavobacteriaceae* led to comparative phenotypic and genomic studies with closely related reference strains that had recently undergone reclassification. The genus *Kaistella* was established in 2004 with the description of *K. koreensis*. The genus *Sejongia* was established in 2005 with the description of *S. antarctica* and *S. jeonii*. These species were moved into the genus *Chryseobacterium* in 2009 based on their similarity to *C. haifense* which itself is only distantly related to *C. gleum*, the type species of the genus. Many other species that cluster with this group have also been assigned to the genus *Chryseobacterium*. We sequenced the genomes of six members of the cluster as well as eight other members of the genus *Chryseobacterium.* Here we show that this cluster forms a monophyletic group with characteristics such as small genome size, fatty acid composition, antibiotic sensitivity and a lack of flexirubin pigment production that distinguish the group from "true" *Chryseobacterium* species. We propose that the genus *Kaistella* be reinstated with *K. koreensis* as the type species, and that the former members of the genus *Sejongia*, as well as nine *Chryseobacterium* species, including *C. solincola, C. haifense*, and *C. palustre* should be moved into the genus *Kaistella*.

K. Ogura[1], S. Watanabe[2], T. Kirikae[1], **T. Miyoshi-Akiyama**[1]; [1]Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan, [2]Jichi Med. Univ., Tochigi, Japan

Abstract Body:

Streptococcus pyogenes (GAS) can be subtyped according to serotype or the serotypes or genotype of the M proteins encoded by the *emm* genes. The GAS isolates harboring *emm1* or *emm3* have been found to predominate in patients with streptococcal toxic shock syndrome (STSS). To analyze the genomic background of *emm3* isolates, we have determined the complete genome sequence of an *emm3* GAS M3-b strain isolated from a patient with STSS case. The sequence showed 99% of genome coverage compared to those with the complete sequences of three previously completely sequenced *emm3* GAS isolates, MGAS 315, SSI-1, and STAB902 based on BLAST algorithm. None of these strains did not harbor functionally clustered, regularly interspaced short palindromic repeat. The sequence of the M3-b strain was compared with whole the entire genome sequences of the three strains, other MGAS 315, SSI-1, STAB902, 11 *emm3* strains isolated in the USA, and five additional 5 isolates sequenced in this study. Bayesian phylogeny using SNP concatemers showed that the most recent common ancestor of these 19 *emm3* strains appeared 84 years ago. Phylogenetic comparison and analyses of the distribution of virulence factors suggestedthat *emm3* isolates from the patients with and without STSS cases are not distinguishable from those of non-STSS cases were indistinguishable.

Population and Comparative Genomics of the Dimorphic Human Pathogenic Fungi

Author Block:

J. F. Muñoz[1], R. A. Farrer[2], C. A. Desjardins[2], J. E. Gallo[1], E. Misas[1], J. G. McEwen[3], O. K. Clay[4], C. A. Cuomo[2]; [1]Cellular and Molecular Biology Unit, Corporación para Investigaciones Biológicas, Medellín, Colombia, [2]Broad Inst. of MIT and Harvard, Cambridge, MA, [3]Sch. of Med., Univ. de Antioquia, Medellín, Colombia, [4]Sch. of Med. and Hlth.Sci., Univ. del Rosario, Bogota, Colombia

Abstract Body:

The Ajellomycetaceae family includes several of the dimorphic human pathogenic fungi such as *Paracoccidioides*, *Blastomyces* and *Histoplasma*. Related genera rarely cause disease in humans or are not pathogenic, such as *Emmonsia*, *Polytolypa* and *Spiromastix*. The *Paracoccidioides* genus includes two species that cause paracoccidioidomycosis (*P. brasiliensis*, *P. lutzii*). To better understand the evolution of pathogenicity of *Paracoccidioides* and other dimorphs, we performed population and comparative genome analyses of these fungi. We sequenced the genomes of 31 different isolates of *Paracoccidioides* belonging to all lineages. We completed the first annotated genomes for the PS3 and PS4 lineages, and examined gene content across each of the four lineages of *P. brasiliensis* and compared to *P. lutzii*. Comparing these reference genomes of *Paracoccidioides* and with SNPs identified in 26 additional isolates, we established the relationships of the *Paracoccidioides* lineages; we found good support from both phylogenetic analysis and principal component analysis for a separation of S1 into two subgroups (S1A, S1B). In addition we found evidence of higher exchange between the S1B group and all other lineages, and established patterns of population structure. Additionally, we sequenced, assembled and annotated the genomes of *Emmonsia* species, *P. hystricis* and *S. grisea*. Comparative analyses of these fungi with the dimorphic human pathogens identified patterns of gene conservation, protein family evolution and genomic features correlated with virulence. This population analysis provides a better understanding of the diversity and genetic exchange of *Paracoccidioides*, and the comparative analysis provided insight into the pathogenesis and life cycles of the dimorphic human pathogenic fungi.

Genomic Analysis and Classification of Novel Species *Flavobacterium douthatii* Abg sp. Nov

Author Block:

K. Fischer, J. Newman; Lycoming Coll., Williamsport, PA

Abstract Body:

Strain ABG was identified in the Lycoming College Microbiology class as a potentially novel species of *Flavobacterium*, a highly diverse and well-studied genus that is particularly important in freshwater biology and fish health. 16S rRNA pairwise similarity suggested that *F. succinicans* and *F. glaciei* were most closely related to ABG. However, 16S rRNA comparisons alone are insufficient when describing a new species. Instead, global orthology scores, phylogenomic metrics, and phenotypic data should all be taken into account. *Flavobacterium* sp. ABG's genome was sequenced at 90x coverage and was assembled into 89 contigs totaling 5,270,010 base pairs. The Rapid Annotation using Subsystems Technology (RAST) website was used to annotate the genome and compare it to other Flavobacteria. Genome-wide comparisons indicated *F. hibernum* and *F. chilense* were the most closely related species. Estimated DNA-DNA Hybridization showed sufficient differences from *F. hibernum* (24.8%) and *F. chilense* (24.6%) to confirm ABG's novel species status. Average Amino Acid Identity (AAI) and Average Nucleotide Identity (ANI) were also below the species threshold of 95% further supporting that ABG should be a novel taxon. Comparative genomics identified 1272 unique genes including a paralog of lantibiotic synthesis protein LanB synthetase not yet found in other *Flavobacterium* species. The presence of a large number of unique genes and the low genome similarity of strain ABG to its closest relatives are sufficient evidence to establish this organism as a novel species within the genus *Flavobacterium* with the proposed name *Flavobacterium douthatii*. The results also support the need to compare genomes instead of relying on single gene comparisons when classifying organisms.

Assessing Genome Wide Diversity Among Strains of *Streptococcus salivarius* Using Single Nucleotide Polymorphisms

Author Block:

R. R. Butler, III[1], J. T. A. Soomer-James[1], M. Frenette[2], J-F. Pombert[1]; [1]Illinois Inst. of Technology, Chicago, IL, [2]Université Laval, Québec, QC, Canada

Abstract Body:

Streptococcus salivarius is a ubiquitous primary colonizer of the human oral mucosa. However, little is known about the genetic diversity of this species as most of the current knowledge is restricted to limited MLST analyses. To better assess the genetic variability in this Gram-positive commensal species we sequenced two strains available from the American Tissue Culture Collection, ATCC 25975 and ATCC 27945, which are Lancefield K- and K+ respectively, the former possessing fimbriated appendages for mucosal adherence. Whole genomes of each strain were assembled using PacBio and Illumina sequencing and annotated. Genome wide pairwise SNP comparisons of these two strains plus those of four complete *S. salivarius* genomes available in GenBank were contrasted with the pairwise comparisons of ten strains of *Streptococcus thermophilus*. *S. thermophilus* is well characterized in the fermentation of dairy products, and is one of the most closely related species to *S. salivarius*. Synthetic read data for SNP comparison was generated for all strains using a portable Perl script, SSRG.pl (available via our lab's GitHub page). Pairwise SNPs for the *S. salivarius* strains ranged from 18.6-32.0 SNPs/kb, reflecting a sizeable variability in genomic content. The *S. thermophilus* strains showed markedly less variability, ranging from 0.0-8.6 SNPs/kb. The difference in polymorphism in each of the two species suggests that different environmental pressures have selected for increased divergence in *S. salivarius*, a species living in a complex oral microbiome.

Publishing Title:

Functional Importance of Inteins in Microbial World

Author Block:

O. Novikova, M. Belfort; Univ. at Albany, Albany, NY

Abstract Body:

Inteins, also called protein introns, are self-splicing mobile elements found in all domains of life. A bioinformatic survey of genomic data highlights a biased distribution of inteins among functional categories of proteins in both bacteria and archaea, with a strong preference for a single network of functions containing replisome proteins. Many non-orthologous, functionally equivalent replicative proteins in bacteria and archaea carry inteins, suggesting a selective retention of inteins in proteins of particular functions across domains of life. Inteins cluster not only in proteins with related roles, but also in specific functional units of those proteins, like ATPase domains. This peculiar bias does not fully fit the models describing inteins exclusively as parasitic elements. In such models, evolutionary dynamics of inteins is viewed primarily through their mobility with the intein homing endonuclease (HEN) as the major factor of intein acquisition and loss. Although the HEN is essential for intein invasion and spread in populations, HEN dynamics does not explain the observed biased distribution of inteins among proteins in specific functional categories.We propose that the protein splicing domain of the intein can act as an environmental sensor that adapts to a particular niche and could potentially increase the chance of the intein becoming fixed in a population. There are inteins modulated in a stimulus-dependent manner which points to the possibility that some inteins may adapt to their intracellular niche and become post-translational regulatory elements. Indeed some inteins can act as sensors, and through intein chemistry can inhibit splicing under stressful environmental conditions, such as redox modulation (Callahan et al. 2011), oxidative and nitrosative stress (Topilina et al. 2015a) or cold shock (Topilina et al. 2015b). Thus, we argue that selective retention of some inteins might be beneficial under certain environmental stresses, to act as panic buttons that reversibly inhibit specific networks, consistent with the observed intein distribution.

Phylogenomic Analysis of *Streptococcus sinensis* Hku4^{t} Reveals a Novel Phylogenetic Group in the Genus *Streptococcus*

Author Block:

Y. TANG, Y. Huang, S. K. P. Lau, P. C. Y. Woo, J. L. L. Teng; The Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Currently, the genus *Streptococcus* comprised more than 90 species and was divided into 7 major groups, namely anginosus, mitis, salivarius, mutans, bovis, pyogenic and sanguinis. *Streptococcus sinensis* has been discovered by our group from patients with infective endocarditis in Hong Kong in 2002. Subsequently, additional cases reported from worldwide suggested that the bacterium is an emerging pathogen of global importance. Phenotypic profile of *S. sinensis* was similar to members of anginosus, mitis and sanguinis groups. Phylogenetic analyses based on *groEL* gene sequences showed that this species clustered with members of anginosus and sanguinis groups, but 16S rRNA gene sequences revealed that this species branched out from members of anginosus, mitis and sanguinis groups. Thus, the phylogenetic position of this species remained unclear.In this study, a polyphasic approach has been used to determine the taxonomic position of *S. sinensis.*The whole genome sequencing of *S. sinenesis* HKU4^{T} was performed by Illumina Hi-Seq 2500. The draft genome of *S. sinenesis* HKU4^{T} was 2.06 Mb with G+C content of 42.2%. Phylogenomic analyses using the genome sequence of *S. sinensis* HKU4^{T} and those of 69 *Streptococcus* genomes and 50 ribosomal protein gene sequences from 87 *Streptococococcus* genomes showed that *S. sinenesis*, together with *S. oligofermentans* and *S. cristatus*, formed a distinct phylogenetic clade. Dendrogram generated from hierarchical cluster analysis of matrix-assisted laser desorption ionization time-of-flight mass spectrometry also formed the same clade.On the basis of these genomic evidences, it is proposed a novel phylogenetic group, “sinensis group”, to include species of *S. sinenesis*, *S. oligofermentans* and *S. cristatus*. This study presents the first draft genome of *S. sinenesis* and reveals a novel phylogenetic clade in the genus of *Streptococcus*. The findings demonstrate the superior power of phylogenomic analyses to resolve the ambiguities in bacterial taxonomy. Detailed comparative genomic analysis on members belonging to the “sinensis group” and those of the mitis group may illustrate not only the ecology and biology of *S. sinensis* but also pathogenesis of infective endocarditis caused by members of this novel phylogenetic group.

New Perspective on Cleanrooms and Human Pathogens

Author Block:

m. bashir[1], m. ahmed[2], t. Weinmaier[3], n. ivanova[4], t. pieber[5], **p. vaishampayan**[2]; [1]Med. Univ. of Graz, graz, Austria, [2]California Inst. of Technology, Jet Propulsion Lab., Pasadena, CA, [3]Univ. of Vienna, vienna, Austria, [4]Joint Genome Inst., walnut creek, CA, [5]Med. Univ. of Graz, Graz, Austria, graz, Austria

Abstract Body:

Strict planetary protection practices are implemented during spacecraft assembly to prevent inadvertent transfer of earth microorganisms to other planetary bodies. We wanted to evaluate if these practices selectively favors survival and growth of hardy microrganisms, such as pathogens. Three geographically distinct clean rooms were sampled during the assembly of three NASA spacecraft: Dawn, Phoenix, and Mars Science Laboratory mission. During Phoenix mission, sample sets were collected from clean room at three time points: before arrival of the Phoenix spacecraft, during the assembly and testing of the Phoenix spacecraft, and after removal of the spacecraft from the PHSF facility. All samples were subjected to whole genome shotgun metagenome sequencing on an Illumina HiSeq 2500 platform. We screened for pathogens and other virulence factors, which determine pathogenicity. Potential pathogens and their corresponding virulence factors were present in all the samples. Though the relative abundance of pathogens was lowest during the Phoenix assembly, virulence factors increased from before to during to after assembly, potentially offering a survival advantage. Decreased microbial and pathogenic diversity indicates that decontamination and preventative measures were effective and well implemented. This is the first metagenome study describing presence of pathogens in controlled enclose environments and their corresponding virulence factors. The results of this study should be considered for build environments, International space station and future manned mission to Mars.

Comparative Phylogenetic Analysis of the Microbial Communities in a Spacecraft Assembly Facility and in Epsomite Lakes

Author Block:

F. Chen[1], P. Vaishampayan[1], A. Probst[2], M. La Duc[1], B. Clark[3], M. Schneegurt[4]; [1]Jet Propulsion Lab., Pasadena, CA, [2]UC Berkeley, Berkely, CA, [3]Space Sci. Inst., Boulder, CO, [4]Wichita State Univ., Wichita, KS

Abstract Body:

The Martian surface presents numerous challenges for microbial survival. Initially discovered by the Viking lander, the high-sulfates, especially $MgSO_4$-rich nature of Martian regolith might play a role in precluding the survival and proliferation of any inadvertently introduced contaminant microorganisms. Such a notion sparks concerns relating to the unlikely event of an off-nominal landing of a spacecraft equipped with a perennial heat source. Under these conditions meltwater stemming from the subterranean ice-rich regolith might persist for an extended period of time, providing refuge for contaminant microbes to propagate, sheltered from the environmental pressures and stresses above. With this in mind, $MgSO_4$-tolerant microbes were screened from two environments relevant to the robotic exploration of Mars: a spacecraft assembly cleanroom (SAC) and natural $MgSO_4$-rich epsomite lakes. The microbial population observed in the former environment suggests the types of microbes most likely to gain access to, and contaminate, outbound spacecraft. Microbes populating the latter environment represent phylotypes whose fitness renders them capable of surviving $MgSO_4$-rich conditions. Tag-encoded 454 FLX amplicon pyrosequencing (TEFAP) was carried out on direct metagenomic extracts of environmental samples collected from a spacecraft assembly cleanroom (JPL, Pasadena, CA), Hot Lake (Oroville, WA), and Basque Lake (Kamloops, BC) using primers targeting hypervariable regions in the bacterial and archaeal 16S rRNA gene. Pyrosequencing protocols were also designed to assay the presence of certain functional genes, such as *nifH* in diazotrophs, *mcrA* in methanogens, and *dsrAB* in sulfate-reducing microorganisms. The results of this investigation, presented here, empower more knowledgeable hypotheses pertaining to the types of microbes most likely to gain access to SAC environments and thus pose a potential threat of forward contamination, and might persist for extended periods of time given an off-nominal landing or transfer to wet salty environments.

Methanogen Growth and Adaptability to Ammonium Chloride

Author Block:

C. McFerrin, R. L. Mickol, T. A. Kral; Univ. of Arkansas, Fayetteville, AR

Abstract Body:

The internal environment of Enceladus appears potentially habitable, containing mostly water, along with a few percent of carbon dioxide, methane, ammonia, and some organics. Due to a lack of oxygen and extreme subsurface environmental conditions, life there would likely be restricted to extremophilic, anaerobic organisms. On earth, methanogens, microorganisms from the domain Archaea, can thrive in anaerobic and extreme terrestrial ecosystems, suggesting methanogens could be a model for life on Enceladus. While the presence of water and nutrients, as well as the detection of methane, provide hope for life on Enceladus, the concentration of ammonia is concerning. Four methanogen species (Methanothermobacter wolfeii, Methanobacterium formicicum, Methanosarcina barkeri, Methanococcus maripaludis) were tested for their ability to survive and adapt in the presence of ammonium chloride (NH4Cl). Fifty-milliliter aliquots of four types of anaerobic methanogen growth media (MM, MSH, MSF, MS) were prepared. Ten milliliters of each medium were anaerobically transferred to each of five test tubes (n = 5). Ammonium chloride was added to each test tube, resulting in concentrations up to 6% NH4Cl. Following sterilization via autoclave, each tube was inoculated with 0.5 mL of the corresponding medium and methanogen species (MM: M. wolfeii; MSH: M. maripaludis; MSF: M. formicicum; MS: M. barkeri). The tubes were pressurized with 200 kPa H2, incubated at the organisms' ideal growth temperatures and monitored for methane production. M. wolfeii has shown methane production in 5% NH4Cl and is in the process of being adapted to higher concentrations. M. formicicum has produced significant methane in 3% NH4Cl. M. barkeri and M. maripaludis have continued to show limited success up to 3% NH4Cl. The data indicate that less methane is produced as NH4Cl concentration increases. However, the data suggest that each of the species studied could survive and produce methane in at least 3% NH4Cl concentrations. Future studies will aim to replicate findings and test additional concentrations of NH4Cl in order to determine the survival threshold for each of species.

FRIDAY-026

Publishing Title:

Methanogen Growth in the Presence of Nontronite

Author Block:

R. L. Mickol, M. Williams, J. Wray, T. A. Kral; Univ. of Arkansas, Fayetteville, AR

Abstract Body:

Spectral data indicate the presence of various clay minerals across the martian surface. Clay minerals are often created through hydrothermal alteration, suggesting long-term water-rock reactions on the planet. In certain locations, spectral signatures are consistent with those of nontronite, an Fe- and Mg-rich smectite clay. Nontronite is a hydrous phyllosilicate and, thus, can contain variable amounts of adsorbed water within its layers. Over Mars' history, these clay mineral-water assemblages may have supported microbial life. Four methanogen species (*Methanothermobacter wolfeii*, *Methanobacterium formicicum*, *Methanosarcina barkeri*, *Methanococcus maripaludis*) were tested for their ability to grow in the presence of nontronite. Methanogen growth media (MM, MSH, MSF, MS) were prepared and distributed into test tubes (10 mL per tube) in an anaerobic chamber. One, two or three grams of nontronite were placed into each type of medium. Media without nontronite served as a control. There were three tubes for each combination. Following sterilization via autoclave, each tube was inoculated with 0.5 mL of the corresponding methanogen species (MM: *M. wolfeii*; MSH: *M. maripaludis*; MSF: *M. formicicum*; MS: *M. barkeri*). The tubes were pressurized with 200 kPa H_2, incubated at the organisms' ideal growth temperatures and monitored for methane production. *M. wolfeii* and *M. formicicum* demonstrated decreased methane production with increased nontronite. Methane production was generally similar for the control, 1 g and 2 g nontronite tubes for both *M. maripaludis* and *M. barkeri*. In a second experiment, *M. barkeri* and *M. formicicum* cells were washed (centrifuged at 4200 rpm, rinsed with sterile buffer) to remove residual media, suspended in sterile buffer, and added anaerobically to tubes containing 2 g nontronite (sterile) and only sterile buffer. Tubes were pressurized with 200 kPa H_2, incubated at 37 °C and monitored for methane production. After 31 days, no methane was produced by either *M. barkeri* or *M. formicicum* in the presence of nontronite in buffer alone. This suggests that nontronite, by itself, does not provide all essential nutrients to warrant growth of methanogens. Future studies will test additional clays and clay mixtures detected on Mars for the ability to support methanogen growth.

Bacterial Growth Tolerance to Chlorate and Perchlorate Salts Relevant to Mars

Author Block:

A. Al Soudi[1], O. Farhat[1], F. Chen[2], B. C. Clark[3], **M. A. Schneegurt**[1]; [1]Wichita State Univ., Wichita, KS, [2]NASA Jet Propulsion Lab., Pasadena, CA, [3]Space Sci. Inst., Boulder, CO

Abstract Body:

Near-surface environments on Mars are hyperarid with limited liquid water to support microbial growth. Potential sources of liquid water include deliquescent brines, liquids that form when hygroscopic salts absorb atmospheric moisture. (Per)chlorate salts form brines with low eutectic points that would remain liquid well below 0 °C on frigid Mars. Phoenix lander detected (per)chlorate salts at ~1% in polar regolith. Humidity in Mars' atmosphere appears sufficient to form deliquescent brines of (per)chlorate salts with the counterions calcium, iron, magnesium, and sodium. (Per)chlorate salts seem too oxidizing to be compatible with life, however these salts are stable and not reduced in aqueous solution. Previous studies on perchlorate-respiring anaerobes were done at concentrations far below those that significantly affect water activity or freezing point. We have examined growth tolerances to high concentrations of (per)chlorate salts using bacterial isolates from the Great Salt Plains of Oklahoma (NaCl-rich) and Hot Lake in Washington ($MgSO_4$-rich). Microbial growth tolerance to the 1% (~0.1 M) (per)chlorate level observed on Mars appears widespread among salinotolerant isolates of *Bacillus, Halomonas, Marinococcus, Nesterenkonia*, and *Planococcus*. Remarkably, growth was observed for certain isolates at 1 M (~10%; Aw ~0.96) concentrations of Na or Mg perchlorate. Tolerances to chlorate salts were higher, with growth observed at 2.75 M Na chlorate (Aw 0.89). Media with higher salt concentrations form precipitates unless acidified and iron and calcium salts were not soluble enough to substantially affect water activity. The bacteria do not appear to detoxify, reduce, or respire the anions, based on chromatographic measurements of (per)chlorate concentrations before and after cultivation. Most probable number analysis was used to measure the abundance of tolerant microbes in common oligohaline soils. Tolerance to 1% Mg perchlorate is prevalent and at 5%, 7 to 70 x 10^2 cells g^{-1} soil were observed, although no growth was detected at 10% Mg perchlorate. Our findings on microbial tolerance to (per)chlorate salts has relevance to the refinement of forward planetary protection protocols for missions to Mars and helps to set boundaries for potentially habitable regions on Mars.

Perchlorate-Coupled Carbon Monoxide Oxidation by Extremely Halophilic *Halobacteriaceae*

Author Block:

M. R. Myers, G. King; Louisiana State Univ., Baton Rouge, LA

Abstract Body:

Recent studies have documented (per)chlorate reduction coupled to heterotrophic metabolism by extremely halophilic Euryarchaeota (*Halobacteriaceae*). (Per)chlorate reduction appeared to be a consequence of non-specific activity by the particulate dissimilatory nitrate reductase, pNar. The discovery of denitrifying CO-oxidizing *Halobacteriaceae* suggested that CO-based lithotrophic metabolism might also be coupled to (per)chlorate. This process is of particular interest, as it could support microbial activity in perchlorate-rich brines on Mars, the atmosphere of which contains substantial amounts of CO. We report here the first documented results of perchlorate-linked CO oxidation in extremely halophilic Euryarchaeota.Enrichments of salt crusts from the Bonneville Salt Flats and surrounding saline soils have yielded a library of novel CO-oxidizing isolates, including members of *Halobacterium, Haloarcula, Halorubrum, Haloterrigena, Natrinema, Halobaculum,* and *Halovenus.* Of these, isolates, *Halorubrum, Halobacterium, Haloarcula,* and *Halovenus* have been observed to denitrify using pyruvate as an electron donor. Isolates were screened for perchlorate-linked CO oxidation using a saline medium containing 10 mM perchlorate and 2.5 mM pyruvate, with or without 0.25 mM nitrate added to induce nitrate reductase. Anaerobic headspaces contained nitrogen with 10 ppm CO. Perchlorate and chlorate concentrations were quantified at the beginning and end of incubations with an ion-selective electrode or spectrophotometric analyses, respectively. Chlorite was also quantified spectrophotometrically. CO oxidation by *Halorubrum* sp. *WSN3* occurred in the presence of perchlorate and nitrate (0.25 mM), but not with perchlorate alone. Nitrate concentrations at 0.25 mM were not coupled to CO oxidation, but CO was oxidized in the presence of 25 mM nitrate. No CO uptake occurred with autoclaved controls or treatments lacking electron acceptors. Perchlorate was reduced when CO and pyruvate were present, but in incubations with CO alone, 10 ppm concentrations were too low to drive a detectable decrease. These results established CO as an electron donor for perchlorate reduction in denitrifying extreme halophiles for which nitrate reductase acts as a non-specific perchlorate reductase.

Community Analysis and Mercury Speciation in Flue Gas Desulfurization Units

Author Block:

G. Martin, J. M. Senko; The Univ. of Akron, Akron, OH

Abstract Body:

Although wet flue gas desulfurization (wFGD) systems have been largely successful at reducing SO_2 and NO_x emissions from coal combustion, they have only partially reduced Hg emissions. Hg found in forced-oxidation flue gas primary exists as elemental (Hg^0), oxidized (Hg^{2+}) and particle bound (Hg^p) mercury. Studies have shown a complex range of factors affect Hg speciation in wFGD, including physiochemical characteristics of the slurry such as ash/unburned carbon, chloride concentration, pH, and oxygen concentrations. Additionally, microbiological activities may modulate the speciation of Hg within wFGD units. On one hand, Microbiological activities may lead to reduction Hg^{2+} to Hg^0 removing the Hg by making it more volatile, thus enhancing "reemission." On the other hand, Hg^0 may be biologically oxidized to Hg^{2+}, thus minimizing Hg emission, although this Hg^{2+} may be methylated by microorgnisms, transforming the element to a species that is quite toxic and readily bioaccumulated. While microorganisms are present in wFGDs, little work has been conducted into the impacts microbial activities in wFGD units have on Hg re-emission or retention, despite the vital role of microbes in cycling Hg in the environment. wFGD slurry is a physicochemically extreme environment, operating at temperatures around 60^0C. They also contain high concentrations of dissolved solids, notably calcium, magnesium, sulfate, and chloride. Although these microorganisms have been found in wFGDs, the types and extents of their activities are not clear. The goal of this project is to characterize the wFGD slurry system and identify the microbial communities and activities within them. FGD slurry was collected from three power plants, designated A, B, and C. All systems operate at approximately 57^0C with pH 5-6, and high dissolved chloride and/or sulfate concentrations (as high as 130 mM and 118 mM, respectively). Broad microbiological activity was evaluated based on respirometry and Hg metabolism incubations. Preliminary results indicate that O2 consumption in non-sterile slurry exceeds that of biologically deactivated slurry, suggesting that at least a portion of the microorganisms associated with wFGD slurries are active. DNA was recovered from slurries (1.0-1.5 ng/.8 mL slurry) and a survey of the microbial community based on 16S rRNA gene sequences will be conducted.

Publishing Title:

Heterogeneous Distribution of Microbial Life Within Bonneville Salt Flats

Author Block:

S. Tahan, H. Zweifel, J. Shaver, B. KLEBA; Westminster Coll., Salt Lake City, UT

Abstract Body:

The Bonneville Salt Flats (BSF) of northwestern Utah is characterized by a perennial salt crust that spans ~ 75 square kilometers. Below the crust is a shallow brine aquifer and in the winter the aquifer increases in volume to form a shallow pond that covers the crust until temperatures warm again. Though the hydrology of the basin has been studied extensively with interest in potash mining the region has historically been viewed as void of life as no macro flora are present. Nonetheless, work from our lab has shown that viable cells can be found on the surface of the crust suggesting that BSF is inhabited after-all. Because the cultivated organisms came from surface halite we reasoned that the viable cells could take up residence on BSF via two possible, mechanisms: 1) halophiles were deposited on the surface of BSF via wind from neighboring Great Salt Lake or 2) BSF harbors its own community of halophiles that thrive in underlying strata of the crust. To begin to discern between these two possibilities we set out to determine whether viable cells could also be found in brines and subsurface strata of the crust using both culture-dependent and culture independent techniques. Fluorescence microscopy and cultivation on modified R2A plates containing 23% salt demonstrate that viable cells can be found within subsurface compartments. Because the crust is comprised of a number of chemically defined strata, the mineralogical composition of which may impede growth, we then hypothesized that different strata might harbor different concentrations of cells. To test this idea, we measure CFUs obtained from each sample and live-dead staining to calculate the density of viable cells in each compartment. The greatest concentration of living cells was found within a green layer below the surface halite layer suggesting that BSF harbors its own resident community of microbes and that specific strata within the crust are more conducive to life than others. Because salt is known to preserve ancient life-forms and salt deposits have been identified on planetary bodies other than Earth BSF has the potential to serve as a model system to address questions about the relationship between the mineralogy and chemistry of evaporite deposits and habitability as well as the preservation of life in extreme environments on Earth and beyond.

Bacterial Biodiversity from the Eroded Surface Soils of the Island of Mayotte

Author Block:

J. R. Osman Naoum, C. Regeard, G. R. Fernandes, M. DuBow; Université Paris-Saclay, Orsay, France

Abstract Body:

"What microbes are where, and how do they live there" is now an essential question to understand life on Earth, even when comparing seemingly similar ecosystems in different locations. Metagenomic approaches, using high-throughput DNA sequencing, have become indispensable for studying populations of environmental microbes, as the vast majority of these microbes have been found to be non-cultivable under laboratory conditions. We examined the "Padza de Dapani" on the island of Mayotte off the east coast of Africa as this region is not a true (hot) desert, but resembles one due to extensive soil erosion. We collected surface soil samples from five different sites of the Padza de Dapani in Mayotte. We examined bacterial biodiversity using pyrosequencing of PCR-amplified 16S V3-V4 rDNA sequences from total extracted DNA. Our results show that in the acidic (pH 4.6 - 6), oligotrophic (organic carbon: 0.1-0.7 g/kg of soil) and mineralized (Fe: 18g/100g; Al: 12g/100g) soil samples from Mayotte, members of the *Actinobacteria*, *Proteobacteria* and *Acidobacteria* phyla dominated the bacterial populations. Interestingly, members of the genera *Acinetobacter*, *Arthrobacter* and *Bacillus* were found to be predominant in our samples, as is also observed in hot Asian deserts such as the Gobi (northern China) and Taklamaken (northwest China) deserts. The number of species (OTUs) and richness (Chao1) is higher in samples with pH >5.5, whereas the diversity (Shannon index) was found to be higher in samples with lower pH (<5) and containing organic carbon higher than 0.32 g/kg of soil. The bacterial populations were predicted based on the normalized copy number of the 16S rRNA gene using the program Tax4fun. Amino acid metabolism (12%), carbohydrate metabolism (14%) energy metabolism (7%) and membrane transport (10%) are the principal KEGG pathways in the functional diversity of bacteria present in our samples. Ongoing analyses will permit us to compare the bacterial diversity of selected worldwide soil samples with that we observe here to better understand microbial populations in oligotrophic soils and perhaps lead to ideas to prevent, stop and even reverse soil erosion.

Melainabacteria Found in Antarctic Ice-Covered Lake Vanda Pinnacles

Author Block:

K. Wall[1], T. Mackey[1], A. Jungblut[2], I. Hawes[3], D. Sumner[1]; [1]UC Davis, Davis, CA, [2]The Natural HIstory Museum, London, United Kingdom, [3]Univ. of Canterbury, Christchurch, New Zealand

Abstract Body:

Lake Vanda is a perennially ice-covered lake in Wright Valley of the McMurdo Dry Valley region of Antarctica. The lake is a microbially dominated ecosystem, with few macroscopic metazoans. Within the photic zone, the lake floor is covered with thick microbial mats, with decimeter-tall pinnacles. Previously, the biota of the the pinnacles was only known from limited morphology studies. In 2013, Lake Vanda pinnacles of a range of sizes and from two different depths were collected, and dissected into subsamples based on mat stratification. DNA was extracted and used as templates for 16s rRNA PCR. The barcoded PCR products were then sequenced on the Illumina MiSeq. DNA analysis of the mats demonstrated the presence of Melainabacteria, a deeply branching clade of bacteria which share ancestry with Cyanobacteria. Known Melainabacteria lack photosynthesis genes and have thus far been found to generally be fermenting organisms, with a reduced genome. They are typically found in the gut, and other anaerobic habitats such as aquifers and bioreactors. In contrast, Lake Vanda pinnacles are supersaturated with respect to O_2, at least in summer when the mats were sampled.The Lake Vanda pinnacles showed an unusually high percentages of Melainabacteria for environmental samples, with some samples having abundances as high as 2.9% of reads. Representatives of three groups of Melainabacteria were present, the Gastranaerophilales (YS2), Obscuribacteriales (MLE1-12), and Vampirovibrionales (SM1D11). Out of 161 samples analyzed, 157 contained Melainabacteria, and of those, 31 had abundances of greater than 1%. Of the groups of deeply branching Cyanobacteria present, the Obscuribacteriales were the most abundant, making up 94% of the Melainabacteria, and 0.68% overall abundance. The Vampirovibrionales made up most the remainder, and were present at 0.03% abundances overall. Gastaranaerophilales were present but at neglible amounts. The Melainabacteria showed distinct preferences towards certain pinnacle regions, but no distribution trends with lake depth or size of pinnacle could be determined.

Fumaroles Support Oases of Microbial Life in the Highest Elevation Fumaroles on Earth

Author Block:

A. J. Solon, J. L. Darcy, L. Vimercati, S. K. Schmidt; Univ. of Colorado- Boulder, Boulder, CO

Abstract Body:

In a previous study in the dry Andes of mountains above 6000 meters above sea level (m.a.s.l.), a fumarole (geothermal vent) was discovered that supports an oasis of life in an otherwise mostly barren landscape. The initial study focused on only one fumarole at an elevation of 5825 m.a.s.l., whereas the current study re-sampled that fumarole and an additional fumarole discovered near the summit at an elevation of 6050 m.a.s.l.; the highest elevation fumarole ever investigated. For comparative purposes, three non-fumarole sites were also sampled, two at 5825 m.a.s.l. and one at 6050 m.a.s.l. Biogeochemical parameters (enzyme activity, percent carbon and nitrogen, and gas fluxes) were measured on most of the samples in addition to microbial community structure. Following DNA extraction of the soils, the QIIME pipeline was used to compare each community and statistical tests (e.g. Adonis) were done to determine the effects of fumarolic activity, elevation, and biogeochemical parameters on Alpha and Beta diversity of SSU rRNA identified18S and 16S communities. Fumarole samples had much higher Alpha diversity than all non-fumarole samples, e.g. >575 16S OTUs per 5000 sequences for fumarole soils compared to <175 per 5000 sequences for non-fumarole sites. The same pattern was seen with eukaryotes with 275 18S OTUs per 7800 sequences for fumarole soils compared to 75 per 7800 sequences for non-fumarole sites. Furthermore, Beta diversity using weighted unifrac metrics grouped fumarolic soils closely together to the exclusion of non-fumarolic soils revealing a similarity of community composition for all three domains of life. Statistical significance was confirmed using Adonis (R vegan package) to compare fumaroles to non-fumaroles; elevation and biogeochemistry had no significant effect on diversity. These findings indicate that fumarolic activity allows the proliferation of complex microbial communities even in environments that are devoid of much life due to dryness and cold associated with extreme elevation.

Physiological Study of Purple Non-Sulfur Bacteria from Aquatic Environments in Puerto Rico

Author Block:

J. Rullan-Cardec, C. Rios-Velazquez; Univ. of Puerto Rico at Mayaguez, Mayaguez, PR

Abstract Body:

Purple non sulfur bacteria (PNSB) have been attracting the scientific community due to its metabolic diversity, physiology and biotechnological potential. Physiologically, some members of PNSB can growth in a wide range of temperature, salt and pH for what they are ubiquitous in nature, being isolated from different environments including those with extreme conditions. Despite of its wide distribution, it is estimated that only 3.7% of members of this group have been fully identified. The goal of this research is to study the physiology for future identification purposes of PNSB members, isolated from Heliconia and Bromeliad phytotelmata as well as water reservoirs of Puerto Rico. The isolates were partially identified by PCR amplification of 16SrDNA, followed by further sequencing and in silico analysis. To address the physiology of the isolates, growth in NaCl and pH ranging from 0 to 1% and 4 to 11 respectively were studied for each isolate. These tests were performed in 2mL-96 wells plates in Sistrom Media under phototrophic conditions for 5 days, measuring cell grow at 600nm. The data showed that 50 and 38% of the PNSB isolates from Heliconia phytotelmata could growth in a pH range from 6 to 11, and NaCl up to 3% respectively. One of these isolates was able to grow as high as 5% NaCl in the media with an optimum of 4%. In the Bromeliad phytotelmata, 79% and 60% of the isolates were able to growth in a pH range from 6 to 9 and NaCl up to 2% respectively. Two of the isolates of Bromeliad phytotelmata grew in a pH range from 5 to 11 and one of these isolates also grew at 4% of NaCl. From water reservoirs, 90% of the isolates grew in a pH range from 6 to 9, and 40% in up to 2% of NaCl in the media. Isolates belonging to the genus of *Rhodobacter* predominated in the Heliconia phytotelmata while the genus *Rhodopseudomonas* was predominant in Bromeliad phytotelmata and water reservoirs. This study confirms the diversity and versatile physiological traits of the PNSB in the studied environments, and suggests the need of a more extensive phylogenetic analysis for novel groups' determination. To our understanding this research represents the first attempt to study the physiology of PNSB from Bromeliad and Heliconia phytotelmata and water reservoirs in Puerto Rico.

Comparison of Halophyte (*Salsola stocksii*) Microbiome with Non-Halophyte (*Triticum aestivum*) Microbiome

Author Block:

S. Mukhtar; Forman christian Coll., Lahore, Pakistan

Abstract Body:

The distribution of saline soils on more than half a billion hectare worldwide, warrants attention for their efficient, economical and environmentally acceptable management practices. Halophytes are progressively utilized for human benefits. Halophyte microbiome contributes significantly to plant performance and can provide information regarding complex ecological processes involved in osmoregulation of halophytes. The basic aim of this study is to investigate the microbiomes associated with aboveground (phyllosphere), below-ground (rhizosphere) and internal (endosphere) tissues of halophytes. Culturable bacteria were characterized morphologically, physiologically, biochemically and identified by PCR amplification of specific 16S rRNA gene sequences. Sixty two strains were selected after screening of salt tolerance. It has been earlier reported that some of the osmoregulatory genes are present on the plasmid. In order to demonstrate it, plasmid curing of isolates was done by using SDS and sodium benzoate to study the effect of plasmid conferring salt tolerance. These plasmids were isolated and transformed into *E. coli* and growth response of original strains. Culture independent bacterial diversity was assessed by sequence analysis of 16S rRNA gene. Almost all strains showed optimum growth at 2-3.5M NaCl. These strains were related to *Bacillus spp.*, *Marinococcus* spp., *Micrococcus* spp., *Planococcus* spp., *Nesterenkonia* spp. and *Kocuria* spp. Mostly transformed *E. coli* were able to grow upto 3.5M NaCl concentrations. Metagenomic analysis from phyllosphere, rhizosphere and endosphere showed that approximately 40% bacteria were uncultured and unclassified. Actinobacteria, Firmicutes, Proteobacteria, Acidobacteria, Bacteriodetes, Plantomycetes, Cyanobacteria, Thermotogae and Choroflexi were predominant groups from halophyte plants. Results for cultured as well as for uncultured bacteria has revealed a wide diversity of halophilic bacterial population present in phyllosphere, rhizosphere and endosphere of halophytes.

Functional Metagenomics, A Novel Qiagen Bioinformatics Pipeline Enables Fast High-Quality Analysis of the Functional Content of Microbial Communities

Author Block:

A. Sand, F. Strino, A. S. Christensen, M. Bundgaard, A. C. Materna; QIAGEN Aarhus, Aarhus C, Denmark

Abstract Body:

BACKGROUND: Next generation sequencing based studies have revolutionized the field of microbial ecology, revealing unprecedented insight into environmental as well as host-associated microbiomes. However, still very few tools offer efficient and user-friendly analysis of the functional content of microbiomes.**METHODS:** We have implemented a pipeline of tools for functional and comparative analysis of microbiomes in the CLC Microbial Genomics Module, a component of QIAGEN's new bioinformatics solution for microbial genomics. The first step in the pipeline produces high-quality metagenome contigs using a novel high-performance metagenome de novo assembler. The resulting contigs are subsequently CDS-annotated using MetaGeneMark, and the CDSs are annotated with PFAM protein families, GO terms and top BLAST hits (using e.g. UniProt). Finally, the relative abundance of the functional elements in each dataset is computed and presented to the user.The functional contents of individual samples can be studied in a tabular format or visualized as pie charts, and visual comparison of multiple samples is done using stacked bar charts, layered area charts and principal coordinate plots. Finally, statistical comparison of multiple microbiome samples is performed to back-up our observations.We present benchmarks of this pipeline performed on both a previously published mock community dataset and on several previously published simulated microbiome datasets designed for benchmarking of microbiome analysis solutions.**RESULTS:** We demonstrate that the new metagenome de novo assembler runs as fast as the fastest alternative but uses only a fraction of the memory required by any other benchmarked de novo assembler. At the same time it produces contigs that are both longer than the contigs produced by other popular metagenome assemblers and are of significantly higher quality than the contigs produced by any other benchmarked de novo assembler.We furthermore demonstrate that the high-quality contigs produced by the new de novo assembler enables taxonomic and functional profiling of very high quality.Finally, we demonstrate that the complete analysis pipeline, producing functional profiles from raw microbiome read datasets, is able to reliably detect changes in the functional content of microbiomes.

Evaluation of Computational Methods for Human Microbiome Analysis Using Simulated Data

Author Block:

E. Castro-Nallar[1], S. L. Valenzuela[1], D. Simone[2], M. Pérez-Losada[2], W. E. Johnson[3], K. A. Crandall[2]; [1]Univ. Andres Bello, Santiago, Chile, [2]The George Washington Univ., Ashburn, VA, [3]Boston Univ., Boston, MA

Abstract Body:

Our understanding of the composition, function, and health implications of human microbiota has been advanced by high-throughput sequencing and the development of new genomic analyses. However, tradeoffs among alternative strategies for the acquisition and analysis of sequence data remain understudied. How do sequencing layout, sample complexity, and analysis pipeline affect taxonomic profiles? In order to approach this, we simulated metagenomic datasets reflecting different read lengths (75-1000 bp), sequencing depths (100 k-10 M), number of species (10-1000), presence of highly related strains, and various combinations of viruses/bacteria. Likewise, we simulated different database composition scenarios including presence/absence of dominant microbes in the database. The resulting simulation design yielded ~1152 datasets analyzed using five pipelines (MetaPhlan2; metaMix, PathoScope2, Sigma, and ConStrains). We evaluated pipeline performance based on ROC analysis (specificity/sensitivity), relative root mean square error, and average relative error.For instance, when one microbial species is dominant (= 50% of simulated reads), marker-based methods tend to decrease in sensitivity. Conversely, genome-based methods do not exhibit this trend, rather sensitivity decreases when simulated reads are more distributed towards the 10-50 percentiles. When simulated reads are homogenously distributed among species, we observed that both marker- and genome-based methods perform relatively better. In addition, both marker- and genome based methods exhibit larger relative errors when dealing with 1000 bp reads, presumably as a consequence of the read mapper not being optimized for such read lengths. We consistently found smaller error estimates for the 75-300 bp read length range irrespective of the method, although genome-based methods show slightly larger relative error at 75 bp.Our study enables researchers to make informed decisions relative to strengths and weaknesses of current taxonomic profiling methods, and adjust their sequencing experiments accordingly. All datasets and parameter values used in the study are freely available to ensure reproducibility and future pipeline benchmarking.

Integrated Microbiome Resource (Imr): Developing an Open and Streamlined Experimental and Analysis Pipeline for Microbiome Research

Author Block:

A. M. Comeau, **M. G. I. Langille**; Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Microbiome studies have revolutionized the microbiology field and are becoming increasingly popular. In recent years, advances in sequencing technologies and in bioinformatic methods have led to faster and more robust methods for generating and analyzing data. The Comparative Genomics and Evolutionary Bioinformatics - Integrated Microbiome Resource (CGEB-IMR: http://cgeb-imr.ca/) has streamlined and connected each essential step of a microbiome study starting with samples and ending with various plots and tables ready for interpretation within a single workweek. Our pipeline can handle up to 380 samples per sequencing run covering a variety of amplicon targets (16S, 18S, ITS, Bar-Seq, etc.). In our first year of operation we have processed 4694 samples generating 423M sequences and 236G bases from a variety of host-associated (e.g. humans, mice, rats, fish, insects, birds, reptiles) and environmental (e.g. soil, waste water, marine) biomes. These samples encompass 52 projects from 26 principal investigators from several countries. We openly present each step of this resource including primer validation, library preparation, sequencing, quality control, paired-end assembly, taxonomic annotation, functional annotation (metagenomes), predictive functional annotation using PICRUSt (16S data), statistical evaluation, and visualization. This pipeline, Microbiome Helper (https://github.com/mlangill/microbiome_helper), is continuously updated based on evolving best practices and can be replicated in other locations with only standard molecular and computational equipment, minimum personnel, and access to a bench top next-generation sequencer (e.g. Illumina MiSeq). Our results illustrate that microbiome studies can be easily conducted in various scientific settings, including for time-sensitive applications, and provide a complete experimental and analysis package that can be replicated by other microbiome researchers.

Analysis of Expanded Human Mircobiome Project Data by the Hmp Data Analysis and Coordination Center

Author Block:

C. McCracken, H. Creasy, J. Crabtree, J. Orvis, A. Brady, V. Felix, **M. Giglio**, A. Mahurkar, O. White; Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Background: The NIH Common Fund initiated the Human Microbiome Project (HMP) to explore the microbial communities of the human host and characterize their role in human health and disease. An initial set of publications in 2012 (HMP Consortium, 2012) reported analysis of the first 681 whole-metagenome-shotgun (WMS) datasets. Since then considerably more sequencing has resulted in a total of ~2400 WMS datasets from the healthy HMP cohort sampled from 18 different body sites, many from multiple visits over time. As the Data Analysis and Coordination Center for the HMP, we have carried out extensive analysis of this updated dataset.**Methods:** We developed a new assembly pipeline for this data utilizing the IDBA-UD (Peng, 2012) and DigiNorm (Brown, 2012) tools. In addition, we have done combined assemblies for all datasets that are derived from samples taken at multiple visits from the same person at the same body site. For functional annotation, we have developed a comprehensive pipeline and applied it to all of the WMS gene sets derived from the assemblies. The pipeline performs HMM, pairwise, and multiple motif searches. We have optimized the pipeline for speed by employing RAPSearch2 (Zhao, 2012) as an alternative to BLAST. Functional annotations are assigned to each predicted protein with Attributor, a tool that we developed which employs an evidence hierarchy to determine the best annotations for each protein based on the highest quality evidence. Finally, we have carried out taxonomic profiling by mapping reads to the MetaRef (Huang, 2014) collection of reference genomes to determine the phylogenetic composition of the samples.**Results:** These analysis results constitute a huge increase in the available set of HMP assemblies, gene sets, annotations and phylogenetic profiles. All results are available on our HMP Data Analysis and Coordination Center web resource at http://ihmpdcc.org/. An advanced query builder allows users to select primary sequence and derived analysis datasets using a variety of metadata filters.**Conclusions:** This work provides the microbiome research community with a significant set of analysis products and resources. These can be directly mined to answer biological questions or used as inputs for additional microbiome analyses.

Bugbase Predicts Community-wide Microbiome Phenotypes

Author Block:

T. Ward[1], J. Lynch[1], D. Sidiropoulos[1], R. Blekhman[1], R. Fink[2], D. Knights[1]; [1]Univ. of Minnesota, St Paul, MN, [2]St. Cloud State Univ., St Cloud, MN

Abstract Body:

With the rapid expansion of microbiome studies, the complexity of microbial communities and the intricacy of host-microbiome interactions have become apparent. Many microbiome studies rely on amplicon sequencing of marker genes to determine the taxonomic composition of a microbiome. Although useful tools such as PICRUSt now allow us to estimate the total genomic content of microbiomes using marker gene surveys, functional characterizations at the level of metabolic pathways can still be challenging to interpret. We hypothesized that we could predict several biologically relevant microbiome-wide traits like Gram staining, oxygen tolerance, the ability to form biofilms, pathogenicity, stress tolerance and mobile element content at the microbiome-wide level based on existing annotations and the presence of open reading frames within the genomes of community members. By combining a curated annotation database with the PICRUSt framework we have developed BugBase, a user-friendly tool that characterizes microbiome phenotypes using marker gene survey data. BugBase, which is available as a web-application or open-source package, requires users to input an OTU table and mapping file, which are used to generate phenotype predictions in the form of publication quality plots with corresponding statistical analyses. Using published data we have predicted microbiome-wide traits to vary significantly across a variety of host and environmental parameters, including bodysite, antibiotic exposure, disease status, geographical location and pH. We believe BugBase will provide researchers with useful, broad phenotypic descriptions of microbiomes that will simplify the interpretation of complex microbial biomarkers and serve as a jumping off point for further hypothesis driven in-depth analysis.

Contact-dependent Signaling (Cds) Facilitates Mobilization of a Genomic Island in *B. Thailandensis*

Author Block:

A. M. Barrero-Tobon, P. A. Cotter; Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract Body:

In their natural environment, bacteria are typically surrounded by other microorganisms and for this reason they have developed complex mechanisms to allow communication, cooperation, or competition with neighboring cells. One such mechanism utilized by bacteria to kill neighboring cells and control the surrounding population is contact-dependent growth inhibition (CDI). A major component of the CDI system is the large exoprotein BcpA, which contains a toxic C-terminus (CT) and is responsible for the induction of cell death upon delivery to a target bacterial cell. However, recent findings suggest that a delivered BcpA-CT also serves as a molecule that mediates intercellular signaling. During contact-dependent signaling (CDS) in *Burkholderia thailandensis*, the incoming BcpA-CT induces changes in gene expression in recipient cells resulting in phenotypes such as production of a yellow/brown pigment and aggregation of cells cultured in minimal media. Absence of the *bcpAIOB* locus or production of a chimeric BcpA abolishes CDS. We isolated a series of spontaneous mutants that arose from chimeric CDS-deficient strains that regained the ability to produce pigment and display other BcpA-dependent signaling phenotypes. We used transposon mutagenesis and RNAseq analyses to study these mutants and identified several pathways, such as flagellar biosynthesis and other metabolic processes, that are affected during CDS. Furthermore, we performed whole-genome sequencing to determine the genetic basis of these pseudo-revertant mutants and found that the *bcpAIOB* locus is located on a large genomic island and mobilization of this genomic element is dependent on CDS. Based on these findings we propose a mechanism in which the BcpAIOB proteins identify a neighboring target cell as "self" or "non-self" based on the *bcpAIOB* allele present. Furthermore, once a bacterial cell encounters a neighboring "non-self" cell, the BcpAIOB proteins then mediate inhibition of the target cell or perhaps transfer of the *bcpAIOB* genes to transform the cell into "self." Our work describes how, within a microbial community, the BcpAIOB proteins have the ability to mediate diverse types of interactions with different outcomes: elimination of neighboring cells to shape the population, intercellular communication, or propagation of the "self" *bcpAIOB* allele.

Toxin Gene Regulation of *Clostridium perfringens* by Signal Substance Produced by *Clostridium butyricum*

Author Block:

K. Ohtani[1], K. Oka[1], M. Takahashi[1], J. Nakayama[2], T. Shimizu[3]; [1]Miyarisan pharmaceutical co.,LTD, Tokyo, Japan, [2]Faculty of Agriculture, Graduate Sch., Kyushhu Univ., Fukuoka, Japan, [3]Graduate Sch. of Med. Sci., Kanazawa Univ., Kanazawa, Japan

Abstract Body:

Background: *Clostridium perfringens* is a Gram-positive anaerobic bacteria responsible for the clostridial myonecrosis (or gas gangrane), enteritis and enterotoxemia in humans and animals by producing numerous extracellular toxins and enzymes. It is well known that the toxin gene expression of *C. perfringens* is regulated by at least two-types of cell- cell signalling systems and VirR/VirS-VR-RNA cascade which controlled under the quorum-sensing. *C. butyricum* is a normally found in soil and animal intestine and strain of MIYAIRI588 has been used as probiotics. There was an old report that *C. butyricum* has inhibitory effect on the *C. perfringens* infection but the detailed mechanisms are still unclear. Therefore, we examined the effect of *C. butyricum* on the growth and toxin gene expression of *C. perfringens.* **Methods:** *C. perfringens* and *C. butyricum* were co-cultured by using cell culture plate and 0.4um pore size ThinCert™ membrane to separate them. Then total RNA was isolated from *C. perfringens* and transcription of toxin genes was analyzed by Northern hybridization. To check the effect of the supernatant, the supernatant was collected at various growth phase and added to the cells and total RNA was isolated after 15min incubation at 37°C.**Results:** The result showed that the growth of *C. perfringens* did not change when it was cultured with *C. butyricum*, but toxin genes expression was strongly repressed. A candidate gene related production of signal substance was cloned and transformed into *C. perfringens*. The result showed the candidate gene had a negative effect on toxin gene expression. Furthermore the supernatant collected from the candidate gene overexpressed strain repressed the toxin gene expression.**Conclusions:** These data indicated that inter-species signaling of toxin gene expression of *C. perfringens* was repressed by *C. butyricum* and reduces toxin production. Now we are trying to analyze the mechanism and components of the toxin genes regulation by C. butyricum in detail.

Evolution in Action: *In Vivo E*xperimental Evolution of the Pathogenic Bacterium *Citrobacter rodentium*

Author Block:

S. Wiles; Univ. of Auckland, Auckland, New Zealand

Abstract Body:

Bacteria are masters at adapting to their environment, rearranging, losing or mutating their genetic material or gaining new genes from their surroundings. Indeed, studies of bacterial adaptation in simple laboratory environments have provided direct insights into important evolutionary processes. We have moved microbial evolution experiments out of the flask and into a highly complex environment which can be manipulated with ease, the laboratory mouse, to experimentally investigate the factors that influence the adaptation of pathogenic microbes. We are using the bacterium *Citrobacter rodentium* which naturally infects mice using the same 'modus operandi' as some life-threatening human *Escherichia coli* strains. C57BL/6 mice were orally inoculated with bioluminescently-tagged *C. rodentium* and individually housed animals allowed to infect naïve animals through tightly controlled mouse-to-mouse exposure, a process which was repeated weekly over a period of 6 months. 'Evolved' *C. rodentium* have been isolated following 20 transmission steps, and we are currently assessing the strains for phenotypic and genotypic changes. The strains have shown varying improvements in fitness and transmissibility compared to their ancestor, with the evolution of a hypertransmissible isolate identified. This work extends existing flask-based experimental evolution with an *in vivo* model which focuses on complex, medically applicable real-world environments.

Statistical Mechanics and Thermodynamics of Viral Evolution

Author Block:

J. H. Kaufman[1], B. Jones[1], S. Bianco[1], J. Lessler[2]; [1]IBM Res. Almaden, San Jose, CA, [2]Johns Hopkins, Baltimore, MD

Abstract Body:

Background: In this work we use methods drawn from physics to study the life cycle of viruses. **Methods:** We will present and analyze a model of viral infection and evolution using the "grand canonical ensemble" and formalisms from statistical mechanics and thermodynamics. This approach is interesting because it make it possible to enumerate all possible genetic states of a model virus and host as a function of two independent pressures-immune response and system temperature. **Results:** Our results prove the system has a real thermodynamic temperature, and we discover a new phase transition between a positive temperature regime of normal replication and a negative temperature “disordered” phase of the virus. From an evolutionary biology point of view, at steady state the viruses naturally evolve to distinct quasispecies. The analysis also reveals a *universal* relationship that relates the order parameter (as a measure of mutational robustness) to evolvability in agreement with recent experimental and theoretical work. **Conclusions:**Given that real viruses have finite length RNA segments that encode proteins which determine virus fitness, the approach used here could be refined to apply to real biological systems, perhaps providing insight into immune escape, the emergence of novel pathogens and other results of viral evolution.

MDSINE: Microbial Dynamical Systems Inference Engine for Microbiome Dynamics Forecasting

Author Block:

V. Bucci[1], B. Tzen[2], N. Li[2], M. Simmons[1], T. Tanoue[3], E. Bogart[2], L. Deng[2], V. Yeliseyev[2], M. L. Delaney[2], Q. Liu[2], B. Olle[4], R. R. Stein[5], K. Honda[3], L. Bry[2], G. G. Gerber[2]; [1]Univ. of Massachusetts Dartmouth, N. Dartmouth, MA, [2]Brigham and Women's Hosp., Harvard Med. Sch., Boston, MA, [3]RIKEN Ctr. for Integrative Med. Sci., Yokohama, Japan, [4]Vedanta BioSci.s Inc., Boston, MA, [5]Sloan Kettering Inst., New York, NY

Abstract Body:

Background: The microbes that colonize our bodies are important in maintaining health. Efforts are intensifying to manipulate the microbiota to treat a variety of human diseases. Predicting temporal dynamics of host-microbial ecosystems is crucial for rational development of these treatments, to forecast how interventions will affect the microbiota over time. However, standard computational methods for analyzing microbial community structures cannot be used to predict dynamic behaviors of these ecosystems. Dynamical systems models provide an alternative and powerful analysis framework, but existing algorithms for inferring these models from microbiome time-series data suffer from major shortcomings; moreover, complete software packages have not been made available to the community. **Results:** We present the Microbial Dynamical Systems INference Engine (MDSINE), an open-source software package for inferring dynamical systems models from microbiome time-series datasets, predicting future behaviors of the microbiota, and visualizing results. Using data simulated to mimic key properties of real microbiome studies, we demonstrate that MDSINE significantly outperforms the existing method for microbial dynamical systems inference on multiple metrics. We then demonstrate the utility of our method on two new gnotobiotic mice experimental datasets, investigating infection with an enteric pathogen, *Clostridium difficile*, and stability of an immunemodulatory probiotic cocktail. For the *C. difficile* dataset, we use MDSINE to accurately forecast dynamics of the pathogen and to predict minimal sub-communities of commensal bacteria that stably coexist and inhibit *C. difficile* colonization. In the second example application, we use a new quantitative "keystoneness" measure implemented in MDSINE to determine which bacteria in the probiotic cocktail are predicted to be most crucial to maintaining integrity of the community structure in response to a dietary perturbation.

Diverse Modes of Eco-Evolutionary Dynamics in Communities of Niche-Constructing Bacteria

Author Block:

K. Vetsigian; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Background: A recent theoretical work demonstrated that the interplay between antibiotic production and degradation can lead to robust coexistence of many microbes with different antibiotic production and resistance capabilities. The question however remains whether evolution can naturally arrive at such stable communities. **Methods:** We performed long-term, spatially-explicit eco-evolutionary simulations in which bacteria competed for a single resource in a homogeneous two-dimensional environment that was subjected to periodic mixing. The bacteria could mutate their antibiotic production and degradation capabilities with respect to multiple antibiotics, and we recorded how the diversity of phenotypes evolved over time and how it depended on parameters such as the costs of production and resistance.**Results:** We discovered that the eco-evolutionary dynamics can spontaneously arrive at diverse evolutionary-stable states, demonstrating that the interplay between production and degradation is a viable mechanism for generating diversity in one-niche environments. Moreover, evolutionary stable states were just one of the possible outcomes of the eco-evolutionary dynamics. As we varied parameters, we observed regimes with Red-Queen dynamics with no long-lived phenotypes, sudden transitions between long-persisting ecologically stable states, and intermittency in which chaotic evolutionary dynamics was interrupted by long periods of quasi-stability.**Conclusions:** We found that simple models of evolving niche-constructing bacteria can already exhibit complex and diverse modes of eco-evolutionary dynamics. These findings greatly enhance our understanding of the different possible manifestations of eco-evolutionary dynamics and the factors that control the transitions between different regimes. Our work can also provide a platform for interpreting the diverse outcomes in evolving natural microbial communities and experimental microcosms.

Publishing Title:

Is Specialization a Typical Outcome of 1000 Generations of Evolution in Mutualism

Author Block:

D. Henderson; Univ. of Washington Bothell, Bothell, WA

Abstract Body:

It is thought that species diversification sometimes occurs when isolated subpopulations adapt to the particular features of the predators, prey, or cooperative partners that are specific to their local environment. To what extent might this hypothesis explain the diversification of microbial species, which cooperate or compete with each other in complex communities? We tested whether specialization was a common outcome of evolution in conditions requiring cooperation with another species for survival. The bacterium *Desulfovibrio vulgaris* was propagated for 1000 generations with the archaeon *Methanococcus maripaludis* in conditions that required them to cooperate through the exchange of hydrogen. To test whether *D. vulgaris* populations tended to become specialized for the *M. maripaludis* populations they evolved with (and vice versa), we revived 12 independently-evolved communities, separated the *D. vulgaris* and *M. maripaludis* populations from other another, and then paired each population back up with their sympatric partner or with 5 allopatrically-evolved partners. We then tested whether sympatric pairings were more efficient than allopatric pairings by comparing their growth rate and yield. While some *D. vulgaris* and *M. maripaludis* populations consistently caused faster community growth or productivity, there was not consistent relationship between sympatric and allopatric pairings. We used microscopy to quantify the density of *D. vulgaris* and *M. maripaludis* to test whether the absolute fitness of either species was higher in sympatric versus allopatric pairings. These tests gave similar results, showing that some *D. vulgaris* or *M. maripaludis* populations had higher absolute fitness on average across all 6 partners, but not specifically with sympatric partners. These results suggest that the first 1000 generations of adaptation to a new mutualism are not characterized by specialization.

Abstract Body:

Background: A central issue in ecology is understanding the processes shaping biodiversity. The groundwater in Oak Ridge Integrated Field Research Challenge site provides a rare opportunity to examine ecological processes and drivers shaping subsurface microbial diversity.**Methods:** Groundwater samples from 98 wells were analyzed for 205 environmental variables, as well as 16S rRNA genes by an Illumina MiSeq sequencer. After the phylogenetic signal was determined, the influence of selection was estimated based on beta nearest taxon index (βNTI). Then, turnovers not dominated by selection were analyzed using the Raup-Crick metric (RC) based on Bray-Curtis index to estimate the influence of dispersal limitation (RC>0.95) and homogenizing dispersal (RC<-0.95).**Results:** Across the entire site, both variable selection (44.6%) and dispersal limitation (46.3%) were important in shaping microbial diversity. Environment variables were used to fit the models with βNTI and RC using distance-based redundancy analysis. The model of βNTI identified 25 significant principal coordinates (PCs) imposing selection, with high loading of heavy metals, pH, nitrate, and DO. The model of RC identified 10 significant PCs imposing dispersal limitation, with high loading of spatial eigenvectors or metals in pellets. The spatial distribution of ecological processes showed the areas with little dispersal limitation for the microbial communities were those areas having low elevation, good diffusion of contaminants or a high level of dissolved oxygen.**Conclusions:** while contaminants and oxygen availability imposed obvious selection on subsurface microbial communities, the microbial spatial turnover was also largely affected by dispersal limitation, which may reflect actual underground dispersal conditions.

Nitrate Tolerance Mechanisms In *desulfovibrio Vulgaris* Hildenborough By A Long-Term Evolution

Author Block:

B. Wu[1], A. Zhou[1], J. Li[2], J. D. Wall[3], A. Arkin[4], P. P. Adams[4], J. Zhou[1], Z. He[1], S. Chen[5]; [1]Univerisity of Oklahoma, Norman, OK, [2]Hunan Agricultural Univ., Changsha, China, [3]Univ. of Missouri-Columbia, Columbia, MO, [4]Lawrence Berkeley Natl. Lab., Berkeley, CA, [5]Hubei Univ., Wuhan, China

Abstract Body:

Background: Nitrate is considered an inhibitor of sulfate reduction in sulfate reducing bacteria (SRB). It has been suggested that the response of *Desulfovibrio vulgaris* Hildenborough (DvH) to nitrate is linked to the level of osmotic, ionic, nitrite and other less defined stressors. However, it has been reported that nitrate inhibition of DvH may be independent of nitrite production.**Methods:** In order to understand the adaptation and evolutionary mechanisms of *D. vulgaris* responses to elevated $NaNO_3$, we propagated 12 DvH populations under $NaNO_3$ stress (concentration) for 1000 generations and obtained nitrate-evolved populations (EN1-12).**Results:** The EN populations significantly increased nitrate tolerance and cell motility. Whole genome resequencing data indicated that the nitrate-evolved populations had a higher mutation frequency in genes involved in energy, amino acid, carbohydrate, nucleotide and lipid metabolism, cellular process and signal, and information storage and processing compared to the ancestral populations. Through predicting the interaction between mutated genes using String 10, we found that two gene clusters (DVU0251-DVU0245 and DVU2543-DVU2548) with a high mutation frequency may be responsible for nitrate tolerance. Further study with a deletion mutant of *DVU2547*, encoding a Crp/Fnr global transcriptional regulator in the latter gene cluster, confirmed the sequencing results.**Conclusion:** This study provides new insights into our understanding of nitrate tolerance mechanisms in *D. vulgaris.*

Lymphoproliferative Disease Virus in Maine Wild Turkeys

Author Block:

J. Markham, P. Milligan; Univ. of Maine at Augusta, Augusta, ME

Abstract Body:

Repopulation of extirpated wild turkeys in Maine has been successful with an estimated fifty to sixty thousand birds currently living in the state. Assessment of the microbial health of Maine's wild turkey population is important for sustainability of agricultural livestock and the hunting industry. In 2009, Lymphoproliferative Disease Virus (LPDV) was detected by the Southeastern Cooperative Wildlife Disease Study in eastern wild turkeys, exhibiting lymphoid tumors. During the spring and summer of 2012, 15 Maine wild turkeys from Maine, 13 with overt disease, were euthanized for diagnostic examination. Skin and bone samples from the 15 birds were tested for LPDV by PCR. After confirmation of LPDV retroviral DNA in Maine wild turkeys, an additional 142 samples were assayed (4 birds with visible lesions and 138 apparently healthy birds). PCR testing of skin, bone marrow, and / or blood samples showed that 125 of 157 wild turkeys tested were positive for LPDV proviral DNA. Comparison of the estimated LPDV confidence interval in the total 2012 Maine turkey population, and our sample results showed that the margin of error at 95% confidence level (74-84%) encompasses the 80% found in our samples. Twenty-one domestic turkeys sampled in 2013 were negative for LPDV, as were 90 domestic turkeys sampled in 2014 from seven farms in central Maine. Historically, LPDV was only known to occur in domestic turkeys in Europe and Israel; however, since 2009, LPDV has been identified in wild turkeys from multiple sites throughout the Eastern United States. The implications of LPDV for wild turkey populations in Maine, as well as the risks for wild Galliformes (grouse and pheasant) and domestic fowl, are not clearly understood.

Abstract Body:

Background: As the pathogen causing septicaemiae and infectious serositis in waterfowl, *Riemerella anatipestifer* is a Gram-negative facultative anaerobic rod bacterium. Twenty-one serotypes of *R. anatipestifer* had been determined, but immunizations with these serotypes are not cross-protective. Cohemolysin, OmpA, virulence plasmids and biofilm formation were suggested as the virulence factors of *R. anatipestifer*, but their roles in pathogenesis are not well characterized. **Methods:** Crystal staining was used to measure the biofilm formation. *Caenorhabditis elegans* was used as a surrogate host for screening microbial virulence factors. Japanese quail was infected by *R. anatipestifer* via nasal or subcutaneous routes.**Results:** We demonstrated that the biofilm formation ability varied in field-isolated isolates with various serotypes. Meanwhile, the infections of various biofilm-forming isolates differently shortened the life-spans of surrogate host. RA03, a serotype 2 isolate, was found much virulent to *C. elegans*. Moreover, Japanese quail (*Coturnix coturnix*) was tested as a host for *R. anatipestifer*. Riemerellosis was found in RA03 infected quails.**Conclusions:** The nematode and quail infection models may be used as good tools for studying the pathogenesis of *R. anatipestifer*.

Qualitative Assessment Of Salmonella Specie In Poultry And Poultry Facilities

Author Block:

R. Ohenhen[1], E. M. ODOYA[2]; [1]Univ., Ekpoma, Nigeria, [2]Univ., Benin, Nigeria

Abstract Body:

Background: In developing world, many commercial poultry farm are associated with poor personal hygiene of poultry workers, poor sanitation of poultry environment, infestation of the environment with rodents and insects, all of which could aid the transmission of bacteria. Bacteria such as Salmonella species can develop resistance to routine elimination practice, chemical treatment and antibacterial drugs. The Objective of this study was to determine the distribution of Salmonella species in poultry and poultry facilities and to carry out drug susceptibility test on the bacterial isolates. **Materials**:Ten commercial poultry farms were used for this study. Samples were collected from Poultry and Poultry facilities. Selenite F medium was used for the culturing and identification was done using standard microbiological procedures. Using Agar culture plates, drugs susceptibility test was conducted with the following antibiotics: Sulphamethaxozole, Chloramphenicol, Gentamicin, Tetracycline, Ciprofloxacine, Cefotaxime and Doxycycline. **Results**: Salmonella species were isolated from all samples collected except from the floor of one farm. Susceptibility test was positive for Gentamicin only with 17mm zone of inhibition (standard diameter for sensitivity ≥ 15mm). The zone of inhibition diameter in Sulphamethaxozole (9mm/≤10mm standard), Tetracycline (11mm/≤14mm standard) and Deoxycycline (10mm/≤10mm standard). Intermediate diameter of zone of inhibition was recorded in Chloramphenicol at 15mm/ 13-17mm standard, Ciprofloxacine at 16mm/16-20mm standard and Cefotaxime 18mm/15-22mm standard. **Conclusion**: Poultry feaces of various thickness was observed adhered on surfaces in the farms. This could impact negatively on the efficacy of cleaning and disinfection procedure. Salmonella is known tosurvive for weeks in dust in poultry environment and in dried feaces of poultry and poultry feed . Infection would always occur with recontamination.The fact that Gentamicine was the only drug susceptible to isolate prove indiscriminate and abuse in application of antibiotics in the commercial poultry farms studied. We recommend establishment of strict Hygiene Protocols for farm circumstances alongside flexible management of "all in" and " all out" principle.

Unraveling Myxozoan Parasite Diversity In Catfish Aquaculture In The Southeastern United States

Author Block:

T. G. Rosser[1], L. M. Pote[1], L. H. Khoo[2], D. J. Wise[2], N. R. Alberson[1], E. T. Woodyard[1], S. M. Quiniou[3], W. A. Baumgartner[1], T. E. Greenway[2], C. C. Mischke[2], **M. J. Griffin**[2]; [1]Coll. of Vet. Med., Mississippi State Univ., Mississippi State, MS, [2]Thad Cochran Natl. Warmwater Aquaculture Ctr., Mississippi State Univ., Stoneville, MS, [3]Warmwater Aquaculture Res. Unit, Agricultural Res. Service, United States Dept. of Agriculture, Mississippi State, MS

Abstract Body:

Myxozoan parasites are a persistent threat to the health and production of cultured and wild fish species throughout the world. The Myxozoa represent a diverse group of >2,000 described species from fish of both fresh and marine environments. The two-host life cycle usually involves a myxospore stage in the fish intermediate host and a pelagic, waterborne actinospore stage released from aquatic annelids. Of the numerous myxozoan species from economically important fish, <10% have experimentally or molecularly confirmed life cycles. In the southeastern United States, catfish producers experience significant losses annually attributed to *Henneguya ictaluri*, the causative agent of proliferative gill disease (PGD) in channel catfish (*Ictalurus punctatus*) and blue catfish (*Ictalurus furcatus*) x channel catfish hybrids. In addition to *H. ictaluri*, our team has identified at least 10 distinct species of *Henneguya* endemic to catfish aquaculture as well as a new species of *Unicauda*. Moreover, two previously undescribed *Myxobolus* spp. have been identified from smallmouth buffalo (*Ictiobus bubalus*) raised in polyculture with catfish in a failed effort to biologically control PGD. Species descriptions supplemented with 18S rRNA gene sequence data can be linked to corresponding actinospore stages through direct sequence comparisons allowing for molecular elucidation of unknown life cycles. At present, three of the four known *Henneguya* life cycles are from catfish aquaculture in Mississippi, U.S.A. and have been described by our research group. Herein we discuss our most recent findings regarding the diversity of myxozoans indigenous to catfish aquaculture and future studies concerning myxozoans associated with farm-raised catfish in the southeastern United States.

Abstract Body:

Background: Despite over 100 years of research to reduce the incidence and impact of bovine respiratory disease complex (BRDC) in North American feed yard cattle, outbreaks still occur accounting for up to 75% of feed yard cattle morbidity. BRDC is the primary driver of health-related antibiotic treatment and is the most costly disease of feed yard cattle. Pathogenicity and virulence determinants of bacteria associated with BRDC remain incompletely understood and constitute a barrier to effective and precise treatment. **Goal**: Integrate genomic and phenotyping technologies to characterize molecular entities, pathways, and biological processes in nasopharyngeal bacteria to identify pathogenicity and virulence determinants associated with BRDC. **Approach**: A multi-institutional team with expertise in veterinary medicine, microbiology, genomics, and bioinformatics collaborated in a 28-day study to isolate diverse nasopharyngeal bacteria from 180 calves sampled at both sale barn and feed yard. Two thousand bacterial isolates from 28 case and 28 matched control animals were identified to species level. We have initially identified over 40 species that are not represented by closed genomes in GenBank. Closed genomes from these and other bacteria will seed downstream transcriptomic, epigenomic, and biochemical analyses to identify promoters, genes, and pathways from *in vitro* experiments. Antibiotic resistance and metabolic profiles are being characterized. **Results**: The newly closed genomes of over ten nasopharyngeal bacterial species and their antibiotic resistance profiles will be presented and available at GenBank. Genera include *Achromobacter*, *Comamonas*, and *Kurthia*. We will discuss our approaches to integrating genomic information with metabolic phenotypes to identify molecular entities, pathways, and biological processes that are enriched or depleted in genes that distinguish bacteria from case and control animals.

Identifying *Bordetella* Species Cultured from Turkeys with Upper Respiratory Infections

Author Block:

A. Reveille, S. Johnson, H. Madison, A. Brouillette, L. Harb, **L. M. Temple**; James Madison Univ., Harrisonburg, VA

Abstract Body:

Bordetella avium is the causative agent of bordetellosis, a contagious upper-respiratory tract disease that poses a problem to commercially raised turkeys. In recent years clinical manifestations similar to bordetellosis have been appearing in turkeys that are vaccinated against *B. avium*. Tracheal swab cultures of these turkeys revealed the presence of *Bordetella hinzii*, a commensal organism of the respiratory tracts of poultry that has been regarded as non-pathogenic. Reports of humans becoming infected with certain strains of *B. hinzii* have been recorded, creating a health hazard if turkeys are found to be reservoir hosts for these strains. In this study microbiological techniques were used to differentiate *B. hinzii* from *B. avium* in samples of bacterial isolates from various locations including North Carolina, Utah, Missouri, and Iowa. Identification methods included hemagglutination, which differentiates *B. hinzii* (negative) from *B. avium* (positive). Previous identification of these samples was based largely on colony morphology on MacConkey agar and hemagglutination results, with the majority of the isolates identified as *B. avium*. In this study hemagglutination was repeated on these samples, and PCR was run using specific PCR primers for either *B. avium* or *B. hinzii*. Of twenty isolates collecting over 30 years, ten were positive and ten were negative. Gel electrophoresis of the species-specific PCR products from the 20 isolates showed 12 positive for the *B. hinzii*-specific primers and 1 positive for the *B.avium*-specific primers. The remaining 7 isolates, which appeared to be *B. avium* or *B. hinzii* by colony morphology, did not test positive for either species-specific primer set. A similar trend is emerging from some isolates collected within the last year. We conclude that the infectious agent of bordetellosis may include other than either *B. avium* or *B. hinzii*, which is a novel and unexpected finding. Further work will include 16srDNA sequencing and biochemical tests to identify the unknown agents.

Intestinal Colonization of Healthy Brazilian Cattle with Multidrug Resistant Extended-spectrum Beta-lactamase Producing *Escherichia coli*

Author Block:

J. Palmeira, H. Ferreira; Univ. of Porto, Porto, Portugal

Abstract Body:

Background: Intestinal colonization of food-producing animals with extended-spectrum beta-lactamase (ESBL) producers represents a public health concern. Brazil is one of the biggest bovine producers for meat and milk consumption and a big exporter. This study aimed to detect multidrug resistant (MDR) ESBL producing *Enterobacteriaceae* in feces of healthy bovine from the North of Brazil.**Methods:** Isolates were obtained from bovine fecal samples of 22 productions in the North of Brazil. Selection of the isolates was performed on MacConkey agar with oxiimino-beta-lactams, tetracycline, and ciprofloxacin. Samples were previously incubated in TSB. Susceptibility testing was achieved by disk diffusion method according to the CLSI. Bacterial presumptive identification was performed with CHROMagar Orientation. ESBL producers were screened by the double disk synergy test. ESBL coding genes were screened by PCR with specific primers $_{bla}$TEM, $_{bla}$OXA and $_{bla}$SHV; and $_{bla}$CTX-M.**Results:** From 188 cattle fecal samples, 267 *Enterobacteriaceae* isolates were obtained, showing resistance to tetracycline (73%), amoxicillin (59,9%), sulfamethoxazole + trimethoprim (44,9%), ciprofloxacin (33,7%), cefotaxime (30,7%), chloramphenicol (14,9%), amoxicillin + clavulanic acid (14,2%), cefoxitin (5,6%) and gentamicin (4,4%). A total of 176 isolates were MDR. Seventy of the selected *Enterobacteriaceae* isolates (26,2%) were ESBL-producing *Escherichia coli*. Thirty five of the total fecal samples (18,6%) showed ESBL producers with the following beta-lactamase gene profile: $_{bla}$SHV (11,4%); $_{bla}$TEM (11,4%); $_{bla}$CTX-M Group 2 (G2) (7,1%); $_{bla}$CTX-M Group 8 (G8) (7,1%); $_{bla}$CTX-M Group 1 (G1) and $_{bla}$OXA (2,8%); $_{bla}$SHV and $_{bla}$TEM (2,8%); $_{bla}$CTX-M G1 (1,4%); $_{bla}$CTX-M G1 and $_{bla}$TEM (1,4%); $_{bla}$CTX-M G2 and $_{bla}$TEM (1,4%); $_{bla}$CTX-M G2 and $_{bla}$OXA (1,4%); $_{bla}$CTX-M G8 and $_{bla}$SHV (1,4%); and $_{bla}$OXA (1,4%). Results show the prevalence of $_{bla}$CTX-M, present in 24,3% of ESBL-producing *E. coli*. ESBL producing isolates showed different associated resistance with other antibiotic families, showing a polyclonal spread.**Conclusions:** Results show a high prevalence of ESBL-producing *E.coli*, presenting $_{bla}$CTX-M and MDR phenotype, colonizing these animals. Farm animals may act as reservoirs of MDR bacteria, highlighting the relevance of the One Health approach of this reality.

Abstract Body:

Mannheimia haemolytica normally populates the upper respiratory tract of cattle and is recognized as a major cause of bovine respiratory disease. Recently, two major genotypes (1 and 2) of *M. haemolytica* were identified from whole genome sequencing and analyses of 1,145 North American isolates. Only genotype 2 associated with bovine respiratory disease, although genotype 1 isolates were detected in diseased cattle. The genotypes were defined by the mapping of short sequence reads from each isolate to a reference genome followed by nucleotide polymorphism identification. Thus, closed circular genomes for these isolates were not assembled, and gene regions unique to the sequenced isolates in comparison to the reference genome were not identified. The goal of this study was to characterize the *M. haemolytica* pan genome, as well as the core genome for genotypes 1 and 2 using closed circular genomes. This could lead to the identification of effective intervention strategies for controlling genotype 2 *M. haemolytica* in cattle. Accordingly, we went back to the original collection of 1,145 isolates and identified sets of genotype 1 and 2 isolates that efficiently characterized genetic variation within and between the genotypes. The isolates from each set were all re-sequenced and assembled *de novo* into closed circular genomes. Analyses of these genomes revealed the pan genome of North American *M. haemolytica* as well as distinct core genomes for genotypes 1 and 2. These core genomes can be mined for proteins or other biological determinants that are specific to genotype 2, and suitable for potential intervention strategies like vaccine development.

Genetic Characterization of *Listeria monocytogenes* Isolated from Cases of Listeriosis in Ruminants in the Upper-Midwest

Author Block:

A. J. Steckler, M. Cardenas Alvarez, N. Dyer, T. M. Bergholz; North Dakota State Univ., Fargo, ND

Abstract Body:

Encephalitis associated with *Listeria monocytogenes* infections is an important disease of ruminants worldwide. Listeriosis can lead to significant economic losses at the farm level due to morbidity and the high mortality it causes in animals. In addition to these concerns for farmers and ranchers, veterinary listeriosis can also pose a potential food safety risk due to the potential for *L. monocytogenes* to enter the food supply via the farm environment. Our goal was to assess the genetic diversity of clinical listeriosis isolates from ruminants in the upper Midwest states, a population not well-studied. To determine the frequency and distribution of *L. monocytogenes* serotypes, we used a multiplex PCR to assign each isolate to a serogroup. The majority of isolates (7/11) belong to serotype 1/2a, and the remainder belong to serogroup 4bde (2 isolates) and 4ac (2 isolates). Multi-locus sequence typing (MLST) using 7 loci was implemented to investigate the genetic diversity of the isolates from the region. Loci sequences were compared to all known sequence types using the Pasteur Institute *L. monocytogenes* MLST database. One isolate of serogroup 4ac was found to have two loci with novel alleles, leading to a new sequence type, ST 897, which belongs to lineage 3. The seven isolates of serotype 1/2a all belong to lineage 2, with two isolates each assigned to ST 7, ST 91, and ST 230, despite being isolated from geographically distinct areas and at different times over the past year. Isolate information from the MLST database indicates that ST 7 isolates are widespread and have been isolated from food, the environment, and human clinical as well as animal clinical cases worldwide. Our results indicate that the isolates causing listeriosis in ruminants in the upper Midwest are genetically diverse, with new sequence types of *L. monocytogenes* still being discovered. Our results also demonstrate that isolates from ruminants in this region belong to the same genetic subtypes as isolates found in the food supply and human cases of listeriosis, and further studies are warranted to understand the ecology of this pathogen in the farm environment.

Effect of Temperature and Organic Acids on the Viability of *Campylobacter* spp. in Dairy Cattle Manure

Author Block:

I. KHAN[1], M. CLOUTIER[1], G. TALBOT[2], E. TOPP[3], M. G. Miltenburg[1], M. Libby[1]; [1]Ottawa Reaserch and Dev. Ctr. (ORDC), OTTAWA, ON, Canada, [2]Sherbrooke Res. and Dev. Ctr. (SRDC), Sherbrooke, QC, Canada, [3]London Reaserch and Dev. Ctr. (LRDC), LONDON, ON, Canada

Abstract Body:

Background: Livestock manure is stored in concrete tanks and represents a reservoir of human-associated pathogens. With the application of manure as an organic fertilizer, these pathogens transfer to humans via water, food and air and cause potential public health risks. Among several bacterial pathogens, *Campylobacter* spp. exists as a commensal organism in the gastrointestinal tracts of domestic animals which is one of the most common causes of human gastroenteritis worldwide. The study was designed to determine the viability of *Campylobacter* spp. in dairy cattle manure samples from various dairy cattle manure storage tanks. **Methods:** Samples were anaerobically incubated for 28 weeks under two temperature regimens simulating the winter to summer (eight weeks at 4ºC, followed by a gradual four-week increase at 25ºC) or the summer to winter (sixteen weeks at 25ºC, followed by a gradual four-week decrease at 4ºC) seasonal periods. Moreover, another series of *in vitro* manure incubations were performed to study the effect of organic acids (addition of acetate at 8.5 g/L or propionate at 2 g/L; final conc.) on *Campylobacter* survival. Viability was determined using a culture-based viable count plating method. **Results:** Overall, the cells of *Campylobacter* spp. survived at both temperature conditions for 28 weeks with no significant difference, and a maximum of one log reduction was observed. In contrary, cells of *Campylobacter* spp. survived up to two weeks in diluted (three-fold with autoclaved water) manure treated with acetate and in undiluted manure containing acetate and propionate at the above-mentioned concentrations. However, viability of *Campylobacter* cells was observed for at least four weeks in diluted manure suggest that the dilution might influence *Campylobacter* survival. **Conclusions:** The temperature-based assay results show that temperature did not have an impact on the viability compared to the organic acids. This suggests that acetate and propionate could be used for reducing the rate of survival of *Campylobacter* spp. in manure. The results would help in improving guidelines on manure management to minimize the risks of pathogen transfer from animal manures to the human and food chain.

Investigation of Sulfate Reducing Bacteria Populations and Their Activity in Anaerobic Manure Digesters

Author Block:

B. St-Pierre[1], A-D. G. Wright[2]; [1]South Dakota State Univ., Brookings, SD, [2]Univ. of Arizona, Tucson, AZ

Abstract Body:

Background: Biogas produced from anaerobic digestion of manure not only consists of methane and carbon dioxide, but also contains other minor gases, such as hydrogen sulfide (H_2S). Mitigation of H_2S emissions from anaerobic manure digesters is important to minimize health risks and reduce financial losses. In many anaerobic environments, H_2S is produced by sulfate reducing bacteria (SRBs) as a result of their anaerobic respiration. In manure digesters, the phylogenetic affiliation and activity of SRBs remain poorly characterized, and their investigation could yield valuable insight that would improve current mitigation strategies.**Methods:** SRB populations were analyzed in untreated manure and anaerobic digestate samples collected from three dairy farms that operate manure digesters in the state of Vermont (USA). Farms were selected based on the H_2S emissions reported by their respective operators: inherently high (GVS), inherently low (MPH), or moderate as a result of management practices (MXW). SRB diversity was investigated by high-throughput sequencing of PCR-generated amplicons of the SRB-specific *dsrAB* gene.**Results:** Manure samples from all farms showed a similar composition with a high prevalence of SRBs related to species of the genus *Desulfovibrio* (84.2 - 97.6% of sequence reads). In contrast, *Desulfosporosinus*-related SRBs were by far the most dominant in all digestate samples (96.9 - 98.3% of sequence reads). Further analysis revealed two major Operational Taxonomic Units (OTUs) for *Desulfovibrio*-related SRBs, compared to one OTU for *Desulfosporosinus*-related SRBs. We also report that, while digestate from the GVS farm was populated with a higher abundance of SRBs and contained higher levels of sulfate, it produced low (< 300 ppm) to non detectable amounts of H_2S when maintained without supplementation as batch cultures *in vitro*. We were only able to reproducibly observe production of high levels of H_2S (>1000 ppm) from digestate when it was mixed with untreated manure as a co-culture.**Conclusions:** Our results suggest that differences in H_2S production amongst different dairy manure digesters may not be caused by differences in SRB composition, but rather by other factors (chemical and/or biological) that remain to be determined.

Comparison of *Edwardsiella ictaluri* Isolates from Different Hosts and Geographic Origins

Author Block:

M. J. Griffin[1], S. R. Reichley[1], T. E. Greenway[1], S. M. Quiniou[2], C. Ware[1], D. X. Gao[1], P. S. Gaunt[1], R. P. E. Yanong[3], D. B. Pouder[3], J. P. Hawke[4], E. Soto[5]; [1]Mississippi State Univ., Stoneville, MS, [2]USDA, Stoneville, MS, [3]Univ. of Florida, Ruskin, FL, [4]Louisiana State Univ., Baton Rouge, LA, [5]Univ. of California - Davis, Davis, CA

Abstract Body:

The intraspecific variability of *Edwardesiella ictaluri* isolates from different origins was investigated. Isolates were recovered from farm-raised catfish (*Ictalurus punctatus*) in Mississippi, USA, tilapia (*Oreochromis niloticus*) cultured in the Western hemisphere, and zebrafish (*Danio rerio*) propagated in Florida, USA. These isolates were phenotypically homologous and antimicrobial profiles were largely similar. Genetically, isolates possessed differences that could be exploited by repetitive-sequence mediated PCR and *gyrB* sequence, which identified three distinct *E. ictaluri* genotypes: one associated with catfish, one from tilapia, and a third from zebrafish. Plasmid profiles were also group specific, and correlated with rep-PCR and *gyrB* sequences. The catfish isolates possessed profiles typical of those described for *E. ictaluri* isolates, however, plasmids from the zebrafish and tilapia isolates differed in both composition and arrangement. Furthermore, some zebrafish and tilapia isolates were PCR negative for several *E. ictaluri* virulence factors. Isolates were serologically heterogenous, as serum from a channel catfish exposed to a catfish isolate had reduced antibody activity to tilapia and zebrafish isolates. This work identifies three genetically and serologically distinct strains of *E. ictaluri* from different origins using rep-PCR, 16S, *gyrB* and plasmid sequencing, in addition to antimicrobial and serological profiling.

Genotypification and Virulence Genes Detection in *Pasteurella multocida* Isolates from Alpacas

Author Block:

R. Rimac, R. Hurtado, R. Rosadio & L. Maturrano; Univ. Natl. Mayor de San Marcos (UNMSM), Lima, Peru

Abstract Body:

Background: The South Americans camelids (SAC) production is the main economic resource for the Andean communities but the high mortality rates caused by infectious diseases such as acute pneumonia induced by *Pasteurella multocida* is the main restrain in its production. *P. multocida* is frequently isolated from fatal cases alpaca and it appears to be the responsible for the fatality. There is few studies of this bacterium in SAC animals and we lack detail information on type of LPS (serovar) and identification of virulence genes that could lead to develop control strategies including vaccines. For this reason, the objective of this study was genotypified *P. multocida* (n=25) strains isolated from acute pneumonia as well as to identify some virulence genes present in this pathogen. **Materials and Methods:** The 25 strains isolated were evaluated by multiplex PCR following the protocol described by Townsend et al (1998) to test the *P. multocida* specific *kmt* gen, to the serogroup we used the capsular genes as described by Townsend et al (2001) and the LPS genes to genotypified (Harper et al, 2015). Then, the virulence genes *toxA*, *tbpA*, *pfhA* and *hgbB* were tested according to Lichtensteiger et al (1996), Ewers et al (2006) and Atashpaz et al (2009). **Results:** All the *P. multocida* strains tested were classified as serogroup A and genotyped LPS 6 indicating that these serovars could be classified as 10, 11,12 or 15. The virulence genes *toxA* and *tbpA* were detected in all isolates. **Conclusion:** All strains tested were serogroup A, similarly to those detected in cattle and sheep and the presence of *toxA* and *tbpA* genes to those already reported in sheep where the *toxA* in being implicated and main responsible of fatality outcomes. The isolates were positive to genotype LPS 6 similar to those detected in cattle (serovar 10) and goat (serovar 12). The serogroup A and genotype LPS 6 are the most frequently detected in pneumonia from alpacas and the presence of *toxA* and *tpbA* may well be responsible for the pathology of acute pneumonia in Peruvian alpacas.

Warmwater Aquaculture Ctr., Stoneville, MS

Abstract Body:

Edwardsiella spp. have been linked to disease outbreaks in cultured and wild freshwater and marine fish species across the globe. Recent investigations of the genotypic and phenotypic variability of *Edwardsiella tarda* resulted in the division of *E. tarda* into three genetically distinct taxa. This led to the adoption of *E. piscicida* and the proposal of *E. anguillarum* as new species within the *Edwardsiella* genus. Phylogenomic investigations have demonstrated significant genetic differences between these phenotypically ambiguous taxa. To this end, real-time polymerase chain reaction (qPCR) assays were developed for the rapid differentiation and quantification of *E. piscicida*, *E. tarda*, and *E. anguillarum*. *In vivo* studies performed using intracoelomic injections in catfish fingerlings (mean weight: 17.3g; range 7.3 - 40.9g) identified a median lethal dose (LD_{50}) of 3.9×10^5 CFU for *Edwardsiella piscicida* and 5.9×10^7 CFU for *Edwardsiella tarda*. Negligible mortality was observed in catfish injected with *E. anguillarum d*oses as high as 5.0×10^8 CFU, suggesting significant variation in pathogenicity of these isolates in channel catfish. This work supported a previous survey of archived bacterial isolates that suggested *E. piscicida* is more common in North American catfish aquaculture than *E. tarda.* These assays, coupled with a previously established qPCR assay for *E. ictaluri*, were employed in a multiplex fashion for the purpose of rapidly discriminating between fish pathogenic *Edwardsiella* spp. (*E. ictaluri*, *E. piscicida*, *E. tarda*, and *E. anguillarum*). In addition to this work, forty-seven *Edwardsiella* spp. isolates from different hosts and geographic origins were characterized by two commercial phenotypic identification kits, plasmid profiling, PCR-mediated DNA fingerprinting and sequencing of 16S rDNA, *gyrB*, and *sodB* genes in efforts to consolidate the current dissonance associated with previous reports of *Edwardsiella* spp. infection in fish.

Evaluation Of Exposure To Common Tick-Borne Bacteria In Select Northeastern Oklahoma Equine Population

Author Block:

T. L. Orme, D. Kirk, **S. Ruskoski**; Northeastern State Univ., Broken Arrow, OK

Abstract Body:

Background: *Anaplasm*a *phagocytophilium, Ehrlichia canis, Borrellia burgdorferi,* and *Rickettsia rickettsii* are common tick -borne bacteriapathogens that infect both humans and animals. via tick bites. There is a paucity of information regarding exposure to these organisms in horses. The purpose of this study is to evaluate and document equine exposure to these tick-borne pathogensbacteria in Northeast Oklahoma during the 2014 and 2015 tick seasons.**Materials:** Blood was collected form from 41 horses in March/April and again in November/December of 2014 and 2015. Sera were tested for antibodies to *A. phagocytophilium, E. canis, B. burgdorferi,* and *R. rickettsii* using an indirect immunoflourescent antibody (IgG) assay.**Results:** While none of the horses presented with fever or lethargy at the time of collection, the largest exposure was to *R. rickettsia* with 9(22%) showing a 4-fold or greater increase in antibody titers. Only 1 (3%) and 2 (5%) horses had a 4-fold or greater exposure to *A.phagocytophilium* and *E. canis,* respectively. However, 21 (51%) of the horses tested positive to antibodies against *B. burgdorferi,* while 10 (24%), 8 (20%), 8 (20%) had antibodies present against *A.phagocytophilium, E. canis,* and *R. rickettsiia,* respectively.**Conclusion:** The results of this study indicate that these horses were exposed to *R. rickettsiia* and *B. burgdorferi* to a greater extent than to *A. phagocytophilium* and *E. canis* during the 2014 and 2015 summers.

K. Perez[1], N. Mullen[1], J. Canter[2], D. H. Ley[3], M. May[1]; [1]Univ. of New England, Biddeford, ME, [2]Univ. of Connecticut, Storrs, CT, [3]North Carolina State Univ., Raleigh, NC

Abstract Body:

Parameters of disease ecology are affected by contact between individuals in the population, transmission rates, clinical presentation, and virulence capacity of the infectious agent. The avian pathogen *Mycoplasma gallisepticum* (MG) is a known pathogen of poultry, and newly emerging pathogen of house finches wherein it is associated with lethal conjunctivitis. Factors known to mediate virulence of MG in poultry include cytadherence, sialidase activity, peroxide production, and possibly biofilm formation. We have quantitatively assessed these factors for over twenty MG isolates from house finches from a wide geographic distribution across the continental United States. Statistically significant ($P<0.05$) differences were observed across strains for sialidase activity, cytoadherence, and hydrogen peroxide production. No significant differences were observed for biofilm formation. Analysis of variance in adherence to distinct sialic acid linkages representing diverse cellular host ligands is ongoing. Quantitative variance in virulence-associated traits is consistent with within-host evolutionary adaptation in response to a change in ecological niche by a parasitic pathogen.

Proline as a Formic Acid Stress Protectant on the Fermentation of Glucose to Ethanol by *Saccharomyces* spp.

Author Block:

C. E. Oshoma[1], C. Powell[2], C. Du[3]; [1]Univ. of Benin, Benin City, Nigeria, [2]Univ. of Nottingham, Loughborough, United Kingdom, [3]Univ. of Huddersfield, Huddersfield, United Kingdom

Abstract Body:

Background: During bioethanol production from lignocellulosic hydrolysate yeasts are frequently exposed to various forms of fermentation stress such as nutritional starvation, metabolites production and fermentation inhibiting compounds produced during pretreatment and hydrolysis of the lignocellulosic material. These inhibitors hamper efficient ethanol production as they are toxic to the microbes conducting the fermentation. Formic acid is one of these inhibitors released into the hydrolysates at a concentration of 10 -30 mM. Previously found that proline act as a compatible solute that enhances yeast tolerance to stress by improving fermentative ability. Proline functions, in vitro, maybe protein and membrane stabilization, lowering T_m of DNA and scavenging of reactive oxygen species.**Methods:** The strains used in this study were *Saccharomyces cerevisiae* NCYC2592 and *Saccharomyces arboricolus* 2.3319. Phenotypic microarrays (PM) was carried out to study the effect of different concentrations of proline (0 - 50 mM) on metabolic profiles of *S. cerevisiae* NCYC2592 and *S. arboricolus* 2.3319 strains in the presence of 40 mM formic acid. Experimental procedure was carried out in 150 ml (mini) fermentation vessels using Yeast nitrogen base (YNB) medium.**Results:** In this study, addition of proline to the media to improve tolerance of yeast to formic acid during fermentation was investigated. The observation was that proline at 30 mM in the medium had higher cell count than the control medium as the fermentation progresses, and cell viability of proline medium was 94 and 91% after 24 hours for strain *S. cerevisiae* NCYC2592 and *S. arboricolus* 2.3319 respectively. The proline medium revealed a higher accumulation of ethanol than the control medium in both strains. The results showed that the modification of growth medium with little concentration of proline increased formic acid tolerance and fermentative ability of yeast cells.**Conclusions:** Overall results suggest that lower concentrations of proline in the media may improve yeast tolerance to formic acid and increase bioethanol production, although the mechanism of leading to this increase remains to be elucidated.

Glycerol Fermentation and Hydrogen Metabolism by *Escherichia coli*: New Approaches to Enhance Hydrogen Production

Author Block:

A. POLADYAN, K. Trchounian, A. Trchounian; Yerevan State Univ., Yerevan, Armenia

Abstract Body:

Hydrogen (H_2) metabolism is a basic process upon bacterial fermentation. H_2 is produced from formate, the end product of glycerol or glucose fermentation of *Escherichia coli*, by formate dehydrogenase H and hydrogenase (Hyd) enzymes. *E. coli* possesses four [Ni-Fe]-Hyd enzymes for activity of which heavy metals can be required. Besides, H_2 is efficient energy source for the future and organic waste glycerol can be used as a cheap carbon source. Glycerol and glucose fermentation redox routes by *E. coli* and their regulation by oxidizing and reducing reagents were investigated at different pHs: cell growth was followed by decrease of pH and redox potential. H_2 production and redox potential (ORP) kinetics from positive to negative level were investigated with two redox Pt (sensitive to H_2) and Ti-Si electrodes: simultaneously using both electrodes during bacterial growth provides information not only on general redox processes but also H_2 production rate and yield. Depending on carbon (glycerol and glucose) source different ORP kinetics was observed. Reducers (DL-dithiothreitol or dithionite) stimulating effect on H_2 production was shown. The influence of formate alone or its mixture with glycerol on growth of *E. coli* wild type and mutants with deletions of key subunits of different Hyd enzymes and H_2 production in batch culture was analyzed at different pHs. The results obtained identify the conditions when formate alone or with glycerol had stimulatory effects on bacterial growth and H_2 production. Furthermore, the importance of some heavy metals and their mixtures at low concentrations (<0.1 mM) for H_2 production was shown: H_2 yield was markedly stimulated 1.7- to 3-fold in the presence of Ni^{2+}+Fe^{3+}, Ni^{2+}+Fe^{3+}+Mo^{6+} and Fe^{3+}+Mo^{6+} mixtures. Discrimination between Fe^{2+} and Fe^{3+} was established. Some interaction of Ni^{2+} with Fe^{2+} was suggested to be effective increasing bacterial biomass and with Fe^{3+} determining activity of H_2 producing Hyds. The findings reveal the ORP level and reductive conditions essential role for H_2 production in *E. coli* upon glycerol fermentation. Mixed carbon sources or addition of some heavy metal ions enhance H_2 production. Co-fermentation with organic acids and oxidizing and reducing reagents effects and heavy metals ions can be considered as novel approaches to regulate and enhance H_2 production.

Comparative Effects of Cu(Ii) and Ni(Ii) Ions Low Concentrations on *Rhodobacter sphaeroides* Growth Characteristics and Hydrogen Production

Author Block:

L. Gabrielyan, A. Trchounian; Yerevan State Univ., Yerevan, Armenia

Abstract Body:

Different heavy metals are involved as "essential" elements in metabolism and hydrogen (H_2) production by bacteria through stimulating the responsible enzymes and related metabolic pathways. Copper (Cu) and nickel (Ni) ions in high concentration (>0.1 mM) are toxic, disturbing the membrane permeability and inhibiting enzymes activity. The inhibitory effect of these ions was reported for various bacteria, but the effect of Cu and Ni ions low concentrations on photosynthetic bacteria *Rhodobacter sphaeroides* has not been investigated yet. Many chemical reagents and biologically active compounds show bioeffects at low and ultra-low concentrations. It is interesting, how the effects of compounds at low concentrations differ from those of relatively high concentrations. The aim of the present work was the investigation of comparative effects of Cu(II) and Ni(II) low concentrations on growth properties and H_2 yield in *R. sphaeroides* MDC6522 from Armenian mineral springs. The bacterial growth characteristics were studied during phototrophic growth of *R. sphaeroides* in 1-5 μM Cu^{2+} and Ni^{2+} containing media. Specific growth rate by addition of Cu^{2+} and Ni^{2+} changed in differed manner: in the presence of 5 μM Cu^{2+} growth rate was ~3.5-fold lower in comparison with control (no addition), and has increased ~1.5-fold in medium with 5 μM Ni^{2+}. These changes may be resulted by action of the ions on redox potential (E_h) or by direct effect of these ions on bacterial membrane. Low concentrations of Cu and Ni ions were discovered to affect the E_h drop of the *R. sphaeroides* growth medium. Cu^{2+} and Ni^{2+} were shown to have an enhancing effect on the E_h drop after 72 h of bacterial growth. The increase of concentration from 1 to 5 μM enhanced the stimulatory effect of Ni^{2+}. The effect of Cu and Ni ions on H_2 yield in *R. sphaeroides* presented a different picture. H_2 yield in R. sphaeroides after 72 h of growth was enhanced ~1.5- and ~2.5-folds with 1 μM $Cu^{2+}$and Ni^{2+}, respectively. 5 μM Cu^{2+} inhibited H_2 production ~1.3-fold, whereas in the presence of 5 μM Ni^{2+} H_2 yield was ~3 fold higher in comparison with control. Thus, the results point out discrimination between Cu^{2+} and Ni^{2+} low concentrations effects and reveal new regulatory pathways to enhance H_2 yield in *R. sphaeroides*.

Publishing Title:

Enhanced Ethanol Productivity Through The Use Of Alginate Gel Threads

Author Block:

A. Nordmeier, D. Chidambaram; Univ. of Nevada Reno, Reno, NV

Abstract Body:

Background: The increasing rate at which our known fossil fuel reserves are being depleted coupled with the increasing production of greenhouse gases (GHG) is of serious concern. Switching to fuels produced through renewable sources will lower net carbon output to the atmosphere and reduce effects caused by GHG. There has been significant focus on the production of ethanol using microbes, as so-produced ethanol is considered biofuel and helps meet the Renewable Fuel Standards *(1)*. Current methods of ethanol production is done through a batch based system, which have long processing times and large infrastructure costs (2). Continuous flow reactors (CFR) are known to reduce cost, size, and time but are not industrially conducted at large production rates (3). CFRs with enhanced rates of productivity are needed. Alginate threads have been shown to have higher diffusion rates over that of the typically used beads(4). **Methods:** *Zymomonas mobilis* strain ZM4 (ATCC 31821) immobilized in Ca-alginate was used for fermentation in a CFR. Ethanol production was studied using two different types of immobilization; beads and threads. The production of ethanol and the consumption of glucose were monitored using a high performance liquid chromatograph.**Results:** Although both methods of immobilization are able to obtain similar ethanol concentrations, the use of threads as an immobilization technique could offer the advantage of increased flow rates for the feedstock. As shown in Figure 1, the threads in the CFR consumed all the glucose present, while the beads were unable to fully ferment all the glucose present at the given flow rate.**Conclusions:** Faster flow rates of the feedstock into CFRs with threads could significantly enhance the ethanol yield as well as the rate of production. Further analysis on the use of threads for ethanol production will be discussed.

Improved Acetic Acid Resistance in *Saccharomyces cerevisiae b*y Overexpression of the *Whi2* gene Identified Through Inverse Metabolic Engineering

Author Block:

Y. Chen, Female, Na Wei; Univ. of Notre Dame, South Bend, IN

Abstract Body:

Developing acetic acid resistant *Saccharomyces cerevisiae* is important for economical production of biofuels from lignocellulosic biomass, but the goal remains a critical challenge due to insufficient knowledge on effective genetic perturbation targets for improving acetic acid resistance in the yeast. This study employed a genome-wide inverse metabolic engineering approach to successfully identify a novel gene target *WHI2* (encoding a cytoplasmatic globular scaffold protein) which elicited improved acetic acid resistance in *S. cerevisiae.* Overexpression of *WHI2* significantly improved glucose and/or xylose fermentation under acetic acid stress in engineered yeast. Analysis of expression of *WHI2* gene products determined that acetic acid induced endogenous expression of Whi2 in *S. cerevisiae*. Meanwhile, the *whi2*Δ mutant strain had substantially higher susceptibility to acetic acid than the wild type, suggesting the important role of Whi2 in acetic acid response in *S. cerevisiae*. Additionally, overexpressing *WHI2* and a cognate phosphatase gene *PSR1* had a synergistic effect in improving acetic acid resistance, suggesting that Whi2 could function in combination with Psr1 to elicit acetic acid resistance. These results enriched our understanding of yeast response to acetic acid stress and provided a new strategy to construct acetic acid resistant yeast strains for renewable biofuel production.

Simultaneous Saccharification and Fermentation of L-Lactic Acid Production from Starch by Genetically Engineered Aspergillus Oryzae

Author Block:

S. Wakai[1], N. Asai-Nakashima[1], H. Tsutsumi[2], Y. Hata[2], C. Ogino[1], A. Kondo[1]; [1]Kobe Univ., Kobe, Japan, [2]Gekkeikan Sake Co Ltd, Kyoto, Japan

Abstract Body:

Background: Lactic acid is a commodity chemical that is widely used in the food, pharmaceutical, textile, leather, and chemical industries. It can be produced biologically, and it is a source of polylactate. Polylactate has been a focus of recent studies for its use as a biodegradable alternative to petroleum-based plastic products. Nowadays, bio-based lactic acid is produced from starchy biomass, while bioproduction by lactic acid bacteria require for utilization of expensive enzymes. Therefore, we attempted to examine bioproduction of lactic acid from starch by a filamentous fungus *Aspergillus oryzae* which has a strong advantage over other organisms because it produces various amylolytic enzymes.**Methods:** Lactic acid-producing *A. oryzae* strains were constructed by genetic engineering. The bovine (*Bos taurus*) *LDH-A* gene sequence was modified based on the codon usage of *A. oryzae* and synthesized. The synthesized artificial gene fragment was cloned into pISI, which contains the *sodM* promoter and *glaB* terminator from *A. oryzae*. Using the resulting plasmid, the *A. oryzae* strain (*A. oryzae* LDH) with the bovine l-lactate dehydrogenase gene was constructed. Furthermore, an authentic lactate dehydrogenase gene on *A. oryzae* chromosome was disrupted by replacing with *pyrG* fragment. The resulting strain named as *A. oryzae* LDHΔ871. Using these strains, lactic acid fermentation from glucose and starch was examined.**Results:** The *A. oryzae* LDH produced 38 g/L of lactate from 100 g/L of glucose. Disruption of the wild-type lactate dehydrogenase gene in *A. oryzae* LDH improved lactate production. The resulting strain *A. oryzae* LDHΔ871 produced 49 g/L of lactate from 100 g/L of glucose. So *A. oryzae* strains innately secrete amylases, *A. oryzae* LDHΔ871 produced approximately 30 g/L of lactate from various starches, dextrin, or maltose (all at 100 g/L). Finally, *A. oryzae* LDHΔ871 produced 45 g/L of lactic acid from a mixture of starch (50 g/L) and glucose (50 g/L) as the substrate.**Conclusions:** This is the first report describing the simultaneous saccharification and fermentation of lactate from starch using a pure culture of transgenic *A. oryzae*. Our results indicate that *A. oryzae* could be a promising host for the bioproduction of useful compounds such as lactic acid.

Substantial Improvement in Methyl Ketone Production in *E. coli* Using Metabolic Engineering and Metabolic Modeling

Author Block:

E-B. Goh, E. E. K. Baidoo, J. D. Keasling, H. G. Martin, H. R. Beller; Joint BioEnergy Inst., Emeryville, CA

Abstract Body:

We have engineered *Escherichia coli* to overproduce aliphatic methyl ketones (MK) in the C_{11} to C_{15} (diesel) range; this group of MK includes 2-undecanone and 2-tridecanone, which have favorable cetane numbers and are also of importance to the flavor and fragrance industry. Overall, we have made specific improvements that resulted in more than 10,000-fold enhancement in MK titer relative to that of a fatty acid-overproducing *E. coli* strain. The first generation of engineered *E. coli* (Goh et al. 2012) produced ~380 mg/L of MK in rich medium and had modifications that included: (a) overproduction of β-ketoacyl-coenzyme A (CoA) thioesters achieved by modification of the β-oxidation pathway (specifically, overexpression of a heterologous acyl-CoA oxidase and native FadB, and chromosomal deletion of *fadA*) and (b) overexpression of a native thioesterase (FadM). We have subsequently made additional genetic modifications that included balancing overexpression of *fadR* and *fadD* to increase fatty acid flux into the pathway, consolidation of the pathway from two plasmids into one, codon optimization, and knocking out key acetate production pathways. These latest modifications have led to a MK titer of 1.4 g/L with 1% glucose in shake flask experiments, which represents 40% of the maximum theoretical yield (the best values reported to date). *In vitro* assays with purified pathway enzymes suggested that flux towards β-ketoacyl-CoAs may be diminished by the promiscuous thioesterase activity of FadM, providing insight on how to fine-tune expression of pathway genes for further optimization of MK production. Using another approach for improving MK production, metabolic modeling was used to identify gene deletions that could improve flux through the MK pathway. One of the specified knockouts, Δ*scgE*, which was annotated as a homolog of Rpe (ribulose-5-phosphate epimerase), improved MK production by >50% relative to the base strain (EGS1710). ^{13}C-glucose experiments have recently been performed on the knockout strain along with the DH1 wild type and base strain (EGS1710) to obtain more comprehensive metabolic flux profiles that will refine the genome-scale model and enable additional improvements in MK production.

Phenotypic Evidence That the Iron Transport Gene *fec*a Can Influence Ethanol Tolerance in *Escherichia coli*

Author Block:

K. Lupino, M. J. Hickman, G. A. Caputo, G. B. Hecht; Rowan Univ., Glassboro, NJ

Abstract Body:

Background: Biofuel research with the long term goal of industrial-scale production of alcohols has focused on fermentations by various microbial biocatalysts. To make such fermentations economical, the biocatalyst must have significant alcohol tolerance and the ability to utilize five carbon sugars that are abundant in lignocellulosic feedstocks. The *Escherichia coli* K12 derivative strain FBR5 was developed for its ability to metabolize five carbon sugars and ferment to ethanol efficiently. Our lab subsequently isolated ethanol tolerant mutants of FBR5. Several of these strains were found to have just a single silent mutation in the iron transport gene *fec*A. It has been reported that upregulation of multiple genes involved in iron transport is associated with increased ethanol tolerance. Thus, it was hypothesized that *fec*A specifically may play a role in the ethanol tolerance of *E. coli*.**Methods:** *E. coli* strains differing in *fec*A expression were tested for ethanol tolerance using two methods: a minimal inhibitory concentration (MIC) assay and cell survival experiments with various ethanol amounts.**Results:** MIC assays were performed with a *fecA* deletion strain and another strain capable of overexpressing *fecA* in the presence of IPTG. MIC assays performed with these strains were inconclusive. However, survival curve experiments demonstrated overexpression of *fecA* conferred 10 fold greater survival compared to control strains after as little as a 10 minute exposure to 16.5% (v/v) ethanol. This difference generally increased with time. Surprisingly, the *fec*A deletion strain also maintained 10 fold greater survival compared to its parental control throughout a 60 minute exposure to 16.5% ethanol. Deletion of *fec*A was additionally associated with increased cell survival in experiments using 17% ethanol.**Conclusions:** These data suggest that mutations resultant in increased or decreased expression of *fec*A are associated with a marked increase in the ethanol tolerance of *Escherichia coli*. Further characterization of the correlation between ethanol tolerance and genes associated with iron transport, including *fec*A, is pertinent to the use of *E. coli* as a microbial biocatalyst in industrial scale production of alcohols.

Production of Oleaginous Biodiesel Precursors in *Acinetobacter baylyi* Adp1

Author Block:

A. Chistoserdov, R. Ukey, R. Bajpai; UL Lafayette, Lafayette, LA

Abstract Body:

Due to a possible threat of the global climate change and dwindling supplies of fossil fuel, the humanity is actively seeking alternative sources for transportation fuel. Heterotrophic microorganisms offer an interesting alternative (or a complement) to the algal biodiesel production. *A. baylyi* produces large quantities of triacylgycerides and wax esters (TAGs and WEs) due to a unique bifunctional enzyme, wax synthase/diacylglycerol acyltransferase (WS/DGAT). To improve the production of biodiesel precursors in *A. baylyi*, a sequential inactivation of several genes (two lipases, acyl-CoA reductase and acyl-CoA dehydrogenase) was carried out using the *loxP*/Cre system. This would allow us to streamline the flow carbon towards fatty acids and then to the final products, TAGs and WEs. A four-fold increase in the TAG production was observed when three mutations (in two lipases and acyl-CoA dehydrogenase) were combined in the same strain of *A. baylyi*. Interestingly, an addition of a mutation in acyl-CoA reductase decreased production of oleaginous compounds. In order to further enhance the flow of carbon towards TAGs and WEs, several genes involved in both TAG and WE were cloned. However, their expression in *A. baylyi* did not markedly improved production of oleaginous compounds. It appears that thioesterases, which hydrolyze both acyl-CoA and acyl-ACP derivatives, plays the key role in production or removal of TAG and WE precursors. Therefore, thioesterases from several sources (*Escherichia coli*, *Enterococcus faecalis*, *A. baylyi*) were cloned and overexpressed and their contribution to production of free fatty acids, TAGs and WEs was investigated. It was shown that a truncated form of the AcTesA thioestratse from *A. baylyi* leads to the highest accumulation of fatty acid intermediates, preferentially producing palmitoleic and myristic acids. An unoptimized expression of AcTesA' in combination with WS/DGAT, led to further twofold increase in accumulation of TAGs in *A. baylyi*.

Engineering *Pseudomonas putida* to Produce Adipic Acid from Lignocellulosic Biomass

Author Block:

J. A. Meadows, J. M. Gladden; Joint BioEnergy Inst., Emeryville, CA

Abstract Body:

Adipic acid is an important industrial dicarboxylic acid that is made worldwide. Annually, about 2.5 billion kg is produced and is primarily used as a precursor in the manufacturing of nylon, as well as plasticizers, food additives, and polyurethane resins, to name a few. With there being no significant occurrence in nature, it is manufactured from chemicals derived from petroleum, an environmentally harmful process. By using plant components as starting material and engineering an industrially relevant bacterial host, we have fashioned an approach that is ecofriendly for making adipic acid. *Pseudomonas putida* KT2440 was metabolically engineered to produce adipic acid from rich and a chemically defined media containing sugar and aromatic compounds derived from lignocellulose. Using a multi-omic approach, we were able to assess the metabolic, transcript, and protein profiles to identify bottlenecks in the engineered pathways. This allowed for targeted modifications to the pathways to increase adipic acid titers. This work demonstrates that *P. putida* is a viable bacterial host for producing adipic acid from biomass and is a potential alternative to manufacturing adipic acid that does not rely on petroleum-based feedstocks.

Investigation of Relationship between 2,3-Butanediol Toxicity and Production during Growth of *Paenibacillus polymyxa*

Author Block:

C. C. Okonkwo, V. Ujor, T. C. Ezeji; The Ohio State Univ./OARDC, Wooster, OH

Abstract Body:

Understanding 2,3-butanediol (2,3-BD) tolerance in *Paenibacillus polymyxa* DSM 365 is critical to its engineering to produce economically viable quantities of 2,3-BD. While *P. polymyxa* is unable to generate more than 3% 2,3-BD in batch fermentation systems in our laboratory, different concentrations of 2,3-BD ranging from 15 to 111 g/L have been reported by various research groups. Hence, we investigated the response of *P. polymyxa* to high 2,3-BD concentrations.To determine the 2,3-BD production capacity of *P. polymyxa*, fed-batch and batch fermentations during which *P. polymyxa* was challenged with 2,3-BD (20, 40 and 60 g/L) at 0 h was conducted. Furthermore, *P. polymyxa* was challenged with incremental 2,3-BD concentrations (20, 40 and 60 g/L at 12, 24 and 36 h, respectively) to mimic 2,3-BD accumulation during batch and fed-batch fermentations. Using serial dilution, gas chromatography, spectrophotometric and HPLC techniques, and assays, cell growth, residual glucose, 2,3-BD and acetoin were analyzed.In fed-batch cultures (6-L bioreactor) 2,3-BD accumulated to a maximum concentration of 47 g/L despite the presence of residual 13 g/L glucose in the medium. Concomitantly, accumulation of acetoin, the precursor of 2,3-BD, in the bioreactor increased after maximum 2,3-BD concentration was reached, suggesting that 2,3-BD was reconverted to acetoin after the concentration threshold for 2,3-BD tolerance was exceeded. Batch cultures of *P. polymyxa* challenged with 20, 40 and 60 g/L 2,3-BD at 0 h showed a concentration dependent growth inhibition response to 2,3-BD, inhibiting the growth by. 18, 33 and 100 %, respectively, relative to the control. Interestingly, 2,3-BD was reconverted to acetoin when its concentration reached 60 g/L in *P. polymyxa* cultures challenged with incremental 2,3-BD at 12, 24, and 36 h, possibly to alleviate 2,3-BD toxicity.Collectively, our findings indicate that 2,3-BD-mediated toxicity is a major metabolic impediment to 2,3-BD overproduction, thus, making it an important metabolic engineering target for rational design of a 2,3-BD-overproducing strain.

Screening for Biofuel Producing *Clostridium* Species

Author Block:

S. Riedel, C. Olumba, K. Lee, G. Barding, W-J. Lin; Cal Poly Pomona, Pomona, CA

Abstract Body:

The search for sustainable renewable energy has been one of the primary areas of research. The solventogenic *Clostridium beijerinckii* is known for its production of biofuels through the acetone-butanol-ethanol (ABE) fermentation pathway. Among the three fermentation products, butanol is considered a direct replacement of gasoline due to its compatibility with the gasoline engine. In our previous study, 92 *C. beijerinckii* strains were isolated from horse fecal samples collected from three horse farms, Cal Poly Pomona, Mt. SAC, and a private farm in Glendora. To screen for strains that possess the ABE fermentation pathway, 3 sets of PCR primers were designed to detect the presence of the genes encoding for acetoacetate decarboxylase, butanol dehydrogenase and alcohol dehydrogenase, which are essential for the production of acetone, butanol, and ethanol, respectively. The screening of the 92 *C. beijerinckii* isolates yielded a total of 5 isolates that are positive for the three genes tested. To set up the quantitative analysis of butanol production, the ABE positive isolates, as well as the positive control (*C. beijerinckii)* and a negative control (*C. perfringens)* were grown in the synthetic P2 medium for 48 hours. The organic compounds were extracted and subjected to gas chromatographic analysis with a flame ionization detector (GC-FID). The presence of butanol peak at 7.4 minutes is confirmed in the positive control, but not the negative control strains. The ABE-gene positive isolates showed variable butanol yields based on our GC-FID analysis. The conditions for optimal butanol production are also studied.

Metabolic Engineering to Enhance Furfural Tolerance during Cellulosic Butanol Fermentation by Glycerol-Supplemented *Clostridium beijerinckii*

Author Block:

C. Agu, V. C. Ujor, T. C. Ezeji; The Ohio State Univ. and Ohio Agricultural research and Dev. Ctr., Wooster, OH

Abstract Body:

The inability of *Clostridium beijerinckii* to efficiently utilize glycerol is a major impediment to adopting glycerol metabolism as strategy to increase NAD(P)H regeneration, mitigate inhibitor (e.g. furfural) toxicity, and improve butanol titer during fermentation of lignocellulosic biomass hydrolysates (LBH). Therefore, it was reasoned that metabolic engineering to enhance glycerol utilization in *C. beijerinckii* will increase NAD(P)H regeneration and improve butanol production from furfural-replete LBHTowards this goal, we sought to systematically excise glycerol catabolic arsenal from a hyper-glycerol utilizing bacterium (*Clostridium pasteurianum*) and clone into *C. beijerinckii*. Glycerol dehydrogenase (gldh), the first enzyme in glycerol catabolism, catalyzes an NAD(P)H yielding reaction, dehydrogenation glycerol to dihydroxyacetone. As a preliminary step, *C. pasterianum* gldh genes - F502 12753 and 6017 were overexpressed as fusion construct in an *E. coli-Clostridium* shuttle vector - pWUR460 under the control of constitutive thiolase promoter, followed by electroporation into *C. beijerinckii*. The generated strain, *C. beijerinckii*-gldh was used to conduct batch acetone-butanol-ethanol (ABE) fermentation with glucose medium supplemented with glycerol and 0, 4, 5, or 6 g/L furfural. Using gas chromatography, high performance liquid chromatography and spectrophotometric assays, cell growth, acetone-butanol-ethanol (ABE) production, glycerol utilization, and furfural detoxifying capacity of *C. beijerinckii*-gldh were analyzed and compared with the wildtype *C. beijerinckii*At high furfural concentration (6 g/L), the growth of and ABE production by *C. beijerinckii*-gldh were 20% and 87%, respectively, higher than the wildtype. Similarly, the ABE productivity was 2.4-folds higher than the *C. beijerinckii* wildtype and glycerol utilization was significantly ($p<0.05$) increased by 15%.Taken together, gldh overexpression in *C. beijerinckii* improved its tolerance to furfural and glycerol utilization, suggesting that overexpression of the entire *C. pasteurianum* glycerol catabolic arsenal and optimization may significantly improve fermentation of dilute acid pretreated LBH to butanol.

Identification of Butanol Tolerant Genes in *Lactobacillus mucosae*

Author Block:

S. Liu, N. Qureshi; USDA, ARS, NCAUR, Peoria, IL

Abstract Body:

Background: Butanol, though in low concentrations, is produced biologically through fermentation of lignocellulosic biomass-derived substrates by Gram-positive *Clostridium* species. However, naturally available butanol fermenting microbes are sensitive to stress caused by increased production of butanol and the presence of various inhibitors from biomass hydrolyzates. Thus for commercial production, new strains with better tolerance to butanol and inhibitors are desired. One strategy is to genetically modify available species of *Clostridium* by introducing stress tolerance genes. The rationale of this study is to seek butanol tolerance genes from other Gram-positive species which might be better suited than those from the Gram-negative *Escherichia coli* or eukaryotic *Saccharomyces cerevisiae*. Several butanol tolerant *Lactobacilli* were found capable of growth in 3-4% butanol after long term adaptation. In this study, *Lactobacillus mucosae* BR0605-3was used to identify new butanol tolerance genes, since this strain showed most robust growth in 4% butanol and the genome sequence of *L. mucosae* is publically available. **Methods:**Total cellular proteins from duplicate cultures of *L. mucosae* BR0605-3 grown in MRS with 0 and 4% butanol were extracted and subjected to 2D-gel electrophoresis. Comparisons of 2D gel images between 0% and 4% butanol grown cultures indicated expression levels changed in response to growth in 4% butanol. Both increases and decreases of individual spots were measured and calculated from the intensity on the gel images. Based on the significance and multitude of changes, 50 spots were chosen and analyzed using LC-MS/MS**Results:** A total of 31 protein spots were identified either from the L. mucosae database through ProteinLynx Global Server (PLGS) or from the Mascot database through NCBI and SwissProt. The identification of butanol stress related proteins will be presented and the results will help us to understand the molecular mechanisms governing tolerance to high butanol concentrations.**Conclusions:** This study will lead to cloning of specific genes related to butanol tolerance, which may be used for improving biocatalysts for efficient conversion of biomass to biofuel butanol.

Engineering Thiolase Enzyme Specificty

Author Block:

Y. Tarasova, B. Bonk, B. Tidor, K. L. J. Prather; Massachusetts Inst. of Technology, Cambridge, MA

Abstract Body:

Inspired by polyhydroxyalkanoate (PHA) biosynthesis, a heterologous pathway for the production of a variety of 3-hydroxyalkanoic acids (3HAs) has been developed in *Escherichia coli*. 3HAs produced by this pathway are chiral and can serve as precursors for many useful biopolymers, pharmaceuticals and solvents. The pathway can also be extended by overexpression of additional enzymes that act on the 3HA-CoAs to produce many other classes of compounds, such as aldehydes and alkanes, of variable chain length. However, this pathway suffers from 3-hydroxybutyrate (3HB) byproduct formation, due to the high catalytic activities of the pathway enzymes towards their native substrates. In this work, we focus on the thiolase enzyme as a selectivity control point for the pathway. A structure-guided computational approach was used to predict mutants with increased activity towards the condensation of longer chain acyl-CoA thioesters and/or with decreased activity towards the condensation of two acetyl-CoA molecules. Candidate mutant thiolases were then screened *in vivo* using formation of PHAs as a readout of enzyme selectivity. The best mutant resulted in over a ten-fold increase in selectivity for formation of the longer chain product, 3-hydroxyhexanoate, as compared to the wild type, while maintaining high overall conversion. This mutant was then characterized *in vitro*, and confirmed to have lower activity towards the condensation of two acetyl-CoAs. Results on the application of these highly specific mutant thiolases towards the synthesis of longer chain products, such as 4-methyl pentanol will be presented. Further *in vitro* characterization of thiolase mutants is underway and will serve to expand our understanding of the sequence-structure-function relationships for this important class of enzymes.

Abstract Body:

Various pharmacological activities of *Curcuma longa* (turmeric) have been reported, including anti-inflammatory and antioxidant effects. In this study, bioprocessed polysaccharide powders (BPPs) from the liquid culture of *Lentinus edodes* fungal mycelia containing *Curcuma longa* (referred to as BPP-Curcuma) were extracted in water at 37°C and examined their biological effects on the avian-specific or zoonotic *Salmonella enterica* species as well as their responses to the chicken-derived macrophage cells, HD-11, during the salmonella infection. Our experimental analyses revealed that the water extracts of BPP-Curcuma (i) did not affect the growth kinetics of *Salmonella* spp. evaluated, (ii) induced the alteration of the bacterial secretome profiles compared to the untreated control groups, (iii) showed increased phagocytic activities in the HD-11 cells when infected by *Salmonella* spp., but did not affect their bacterial killing activities, and (iv) greatly up-regulated the transcription expression of TNF-α IL-1β, iNOS, and IL-10. Interestingly, such cytokine expression appeared to be modulated when the HD-11 cells were pre-exposed with *Salmonella spp*. Taken together, these results imply the biological activity of BPP-Curcuma on both *Salmonella spp*. and macrophages during an avian infection.

Tailor-Made Construction of Yeast Adsorbing Rare Earth Elements through Screening from Yeast Library Displaying Random Peptides

Author Block:

K. Kuroda, R. Ito, H. Hashimoto, M. Ueda; Kyoto Univ., Kyoto, Japan

Abstract Body:

Rare earth elements (REEs) consist of 17 kinds of metal elements and belong to rare metals. REEs are commonly used in high-tech products such as liquid crystal displays, IT devices, and hybrid vehicles. Thus, demands for REEs are increasingly growing with the development of high-tech industries, leading to rising prices of REEs. For stable supply and procurement of REEs, the efficient recovery of REEs from nature, wastewater, and discarded high-tech products is one of the most important technology to be developed. We have established yeast display system and applied it into metal-ion adsorption on yeast cell surface by displaying metal-binding proteins or peptides [1, 2]. However, there is no natural metalloprotein that binds REEs and is few examples of artificial REEs-binding peptides. In this study, we attempted to construct REEs-binding yeast by screening from yeast library displaying random peptides.For the preparation of yeast library, peptides with random sequences based on $(NNK)_{25}$ codon was displayed by fusion with cell wall-anchoring domain of α-agglutinin. After the incubation of the prepared yeast library with Tb^{3+}-charged magnetic beads, yeast cells that were bound to beads were recovered and isolated on agar medium. The isolated clones were examined for adsorption ability in Tb^{3+} solution. Several peptide-displaying yeasts showed the enhanced adsorption of Tb^{3+} compared to wild-type yeast. Furthermore, this enhanced adsorption was specific for Tb^{3+}. Therefore, the combination of yeast cell surface engineering and screening would be an efficient strategy to create a protein or peptide for specific adsorption of target REEs.[1] K. Kuroda and M. Indigenous Hydrocarbon-Contaminated Niger Delta Soil Bacteria Possess Biosurfactant Production Potential for a More Sustainable Environmental Bioremediation

Author Block:

S. B. Akinde, A. A. Adebunmi, I. O. Awoniyi, A. E. Ibilibor; Osun State Univ., Osogbo, Nigeria

Abstract Body:

The work is a preliminary investigation of indigenous biosurfactant production by bacterial flora obtained from chronically hydrocarbon-contaminated Niger Delta soil for microbially enhanced oil recovery (MEOR) and sustainable environmental bioremediation in the region. A total of 99 bacterial strains were isolated from 13 hydrocarbon-contaminated soil samples and presumptively identified by their morphological and biochemical characteristics. Blood haemolysis, oil displacement and emulsification index screening were used to select hyper-active biosurfactant-producing isolates which were identified by 16S rRNA sequencing. The bacterial strains belonged to the genera: *Aeromonas* (38), *Bacillus* (14), *Citrobacter* (1), *Clostridium* (5), *Corynebacterium* (14), *Enterobacter* (9), *Klebsiella* (7), *Providencia* (1) and *Pseudomonas* (4). 16S rRNA sequencing however authenticated the identity of 8 selected hyper-active strains and further characterized them to species level as *Clostridium sporogenes* (NGS-BH1), *Citrobacter freundii* (NGS-BH2), *Clostridium sp* (NGS-BH3), *Aeromonas hydrophila* (NGS-BH4), *Enterobacter cancerogenus* (NGS-M7), *Aeromonas caviae* (NGS-M17), *Aeromonas caviae* (NGS-M18), *Enterobacter hormaechei* (NGS-M19). The dry weight ± standard deviation of biosurfactant produced by the 8 hyper-active strains ranged between 0.39 ± 0.06 g (NGS-M17) and 1.72 ± 0.07 g (NGS-M7). Local biosurfactant production by indigenous microflora can facilitate cost-effective and rapid environmental bioremediation as well as other industrial applications in Niger Delta Nigeria.

Evaluation of Native Bacterial Strains to Formulate an Oil Degradative Consortium

Author Block:

P. Teran Morales, F. Merino Rafael, S. Gutierrez Moreno; Natl. Univ. of San Marcos, Lima, Peru

Abstract Body:

Nowadays the oil industry is the main component of the world´s energetic matrix. The oil extraction and handling processes have the inherent risks of contamination, causing a progressive deterioration of the environment. In spite of this, there are ecofriendly alternatives like bioremediation process that is gaining world recognition. For this process, the selection and characterization of microorganisms is the main key to success. In Peru this process is being applicated, recently. The objective of this research was the evaluation of bacterial strains isolated from oil contaminated soil to formulate a consortium with high oil degradation ability. We evaluated 44 bacterial strains, isolated from Talara oil contaminated soil, provided by SAVIA Peru Company. The selection was based on the degradative activity on crude oil (Mills et al., 1978), emulsifying activity, growth capacity on petroleum derivates: gasoline, kerosene, paraffin and vacuum waste; and the inexistence of antagonism between them. At first, the strains were identified by API20NE and APICH50 system and then by 16S rRNA gene. The results were statistically analyzed with Principal Component Analysis and ANOVA. Results revealed that on crude oil, the 16% of the strains showed a growth comparable with 1-3 McFarland scale. The 7% of strain showed an emulsifying activity higher than 1 UAE/ml. Growth evaluation on different substrates showed that 100% (44) of the strains grew on paraffin and gasoline, whereas only 15% (7) was able to grow on vacuum waste and the 84% (37) on kerosene. These results indicated a great variability of oil degradative ability of the strains. Then, 9 strains were selected to check the antagonism between them: *Pseudomonas aeruginosa* 68P, 202P, 24, 210P, 165, *Bacillus subtilis* 202G, 68G, 106, 210G. After the antagonism test, the consortium was formulated with *Pseudomonas aeruginosa* 68P, 202P and *Bacillus subtilis* 202G. In conclusion, the formulated consortium could be used in the bioremediation process of the oil soil where were isolated.

Biodegradation of Crude Oil by Pure Bacterial Culture in Liquid Medium

Author Block:

H. Kim[1], J. Kim[1], H. Kim[2], S-S. Lee[1]; [1]Kyonggi Univ., Suwon, Korea, Republic of, [2]Hyundai Construction & Engineering, Yongin, Korea, Republic of

Abstract Body:

Byproducts from crude oil are the important energy source for everyday life. However, their accidental and untreated release of the petroleum product into the environment contaminates the soil and water which creates several health and environmental problems. Such long term contamination of crude oil products into the environment has enriched several microorganisms which have potential to degrade such toxic compounds. These microorganisms generally degrades oil components in the order of *n*-alkane, branched-chain alkane, branched alkane, low molecular weight *n*- alkyl aromatic, mono-aromatics, cyclic alkane, polycyclic aromatic hydrocarbon to asphaltene. In this study we selected thirty one bacteria which were previously isolated bacteria from different oil contamination sites. The degradation efficiency by pure cultures were performed using liquid extraction and liquid analysis method via GC-FID. Decrease in the low molecular *n*-alkanes peak was analyzed through GC-FID after 7 and 14 days of interval. In addition, molecular analysis was also performed to analyze the genes involved in the crude oil biodegradation. Among all the tested bacteria, strain *Ochrobactrum pecoris* and strain SBR17 showed highest oil degradation ability. The crude oil degradation efficiency of strain *Ochrobactrum pecoris* and SBR17 was 63.3 % and 69.0 % after 7 days of incubation at their optimal growth conditions. Crude oil degradation ability from strain *Gordonia malaquae*, *Pseudomonas monteilli*, *Massilia niastensis* was also recorded up to 39.5 % after 14 days of incubations. In addition, molecular analysis was also confirmed the presence of *CYP153, alkB* and *ladA* in these bacteria which are involved in the crude oil biodegradation. Our findings from this study indicated the presence of several potential bacteria which have highly efficient crude oil degradation ability. Further studies have to be performed to optimize and enhance the removal efficiency and it gives a gateway for the bioremediation of crude oil contamination. We will do through the GC-MS, figure out product degradation pass way by pure culture bacteria.

Biotransformation of PAHs by *Sphingobium barthaii* and Investigation of DNA Damage by LC/ESI-MS/MS

Author Block:

K. Fukuoka, **R. A. Kanaly**; Yokohama City Univ., Yokohama, Japan

Abstract Body:

During the biodegradation of aromatic environmental pollutants by bacteria, catechols are produced that undergo redox cycling with aromatic quinones. Quinones are a group of highly reactive compounds that react with DNA and cellular macromolecules or produce reactive oxygen species in cells. Not much is known about the effects of these compounds on bacteria during polycyclic aromatic hydrocarbon (PAH) biodegradation. Towards the development of methods to investigate such phenomena, biodegradation and exposure experiments were conducted with the soil bacterium *Sphingobium barthaii* with analyses by liquid chromatography electrospray ionization tandem mass spectrometry (LC/ESI-MS/MS). LC/ESI-MS/MS product ion scan analyses of a 160 Da product detected in extracts from *S. barthaii* during growth on PAHs identified it as the PAH-catechol, 1,2-dihydroxynaphthalene. Thereafter, *S. barthaii* cells were exposed to 1,2-naphthoquinone and cellular DNA was extracted, digested and purified to their corresponding 2'-deoxynucleosides. DNA adductomics methods were applied to detect unidentified DNA modifications by analyzing the 2'-deoxynucleosides by LC/ESI-MS/MS. Results showed that at least one high molar mass DNA modification was detected with a molar mass of 425 Da. Product ion scan analyses revealed fragments that pointed towards an identity of a dihydroxynaphthalene adduct. LC/ESI-MS/MS analysis of products from a reaction of 1,2-naphthoquinone with 2'-deoxyguanosine yielded a 425 Da compound with a retention time that matched the product detected from bacterial cells and supported an identity of 1,2-dihydroxynaphthalene-4-N7-deoxyguanosine. At the same time, other DNA adducts were unambiguously identified from exposed and unexposed cells by LC/ESI-MS/MS techniques including N^6-methyl-2'-deoxyadenosine, and the oxidative adduct, 8-oxo-deoxyguanosine. This work contributes to our understanding of the effects of PAH biodegradation products on cellular functions during exposure to PAHs. Future work shall involve investigation of the production of depurinating adducts.

A New Approach for Phenotype-based Identification of Key Enzymes in Polycyclic Aromatic Hydrocarbon Metabolism from Mycobacteria Using Transposon Mutagenesis and a Pah Spray Plate

Author Block:

S-J. Kim, O. Kweon, C. E. Cerniglia; FDA/NCTR, Jefferson, AR

Abstract Body:

Background: Despite considerable knowledge of bacterial PAH metabolism, key enzymes and their pleiotropic and epistatic behaviors responsible for high-molecular-weight (HMW) PAH biodegradation remain poorly understood. HMW PAHs, such as benzo[*a*]pyrene, are genotoxic compounds that tend to persist in the environment. A number of studies have shown that mycobacteria and other gram positive bacteria have the ability to degrade the HMW PAHs. However, to improve rates of HMW PAH biodegradation, new research approaches and tools are necessary to obtain knowledge on the enzymatic mechanisms involved in the degradation of these environmental contaminants. In this study, we describe, using HMW PAH-degrading *Mycobacterium vanbaalenii* PYR-1 as a model organism, a rapid, low-cost, and high-throughput screening for function-dependent selection of mutants with metabolic discrepancy or defect in the metabolism of HMW PAHs. **Methods:** The approach has four steps: i) preparation of mycobacterial electrocompetent cells, ii) construction of a transposition mutant library using EZ-Tn5 <R6Kγori/KAN-2> Tnp transposome, iii) phenotypic screening, using a PAH spray plate method, and iv) rescue cloning of transposed genomic DNA. **Results:** Using this new method, we identified more than 20 mutants with HMW PAH metabolic discrepancy or defect from ~4,000 transposon mutants of *M. vanbaalenii* PYR-1. For example, a mutant 8F7 lost its ability to degrade pyrene, while still being able to degrade fluoranthene and the mutant was shown to be defective in the gene *nidA*, encoding a ring-hydroxylating oxygenase enzyme, which is essential for the metabolism of pyrene in PAH-degrading mycobacteria. By sequencing analysis, we confirmed the position of Tn5-based genetic perturbation of selected mutants mostly in the genes responsible for PAH degradation. **Conclusion:** Combination of the approaches such as transposon mutagenesis and phenotypic assays has provided insights into HMW PAH biodegradation for bioremediation applications. In addition, this new phenotype-based approach may be applicable to other PAH-degrading bacterial strains and could also be modified to screen a mutant(s) able to degrade only a certain group of PAHs.

Diesel Degradation in Presence of Copper and Microaerobiosis by *Pseudomonas extremaustrali*s

Author Block:

L. Rossi, N. I. Lopez, L. J. Raiger Iustman; FCEyN, Univ. de Buenos Aires, Buenos Aires, Argentina

Abstract Body:

Microorganisms adapted to contaminated environments represent an alternative to bioremediation of pollutants. Diesel is a widely distributed one, being its composition a mixture of alkanes that could be degraded by some microorganisms. Cooper is an essential metal for most organisms, but at high concentrations commonly detected in diesel-polluted waters can be lethal. Previous work show that *P. extremaustralis* was able to degrade diesel in biofilm growth conditions but not in shaken flasks, and tolerate up to 4mM $CuSO_4$ in aerobiosis. It was also described that co-substrate addition could enhance xenobiotic degradation. The aim of this work was to determine if *P.extremaustralis* was able to degrade diesel in microaerobiosis without biofilm formation and to evaluate the effect of glucose as co-substrate and Cu in diesel degradation. *P. extremaustralis* 14-3b strain was used for the assays. Cultures of 20 mL were incubated for 7 days at 30 °C in 100 mL capped bottles with E_2 minimal medium, supplemented with 8 mM KNO_3 and 1% v/v Diesel. To determine the growth variables, different Cu and glucose concentrations were evaluated: $CuSO_4$ 0.1 to 1.5 mM, and glucose 0.5 to 20 g/L. Diesel degradation was evaluated by extracting the remnant hydrocarbon with 10% v/v n-hexane, and analyzing by GC. A residual hydrocarbon percentage was calculated using a control without bacteria as 100%. The growth conditions were finally set at $CuSO_4$ 0.1 mM for it was the highest full soluble concentration in this media, and 0.5 g/L glucose. *P. extremaustralis* was able to degrade 16% of the total diesel when it was added as sole carbon source, and no differences were observed when glucose was added as co-substrate or Cu was present. When the culture media was supplemented with both glucose and Cu, however, 30% degradation was achieved. Analyzing each alkane in particular, there was a clear degradation in the ones with 14 to 21 Carbon atoms, consistent with the results found in biofilm. This suggests that the addition of a co-substrate and a stress promoter as Cu in a sub lethal concentration could enhance diesel biodegradation in *P. extremaustralis*.

Isolation and Characterization of Anaerobic Microbial Communities from Hydraulic Fracturing Fluids

Author Block:

S. Brewer[1], **M. F. Campa**[2], A. G. M. Amaral[1], J. L. Fortney[1], S. M. Techtmann[3], K. S. Fitzgerald[1], T. C. Hazen[1]; [1]Univ. of Tennessee, Knoxville, TN, [2]Bredsen Ctr. for Interdisciplinary Res. and Graduate Ed., Knoxville, TN, [3]Michigan Technological Univ., Houghton, MI

Abstract Body:

Hydrocarbon production from hydraulic fracturing of gas shale in the US has skyrocketed and is projected to keep growing. This water intensive drilling process creates toxic wastewater without an efficient disposal method. Because this method involves projecting fluid 1-3 km deep into the Earth, it is likely that microbial communities adapted to the extreme conditions of the subsurface have accumulated in the produced water. The goal of this study is to identify microorganisms that might have bioremediation capabilities for the toxic flowback water and characterize microbes isolated from fracking water samples in anaerobic conditions. Water samples were obtained from hydraulic fracturing locations in the Marcellus shale of Pennsylvania. These water samples include six different collections of flowback water, a flowback mix tank, and three different treatment tanks. Inoculations from the water samples were grown in anaerobic conditions in high salinity marine media and halotolerant hydrocarbon degradation dependent media. Samples were also grown at ambient temperature and at 37°C. DNA was extracted, and 16S rRNA gene Sanger sequencing was used to identify individually isolated microbes. Illumina sequencing was used to yield genetic information about the overall microbial communities. The Biolog Omnilog, a high-throughput phenotype microarray, was used to determine the genotype-phenotype characteristics of some of the most significant isolates. Early results show presence of numerous anaerobic microbes with metabolic variability and bioremediation potential including sulfate reducers and hydrocarbon degraders. There also have been a considerable number of human pathogens identified with the capability for antibiotic resistance from biocide exposure.

Oil Sludge Degradation by *Lysinibacillus sphaericus* and *Geobacillus sp.*

Author Block:

M. Hernández, J. Dussán; Microbiol. Res. Ctr. (CIMIC), Univ. de los Andes, Bogota, Colombia

Abstract Body:

Bioremediation is an environmentally friendly and affordable technology for the removal of pollutants from petrochemical industry which does not introduce any additional chemicals to the environment. *Bacillus* species have been identified as being involved in crude oil degradation, however, little is known about the degradative potential of other related genera as *Lysinibacillus* and *Geobacillus*. We aim to evaluate the oil sludge degradative capacity of a consortium made up of *L. sphaericus* and *Geobacillus* sp. native strains of Colombia in landfarming processes carried out in greenhouse and field.Twelve impermeable membrane coated containers with oil sludge (API gravity 39.3°) and soil were placed (0.05:0.95) in greenhouse and field. Two kinds of experiments were set, the first one was open to the atmosphere and the second was totally coated. Bacterial consortium composed of *L. sphaericus* and *Geobacillus* sp. strains was added to the soil; negative controls had no inoculum. All of the experiments were replicated three times. Samples were taken after 8, 15 and 50 days to evaluate hydrocarbon degradation by gas chromatography and bacterial growth by plate count method. Samples of volatile organic compounds (VOCs) were taken from the closed containers and analyzed by high performance liquid chromatography. Statistical significance was evaluated by ANOVA and Tukey-Kramer test. Bacterial titer remained almost constant in all of the greenhouse experiments. A significant decrease in the number of bacteria was seen in experiments carried out in field, however a bacterial titer greater than 10^6 was still present on day 50. A significant difference is observed in total petroleum hydrocarbons (TPHs) concentration in open and closed inoculated containers as well as in non-inoculated and inoculated containers. The net TPHs degradation percentages due to biodegradation in greenhouse experiments were 68.7% and 19.4% for open and closed containers, respectively, whereas in field experiments were 39.7% and 33.9%. VOCs concentrations in the headspace were comparable to that of TPHs in soil, however VOCs biodegradation percentages were more than 50% both in greenhouse and field.Both inoculated open and closed containers presented a TPH removal percentage that was higher than the one for non-inoculated containers, which make the oil sludge degradative capacity of the strains under study evident.

Anaerobic Degradation of Alkanes (*n*-Hexane) by the Denitrifying Betaproteobacterium Strain Hxn1

Author Block:

K. Trautwein, A. Strijkstra, L. Wöhlbrand, R. Rabus; Carl von Ossietzky Univ. Oldenburg, Oldenburg, Germany

Abstract Body:

The main source of alkanes in the environment is crude oil and its refined products. Alkanes are the least reactive hydrocarbons due to absence of polar bonds. Nevertheless, aquatic and soil microorganisms are able to completely mineralize these energy-rich compounds under oxic and anoxic conditions. Aerobic degradation employs oxygenases and reactive oxygen species (O_2-derived) to activate the alkane, followed by oxidation of the primary or secondary alcohol to a fatty acid and its further degradation by conventional β-oxidation. In contrast, O_2-independent activation under anoxic conditions proceeds by radical addition of the subterminal carbon atom of the alkane to fumarate by (1-methylalkyl)succinate synthase (MasCDE; with the large subunit MasD bearing the glycyl radical). The enzymes catalyzing the subsequent degradation of the resulting (1-methylalkyl)succinate and regenerate the co-substrate fumarate are still unknown.This study aimed to investigate the proposed anaerobic degradation pathway for *n*-hexane in the betaproteobacterium strain HxN1 (Wilkes *et al.*, 2002), degrading C_6-C_8 alkanes with nitrate as terminal electron acceptor. The availability of a whole-genome shotgun database combined with comprehensive proteome analyses (2D DIGE, shotgun, membrane) allowed the identification of *n*-hexane-specific proteins (soluble and membrane) in strain HxN1. Differential proteome analysis by 2D DIGE revealed proteins specifically formed in cells grown with *n*-hexane, as compared to cells grown with hexanoate (caproate), propionate or acetate. The majority of *n*-hexane-specific identified proteins localize in a confined region (130 kb) of the genomic database, which include two identical copies of MasCDE (encoded in close proximity to each other), substrate:CoA ligases, a methylmalonyl-CoA mutase, and β-oxidation-related enzymes possibly involved in downstream degradation of *n*-hexane-derived, CoA-activated fatty acids. The presence of many genes related to transposases and mobile elements as well as the lower (by 6%) GC content in this region (as compared to the GC content of the whole-genome shotgun database) may suggest that the ability to degrade alkanes was horizontally acquired by the ancestors of strain HxN1.

Hexadecane-Degrading Bacteria: Inoculums For Efficient Soil Rhizoremediation

Author Block:

Y. Bernier-Casillas, K. F. Álamo-Rodríguez, J. R. Pérez-Jiménez; Univ. del Turabo, Gurabo, PR

Abstract Body:

Rhizoremediation has been improved by efficient combination of plants and microbes to reduce harm of pollutants in nature. Bacterial contribution to alkane degradation has been documented for polluted and temperate sites. Alkanes, as hexadecane, reach the environment by anthropogenic activities and natural processes, including plant exudates. We hypothesized that if we stimulate microbes naturally selected in soil then plant development will be enhanced and remediation will proceed. Our objective is to evaluate which hexadecane-degrading bacteria (HDB) promote plant development. Soil samples were collected along Caño Martín Peña (San Juan, PR). HDB were isolated by aerobic cultivation on mineral media supplemented with hexadecane as sole carbon source and subjected to 16S rDNA sequencing. Isolates were tested in vitro for colonization factors. A selection of them was inoculated in soil microcosms, with *Phaseolus vulgaris* seeds, to evaluate their contribution to plant growth. All prospects were able to grow in hexadecane (1% v/v). Colonization factors revealed diverse capabilities among fifty-eight strains: phosphate solubilization (7%), production of indole acetic acid (3%), ammonia (17%), protease (34%), and siderophore (4%). Most of the factors were harbored in twenty strains, including members of *Klebsiella* and *Pseudomonas*. Plant microcosms have shown efficient plant growth, mostly by *Klebsiella* sp. HDB prevailed across Neotropical ecosystems, despite pollution level, are phylogenetically diverse, and harbors novel genetic variants. In the elucidation of colonization factors, the most specialized ones occur in a minimal fraction of the isolates. These hexadecane-degrading bacteria provide novel isolates to deal with pollution and disclose processes in nature.

Novel Taxa Are Dominant In Mangrove Swamp Of Niger Delta, Nigeria

Author Block:

C. J. OGUGBUE, C. C. NWANKWO, G. C. OKPOKWASILI; Univ. OF PORT HARCOURT, Port harcourt, Nigeria

Abstract Body:

Taxonomic study has greatly progressed with the use of metagenomics which provides detailed insights into the microbial diversity of ecosystems that hitherto, was not possible using traditional technique. Three crude oil contaminated soils and three pristine soils in the Niger Delta mangrove swamps were studied. Roche 454 Metagenomic sequencer was used to produce all data sets while bioinformatics were used to analyze data sets. DNA sequencing was performed using the Next Generation Sequencing technique to determine the nucleotide sequences of all microorganisms present in the soil sample while the microbial compositions were identified using CLO bio software after BLASTX Analysis. A total of 20 phyla and 36 classes were identified in both polluted and unpolluted swamp soils. Some of the nucleotide sequences showed no significant similarity and were classified as potential No hits; most of which belonged to the unknown phylum, This unknown phylum was the most dominant phylum in the polluted soils investigated with an abundance of 49.86 % and the second most dominant in the unpolluted soils with an abundance of 27.5 %. They also had a higher relative abundance when compared to *Proteobacteria* phylum and their frequency of occurrence was 91.7%. PCR amplification and sequencing revealed isolates of base pair lengths, 784, 732 and 627 which had no significant similarity with other isolates at the NCBI website. Functional gene analysis indicated a 100% amplification of hydrocarbon degrading genes (alkM, Ppalk B and ndoB genes) of these novel isolates and they were more abundant in the polluted soil when compared to the unpolluted soil. The Agglomerative Hierarchical Clustering method, Pearsons correlation, Principal Component Analysis and Canonical Correspondence Analysis were employed to reveal the similarities among phyla, the ecological interactions at polluted and unpolluted sites, as well as the influence of environmental variables on potential novel isolates.. Results of this study suggest an abundance of potential novel bacteria in the Niger Delta mangrove swamp with potentials for hydrocarbon degradation and bioremediation of crude oil polluted soil.

Identification and Characterization of Oxidized Fatty Acids Biotransformed by Novel Marine Sediment Derived Bacterium

Author Block:

S. Goldberg, B. Haltli, R. Kerr; Univ. of Prince Edward Island, Charlottetown, PE, Canada

Abstract Body:

Background: Marine sediments are known as a rich source of diverse and potentially novel microbes, yet these habitats remain largely underexplored. New species of bacteria have the potential for biosynthesizing novel natural products with pharmaceutical or industrial applications. Here, a bacterial library was derived from marine sediment collected in the Caribbean Sea off San Salvador, Bahamas. We hypothesized that cultivating bacteria from marine sediment using a variety of media would yield novel species with potential for discovery of novel natural products. **Methods:** A bacterial library of 57 isolates was cultivated from marine sediment. Small-subunit rDNA sequencing identified 43 unique OTUs using a similarity cutoff of 99%. A novel gram-negative bacterium, RKSG952, was identified. Based on 16S rDNA gene sequence of 96.9% identity to known species, the bacterium has been phylogenetically described as a new species related to *Labrenzia*. Interestingly, isolate RKSG952 produced some bioactive compounds only when fermented in the presence of oils. This allowed identification of metabolites for further investigation. **Results:** The strain RKSG952 produces large amounts of oxidized fatty acids only when fermented in the presence of oils by bio-transforming the major components of the oils. The purified hydroxy-fatty acids exhibit antibacterial activity against MRSA and VRE. There is precedence in the literature where *Pseudomonas aeruginosa* and *Micrococcus leuteus* are, among others, bacterial species that have been reported to convert fatty acids into a variety of oxidized fatty acids. Additionally, this bacterium also exhibits degradation capabilities of long-chain hydrocarbons. The structure elucidation of the oxidized fatty acid products and the characterization of the biotransformation will be reported here. **Conclusions:**Hydroxy-fatty acids can be used as substrates for secondary metabolites with bioactivity and signaling molecules. They can also be useful for production of industrial fine chemicals. This strain may be producing oxidized fatty acids as a surfactant, to aid in degradation of hydrocarbons. The capabilities of this novel bacterium are interesting when considering environmental applications, such as oil spill bioremediation.

Biodegradation of Engine Oil by Fungi from Mangrove Habitat

Author Block:

F. Ameen Hasan; King Saud Univ., Riyadh, Saudi Arabia

Abstract Body:

Pollution of land and water by petroleum compounds is a matter of growing concern necessitating development of methodologies including microbial biodegradation to minimize the impending impacts. It has been extensively reported that fungi from polluted habitats have the potential to degrade pollutants including petroleum compounds. Red Sea being treaded extensively for transport of oil is substantially polluted due to leaks, spills and occasional accidents. Tidal water, floating debris and soil sediment was collected from mangrove stands on three polluted sites along the Red Sea coast of Saudi Arabia and forty five fungal isolates belonging to 13 genera were recovered from these samples. The isolates were identified on the basis of sequence analysis of 18S rRNA gene fragment. Nine of these isolates were found to be able to grow in association with engine oil as sole carbon source under *in vitro* conditions. These selected isolates and their consortium accumulated greater biomass, liberated more CO_2 and produced higher levels of extracellular enzymes during cultivation with engine oil as compared to the controls. These observations were authenticated by gas chromatography-mass spectrophotometry (GC-MS) analysis, which elucidated that many high mass compounds present in the oil before treatment either disappeared or showed diminished levels.

An Evaluation of the Suitability of Legumes in Phytoremediation of Crude Oil Polluted Soil

Author Block:

F. I. Esumeh, **A. R. AKPE**, O. Agholor, G. I. Okwu; Ambrose Alli Univ., Edo State, Nigeria

Abstract Body:

The remediation of crude oil polluted soils has been a major problem in oil producing countries and the use of plants to clean up such soils has been on investigation. Standard procedures were used in this study to evaluate the suitability of *Glycine max* and *Arachis hypogea* in the remediation of crude oil polluted soil. Results revealed that crude oil pollution had significant ($P>0.05$) negative effect on plant growth parameters such as plants height, leaf area, number of root nodules, leaf number, root length and number, chlorophyll content, shoot fresh and dry weights. Physicochemical analysis showed general increase in pH, organic matter and moisture content in planted soils while nitrogen increased in fertilized planted soils only. Calcium, phosphorus and potassium increased in fertilized soils. A total of 69 bacterial isolates from 13 genera (9 Gram negatives and 4 Gram positives) were encountered in this study while the fungal isolates were 42. *Pseudomonas aeruginosa* and *Aspergillus niger* were the most predominant crude oil degrading bacteria and fungi respectively. The total heterotrophic and crude oil degrading bacterial counts ranged from $1.0\pm0.58 \times 10^7$ to $30.0\pm0.58 \times 10^7$ $cfug^{-1}$and $0.67\pm0.33 \times 10^7$ to $15.0\pm0.00 \times 10^7$ $cfug^{-1}$ respectively. The total heterotrophic and crude oil degrading fungal counts ranged from $1.0 \pm0.00 \times 10^7$ to $15.0 \pm0.58 \times 10^7$ $cfug^{-1}$ and $1.0\pm0.00 \times 10^7$ to $6.0\pm0.58 \times 107cfug^{-1}$ respectively. The total petroleum hydrocarbon (TPH) was significantly ($P<0.05$) lower in planted than unplanted soils with those planted with *Glycine max* having the lowest value. The highest percentage reductions in TPH were 84.59% and 82.35% for 2% crude oil polluted soil sample planted with *Glycine max* and *Arachis hypogea* respectively. The reduction of total petroleum hydrocarbons in unplanted soil (control) was 31.87%. This study has shown that legumes are promising candidates for phytoremediation of crude oil polluted soils. It also revealed that *Glycine max* is a better phytoremediants than *A. hypogea* and that the total petroleum hydrocarbons are degraded better in planted soils than in unplanted soil.

Inventory and Metabolic Potential of Molecular Fossils Degrading Bacteria from Petroleum Hydrocarbon Contaminated Sites

Author Block:

S. Yadav, S-S. Lee; Kyonggi Univ., Suwon, Korea, Republic of

Abstract Body:

Molecular fossils are a group of compounds, primarily hydrocarbons, found in oils, rocks, soil and sediment extracts. They are the most recalcitrant part of the petroleum hydrocarbon which has been persisted from different geological scale of time. There is no available report regarding the degradation of molecular fossils degrading bacteria. This research is focused on the discovery of novel molecular fossils degrading bacteria from desert and coastal samples collected from Kuwait. Desert and coastal habitats of Kuwait are being discharged by high load of petroleum hydrocarbon from more than 20 years of duration. Such contamination of hydrocarbons have enriched highly tolerant and rarer bacterial members which could be potential degrader of the molecular fossils. To analyze the bacterial diversity analysis from selected soil samples from Kuwait an improved cultivation based approach was adopted. Cultivated bacterial strains were identified based on small subunit ribosomal (16S rRNA) gene sequencing. 16S rRNA gene sequence analysis grouped the cultivated bacterial isolates into the genus *Massilia*, *Pseudomonas*, *Noviherbaspirillum*, *Alkanindiges* and *Skermanella*. Morphological, physiological and genetic analysis indicated that long term crude oil contamination have enriched several novel bacterial members with potential metabolic pathway. Their metabolic pathways are involved in the degradation of highly recalcitrant compounds i.e. molecular fossils. Further research focuses on GC-MS metabolite foot-printing and genome sequencing to reveal the metabolic pathway and their potential to degrade the pure compounds of steranes, hopanes, tetracyclic polyprenoids, C^{31} homohopanes, gammacerane and isorenieratane group of molecular fossils

J. YANG[1], Y. YANG[1], W-M. WU[2], J. ZHAO[3], L. JIANG[1]; [1]Beihang Univ., Beijing, China, [2]Stanford Univ., Stanford, CA, [3]BGI-Shenzhen, Shenzhen, China

Abstract Body:

Polystyrene (PS), commonly known as Styrofoam, accounts for about 7.4% (20 Mt/y) of the global petroleum-based plastic consumption. To date, PS is generally considered to be the plastic most resistant to biodegradation and the accumulation of PS wastes in the environment has been a global concern. Here we demonstrate that mealworms, common insect larvae of *Tenebrio molitor* Linnaeus, can eat Styrofoam and degrade it as sole diet for living over one month. We tested mealworms obtained at Beijing, China and found that they consumed Styrofoam up to 30-40 mg per 100 worms per day at ambient temperature. The fecula were collected and the chemical and physical properties were analyzed by gel permeation chromatography (GPC), solid-state ^{13}C cross-polarization/magic angle spinning nuclear magnetic resonance (CP/MAS NMR) spectroscopy, and thermogravimetric Fourier transform infrared spectroscopy (TG−FTIR). Analyses of fecula showed that cleavage/ depolymerization of long-chain PS molecules and the formation of depolymerized metabolites occurred. With a short retention time less than 24 hrs in mealworm digestion system, the carbon of ingested PS was mainly mineralized to CO_2 up to 47.7% during a 16 day test period. ^{13}C-tracer tests confirmed that the ^{13}C-PS was converted to $^{13}CO_2$ and partially incorporated into lipid biomass. Suppression of the gut bacteria of mealworms with antibiotic gentamicin (60 μg/g food) impaired their ability to depolymerize PS and mineralize PS into CO_2. One bacterial strain *Exiguobacterium* sp. YT2, capable of degrading PS, was isolated from the mealworm gut, based on its growth on PS film with obvious damage, change in hydrophobicity and shift of average molecular weight of residual PS film, formation of water-soluble daughter products and PS film weight loss of 7.4% over 60 days. These results indicate that PS can be mineralized rapidly within mealworm gut, and the gut bacteria play an essential role in PS biodegradation. The discovery reveals a new fate for plastic in the environment and suggests a new promising area of research on a technical approach to biodegradation of plastic wastes.

Publishing Title:

Biodegradation Potentials of Indigenous Bacteria in a Nigerian Institute Palm Oil Mill Effluent

Author Block:

C. C. Isitua[1], I. Ahaotu[2], E. I. Atuanya[3]; [1]Afe Babalola Univ. Ado-Ekiti (ABUAD), Ado-Ekiti, Nigeria, [2]Univ. of PortHarcourt, PortHarcourt, Nigeria, [3]Univ. of Benin, Benin City, Nigeria

Abstract Body:

Nigeria produces large quantities of palm oil effluent arising from the processing of palm fruits obtained from various small holdings and big oil palm plantationsscattered all over the country. These effluents ultimately enter the environment, thereby constituting sources of environmental pollution. The biodegradation of palm oil mill effluent by indigenous bacteria was studied by observation of changes in some physico-chemical characteristics of the effluent. Based on cultural, morphological and biochemical characterization, bacteria isolated from the effluent were identified as *Flavobacterium breve*, *Bacillus sphaericus*, *Bacillus brevis*, *Corynebacterium diphtheriae*, *Bacillus licheniformis* and *Pseudomonas aeruginosa*. Incubation of the bacteria at different temperatures and hydrogen ion concentrations for 48 hours, showed that 50% grew at 4^{o}C, 100% grew at 28^{o}C, 83.34% grew at 37^{o}C, while 66.67% grew at 50^{o}C and all the isolates survived only the neutral (7.4) hydrogen ion concentration. *F. breve* and *C. diphtheriae* isolates gave the highest turbidity of screen test for the utilization of palm oil effluent as sole carbon sources. The physico-chemical characteristics of the raw effluent samples were studied and the pH values ranged from 4.10 - 7.30, biochemical oxygen demand (BOD) ranged from 532.40 – 665.50 mg/l while chemical oxygen demand (COD) ranged from 797.25 – 997.50 mg/l. The effects of *F. breve* and *C. diptheriae* isolates on the physico-chemical characteristics of the effluent (supplemented and unsupplemented) were carefully noted and compared using shake flask degradation experiment. There was an observed reduction in pH, from 7.40 – 6.50, BOD, from 440.14 – 45.01 mg/l and COD, from 659.63 – 86.96 mg/l of the carbon supplemented effluent sample with consortium of *F. breve* and *C. diptheriae* isolates. There was a high positive correlation between mean population counts of palm oil mill effluent utilizing bacteria with BOD and COD. T-test values also showed that there were significant differences ($P< 0.05$) in all the parameters analyzed. The study revealed the high potency of *F. breve* and *C. diphtheriae* isolates and the possibility of using them in biodegradation of palm oil mill effluent.

Iron Related Bacteria Near Shipwrecks in the Gulf of Mexico

Author Block:

L. A. FITZGERALD[1], D. Haridas[2], A. L. Cockrell-Zugell[3], J. C. Biffinger[1], P. A. Fulmer[1], L. J. Hamdan[4]; [1]Naval Res. Lab., Washington, DC, [2]American Society for Engineering Ed., Washington, DC, [3]Janssen Pharmaceutical Companies of Johnson & Johnson, Malvern, PA, [4]George Mason Univ., Manassas, VA

Abstract Body:

Background: Water samples were collected near six shipwrecks located in the Gulf of Mexico during April-May 2015 field activities. Two control sites (Ewing Bank and Halo), two heavily impacted sites (Mica and U-166), and two moderately impacted sites (Anona and Viosca Knoll) were chosen in relation to the 2010 Deepwater Horizon oil spill. These samples were examined for iron-related bacterial consortia. **Methods:** Water samples were collected close to the sediment, analyzed by inductively coupled plasma mass spectrometry (ICP-MS), and used as the inoculum in an Iron Related Bacteria Biological Activity Reaction Test (IRB-BART™) assay. All IRB-BART™ assays were performed according to the manufacturer's protocol and were analyzed 4, 8, and 16 days after inoculation. At each of these time points the assay cultures were analyzed to detect changes in the microbiome (metagenomic analysis), estimate Fe^{2+} and total Fe concentrations (bathophenanthrolinedisulfonate (BPS) assay), and observe morphological changes (SEM). **Results:** ICP-MS analysis identified trace levels of iron (<1.5 μM) at the control sites but significantly higher concentrations (220-795 μM) at the heavily impacted sites. One of the control sites (Halo) and one site in the moderately impacted area (Viosca Knoll) had the greatest number of culturable iron related bacterial populations, and culture growth was not correlated with environmental Fe concentrations (0.3 and 30.8 μM, respectively). The BPS assay showed that after 16 days of growth one of the heavily impacted sites (U-166) contained lower concentrations of soluble Fe (~3mM) when compared to the other samples, which could indicate cellular Fe uptake or Fe precipitation. In most samples (except Anona), the concentrations of Fe^{2+} increased until 8 days of growth, then declined between 8 and 16 days. **Conclusion:** Water samples were cultivated in an iron rich environment to examine iron-related bacterial consortia. Mica and U-166 samples took longer to cultivate in an IRB-BART™ assay, indicating lower bacterial numbers, even though the inoculum contained the highest iron concentrations. However, all samples showed changes in Fe^{2+} concentrations over time.

Novel Denitrifying Microbial Consortiums Identified from Shipwreck Sites in the Gulf of Mexico

Author Block:

D. Haridas[1], J. Biffinger[2], T. Boyd[2], P. Fulmer[2], L. Hamdan[2], L. Fitzgerald[2]; [1]American Society for Engineering Ed., Washington, DC, [2]Naval Res. Lab., Washington, DC

Abstract Body:

Background: Shipwreck sites serve as a rich source of unique adaptable microbial populations that have largely remained undiscovered. The low temperature, lack of sunlight and decreased oxygen levels enable microbes to adopt unique metabolic adaptations. Therefore, the marine dark biosphere was sampled **t**o identify cultivable novel microbes that exhibit energy efficient metabolic pathways which include denitrification and carbon fixation.**Methods:** Water samples collected near two shipwreck sites, Halo and U-166, were enriched for denitrifying bacteria using the denitrifying Biological Activity Reaction Test assay. Sterile Nunc tubes containing one of three modified Indole Nitrite (IN) medium (nitrate only (N), carbonate only (C) and without nitrate and carbonate (ONC)) were used. Nitrogen gas was bubbled through the Nunc tubes for 15 mins prior to inoculation. Growth kinetics and variation in elemental composition using Ion chromatography (IC) for the consortia over a period of 24h were analyzed. All analyzes were performed in triplicate.**Results:** Growth kinetic studies of the Halo microbial consortium showed that the microbial population multiplied only in the N medium while no growth was observed in the C and the ONC medium. With the U-166 microbial consortium, growth was observed in all three different medium compositions but optimum growth was observed in the N medium. IC studies showed a steady decline in nitrate levels for the denitrifying microbial supernatants cultured from the water samples obtained from Halo (734mg/L to 0.7mg/L) and U-166 (727mg/L to 2.5mg/L) which was followed with an increase in nitrite levels before leveling off (Halo- 1.4mg/L to 133.59mg/L to 4.25mg/L and U-166- 1.1mg/L to 239.4 mg/L to 2.2mg/L).**Conclusions:** The above study shows that the denitrifying microbial consortia isolated from both the shipwreck sites are cultivable under laboratory conditions and are mutually exclusive as they exhibit varied growth profiles and rates of nitrate utilization. This resulted in different levels of nitrate utilization thus supporting the objective that novel microbial populations exist at various ship wreck sites. This enables the discovery of unique microbes that can pave way for identifying novel microbial processes.

Efficiency of Cholera Smart II Water Test in Detecting *Vibrio cholerae* in Ballast Water

Author Block:

A. Chen, S.M. Rashed, A. Huq, R.R. Colwell; Univ. of Maryland, College Park, MD

Abstract Body:

Ballast water is essential to stabilize and operate ocean-bound shipping vessel safely, but can pose significant ecological, public health, and economic problems. Because ballast water can serve as a vehicle for transmission of pathogenic microorganisms to new environments, ballast water can be treated by filtration, chemical, and/or UV irradiation to remove or inactivate pathogens. Current regulations address acceptable levels of human pathogenic fecal coliforms, such as *Escherichia coli* and *Enterococcus spp.,* and including *Vibrio cholerae,* to control their spread via ballast water discharge. Accurate detection of pathogens that persist after treatment is critical for determining the efficiency of treatment systems. Although there are several EPA approved standard operating protocols for detection of *E. coli* and *Enterococci*, there is none for detection of *V. cholerae* in ballast water. Current regulations allow <1 CFU toxigenic *V. cholerae* per 100 mL and is typically determined using colony blot hybridization, DFA or PCR. However, these methods can be time consuming and difficult to perform. In this study, Cholera SMART II water test was employed to determine its efficacy and potential in the SOP for *V. cholerae* detection. Cholera SMART II is a rapid, lateral flow, colorimetric immunoassay for detection of *V. cholerae* O1 in water samples. Briefly, membrane filtered natural water collected from Baltimore Harbor, MD, was resuspended in 1x APW and amended by addition of 10^1, 10^2, 10^3,10^4 environmental or clinical *V. cholerae* O1 cells and incubated for 4 hours at 35°C and tested using SMART II. Samples were stored at room temperature for 4 days and retested with SMART II. Preliminary results show that SMART II is effective in detecting as few as 10^3 cells after 4 hours and 10^2 after 4 days at room temperature. Use of Cholera SMART II is a simple method for rapid and accurate detection of *V. cholerae* and is beneficial for validation of the safety of ballast water treatment systems.

Visualization of Rhodopsin-utilizing Cells in the Chesapeake Bay

Author Block:

K. Miller[1], J. Keffer[1], C. Sabanayagam[2], J. Maresca[1]; [1]Univ. of Delaware, Newark, DE, [2]Delaware Biotechnology Inst., Newark, DE

Abstract Body:

Microbial rhodopsins are a family of transmembrane proteins, with photosensitive retinal cofactors, found in every domain of life. Rhodopsins respond to light by transporting ions across the cell membrane or by initiating a signaling cascade that leads to altered gene expression. Rhodopsins are abundant in nature, and recent estimates indicate that up to 70 percent of microbial cells in some aquatic environments encode rhodopsin genes, suggesting that more bacteria utilize sunlight than previously thought. However, these estimates are based on gene abundances, not direct observation. In order to determine the abundance of functional rhodopsins, visualization of these low-fluorescing proteins is essential. We recently developed a method that uses total internal reflection fluorescence (TIRF) microscopy to identify rhodopsin-containing cells in environmental samples. Here, we use TIRF microscopy to quantify the total number of rhodopsin-containing cells in water samples collected along the Chesapeake Bay, demonstrating that rhodopsin production is correlated with daylight and salinity. As up to ~65 percent of cells produce rhodopsins, microbial capture and utilization of sunlight by rhodopsin-type photosystems is thus common throughout an estuary.

Xylan-degrading Bacteria Isolated and Characterized from Eastern Mediterranean Sea

Author Block:

K. R. McBride, Anthony Rossi, Hannah Woo, Jing Wang, Nicole Labbe, Terry Hazen; Univ. of Tennessee, Knoxville, Knoxville, TN

Abstract Body:

Hemicellulose xylan is an important structural component within plant cell walls that is difficult to degrade. There is relatively little information on the diversity of bacteria that produce xylan-degrading enzymes, or the necessary conditions to maximize enzyme production. Additional knowledge about xylanase producing bacteria could lead to more efficient ways to break down plant material for biofuels. Marine environments were sampled because they are rich in hemicellulosic biomass. This study aims to identify xylan-degrading bacteria by sequencing isolates from Eastern Mediterranean Sea, and measuring their growth rates on xylan media. Isolates were cultivated from a laboratory incubation of xylan-amended seawater. A set of ninety isolates were sub-cultured several times on synthetic seawater agar with xylan as the sole carbon source. All strains were then identified by 16S rRNA gene sequencing. Isolates were closely related to *Halomonas*, *Pseudomonas*, *Joostella*, *Glaciecola* and *Janibacter*. None of the species found are well-known xylan degraders. Growth curve data and preliminary metabolic tests with xylan show that several isolates have high xylanase producing ability. Understanding more about xylan degradation could find more cost effective ways to produce biofuels.

Challenging Actinomycetes: A Non-Related New Strain M11-108 Isolated from Marine Sediments Off Peru with Unknown Antimicrobial Activity

Author Block:

U. TARAZONA[1], W. serrano[2], K. RODRIGUEZ[2], R. OLAECHEA[2], e. marguet[3], M. VALLEJO[3], L. Liza[4], N. Galindo[4], j. león[1]; [1]Univ. Natl. Mayor de San Marcos, LIMA, Peru, [2]Univ. CIENTÍFICA DEL SUR, LIMA, Peru, [3]Univ. Natl. de la Patagonia SJB, trelew, Argentina, [4]Univ. Natl. Mayor San Marcos, Lima, Peru

Abstract Body:

The emergency of bacterial resistance to antibiotics nowadays represents a huge problem in human health. Actinobacteria are very well known organisms that are able to produce secondary metabolites. As part of a big oceanographic campaign in the central coast off Peru organized between September to Decemeber 2005, we collected marine sediments from two locations. Our main objective was to isolate actinomycetes from unexplored hábitats.Sediments samples were collected from two locations in front of the central coast off Peru: Ancon Bay (11°81S, 77°39W) and Independence Bay (14°34S, 76°18W). Sediments were obtained with a Van-Been grab at depths of 35 to 100 m and surface alliquotes were placed in sterile 50-ml Falcon tube and kept frozen at 4°C. Before culturing, samples were dry and wet warm-treated to eliminate other undesirable microflora. Then 20 gr of wet sediments were diluted in sterile marine sea-water to 10-5 dilutions and 0.1 ml of ech were inoculated in marine agar and Casein-Starch agar plates. Pigmented and non-pigmented forming a concentric ring pattern colonies were selected for further purification in agar slants.Based on colony morphologies, microscopic evaluation and biochemical testing 25 suspected actynomicetes were isolated in pure culture. The most conspicuous strain M11-108 has shown antagonistic activity against pathogenic vibrios and to other drug-resistant pathogens e.g. vancomycin-resistant *Enterococcus faecium*. Comparison of the nearly complete 16S rRNA gene sequences against sequences in the GenBank database indicates that almost all 25 strains belong to the familiy of Actinomicetales. However, this molecular probe also revealed that the strain M11-108 is far related to this group. The close relative of this new isolate were members of the familiy Alcanivoracaceae of the Proteobacteria showing a nucleotide similarity of 83%.This finding may indicate that unexplored habitats in the world still harbor unknown organisms that are able to produce novel antibiotics and other biomolecule therapeutic agents. Based on our study strain M11-108 may represents a novel species in a new genus within the family Alcanivoracaceae.

Preliminary Report on Microbial Flora Isolated from Pollutedand Non-polluted Coastal Waters of Karachi, Pakistan

Author Block:

A. Shaheen[1], H. S. Baig[2], **S. U. Kazmi**[1]; [1]Immunology and Infectious Disease Res. Lab. - Dadabhoy Inst. of Higher Ed., Karachi, Pakistan, [2]Insti1Natl. Inst. of Oceanography, ST-47, Block-1, Clifton, Karachi-75600, Pakistan, Karachi, Pakistan

Abstract Body:

Background: Marine pollution has now become worldwide environmental concern. Continuous discharge of untreated industrial effluent, municipal and power plant's contaminated wastewater has been a serious threat to marine habitat, marine life, aesthetic values and interest of visitors to coastal areas. Karachi, the largest city of Pakistan and industrial hub is located at latitude 24° 48´ N and longitude 66° 59´ E on coast of the Arabian Sea. It suffers serious environmental problems because of population pressure and increasing industrial activities. **Methods:** In this investigation, samples of sediment, water, flora and fauna were taken from nine selected stations on Karachi coast included three stations represented major creeks i.e. Korangi, Gizri and Chinna Creek. These samples were taken in north-east and south-west monsoonal period during 2014. **Results:** Bacterial flora isolated and identified from samples collected from these sites by conventional method. Among isolated and identified bacteria e.g. Vibrio alginolyticus, E.coli and Streptococuss anginosus were the most dominant species contributing 21.43, 19.64 and 15.18 percent of total assemblage respectively. Among selected sample stations, Korangi creek station was found to be most polluted with coliform and other pathogenic bacteria. **Conclusions:** These results clearly indicate that threats from these pathogens are not only to marine life but also to the large number of visitors coming to beaches and residents of surrounding area. Moreover; immediate action should be taken to restrict the growth of these pathogens by taking measures to treat the municipal and industrial effluent to avoid outbreak of any disease in future.

Phylogenetic Analysis of Microbial Sediment Communities from Two Salt Marshes in the South Shore Estuary Reserve

Author Block:

J. M. Coombs, A. Espinosa; Adelphi Univ., Garden City, NY

Abstract Body:

Estuarine ecosystems are becoming increasingly impacted by anthropogenic contaminants from terrestrial sources. In particular, heavy metals can become trapped in estuary sediments after binding to particulate matter in the water column or through precipitation due to gradients in water chemistry. This results in increasing the concentrations of heavy metals in estuary sediment, which can negatively impact sediment microbial communities. In this study, a vibracoring technique was used to obtain an 8 foot sediment core from a salt marsh in the South Shore Estuary Reserve (SSER) of Long Island, NY. Metals analysis was performed on 8 core sub-samples, and 16S rRNA gene clone libraries were constructed from metagenomic DNA extracted at three different core depths. Surface core samples were also obtained from a second salt marsh in the SSER, one located close to two potential point sources of anthropogenic pollution. Although there was some variation in metal concentration with respect to depth in the vibracore-extracted sediment, differences were not significant except for the deepest core sub-sample, which had much lower values for all 6 metals examined in this study. This layer of the core differed from others in that it was comprised mainly of sand. Most environmental clone sequences from the vibracore subsamples clustered phylogenetically with bacterial taxa such as the Deltaproteobacteria or Chloroflexi, which have previously been detected in salt marsh sediments. While some operational taxonomic units (OTUs) appeared to have a cosmopolitan distribution across core subsamples, others such as the Spirochetes appeared to be depth-limited. High throughput sequencing of metagenomic DNA from the second salt marsh site detected some of the same phylogenetic groups although the data set exhibited more phylogenetic diversity due to the depth of sequence coverage. Neither of the two salt marsh sites examined in this study was considered to be impacted by heavy metals. However, the data collected on microbial sediment community structure in these two marshes provides baseline measurements that will inform future work on marshes impacted by point source contamination in the SSER.

Diversity and Distribution of Microbial Communities in Subtropical Coastal Wetland Sediments

Author Block:

M. K. Cheung, C. K. Wong, K. H. Chu, H. S. Kwan; The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Wetland sediments are inhabited by an abundant amount of ecologically important microbes. However, since most molecular studies to date have only focused on the bacterial communities, information on the diversity and distribution of wetland archaea and fungi is still very limited. Here, we elucidated the genetic diversity and composition of bacterial, archaeal and fungal communities in sediments of a coastal Ramsar wetland in subtropical Hong Kong by using Ion Torrent next-generation sequencing and examined their spatial distribution between mudflat and mangrove regions in the wetland.Bulk surface sediment samples were collected in triplicate from seven locations in mudflat and three locations in mangrove during the wet season in 2015. The V1-V2 hypervariable regions of the bacterial and archaeal 16S rRNA genes and the internal transcribed spacer regions of fungi were amplified and sequenced together on an Ion Torrent PGM system. Raw sequence reads were demultiplexed, quality-filtered and analyzed using the QIIME pipeline. Reads from the same microbial group were clustered into operational taxonomic units (OTUs) at 97% similarity. Taxonomic information was acquired by aligning representative OTUs to the Greengenes and UNITE reference datasets for prokaryotes and fungi, respectively.Bacterial communities in the mudflat and mangrove sediments were both dominated by the phyla *Proteobacteria* and *Chloroflexi*. Archaeal communities in the mudflat and mangrove sediments were dominated by, respectively, members in the deep-sea hydrothermal vent euryarchaeotic group I and the ammonia-oxidizing genus *Nitrosopumilus*. Ascomycetes dominated the fungal communities in mangrove whereas unidentified members overwhelmed the mudflat sediments. There were > 2700, >1200 and >180 observed OTUs of bacteria, archaea and fungi in the sediment samples, respectively. For all three microbial groups, mudflat and mangrove samples formed distinct clusters in principal coordinates analysis plots.In conclusion, our study has revealed a high bacterial and archaeal diversity, moderate fungal diversity, and spatial differentiation of all these groups in subtropical coastal wetland sediments.

Identification of Polycyclic Aromatic Hydrocarbon and the Microbial Flora from an Oil Spill Contaminated River in Nigeria

Author Block:

U. Elijah, **S. Machunga-Mambula**; Univ. of Abuja, Abuja, Nigeria

Abstract Body:

Polycyclic Aromatic Hydrocarbons (PAHs) are an important group of obstinate ubiquitous chemicals that occur naturally as organic pollutants in the environment which originate from the incomplete combustion of coal (liquefaction), volcanic eruptions, crude oil and/or accidental leakage of petroleum products (asphalts/creosote) into our environment. Water and sediment samples from Qua Iboe River near an oil pollution site and Akpa Atak Eka River an unpolluted site both in Akwa Ibom State, Nigeria were analysed for microbial and PAH content. The PAHs present in the water and sediment samples analysed through Gas Chromatography Mass Spectrometry (GC-MS) were anthracene and naphthalene with the concentration of 2.4%. The bacterial load of the contaminated and uncontaminated river in CFU were 6.7×10^{6} cfu/ml to $4..8\times10^{8}$cfu/ml and 3.1×10^{6} cfu/ml to 2.0×10^{8}cfu/ml while the total coliform (TC) count ranged from 6.8×10^{6}cfu/ml to 5.6×10^{8}cfu/ml and 3.1×10^{6}cfu/ml to 2.2×10^{8}cfu/ml respectively. The organisms isolated were *Bacillus spp, Rhodococcus, Serratia spp, Escherichia coli, Staphylococcus spp, Micrococcus spp.* The bacterial strains isolated from this environment metabolized Anthracene and Napththalene. The degradability of this polycyclic aromatic hydrocarbon by these indigenous bacterial isolates shows a promise towards its application in bioremediation technique.

Detection of Free-Living Amoebae and Amoeba Resisting Bacteria in Beach Waters in Southeastern Georgia

Author Block:

M. Mears, C. Karcs, D. Capps, S. Warang, A. Aslan, M. E. Eremeeva; Georgia Southern Univ., Statesboro, GA

Abstract Body:

Background: Kings Ferry Park in Savannah, Georgia, has been under a permanent health advisory since 2004 due to high levels of Enterococci; however, other information about microorganisms circulating at this site is lacking. We examined the occurrence and distribution of free-living amoebae (FLA), and FLA associated bacteria in water and sediment samples in the park and the surrounding area along the Ogeechee River.**Methods:** Water and sediment samples were collected monthly from 14 sites along the beach and river around Kings Ferry Park. Sample filtrates were used for isolation of FLA and bacteria. Amoebae were isolated using the walk-out method. Bacterial isolates were established using co-culturing with *Acanthamoeba castellanii* followed by colony isolation on charcoal yeast extract agar plates with and without BCYE supplement. DNA was extracted using Qiagen QIAmp protocol. Identification of amoeba isolates was completed by sequencing 18S rRNA gene; bacteria were identified by sequencing 16S rRNA gene and *Legionella* 23S-5S rRNA intergenic region.**Results:** 155 isolates of amoebae were obtained from water and sediment samples collected from the beach and surrounding sites. *Vermamoeba vermiformis* was a predominant species; *Naegleria clarki* and *Acanthamoeba spp.* were also found. 17 species of bacteria which are obligate or opportunistic pathogens of human and animals were recovered. Bacteria of *Bacillus cereus* complex were the most frequently isolated followed by *Stenotrophomonas maltophilia and Acinetobacter baumanii. Legionella anisa* and *Mycobacterium sp.* were also detected. **Conclusions:** All three species of amoebae isolated as a part of this study can harbor diverse amoeba-resistant bacteria; many bacteria isolated are known to carry a variety of antibiotic resistance genes. The origin, sources, and spatial and temporal distribution of these pathogens in the area need further study. In depth characterization of these microorganisms and their interactions is critical to assess the risk of human and companion animal exposure to these common groups of organisms as a result of various aquatic recreational activities.

Abstract Body:

Experimental environmental disturbance is a means of analyzing successional processes in natural ecosystems. We investigated several sites in a small area of Trunk River, an organic-rich, sulfidic pool near Woods Hole, MA. In its undisturbed steady state this ecosystem contains thick layers of decaying seagrass in a shallow water column with steep gradients of sulfide, light, and temperature. Some areas exhibit a bright yellow microbial suspension, termed “Lemonade”, that transiently forms above the organic matter and disappears within a few days. We hypothesized that the microbial succession within this “bloom” is linked to a physical disturbance and follows distinct spatiotemporal patterns.We removed the organic matter layer, mixed the water column and studied the reestablishment of habitats and microbial communities using next-generation sequencing and a comprehensive set of physicochemical parameters. After the press disturbance the ecosystem was homogeneous comprising the taxonomically diverse communities, which were characteristic for Trunk River. With time the communities underwent substantial change, evolved striking sulfide and oxygen gradients while distinct niches emerged. After around 7 days the ecosystem seemed to be mature and was largely dominated by a single species of Green Sulfur Bacteria, *Prosthecochloris vibrioformis*, a member of the phylum *Chlorobi*, while other layers in the floating mats included *Chlorobi* that consisted mainly of organisms belonging to the genus *Chlorobaculum*.

A. Shen, D. Deng, F. Liu, M. Reed, M. Dolan-Timpe, **G. ZHENG**; Lincoln Univ., Jefferson City, MO

Abstract Body:

Background: Information on contaminant sources and history of surface water and groundwater is important for water resource management. The putative glucosyltransferase gene (*ycj*M) of *Escherichia coli* (*E. coli*) was reported to be highly associated with enteric *E. coli.* The objective of this study was to determine if gene *ycj*M could be used as a biomarker in assessing the sources and history of surface water and groundwater. The underlying hypothesis was that surface water and shallow groundwater (mostly young water) were highly linked with enteric *E. coli* (*ycj*M positive), while deeper groundwater (mostly old water) with environmental *E. coli* (*ycj*M negative).**Methods:** A total of over 200 strains of *E. coli* were isolated from surface water and groundwater with different depths at eight different locations within the Goodwater Creek Experimental Watershed in northern central Missouri. Presence or absence of gene *ycj*M for each *E. coli* isolate was determined by the polymerase chain reaction (PCR) assay. The association of *ycj*M with the relative age of water was statistically analyzed (Student's t-test) using both the electric conductivities of the water samples collected at different depth, which was considered a chemical indicator of the relative age for water, and the history of fertilizer uses. **Results:** The ycjM positive rates in the E. coli population were relatively high and similar for surface water and shallow groundwater, suggesting recent contamination from animal wastes. The rates for groundwater were relatively low and negatively correlated with electric conductivities and the depths of groundwater well, demonstrating increasing domination of environmental E. coli (ycjM negative) in deeper groundwater (older). **Conclusions:** Gene *ycj*M of *E. coli* may be used as a biomarker in determining the sources and history of surface water and groundwater for effective water resource management.

Detection of Enteric Viruses and Index Indicators for Evaluating Sachet Water Quality

Author Block:

O. T. Adekunle[1], O. B. Shittu[1], F. O. Olufemi[1], O. O. Odedara[1], T. O. C. Faleye[2], M. O. Adewumi[2], J. A. Adeniji[2]; [1]Federal Univ. of Agriculture, Abeokuta, Nigeria, [2]Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Microbiological safety of sachet water remains a public health problem in Nigeria as most brands on quality assessment do not conform to drinking water standards. There is a need to assess sachet drinking water for possible enteric viruses and some index indicators.**Methods**: A total of sixty samples of sachet water were obtained from 5 different brands between February (peak of dry season) and April (rainy season) 2013. Water samples of the same brands were pooled together and concentrated with Polyethylene glycol (PEG) 6000. Viral detection was conducted using Polymerase Chain Reaction techniques targeting specific genes in adenovirus, rotavirus and norovirus. *Cryptosporodium parvum, Giardia lamblia* and *Escherichia coli* as index indicators along with other organisms were detected using standard methods.**Results**: Viral analyses revealed that only one sample which was collected at the peak of dry season tested positive for adenovirus while rotavirus and norovirus were absent in all samples. Adenovirus had a prevalence rate of 20% (1/5) in February and 6.7% (1/15) over three months of collection. No oocyst of *Cryptosporodium parvum* or ova of *Giardia lamblia* or any form of parasite was found in all batches of water collected. However, *Salmonella enterica* serovar *Typhi*, *Pseudomonas aeruginosa*, *Shigella dysentariae*, and *Escherichia coli* were detected.**Conclusions**: Adenovirus was detected by PCR in a sachet water sample that tested negative for *Escherichia coli*, oocyst of *Cryptosporodium parvum* and ova of *Giardia lamblia.* There is the need to screen sachet water periodically for enteric viruses even when they meet bacteriological standards.

Lapse in Municipal Water Corrosion Control Linked to Elevated *Legionella* Levels in Building Plumbing

Author Block:

D. O. Schwake, E. Garner, O. Strom, A. Pruden, M. Edwards; Virgnia Tech, Blacksburg, VA

Abstract Body:

A recent crisis occurred in Flint, MI after the city switched to the corrosive Flint River as its drinking water source and discontinued corrosion control. Though the city has since returned to their former supply, the distribution system may have been irreversibly damaged. During a period of rampant corrosion, water problems were widespread, chorine residuals were low, and microbial growth in the distribution system was high. As low chlorine residual and conditions conducive to microbial growth are known factors associated with *Legionella pneumophila* proliferation, we hypothesized that the lack of corrosion control could elevate the levels of these bacteria in buildings. In a broad field sampling of water from the municipal distribution system just before the switch back to the former water source, we detected low levels of *Legionella* in residences, but a more in-depth sampling at two local hospitals revealed high levels of *L. pneumophila* gene markers. Furthermore, publically available data suggest a legionellosis outbreak occurred concurrently with the use of the corrosive water within Flint. This unfortunate situation presented a unique opportunity to examine how deteriorating infrastructure and shifts in water management practices may influence waterborne disease. As this study is ongoing, the main objectives are to: 1) monitor *Legionella* within high-risk premise plumbing systems for comparison to data gathered while the city was sourcing drinking water from the Flint River; 2) measure water quality parameters associated with the previously utilized water source and examine correlations with occurrence of *Legionella*; and 3) explore associations between these results with reported legionellosis infection data in Flint to identify factors that may trigger increased incidence. Though Flint is an extreme case, the findings regarding the relationship between corrosion related infrastructure damage and opportunistic pathogen proliferation will have broad relevance. As water utilities continue to grapple with aging water infrastructure, reduced water demand due to water conservation, dwindling water resources, and poorer water quality, water distribution will become more conducive for the growth and survival of *Legionella* and other opportunistic pathogens, putting communities at increased risk of contracting disease.

Reduced Infectivity Of Viable But Non-Culturable *helicobacter Pylori* in Water

Author Block:

K. F. Boehnke[1], K. A. Eaton[2], C. Fontaine[2], M. Valdivieso[2], L. H. Baker[2], C. Xi[1]; [1]Univ. of Michigan, Sch. of Publ. Hlth., Ann Arbor, MI, [2]Univ. of Michigan, Med. Sch., Ann Arbor, MI

Abstract Body:

Background: In epidemiologic studies, *Helicobacter pylori* infection has been consistently associated with lack of access to clean water and proper sanitation. We previously showed that exposure to culturable *H. pylori* in drinking water can be infectious in mice (estimated ingested doses of $5.26*10^2$-$5.26*10^6$ CFU). However, *H. pylori* exists in a viable but non-culturable (VBNC) state in water, and the infectivity of this form is not well characterized. In this set of studies, we examined the infectivity of VBNC *H. pylori* in mice.Materials and Methods: *H. pylori* strain SS1 was used in all studies. The VBNC state was induced by adding freshly grown SS1 to sterilized tap water and waiting until culturability was lost. Viability of VBNC *H. pylori* was examined using Live/Dead staining microscopy. Four studies were performed, with *Helicobacter*-free C57/Bl6 mice exposed to different doses of VBNC *H. pylori* via gavage or in drinking water (Table 1). After exposure, *H. pylori* infection in the stomach was evaluated using quantitative culture, PCR for the VacA gene, and urease test.Results: See table 1. Live/Dead staining showed that all inocula contained viable cells. Quantitative culture results were negative for all mice. In DNA extracted from stomachs of the gavaged mice, PCR was positive in 8 of 16 mice.Table 1. Overview of experiments

Exposure groups	***Exposure and duration***	***Estimated dose of VBNC cells***	***Quantitative culture outcome (positive/total)***	***PCR outcome (positive/total)***
40 C57/BL6 immunocompetent mice (20 male, 20 female)	Exposure to one day of 10^9 cells/L of VBNC *H. pylori* in drinking water. Sacrificed 4 weeks after final exposure.	~$3.4*10^6$ cells	0/40	0/40
40 C57/BL6 immunocompetent mice (20 male, 20 female)	Exposure to six days of 10^9 cells/L of VBNC *H. pylori* in drinking water.	~$5.3*10^7$ cells	0/40	0/40

	Sacrificed 2 weeks after final exposure.			
10 C57/BL6 Severe Combined Immunodeficient mice (4 male, 6 female)	Exposure to one day of 10^9 cells/L of VBNC *H. pylori* in drinking water. Sacrificed 1 week after final exposure.	~$5.4*10^6$ cells	0/10	0/10
16 C57/BL6 immunocompetent mice (16 male)	Gavaged with 4 doses of ~10^8 cells of VBNC *H. pylori* over 2 weeks. Sacrificed 4 weeks after final dose.	~$6*10^8$ cells	0/16	8/16

Conclusions: In this study, doses of VBNC failed to cause infection, despite being substantially higher than infectious doses of culturable *H. pylori*. This suggests that VBNC *H. pylori* is less infectious in mice than the culturable form. Future studies will evaluate the VBNC infectivity of other *H. pylori* strains. This study provides a new approach to evaluate risks of waterborne *H. pylori*.

Inevitability of an Enhanced Monitoring Strategy to Reduce Water Borne Illness Combining Indicators of Sanitary Protection and Measuring Water Quality

Author Block:

N. T. Bukhari[1], S. U. Kazmi[2]; [1]RRRL, Karachi, Pakistan, [2]DIHE, Karachi, Pakistan

Abstract Body:

Background: World Health Organization estimated after 2000 assessments that there are 4 billion cases of diarrhea burst each year in addition to millions other cases of illness associated with lack of access to clean water. It is now well established that infectious diseases are transmitted primarily through water supplies contaminated with human and animal excreta and inappropriate storage procedures. Out breaks of water borne diseases continue to occur throughout the world but such out breaks in developing counties like Pakistan lead to millions deaths among children.**Objective:** The objective of the study was to identify pathogens in contaminated drinking water as a major contributing factor in infantile diarrhea. **Methods:** Total 57 drinking water samples from each source of low socio economic areas of Karachi Pakistan were collected according to WHO guidelines for drinking water quality assessment. Water Sample of about 200 ml each was collected from Government filter plants, cooling containers, storage tank and Municipal tap water, labeled and transported to IIDRL lab for bacteriological analysis. Detailed examination was done by direct microscopy of centrifuged water sample deposit. Water Samples were analyzed and indicator organisms i.e. total and fecal coliform (*E.coli*) were detected by most probable number (MPN) method. Rotavirus antigen was detected by PCR method.**Results:** Out of 57 samples collected, 32 (56%) found positive after bacteriological analysis by MPN technique. Further found that samples were carrying E.coli in 9 (16%), salmonella in 3 (5%), Klebsiella in 2 (4%), Pseudomonas in 6 (11%), mix infection in 5 (8.78% including Rota virus presence, and parasites in 3 & EPEC in 2) samples. Rota virus and EPEC were confirmed by PCR method. Presence of pathogens in every sample confirmed that the water transportation and storage method are not hygienic.**Conclusions:** Enhanced Monitoring system is required in Karachi Pakistan and it should be placed at different disposal points like Water Storage, Water Delivery Channels, Municipality Storage Areas, different point within water supply system and End User Storage Point. This monitoring system will help to identify the area where water is being contaminated leading towards preventive measures. which may reduce the epidemics as well as the financial burden.

High Prevalence of Virulent *Escherichia coli* Belonging B1 Phylogroup in Municipal Water Supply in Dhaka, Bangladesh

Author Block:

J. Ferdous[1], R. B. Rashid[1], S. Saima[1], S. Tulsiani[2], P. K. M. Jensen[2], **A. Begum**[1]; [1]Univ. of Dhaka, Dhaka, Bangladesh, [2]Univ. of Copenhagen, Copenhagen, Denmark

Abstract Body:

Escherichia coli is a commensal organism of the digestive tracts of many vertebrates, including humans. Contamination of drinking water with pathogenic *E. coli* is a serious public health concern.This study focused on the distribution of phylogenetic groups and virulence gene profile of *E. coli* isolated from drinking water in Arichpur, a low income area of Dhaka, Bangladesh.The distribution of the phylogroups and virulence genes were investigated in 200 isolates among them 110 isolates were from municipal water supply system and 90 were from household drinking water. Gene profile of virulence factors was done based on the presence of *eltB, estA, vt1, vt2, eaeA,* pCVD432, *bfpA, ial, ipaH* by PCR. The classification of the isolates into 4/5 major groups (A, B1, B2, D2, D3) was done based on the distribution of *chuA, yjaA* and DNA fragment tspE4.C2 genes.Results demonstrated predominance of phylogroup B1 78.5 % (157/200) followed by B2 phylogroup 13% (26/200) and phylogroup D 8.5% (17/200).The genes *eltB, estA* and *eaeA* was present in 27.39% (43/157), 37% (74/157), and 10.5% (21/157) of B1 phylogroup isolates, respectively. The calculated chi-square value and P-value were 10.23 and 0.001. Therefore, it can be inferred municipal water supply was a greater contributor of pathogenic *E. coli* from the B1 phylogroup.Usually commensals fall in the Phylogroups A and B1. The presence of greater number of virulent B1 phylogroup isolates originating from municipal water supply indicates that the supply system might be contaminated with virulent *E. coli* such as enterotoxigenic *E. coli* carrying mobile genetic elements such as plasmids which might be transferred to the commensal strains. Greater proportion of commensal strains in household water demonstrates low level of contamination of virulent *E.coli* from asymptomatic shedders.

Evaluation of Ultrafiltration and Elution Solutions as a Means to Concentrate Indicators of Fecal Contamination in Water Bodies

Author Block:

J. W. Conrad, V. J. Harwood; Univ. of South Florida, Tampa, FL

Abstract Body:

Fecal contamination of recreational and drinking water is a major concern for public health as it can lead to infections from waterborne pathogens. Usually these pathogens are in low densities and are difficult to detect. Microorganisms that are abundant in feces, e.g. enterococci, *Escherichia coli* and members of *Bacteroidales* (GenBac) are used to detect fecal contamination and as a proxy for pathogens; however, pathogens generally require more extensive concentration strategies such as ultrafiltration via a semipermeable membrane and techniques to recover organisms from filters. Here, the efficiency of ultrafiltration, with hollow fiber filtration (HF) (with a Rexeed-25S filter cartridge) and HF with foam elution (HF-FE) (Innovaprep high volume elution fluid 0.75% tween/25mM Tris), were tested for enterococci, GenBac and human polyomaviruses (HPyVs) in Florida fresh (HF n=2, HF-FE n=2) and salt (HF n=2, HF-FE n=2) surface waters, with enumeration by quantitative PCR (qPCR). Microorganisms in 10L of water were concentrated ~50 fold (to ~200ml) by HF, resulting in no loss of enterococci or GenBac, compared to the control membrane filtration; however, 90% of HPyVs were lost. The HF concentrate was further reduced in volume 5-10000-fold by centrifugal ultrafiltration (CUF) which resulted in up to a 99% loss of enterococci and GenBac by qPCR. Inhibition of qPCR and DNA recovery from extraction procedures were tested using salmon sperm DNA. Inhibition was not detected in the HF concentrate of any sample (n=4) but minor inhibition (change of < 2 C_T) and DNA loss was noted in some CUF samples. CUF was deemed unsatisfactory for concentrating the targets due to loss and inhibition. HF-FE may enhance recovery of bacterial and viral targets from large-volume samples compared to HF alone for analysis of waterborne pathogens and microbial source tracking (MST) targets.

Efficacy of Inactivation of Human Enteroviruses by Multiple-wavelength Uv Leds

Author Block:

H. Ryu[1], S. Beck[2], L. Boczek[1], N. Brinkman[1], K. Linden[2], O. Lawal[3], S. Hayes[1]; [1]Environmental Protection Agency, Cincinnati, OH, [2]Univ. of Colorado, Boulder, CO, [3]AquiSense Technologies, Florence, KY

Abstract Body:

Background: Ultraviolet (UV) light has been successfully used for treating a broad suite of pathogens without the concomitant formation of carcinogenic DBPs. However, conventional mercury UV lamps have some practical limitations in water treatment applications, such as the inefficiency of energy consumption and more importantly potential mercury contamination upon disposal of the lamps. The recent invention of a novel light-emitting-diodes (LED) device generating germicidal UV wavelengths could eliminate the aforementioned limitations. In this study, we investigated the efficacy of multiple-wavelength UV LEDs for inactivating USEPA contaminant candidate list (CCL) RNA enteroviruses.**Methods:** Serotype representatives of the four human enteric species of enteroviruses such as coxsackievirus A10 (CVA10), echovirus 30 (Echo30), poliovirus 1 (PV1), and enterovirus 70 (EV70) respectively were selected as testing RNA viruses. Bench-scale performance evaluation was conducted using a collimated beam (CB) apparatus with LEDs emitting at 260 nm, 280 nm, and the combination of 260|280 nm together, as well as a monochromatic low-pressure (LP) UV lamp at 254 nm for comparison. The CB tests were performed with mixed stocks of four viruses. Infectious virus concentrations were determined using an ICC-RTqPCR.**Results:** The 260 nm LED was most effective at inactivating all enteroviruses tested, followed by the 260|280 nm LED, LP UV and lastly the 280 nm LED. These results are favorably comparable to our companion study with MS2 coliphage (RNA virus), suggesting no synergistic inactivation of RNA viruses by the 260|280 nm combination. Specifically, for a 2-log inactivation credit by the most effective 260 nm LED, UV doses averaged approximately 8 mJ/cm^2 for CVA10 and PV1, 10 mJ/cm^2 for EV70, and 13 mJ/cm^2 for Echo30. These UV doses for the viruses tested yielded much greater inactivation rate constants than MS2 coliphage and the most UV resistant adenoviruses.**Conclusions:** Overall, UV LEDs showed the capability to effectively inactivate the CCL enteroviruses tested. Superior performance of the 260 nm LED to conventional LP UV encourages further studies on its applicability for sustainable water treatment and other CCL pathogens.

Microbiological Quality and Microbial Diversity of Packaged Ice in Southern California

Author Block:

K. Lee, P. Lwin, L. Ab Samad, S. Riedel, A. Magin, W-J. Lin; Cal Poly Pomona, Pomona, CA

Abstract Body:

Background: Microbial contamination in food and water may post a threat to public health. Ice is defined as a food by the U.S. Food and Drug Administration (FDA). According to the International Packaged Ice Association (IPIA), approximately 2 billion bags of ice are sold from retail, wholesale, and vending producers each year in the U.S. Out of 700 commercial ice-making companies, 200 of the aforementioned are not presented by the IPIA and do not comply to specific packaged ice processing standards.**Methods:** Non-IPIA complied samples were collected from gas stations, liquor stores, or convenient stores in Los Angeles, Orange, San Diego/Imperial, and San Bernardino/Riverside counties. The microbiological quality of non-IPIA complied ice samples were compared with the IPIA-complied packaged ice samples using microbiological, molecular, and sequencing analyses.**Results:** Among 132 non-IPIA complied packaged ice samples analyzed, 15 samples contained unsatisfactory level of heterotrophs, (≥ 500 Most Probable Number [MPN]/100 ml), 41 samples contained unsatisfactory level of coliforms (≥1 MPN/100 ml), 19 samples had staphylococci, and 70 samples had yeast/mold. None of the 24 IPIA-complied samples had unacceptable microbial levels. None of the samples analyzed showed the presence of the pathogens, *Salmonella*. Next generation sequencing (NGS) results revealed that there are more diverse microbial populations in non-IPIA than IPIA samples, including opportunistic pathogens.**Conclusions:** Our results revealed the microbiological quality of non-IPIA and IPIA complied ice samples in southern California. These findings may lead to a better enforcement of processing standard on packaged ice.

Occurrence of Opportunistic Pathogens *Legionella pneumophila* and Non-Tuberculous Mycobacteria in Hospital Plumbing Systems

Author Block:

J. Hoelle[1], M. Coughlin[2], E. Sotkiewicz[2], J. Lu[1], S. Pfaller[1], M. Rodgers[1], H. Ryu[1];
[1]Environmental Protection Agency, Cincinnati, OH, [2]Weas Engineering, Westfield, IN

Abstract Body:

Background: Opportunistic premise plumbing pathogens (OPPPs) such as *Legionella pneumophila*, *Mycobacterium avium*, and *Pseudomonas aeruginosa* are frequently detected in the plumbing systems of large buildings. The ability of these organisms to form biofilms and to grow in phagocytic amoeba are thought to provide some insulation from chlorine and other conventional water disinfectants. Copper-silver (Cu-Ag) ionization is one water treatment technology used in many hospital water systems as an additional barrier to the growth of waterborne pathogens. In this study, we investigated the occurrence of three OPPPs and phagocytic amoebae and the efficacy of Cu-Ag ionization in hospital plumbing systems.**Methods:** A total of 197 water and 31 swab samples were collected from 14 buildings in one city, including two installed with Cu-Ag ionization. The samples were analyzed for *Legionella* by culture and *L. pneumophila*, nontuberculous mycobacteria (NTM) (*M. avium* and *M. intracellulare*), *P. aeruginosa*, and two amoeba (*Acanthamoeba* and *Vermamoeba vermiformis*) by qPCR.**Results:** Of the 166 water samples from facilities without Cu-Ag ionization, *L. pneumophila* were the most prevalent pathogen detected by qPCR (44%, 73/166), followed by *V. vermiformis* (13%), NTM (11%), and *P. aeruginosa* (6%). Of *Legionella* positive samples, 35 and 25 were confirmed as *L. pneumophila* serotype 1 by culture and qPCR, respectively. Overall, OPPPs were more prevalent in warm water with low chlorine residuals than in cold water with higher chlorine residuals. In the two facilities using Cu-Ag ionization, the prevalence of *Legionella* in the water was low (3%, 1/31), whereas *M. avium* was detected at a high frequency (61%, 19/31) by qPCR. In addition to water, six of 26 swab samples were positive by qPCR for *L. pneumophila* including four serotype 1 positives, whereas *M. avium* was detected in one of five swabs from Cu-Ag ionization facilities. The other target microorganisms were not detected in any swab samples.**Conclusions:** Our observations that Cu-Ag ionization may control *Legionella* but enhance colonization of NTM in building plumbing systems should encourage further studies on the reduction in risks from waterborne pathogens afforded by new treatment technologies.

Assessment of Next Generation Sequencing as a Tool for Microbial Community Signature Analysis in Reused Water

Author Block:

M. Leddy[1], N. Hasan[2], C. Foster[1], R. Colwell[3]; [1]Orange County Water District, Fountain Valley, CA, [2]CosmosID, Rockville, MD, [3]Univ. of Maryland, College Park, MD

Abstract Body:

Background: Recycled water can be used for almost any purpose when treated from a health and environmental perspective. The Groundwater Replenishment System (GWRS), California, is the world's largest water purification system (100 million gallons per day). GWRS takes highly treated wastewater and disinfects it using a three step advanced treatment process: microfiltration (MF), reverse osmosis (RO), and ultraviolet light with hydrogen peroxide, producing high quality reclaimed water for injection into the groundwater basin that is the principal water supply for over two million people. Despite rapid growth of use and reuse practices for reclaimed water, the identification of microbial community at different levels of treatment remains largely unknown. The lack of rapid and accurate identification methods for total communities is one important reason for this knowledge gap. Culture-based methods are too limiting since they can only identify the organisms that can be grown. PCR based methods are faster, but targeted only to a limited number of organisms and static markers, which erode over time. Moreover, these approaches frequently underestimate pathogen removal through the advanced treatment process that can lead to overdesign and unnecessary costs. Next Generation Sequencing (NGS) combined with the GENIUS algorithm is used to identity microbial community signatures and their transformations through GWRS treatment. **Methods:** Total DNA is extracted from water and biofilm samples collected from plant influent (Q1) and biofilm scrapings from MF and RO membranes. Samples are sequenced by Illumina HiSeq and analyzed by GENIUS Bioinformatics Package. **Results:** Diverse communities are identified in Q1 and from biofilm scrapings and enables detection of fecal indicators, pathogens, antibiotic resistance and virulence factors, as well as genes encoding biogeochemical processes such as pollutant biodegradation. Fewer organisms are expected through MF and RO filtration, with the least number of organisms in the RO. Unique signatures of microbial community are identified in the MF and RO. **Conclusion:** The results will be used to assess the application of NGS for recycled water, highlighting both the benefits and limitation of this technology for water treatment processes.

Assessment of Microbial Diversity in Water Samples Using Next Generation Sequencing

Author Block:

N. Jothikumar, A. K. Kahler, V. R. Hill; CDC, Atlanta, GA

Abstract Body:

Next-generation genomic and metagenomic sequencing represents a powerful tool for environmental testing , including improving methods for detecting pathogens in environmental samples, characterizing the microbiological community associated with environmental pathogens, improving understanding of environmental mechanisms of disease transmission, and determining the effectiveness and impacts of water and waste treatment systems. We developed multiple sets of primers targeting different regions of the 16S gene for metagenomic analysis to identify a broad range of bacteria in environmental samples. The primers targeted divergent taxa likely to be present in diverse water types. We performed 16S metagenomics sequencing using the Illumina MiSeq platform and a 600 cycle reagent kit for environmental water samples for a comprehensive assessment and to compare taxonomic diversity. Out of the five hyper variable V regions studied, V3 yielded the highest number of identified species, followed by the V1-V3 region, V5-V6 region, V4-V5 region, and V4-V6 region. The V3 assay, with amplicon lengths of 193 bp, showed the greatest species diversity. The V3 primer set enabled identification of more bacterial species from water samples than a commercially available primer set targeting the V1-V3 region. Based on these study results, the 16S rRNA gene V3 region provided more information to identify a greater number and diversity of bacterial species, and should be a useful tool for bacterial community studies of water systems.

Unique Environmental *E. coli* Strains Isolated from Aquatic Environments

Author Block:

T. Seale[1], E. T. Steenkamp[1], V. S. Brözel[2], S. N. Venter[1]; [1]Univ. of Pretoria, Pretoria, South Africa, [2]South Dakota State Univ., Brookings, SD

Abstract Body:

The gut of warm-blooded animals is widely considered to be the primary habitat of *E. coli*, but some strains can persist and possibly multiply in environments outside of the primary host. Several studies have indicated that *E. coli* isolates from the environment primarily belong to phylogroups A and B1. These environments are also thought to be the primary habitat for the closely related species currently designated as Clades III - V. The aim of this study was to determine whether the *E. coli* populations associated with freshwater reservoirs in subtropical South Africa belonged to the typical phylogroups and clades associated with this type of environment. For this purpose, *E. coli* was initially isolated from water plants, sediment and water from two peri-urban reservoirs as well as from sewage before treatment and release into these reservoirs. *E. coli* was also isolated from aquatic plants collected from six additional reservoirs in the area. Phylogroups were assigned using the Clermont method and isolates were clustered using phylogenetic analysis of the concatenated *uidA, rpoS, mutS* and *fadD* gene fragments. As expected, most of the isolates belonged to phylogroup B1 (35%), but numerous isolates belonging to phylogroups B2 (22%) and D (25%) were also obtained. Amongst the B2 and D isolates obtained from water hyacinths and plant debris many formed part of unique clusters that were not closely related to any of the sewage isolates. The genome sequences for four isolates from these unique clusters were determined to compare their gene content with those of typical phylogroup B2 or D isolates. The isolates associated with hyacinths and plant debris encoded a number of unique genes but also lacked several of the genes typically encoded by isolates of phylogroups B2 or D. These findings indicate that phylogroup B2 and D isolates exist that have undergone niche adaptation for persistence in aquatic environments.

Abstract Body:

Open water features such as water ponds and fountains are common in modern architecture and interior design. Improper maintained, they could become reservoir for microbes and pests. Chemical disinfectants (i.e., chlorination) are often used, but can lead to malodor and material corrosion. This work examines an alternate water disinfection technology based on pulsed-electric field (PEF). Microbes subjected to pulsed-electric field often experienced a change in cell permeability and on occasion irreversible poration that lead to cell death. A miniature PEF device using a low voltage circuit and micro-engineered electrodes were designed and fabricated. The narrow gap between electrodes means intense electric field can be generated, whereas using a low voltage, low powered circuit allows the use of battery to power the device. Laboratory studies show the miniature PEF is effective against common Gram- bacteria (i.e., *E. coli*) commonly found in water with 2 log reduction in less than 1 min. The device was used in a water feature located at HKUST to measure its effectiveness under practical use condition. An unpowered device was used for control. Study showed that better than 70 % reduction in heterotropic bacteria can be achieved by the powered device under a 1 L per min flow. The device can be operated without battery recharging for up to a month and is effective in controlling the bacteria contamination in the water.

Multiple-Year Investigation of Bacterial Contamination in a Midwest Agricultural Watershed

Author Block:

E. Badger, A. Johnson, J. Denney, J. Enos-Berlage; Luther Coll., Decorah, IA

Abstract Body:

Background: Surface waters in the midwestern United States face serious water quality challenges, in part due to the intensity of agricultural activity in this region. In Iowa, where over 90% of the land is used for agriculture, approximately 75% of assessed waterways are impaired (1). The 20,000 acre Dry Run Creek Watershed in Northeast Iowa is impaired for bacteria, a particular concern because this stream flows through major recreational areas. To increase our understanding of contributing factors, as well as explore complexities of bacterial water quality analysis, we assessed distinct watershed sites under varying environmental conditions over a multi-year period. **Methods:** Between 2010-2015**,** ten sites were evaluated for land use and water quality under both dry and wet weather conditions. Levels of *Escherichia coli*, and physical and chemical field parameters, were measured from May-October during 2010, 2011, 2013, and 2015. In addition, phosphorus and nitrogen compounds were measured during 2010 and 2011. AN(C)OVA tests, 99% bootstrapped CIs, and Spearman rank order correlations were performed as appropriate. **Results:** Watershed sites were distinguished by adjacent land use, including relative levels of row crop agriculture, direct livestock access, perennial grass cover, and natural woodlands. Average levels of *E. coli* varied between sites and increased dramatically in response to rain events. Interestingly, different patterns were observed during dry and wet weather conditions in terms of site-specific average *E. coli* concentrations. Positive correlations were found between *E. coli* levels and some nutrients ($p < 0.01$). In addition, *E. coli* levels were positively correlated with amount of rainfall but negatively correlated with time elapsed between rainfall and sampling ($p < 0.05$). Finally, our data exhibited seasonal patterns, as well as substantial changes in some parameters between years having dramatic precipitation differences. **Conclusions:** The condition-dependent shifts in the highest bacteria-contributing sites suggest different types of sources and mitigation strategies. Collectively, these data underscore the importance of sampling during diverse conditions, and taking site-specific characteristics, rainfall amount, timing of sampling, and seasonal and annual variation into consideration when interpreting bacterial water quality data.

Performance of a Pepper Mild Mottle Virus Rt-Qpcr Method in Coastal Waters Exposed to Untreated Wastewater Pollution and Its Simulated Risk of Gastrointestinal Illness

Author Block:

E. M. SYMONDS[1], C. Sinigalliano[2], M. Gidley[2], W. Ahmed[3], S. M. McQuaig-Ulrich[4], M. Breitbart[1]; [1]Univ. of South Florida, Saint Petersburg, FL, [2]U.S. Natl. Oceanographic and Atmospheric Admin., Miami, FL, [3]Commonwealth Scientific and Industrial Res. Organisation, BRISBANE, Australia, [4]St. Petersburg Coll., Clearwater, FL

Abstract Body:

Pepper mild mottle virus (PMMoV) is a sensitive indicator of human fecal pollution. Its elevated concentrations in untreated domestic wastewater, as well as persistence throughout the wastewater treatment process, create the possibility that PMMoV detection in surface waters may overestimate the extent of fecal pollution. In order to better understand the significance of PMMoV detection in surface waters, this study determined the potential health risks associated with detecting PMMoV using a previously published RT-qPCR assay. First, the limits of detection (LOD) and quantification (LOQ) of this assay were determined for coastal waters seeded with untreated wastewater. The analytical LOQ for the RT-qPCR PMMoV was between 10 and 100 gene copies and the assay's standard curves average regression coefficient of 0.990 and an efficiency of 99.38%. In Florida coastal waters exposed to known sources of fecal pollution, PMMoV was detected in greater concentrations and/or more frequently at all sites compared to the following markers: human polyomavirus (HPyV), animal-specific *Bacteroidales* markers, and *Enterococcus* spp. Following the assumption that viruses within untreated wastewater would be diluted to the same extent upon discharge, Quantitative Microbial Risk Assessment (QMRA), with human norovirus (NoV) as a reference pathogen, was then used to calculate the health risks associated with untreated wastewater pollution. Simulated QMRA suggests that PMMoV detection in coastal waters exposed to untreated wastewater exceeds the 2012 U.S. Environmental Protection Agency illness benchmark (1986 equivalent, 36 illnesses/1,000 swimmers). Future work, including epidemiological studies, is needed to further investigate the use of PMMoV as an indicator as well as to confirm the relationship between PMMoV presence and gastrointestinal illness in coastal waters.

Necrotizing Fasciitis Due to *Vibrio cholerae* Non-O1/Non-O139 after Exposure to Austrian Bathing Sites

Author Block:

F. J. Allerberger[1], S. Hirk[1], S. Huhulescu[1], E. Gschwandtner[2], M. Hermann[2], S. Neuhold[2], A. Zoufaly[2], A. Indra[1]; [1]Austrian Agency for Hlth.and Food Safety (AGES), Wien, Austria, [2]Wiener Krankenanstaltenverbund, Wien, Austria

Abstract Body:

We report on two cases of necrotizing fasciitis of the lower leg due to nontoxigenic *Vibrio cholerae*. A 73 year old woman (case 1) and an 80 year old man (case 2) were hospitalized with symptoms of necrotizing fasciitis on July 18 and August 15, 2015, respectively. In both cases, symptoms started the day after swimming in local ponds. Swabs gained intraoperatively and a blood culture from the male patient, yielded *Vibrio cholerae* non-O1/non-O139, negative for cholera toxin gene *ctx* and positive for hemolysin genes *hly*A and *hly*B. Water samples taken from pond A on August 17, 2015 (32 days after exposure of case 1) and from pond B on August 20, 2015 (7 days after exposure of case 2) yielded non-O1/non-O139 *Vibrio cholerae* in most-probable numbers of >11,000 per 100 ml each. The occurrence of two cases of necrotizing fasciitis within a one month period related to two Austrian non-saline bathing waters, previously not known to harbor *Vibrio cholerae*, is probably linked to the prevailing extreme weather conditions (heat wave, drought) this summer in Austria. While case 1 was discharged in good clinical condition after 73 days, case 2 died after four months of hospitalization. Public health authorities are challenged to assess the effects of long-term climate change on pathogen growth and survival in continental bodies of fresh water.

Survival of Various Pathogenic Microorganisms in Surface Water and Sediments in Western New York

Author Block:

L. Farovitch, J. Lodge; Rochester Inst. of Technology, Rochester, NY

Abstract Body:

Western New York (WNY) is well known for its vacation and recreational water spots. In 2005-2006, of the 4,412 reported cases of disease outbreak due to recreational water use, 91% were associated with acute gastrointestinal (GI) illness. Several recreational waters in WNY include: Durand Eastman Beach, Charlotte Beach, Genesee River, Black Creek, Irondequoit Bay and Oatka Creek. To improve the safety of swimming in recreational water, adequate monitoring of water-quality is necessary. In addition to *Escherichia coli* strains (e.g., O157:H7), other enteric pathogens such as *Salmonella typhimurium, Shigella sonnei*, and *Yersinia enterocolitica*, may be responsible for contaminated recreational waters. Because these enteric pathogens are not normally found in surface waters and sediments, it is important to determine the survival rates of these enteric bacteria in recreational waters in WNY. Also, the survival of *Pseudomonas aeruginosa* (pathogenic strain) was determined in some of the local water and sediment samples. All bacterial strains used in this study were isolated from various patients presenting GI disease symptoms. The data from late Fall samples indicated that ~90% of *P. aeruginosa* and *Y. enterocolitica* survive longer (6 and 4 days, respectively) in both sediment and water samples from Black Creek and Durand Eastman Beach than other samples. On average, the survival of organisms in surface waters and sediments ranked from greatest to least as follows: *P. aeruginosa* > *Y. enterocolitica* > *S. sonnei* > *S. typhimurium* > *E. coli*. However, the preliminary data from late Summer samples showed that *E. coli*, *S. typhimurium* and *Y. enterocolitica* but not *S. sonnei* survived longer in water from Durand Eastman Beach (*P. aeruginosa* was not tested in late Summer samples) where it suggests that changes in survival of these pathogenic organisms in recreational waters in WNY depend on seasonal variation. The pH of surface waters and sediments differed by ~1 pH unit (8.1 and 7.4, respectively), indicating that pH does not appreciably affect survivability of these pathogenic organisms. Future studies will examine the effects of climate changes and nutrients on the survival of pathogens by collecting the samples in winter and spring.

Ultraviolet A Induced Phenotype Heterogeneity of *Pseudomonas aeruginosa* and *Enterococcus faecalis* in Synthetic Stormwater

Author Block:

D. Ng, A. Kumar, B. Cao; Nanyang Technological Univ., Singapore, Singapore

Abstract Body:

Background: Stormwater is an important resource. In surface reservoirs, stormwater is subjected to natural self-purification activities such as UV disinfection by sunlight. UVA radiation in sunlight plays a key role in inactivation of bacterial pathogens [1]. However, there is limited knowledge on the fate of bacterial pathogens in stormwater during solar disinfection, especially on how some bacteria survive solar disinfection, which is critical for stormwater management. In this study, the effects of UVA radiation in sunlight on the fate of an opportunistic pathogen *Pseudomonas aeruginosa* and a fecal indicator bacterium *Enterococcus faecalis* in synthetic stormwater were investigated. **Methods:** Bacteria were exposed to a UVA radiation intensity similar to that in sunlight for a period of 2 weeks and culturability was determined every 2 days by CFU counts. qPCR analysis was used to determine the viable but not culturable (VBNC) state of *E. faecalis*. The decrease in culturability of *E. faecalis* and *P. aeruginosa* was described by the single-phase decay model. Small colony variants of *P. aeruginosa* were characterized by biofilm, motility and reactive oxygen species (ROS) assays.**Results:** In the presence of UVA, the culturability of *E. faecalis* decreased drastically while culturability of unexposed *E. faecalis* persisted. Exposure to UVA induced *E. faecalis* to enter the viable but not culturable (VBNC) state. In contrast, there was only approximately a 2-log reduction in the CFU counts of *P. aerguinosa* exposed to UVA radiation. Instead, *P. aeruginosa* formed small colony variants (SCV) in response to UVA radiation treatment. Compared to typical colonies, SCV had reduced biofilm formation ability and motility as well as faster adaptation to reactive oxygen species stress. Culturability of unexposed *P. aeruginosa* persisted throughout the duration of the experiment.**Conclusions:** UVA induces phenotype heterogeneity in *P. aeruginosa* and *E. faecalis* which may enable their survival when exposed to sunlight. Hence, phenotype heterogeneity may play a key role in the survival of bacteria during solar disinfection. The findings of this study will contribute towards effective stormwater management strategies.

Interaction between *Legionella pneumophila* and *Pedobacter glucosidilyticus*

Author Block:

K. Paranjape, H. Trigui, N. Mendis, D. Rodriguez-Mendez, S. P. Faucher; McGill Univ., St-Anne de Bellevue, QC, Canada

Abstract Body:

Background: *Legionnella pneumophila* (*Lp*), a Gram-negative bacterium, is the causative agent of Legionnaires' disease and Pontiac Fever. The primary source of Legionnaire's disease outbreaks is cooling towers, which get contaminated by microorganisms. The contamination within a cooling tower can create an ecosystem that is favourable for the establishment of *Lp* strains. *Lp* is a known facultative intracellular parasite of 13 different amoebal species and thus problematic cooling towers usually contain some of these species. Chemical and thermal control methods are implemented, in order to decrease outbreaks. However, these methods are usually expensive, damaging and harmful. Moreover, different microorganisms present within a cooling tower may either impede or promote the establishment of different *Lp* strains.The research presented here examines the interaction between the bacterial species *Pedobacter glucosidilyticus* (*Pg*), a Gram-negative environmental species isolated from an artificial water system, and *Lp*.**Methods & Results:** *Pg* was isolated from a man-made water system. This species was examined for its capacity to survive in water for extended period of time, its effect on *Lp* survival in water and its effect on *Lp* when co-cultured in the presence of *Acanthamoeba castellanii (Ac)*, an amoebal host cell for *Lp*. *Pg* and *Lp* can both survive in water for extend periods of time. When co-cultured together in water, no significant decrease in CFU count could be observed. However, when these two strains were co-cultured in the presence of *Ac*, *Lp* showed no signs of growth whereas *Pg* grew rapidly over the incubation period. Additionally, *Pg* grew with *Ac* exclusively but not in the infection buffer alone.**Conclusion:** In conclusion, our results suggest that *Lp* and *Pg* can both survive in water for extended periods of time. Furthermore, both these strains do not affect one another's survivability in water. However, both strains are capable of growing in the presence of *Ac*, but *Pg* seems to outcompete *Lp* for intracellular growth. This would indicate that *Pg* is probably using the amoebal species for its own growth and thus may be a potential parasite of *Ac.* The lack of growth of *Lp*, when co-cultured with Amoeba and *Pg*, may either be due to an active inhibition by *Pg* or could be caused by *Pg* higher growth efficiency in *Ac*.

Development of the Smart Sample Concentration System for Microbial Monitoring of Potable Water in the International Space Station

Author Block:

A. Page[1], A. Adolphson[1], M. Hornback[1], A. Checinska[2], K. Venkateswaran[2]; [1]InnovaPrep LLC, Drexel, MO, [2]Jet Propulsion Lab., Pasadena, CA

Abstract Body:

Human habitation of space requires unique systems for providing safe potable water. The International Space Station (ISS) Water Processor Assembly treats wastewater and condensate, turning it into potable water, and as such requires routine microbial monitoring. The existing microbial detection methods are culture-based, posing a high risk of additional health hazards in the space environment, and operational challenges in micro-gravity. Molecular detection technologies have progressed significantly in the last several decades and provide the greatest potential for overcoming these challenges. However, these methods outpaced development of sample concentration techniques, which are necessary for rapid detection of low concentrations of pathogens in drinking water. At present, NASA is challenged with a system that could reliably measure 50 cells per mL of drinking water. Since most available molecular detection technologies use only a few microliters of sample per reaction, water samples must be concentrated at least 1,000 times to achieve reliable and reproducible results. In response to this need, InnovaPrep joined with NASA to develop the ISS Smart Sample Concentrator (iSSC).In a pilot study, multiple one-liter water samples were processed through a hollow fiber membrane filter concentration cell, capturing microorganisms in the fiber lumen. Following capture, the microorganisms were eluted using a novel wet foam elution process in which a viscous, wet foam was used to sweep the captured particles from the membrane surface and dispense them in a concentrated sample volume of less than 500 μL. Microbiological tests performed with one-liter water samples spiked with *Pseudomonas aeruginosa*, *Escherichia coli* and *Staphylococcus epidermidis* and assayed by qPCR confirmed that the iSSC effectively produces samples that are over 1,000 times more concentrated than unprocessed samples.Findings from completed and future development of the iSSC will provide a foundation for improvement of future rapid concentration and microbial detection systems for space- and earth-based drinking water.

Preliminary Report on Microbial Flora Isolated from Polluted and Non-polluted Coastal Waters of Karachi, Pakistan

Author Block:

a. shaheen, Ms[1], H. s. baig[1], S. u. kazmi[2]; [1]Natl. Inst. of oceanography, karachi, Pakistan, [2]Univ. of karachi, karachi, Pakistan

Abstract Body:

Marine pollution has now become worldwide environmental concern. Continuous discharge of untreated industrial effluent, municipal and power plant's contaminated wastewater has been a serious threat to marine habitat, marine life, aesthetic values and interest of visitors to coastal areas. Karachi, the largest city of Pakistan and industrial hub is located at latitude 24° 48´ N and longitude 66° 59´ E on coast of the Arabian Sea. It suffers serious environmental problems because of population pressure and increasing industrial activities. In this investigation, samples of sediment, water, flora and fauna were taken from nine selected stations on Karachi coast included three stations represented major creeks i.e. Korangi, Gizri and Chinna Creek. These samples were taken in north-east and south-west monsoonal period during 2014. Bacterial flora isolated and identified from samples collected from these sites by conventional method. Among isolated and identified bacteria e.g. *Vibrio alginolyticus, E.coli* and *Streptococuss anginosus* were the most dominant species contributing 21.43, 19.64 and 15.18 percent of total assemblage respectively. Among selected sample stations, Korangi creek station was found to be most polluted with coliform and other pathogenic bacteria. These results clearly indicate that threats from these pathogens are not only to marine life but also to the large number of visitors coming to beaches and residents of surrounding area. Moreover; immediate action should be taken to restrict the growth of these pathogens by taking measures to treat the municipal and industrial effluent to avoid outbreak of any disease in future.

Study of Microbial Communities across the Rio Piedras River Watershed

Author Block:

A. Lugo, E. Torres, F. Godoy-Vitorino; Inter American Univ. of Puerto Rico, San Juan, PR

Abstract Body:

Background: The Río Piedras river is located in an urban watershed fully contained within the metropolitan area of San Juan within two geographic regions of Puerto Rico: the Northern Coastal Lowlands Humid Alluvial Section and the Humid Northern Foot Hills Northeastern Cretaceous Section. Due to an increase in the urban population, it has been impacted with human activity over the years raising numerous conservation challenges for this important water resource in the San Juan area. We have evaluated the microbiome complexity at three sites of the river, over an urbanization gradient, and hypothesize that the structure and diversity of the bacterial communities change according to the anthropogenic impact levels. **Methods**: Three 1L water samples were collected in Las Curias (pristine site 1), Old aqueduct (medium human impact site 2) and University Gardens (high human impact site 3). The water was filtered using 0.2 uM membrane disk filters, followed by gDNA extraction using the MOBIO Power soil and Illumina sequencing of the V4 region of the 16S rDNA gene. Data analyses was done using QIIME with the SILVA database as taxonomic reference. **Results:** A total of 1,444,201 raw sequences underwent strict quality and size filtering resulting in 135,237 high quality sequences (>250bp, no singletons and no chloroplasts) which clustered into 1,034 OTUs based on a 97% similarity. A total of 26 phyla in 135 families were found with overall dominance of Proteobacteria, Actinobacteria, Bacteroidetes, Chlorobi, Cyanobacteria and Firmicutes. The more pristine site showed only 6 phyla with a dominance of Proteobacteria (Rhodobacteraceae) and Actinobacteria (Sporichthyaceae) while the medium impacted areas had 15 phyla and a dominance of Chlorobi (f__OPB56), Actinobacteria (Sporichthyaceae) and Bacteroidetes (Bacteroidaceae); and the most impacted site had 24 phyla with a dominance of Proteobacteria (Comamonadaceaea), Firmicutes (Ruminococcaceae) and Bacteroidetes (Bacteroidaceae). Richness was as high as 500 species in areas of high human impact and as low as 100 taxa in the low impact site. **Conclusion:** We found an unprecedented diversity of microbial communities in water samples of medium and high human impacts, indicating greater ecological complexity alerting for the risk of water contamination due to sewage discharges and posing a public health risk.

Chemical Transmutation of *Penicillum italicum* rlm55$_i$ for Enhanced Cellulase Hyper-production

Author Block:

T. C. EKUNDAYO; FEDERAL Univ. OF TECHNOLOGY AKURE, Akure, Nigeria

Abstract Body:

The inability of wild fungi to secrete appreciable amount of enzymes limited their potential application in enzyme production technology. This study investigated the enhancement of cellulase biosynthesis potential of *Penicillum italicum* RLM55$_i$ through chemical treatment. The fungal spores were incubated with a fixed concentration of different chemical mutagens (sodium azide, ethyl methane sulphonate, nitrous acid and hydroxylamine) over a period of 90 min. with the recovery of mutants at every 15 min. Mutant with highest cellulase-producing capability at the selection points was further screened in a submerged culture system at 28±2^{o}C and 120 rpm for 5 days, for quantitative estimation of cellulase production. The chemicals exhibited different stimuli on the isolate. Results of the study revealed that the chemicals impacted cellulase activity as follows; nitrous acid, 2.26 fold in *RLM$_{NO}$45*; sodium azide, 2.34 fold in *RLM$_{NA}$-30;* ethyl methane sulphonate, 3.51 fold in RLM$_{MS}$*75*; and hydroxylamine, 3.94 fold in *RLM$_{NH}$*45 as compared to the parent strain; and the highest achieved with the respective mutagen under the experimental conditions. Protein biosynthesis was highly enhanced in the following mutants by the corresponding chemical treatment: *RLM$_{NA}$-90* (2.08 fold), *RLM$_{MS}$60* (4.34 fold), *RLM$_{NO}$60* (5.60 fold), and *RLM$_{NH}$*30 (5.13 fold). Of all the agents, hydroxylamine exhibited the most suitable mutagenic potential, thus could be further exploited in the improvement of the strain for overproduction of cellulases.

Plant Cell Wall Degrading Enzymes From *A. niger* Using Novel Natural Substrates

Author Block:

D. Kumari, S. A. Khan; Univ. of Karachi, Karachi, Pakistan

Abstract Body:

Background: Fungi elaborate a wide variety of plant cell-wall degrading enzymes, including xylanases, pectinases, amylases and cellulases. Although these enzymes have applications in a number of industries, but their production at the commercial scale is limited because of higher costs of the purified substrates. Hence, natural substrates can be considered as an alternate source for their production. The present study was aimed to explore the novel and unconventional substrates for production of plant cell-wall degrading enzymes.**Methods:** Enzyme production was studied using indigenously isolated fungal strain of *Aspegillus niger* by growing it on peels of banana, grapefruit and pomegranate, sugarcane bagasse, leaves of *Eucalyptus camaldulensis*-and stem of two halophytic plants i.e. *Halopyrum mucronatum*, *Desmostachya bipinnata* under solid-state fermentation (SSF) and submerged fermentation (Smf) conditions. The crude enzyme preparation was screened for xylanase, pectinase, amylase and cellulase (β-glucosidase, endoglucanase and filter-paperase) production**Results:** The results revealed the highest levels of xylanase production as compared to other enzymes; higher titres were obtained under SSF when strain was grown on stems of *D. bipinnata* and *H. mucronatum*. Xylanase production was followed by pectinase levels in *E. camaldulensis*-leaves. Considerable levels of amylase were produced from sugarcane baggasse and *E. camaldulensis*-leaves. Additionally, appreciable amounts of endoglucanase and β-glucosidase were noted using grapefruit-peels and *H. mucronatum*-stem respectively.**Conclusions:** Hence, significant level of xylanase production was observed from stems of *D. bipinnata* and *H. mucronatum*, and could be used for large scale xylanase production at the commercial level.

Microbiological Status of Cocoa Beans Fermentation for Optimal Utility

Author Block:

M. I. Araoye; Federal Coll. of Ed. (Special), Oyo, Oyo, Nigeria

Abstract Body:

Raw cocoa, *Theobroma cacao,* with its astringent taste and flavor needs fermentation to obtain the usual characteristic cocoa flavor and taste. A number of microflora are involved in spontaneous cocoa beans fermentation but not all are desirable. The quest for food security for the now and future, one of the primary objectives of the 2000 Millennium Development Goals, demands improvement in processes. This research examined the microbiological status of cocoa bean fermentation for optimal utility.A five-day fermentation of fresh cocoa bean of variety S/7, F3 Amazon hybrid was carried out in 50kg wooden boxes. A mixed microbial population of yeast and bacteria were isolated as the microflora. The physio-chemical were determined during the fermentation period. Morphological and biochemical characteristics for the identification of the isolates were carried out. Qualities of fermented beans were established using the Cut Test Method. The Nutritional Status of the final product (cocoa powder) was determined by standard chemical method of food analysis.Results gave gradual increase in the Temperature, with corresponding decrease in P^H while Titretable acidity increased due to the microbial activities. The Total Viable Count of the fermenting isolates in CFU/g, gave a growth format of progressive increase in microbial population throughout the fermentation period, though these were highest between day 1 and day 3 and gradually slowed down in day 4 and 5 which could have resulted from the different physiological roles of the mixed microbial population. Twenty five (25) isolates of the essential flora were obtained with a distribution that showed that Yeasts dominated the fermentation the first 24 hours followed by Lactic acid bacteria and then Acetic acid bacteria. The proximate analysis showed that Protein content of the fermented samples increased with the microbial fermentation in compliance with the recommended level for normal child growth. Crude fibre, Crude ash and Crude fat contents all decreased after fermentation.A mixed microbial controlled fermentation with *Saccharomyces cerevisiae*, *Lactobacillus plantarum* and *Acetobacter acetic* played vital roles in enhancing cocoa beans quality for optimal utilization, and therefore recommended.

M. Munir[1], M. Hamid[1], S. T. Hakim[2], S. G. Nadeem[1]; [1]Mycology Res. & Reference Lab., Jinnah Univ. for Women, Karachi, Pakistan, [2]Virology & Tissue Culture Lab., Jinnah Univ. for Women, Karachi, Pakistan

Abstract Body:

Background: To quantify and compare the Ethylene gas production by a range of selected microorganisms.**Methodology & Results:** Ethylene is a plant hormone that triggers the ripening of fruit which results in the transformation of complex sugars to the simpler forms, fruit softening, and degreening of the skin of the fruit. This plant hormone is involved in processes like plant growth, fruit ripening, senescence and development of plant. Both endogenous and exogenous ethylene can induce the ripening of fruits. Ethylene coordinates in the expression of such genes, which increase the rate of respiration, autocatalytic ethylene production, degradation of chlorophyll, synthesis of carotene, conversion of starch or complex sugars into their simpler forms and increased enzymatic activity of cell-wall degradation.Different microorganisms were checked for the production of ethylene under controlled condition at different pH values and various temperature.Ethylene gas was detected by commercially available Ethylene specific analyzer., Listeria produced Ethylene in highest amount, i.e. 19.5ppm /100ml of TSB. **Conclusion:** This method can be adapted easily because of its easy production and cost effectiveness

Colonic Fermentation of Cranberry A-Type Proanthocyanidins: Prebiotic Potential?

Author Block:

L. A. Doherty[1], K. Racicot[1], S. Arcidiacono[1], K. Kensil[1], O. Chen[2], J. W. Soares[1]; [1]US Army NSRDEC, Natick, MA, [2]Tufts Univ., Boston, MA

Abstract Body:

From a military perspective, the gut microbiome may serve as a useful tool to not only enhance Soldier gut and immune health, but also improve survivability, protection and performance. Our works centers on elucidating the systematic processes of colonic bacterial metabolism of dietary components and the influence on bacterial community dynamics, inflammation and immunity. To date, primary focus has been related to investigating the prebiotic potential of cranberry A-type proanthocyanidins (PAC) through *in vitro* colonic fermentation. Static and dynamic batch fermentations were performed utilizing fecal inocula derived from three individuals in a nutrient-rich anaerobic media supplemented with purified cranberry PAC. Total growth assessment through protein content analyses revealed a linear increase in growth as a function of PAC dosage. Bacterial population dynamics, determined through 16S RNA sequencing, indicated an increase in *Blautia spp.*, associated with increased metabolic byproducts and nutrient assimilation, and *Bifidobacterium spp.*, a known probiotic, concomitant with a decrease in *Bacteroides spp.*, associated with gut inflammation. GC-FID analysis of metabolic products indicated a PAC-dependent increase in propionate production, which possesses putative health effects. GC/MS identified two phenolic metabolites, (4-hydroxyphenyl) acetic acid and (3-(4-hydroxyphenyl)-propionic acid that are associated with anti-inflammatory activity. The results suggest cranberry PAC may have a prebiotic effect on gut microbiota in vitro with potential effects in vivo, particularly at an elevated intake. To further elucidate knowledge related to PAC metabolism, PAC-dependent growth under conditions simulating the multiple domains of the colon was investigated, revealing domain-dependent growth behavior. Domain-specific bacterial population and metabolic byproduct assessments are ongoing. Efforts toward understanding the gut microbiota metabolism of PAC and the influence on innate immune function could impact future dietary supplementation approaches, particularly in relation to building resiliency to military-relevant stressors through nutritional strategies to enhance performance.

Industrially Important Enzymes and Microbial Lipids for Biodiesel Synthesis from Organic Municipal Solid Wastes

Author Block:

A. Azad, Islam K, Ahmed J, Iqbal A, Sohag MMH, RakibuzzamanSM, Rana MM, Hakim A, Hasan M and Hossain S; Shahjalal Univ. of Sci. and Technology, Sylhet, Bangladesh

Abstract Body:

Municipal solid wastes (MSW) in the open dumping of developing countries result in environmental pollution, public health hazards and climate change. Organic MSW (OMSW) can be converted to bioresources through production of industrially and commercially important products, and thus the environmental pollution and climate change caused by MSW may be mitigated. We have isolated and identified proteolytic and cellulolytic bateria and fungi from MSW and cowdung. Based on the 16S rDNA sequence, the bacterial isolates were *Bacillus cereus*, *Serratia marcescens* and *Pseudomonas aeroginosa*, and based on the 18S rDNA sequence, the fungal isolates were *Aspergillus oryzae, A. fumigatus and A. Flavus*. Significant level of protease and cellulase were produced from bacterial and fungal isolates, respectively by using OMSW as raw materials in the shake flask and bioreactor. Physicochemical parameters such as temperature, pH, aeration, agitation, substrate concentrations etc were optimized for protease and cellulase production in the bioreactor. Protease production was scaled-up 2.5-3.0 fold in the bioreactor with reduction in fermentation period. The SDS-PAGE showed that the estimated molecular mass of the partially purified protease from *S. marcescens* was ~38 kDa and that from *P. aeroginosa* was ~25 kDa. Partially purified protease from both sources was characterized and enzyme kinetics were determined. Genome-wide analysis revealed that the genomes of *A. oryzae, A. fumigatus and A. Flavus* had 22, 25 and 23 cellulase genes, respectively. Some homologous cellulase genes were isolated from the three fungus isolates. Physicochemical parameters for microbial lipids production from oliagenous yeast *Lipomyces starkeyi* for biodiesel synthesis by using OMSW were optimized. Amount of accumulated lipids of *L. starkeyi* grown in OMSW hydrolysate media under optimal conditions was ~45% (v/w) of dry biomass of the yeast cells. Gas chromatographic analysis revealed that the fatty acid composition of this microbial lipid is similar to that of vegetable oils. Our study indicates that OMSW might be a valuable alternative feedstock for production of microbial lipids and industrially important enzymes.

Transcriptional Profiling Reveals Molecular Basis and Novel Gene Targets for Improved Resistance to Multiple Fermentation Inhibitors in *Saccharomyces cerevisiae*

Author Block:

Y. Chen, Jiayuan Sheng, Tao Jiang, Joseph Stevens, XueyangFeng, Na Wei; Univ. of Notre Dame, South Bend, IN

Abstract Body:

Lignocellulosic biomass is a promising source of renewable biofuels and bioproducts. However, pretreatment of lignocellulosic biomass generates fermentation inhibitors that are toxic to industrial microorganisms such as *Saccharomyces cerevisiae*. A critical challenge on developing *S. cerevisiae* with improved inhibitor resistance lies in incomplete understanding of molecular basis for inhibitor stress response and insufficient knowledge on effective genetic targets for increasing yeast resistance to disparate fermentation inhibitors. We applied comparative transcriptomic analysis to determine the molecular basis for acetic acid and/or furfural resistance in *S. cerevisiae*. The genes associated with stress responses of *S. cerevisiae* to single and mixed inhibitors were revealed. Specifically, we identified 184 consensus genes that were differentially regulated in response to the distinct inhibitor resistance between wide type and mutant *S. cerevisiae*. Bioinformatic analysis next revealed key transcription factors (TFs) that regulate these consensus genes. Two transcription factors, Sfp1p and Ace2p, were uncovered as novel overexpression gene targets for the first time for their functions in improving yeast resistance to mixed fermentation inhibitors. The study demonstrated an omics-guided metabolic engineering framework and also helped advance the fundamental understanding of the mechanisms of inhibitor resistance in yeast.

Could Sucrose Be a Better Alternative Carbon Source for Methionine Production by *Bacillus cereus* S8?

Author Block:

V. N. Anakwenze[1], C. C. Ezemba[2], C. M. Ogbukagu[1], A. B. Ilodinso[1], C. C. Ekwealor[1], O. G. Anakwenze[1], I. A. Ekwealor[1]; [1]Nnamdi Azikiwe Univ., Awka, Anambra, Nigeria, Awka, Nigeria, [2]Renaissance Univ., Ugbawka, Enugu, Nigeria, Enugu, Nigeria

Abstract Body:

Methionine is one of the essential amino acid secreted by various microorganisms. It can be supplemented in food and feed for proper growth and body functions of mammals. There is an increased need for methionine production by fermentation as a result of the ban on the use of synthetic methionine in organic farming in many countries. *Bacillus cereus* S8 recovered from Nigerian soil and characterized by 16S rRNA sequencing was used for methionine production in submerged medium employing sucrose as the carbon source. The effects of medium/fermenter volume ratio, inoculum size, nitrogen, growth factors, bivalent metals, surfactants, vitamins and amino acids were studied. In shake flask experiments, a 20% medium/fermenter volume ratio and a 5% inoculum size increased methionine yield. Sucrose at 40g/l stimulated methionine production in *B. cereus* S8. Ammonium sulphate was the best nitrogen source for methionine production and at 10g/l improved methionine yield. All growth promoting substances except the mixture of yeast extract and casein enhanced methionine yield by *B. cereus* S8. Tween 80 at 0.2 (%v/v) gave the highest methionine yield of 1.53mg/ml. All the vitamins studied improved methionine production by *B. cereus* S8 with the highest concentration being produced when pyridoxine at 10.0µg/ml was used. Ba^{2+} at 0.1µg/ml improved methionine production in *B. cereus* S8. DL-leucine stimulated the highest methionine production of 1.54mg/ml in *B. cereus* S8 . Time course experiments for methionine production by *B. cereus* showed that maximum methionine production was obtained after 96h. This study has shown that methionine producing bacteria can be recovered from Nigerian soil. When compared with previous study, sucrose was found to stimulate less of methionine than other carbon sources studied.

Production of Galacto-Oligosaccharides Using Chitosan Based Immobilized Whole Cells of *Lactococcus lactis* Containing a Hyperthermostable Beta-Galactosidase Enzyme

Author Block:

L. Yu, D. J. O'Sullivan; Univ. of Minnesota, St. Paul, MN

Abstract Body:

Galacto-oligosaccharides (GOS) are desirable prebiotics that are non-digestible and are proposed to have a 'bifidogenic' effect. Recently, we developed an efficient whole-cell production system for GOS using a hyperthermostable beta-galactosidase enzyme from *Sulfolobus solfataricus* that was overexpressed in *Lactococcus lactis*. In order to facilitate the food-grade use of this whole-cell GOS production system, we developed an immobilization process for the whole-cells that could function at very high temperatures. Permeabilized whole-cells of *L. lactis* containing high levels of this beta-galactosidase enzyme were encapsulated in chitosan beads. Prior to immobilizing the whole cells, a UV treatment methodology was developed to degrade DNA from the permeabilized cells such that the recombinant DNA in the cells was below the level of detection by PCR. The efficiency of GOS production was analyzed by incorporating the immobilized beads in a reaction mixture containing lactose at various concentrations and conditions. This revealed that the optimum pH for GOS synthesis using these immobilized cells was 5.5, which is slightly lower than the free whole-cells (pH6). Also, the optimum temperature for GOS synthesis using the immobilized whole-cells increased to 90^{o}C, which is 5 degrees higher than the free whole-cells (85^{o}C). The highest GOS production was obtained using 40% lactose. Approximately 60% of lactose was converted into 3-OS and 4-OS starting with 5% of initial lactose using immobilized enzyme. The enzyme beads retained ~ 50% activity after 2 cycles of GOS production. In conclusion, these immobilized whole-cells can be used for efficient GOS production in a food-grade manner.

Sequence-Based Mining and Characterisation of a Novel Acetyl Xylan Esterase from a Hot Desert Hypolith Metagenome

Author Block:

F. A. Adesioye, T. Makhalanyane, S. Vikram, D. A. Cowan; Univ. of Pretoria, Pretoria, South Africa

Abstract Body:

Acetyl xylan esterases (AcXEs) are Carbohydrate-Active Enzymes (CAZymes) that hydrolyse ester bonds to liberate acetic acid in acetylated polymeric xylan and xylooligosaccharides during enzymatic saccharification of hemicellulose, a major bottle-neck during bioconversion of lignocellulosic biomass for sustainable biofuel production. While most AcXEs have been identified from a range of lignocellulose-degrading microorganisms via culture-based methods, metagenomic screening methods allow access to novel genes of the ≥90% uncultured microorganisms within any given environmental sample.In this study, NaMet2, a novel AcXE-encoding gene was identified via *in silico* bio-mining of a Namib Desert (a hot coastal desert possessing unique climatic conditions) soil hypolith metagenomic sequence dataset. Sequence homology data showed that NaMet2 possessed highest similarity (69%) to AcXE from *Arthrobacter* sp. 35W (WP 02655436.1) and 53.4% similarity to the AcXE gene from *Bacillus pumilus* (a well characterized model CE7 AcXE). NaMet2 shared the GXSXG conserved motifs, characteristic of the CE7 CAZy family, and was found to possess the Ser-His-Asp catalytic triad with active site residues located at Ser187, His307 and Asp273. Gene synthesis, restriction cloning and expression of NaMet2 yielded a recombinant functional AcXE, NaM2, with a molecular weight of 35.9kDa and estimated isoelectric point of 5.47 evidenced by SDS-PAGE analysis. A >95% pure fraction of NaM2 was obtained as a his-tagged protein via cobalt-affinity purification and fast-pressure liquid chromatography. Agar well diffusion assays indicated its activity on tributyrin and acetylated xylan. Acetylesterase activity and specific activity of NaM2 on p-nitrophenol acetate as determined via spectrophotometric assays were $0.55Uml^{-1}$ and $27.5Umg^{-1}$, respectively. The V_{max} and K_M values of the enzyme were $0.46Uml^{-1}$ and 0.1mM, respectively, with a turnover rate (k_{cat}) of $0.26s^{-1}$. Crystallization studies using sitting drop method yielded x-ray diffracting protein crystals suitable for structural analysis. These results suggest that novel functional AcXEs may be discovered via sequence-based metagenomics.

Bioreactor Production Optimization of the Family of Fungal Antibiotics Mdn-0057 & Mdn-0058

Author Block:

V. Gonzalez-Menendez, J. Martin, N. el Aouad, J. Tormo, F. Reyes, **O. Genilloud**; Fundacion MEDINA, Granada, Spain

Abstract Body:

The novel family of broad spectrum Gran negative antibiotics MDN-0057 and MDN-0058 was previously reported as isolated from the liquid cultures of a grass endophytic fungus. In this study we describe the optimization of the *antibiotics* production and scale-up fermentation in 7L bioreactors as part of the development studies performed to ensure the large scale production of these novel compounds. The Biolog FF MicroPlate system was applied for evaluating the use of 95 carbon and nitrogen sources in fermentation media by the producing fungal strain. The substrate utilization patterns guided the selection of nutritional components for media optimization of MDN-57 production. Scaled-up fermentations were performed in 7L Applikon BioBundle bioreactors combining both 6 bladed Rushton impellers (100 mm) and marine 3 bladed impellers (60 mm, vortex). Cultivations were carried out for 10 days at 22 ^{o}C, air flow rate was adjusted to 2L/min, with an agitation speed of 500 r.p.m and a pH initially adjusted to 5.5. In fungal pre-optimization studies, fungal culture growth was monitored by absorbance in each well of the FF MicroPlate and D-cellobiose resulted to be the best substrate for our strain. The the optimized medium YEC containing D-cellobiose as principal carbon source ensured the best yield for antibiotic production in the 7 liter bioreactor, with a 2-fold yield in comparison with YES medium (sucrose as carbon source). The FF MicroPlate was shown to be a useful tool for the prior selection of the best nutritional conditions for large scale fungal fermentations in large scale. A strong correlation was found between substrate utilization, growth, and MDN-57 production.

Fermentation Optimization of an Engineered *Streptomyces* Strain for Production of Wdb-002, A Novel Fk506-Like Compound

Author Block:

R. A. Giacobbe, D. Nguyen, D. Vo, K. Kenyon, U. Swaminathan, L. Yang, H. Huang, J-Q. Gu, B. R. Bowman, K. Nguyen; WarpDrive Bio, Inc., Cambridge, MA

Abstract Body:

Background: An engineered strain of *Streptomyces* S583 was found to produce the novel FK506-like compound WDB-002, which comprises two isomeric forms WDB-002a and WDB-002b. S583 fermentation was optimized to improve production yield for isolation of gram quantities of WDB-002 to support *in vitro* and *in vivo* studies. In this work, we evaluated the effect of various carbon and nitrogen sources, pH and fermentation time on WDB-002 yield. **Methods:** Components at various concentrations in 8430, a complex medium containing mannitol, cottonseed meal, yeast extract, minerals and oil were examined in shake flasks. Selected media were also tested in 5 L bioreactors. Medium pH values, packed cell volume and WDB-002 yield determined by HPLC were monitored over a time course.**Results:** A sequential drop-out experiment identified critical and inhibitory components in the complex, mannitol-containing medium 8430. Yeast extract and phosphate were found to be inhibitory for WDB-002 production. The culture experienced an initial drop in pH (from pH 6.5 to 4.5) followed by a pH increase to pH >8 at day 6, concomitant with ceased WDB-002 production. The pH increase may be an indicator of culture lysis, consistent with the decreased packed cell volume. Mannose, maltose and fructose were found to be superior carbon sources to mannitol. In a 5 L bioreactor, the production rates with the tested carbon sources did not change significantly, but fructose supported a prolonged production phase compared to that in a mannitol medium. In the best medium tested, WDB-002 production reached 700 mg/L in shake flasks and 300 mg/L in 5 L bioreactors versus the original yields of 200 and 140 mg/L, respectively. In addition, WDB-002a and WDB-002b were preferentially produced in pH <7 and pH >8, respectively.**Conclusions:** *Streptomyces* S583 fermentation for WDB-002 production in a complex medium was significantly enhanced by >3-fold in shake flasks and >2-fold in 5 L bioreactors using fructose compared to mannitol. The medium pH profile could serve as an indicator for the completion of WDB-002 production phase.**Key words:** *Streptomyces* S583, WDB-002, fermentation, flask, bioreactor, FK506-like

Flavodoxin Reduction by Electron Bifurcation and Na^+-Dependent Oxidation by Nad^+ in *Acidaminococcous fermentans*

Author Block:

N. Pal Chowdhury, W. Buckel; Max Planck Inst. for Terrestrial Microbiol., Marburg, Germany

Abstract Body:

Electron bifurcation with electron transferring flavoprotein (Etf) and butyryl-CoA dehydrogenase (Bcd) in *Acidaminococcous fermentans* enables the endergonic reduction of ferredoxin by NADH driven by the exergonic reduction of crotonyl-CoA to butyryl-CoA also by NADH [1]. Here we show that recombinant flavodoxin from *A. fermentans* produced in *Escherichia coli* can replace ferredoxin. Under limiting concentrations of crotonyl-CoA, flavodoxin is reduced to the semiquinone, whereas with an excess of this oxidant the fully reduced quinol state of flavodoxin is obtained. Kinetic data show that the reduction of the quinone to the semiquinone ($E°'_1$ = -60 mV) is about 3-times slower than that of the semiquinone to the quinol ($E°'_2$ = -430 mV), though the opposite is expected when considering the redox potentials. Re-oxidation of the quinole is achieved by hydrogenase resulting in the equation: Crotonyl-CoA + 2 NADH + 2 H+ → Butyryl-CoA + 2 NAD^+ + H_2. Membrane preparations of *A. fermentans*, containing a very active ferredoxin-NAD reductase (Rnf), catalyze the re-oxidation of the quinol to the semiquinone by NAD^+. Due to the high redox potential of the semiquinone, further oxidation to the quinone is not possible. The combination of Etf, Bcd and Rnf recycles not only the semiquinone but also half of the NAD^+, resulting in the simple equation: Crotonyl-CoA + NADH + H^+ → Butyryl-CoA + NAD^+. In this system the apparent K_m of flavodoxin was determined as 9 µM, 45-times higher than that of ferredoxin by recycling with hydrogenase, K_m = 0.2 µM [1]. Furthermore, this assay allowed demonstrating the postulated dependence of Rnf from *A. fermentans* on Na^+ or Li^+ [2], which has been already verified for Rnf from *Acetobacterium woodii* [3]. Following values were measured: K_m = 120 µM Na^+ or 275 µM Li^+. Etf contains two FAD, one of which exhibits normal redox potentials, $E°'_1 < E°'_2$, whereas those of the other are similar to the potentials of flavodoxin, $E°'_1 > E°'_2$ (see above). This inverse behavior leads to a model of flavin-based electron bifurcation.

Selection of a Potential Starter Culture for Milk Fermentation

Author Block:

S. O. Akintayo, I. F. Fadahunsi; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

The ability of Lactic acid bacteria (LAB) to grow and survive in milk is being exploited in industrial and biotechnological applications. Although considerable studies have been reported on the fermentation of milk, however, not so much work has been documented on the selection of LAB strains from milk of the Nigerian local cattle breeds for their starter culture potentials. A total of 110 LAB were isolated from raw milk of *Sokoto gudali* cattle breed. The isolates were screened for their proteolytic activities on skimmed milk media with isolates A07, F06 and A01 showing the highest zone of clearance of 18.5mm, 18.5mm and 18.0mm respectively and were selected for the studies of their growth in different constituents of milk. A01, F06 and A07 were identified as *Pediococcus acidilactici*, *Lactococcus raffinolactis* and *Leuconostoc mesenteriodes* respectively using cultural, biochemical, physiological and molecular characterization techniques. *Leuconostoc mesenteriodes* showed the highest growth in all the milk components that were used in this study. The three LAB species selected showed a growth range of 6.46 log cfu/ml to 10.91 log cfu/ml in lactose with *Leuconostoc mesenteriodes* showing the highest growth of 10.91 log cfu/ml while *Pediococcus acidilactici* recorded the lowest growth of 9.78 log cfu/ml. In medium containing leucine as the only amino acid, the viable counts of *Pediococcus acidilactici*, *Lactococcus raffinolactis* and *Leuconostoc mesenteriodes* in log cfu/ml at zero hour were 6.39, 6.36 and 6.38 respectively which increased to 9.31 log cfu/ml, 9.21 log cfu/ml, 9.92 log cfu/ml respectively after 24 hours. Similarly in all other substrates (casein, lysine, glutamic acid, aspartic acid, stearic acid and oleic acid) tested in this study, *Leuconostoc mesenteriodes* showed the highest growth. It was observed that the highest quantity of lactic acid (15.31mg/ml) was produced by *Leuconostoc mesenteriodes*. The same trend was also observed in the production of diacetyl and hydrogen peroxide by the three tested microorganisms. Due to its ability to grow maximally in milk components, *Leuconostoc mesenteriodes* shows potential as starter culture for milk fermentation.

Optimization of Fermentation Conditions for Improved Biosurfactant Production by *Pseudomonas monteilii* AF064458 and *Citrobacter murliniae* AF025369

Author Block:

C. G. Anaukwu[1], C. C. Ezemba[2], V. N. Anakwenze[1], I. A. Ekwealor[1]; [1]Nnamdi Azikiwe Univ., Awka, Nigeria, Awka, Nigeria, [2]Renaissance Univ. , Enugu Nigeria, Enugu, Nigeria

Abstract Body:

Background: Biosurfactants are secondary metabolites produced by microorganisms. Owing to their unique features which includes low toxicity and biodegradability, biosurfactant have gained importance over synthetic surfactants. The composition and emulsifying activity of the biosurfactant not only depends on the producer strain but also on the fermentation conditions such as the carbon source, the nitrogen source as well as the C:N ratio and other physical parameters. The effects of fermentation conditions on biosurfactant production by *Pseudomonas monteilii* AF064458 and *Citrobacter murliniae* AF025369 were studied.**Methods:** *Pseudomonas monteilii* AF064458 and *Citrobacter murliniae* AF025369, isolated from soil contaminated with spent-engine oil were used for biosurfactant production. Shake flask fermentation experiments were conducted in mineral salt medium and the effects of medium/fermenter volume ratio, carbon and nitrogen sources, growth factors, pH and agitation speed on biosufactant production by the isolates were examined.**Results:** An increase in biosurfactant production by *P. monteilii* AF064458 was observed when 40% medium/fermenter volume ratio was used, while 50% ratio improved biosurfactant accumulation in the broth culture of *C. murliniae* AF025369. Maltose at 1% and glucose at 2% concentrations enhanced biosurfactant production by *P.monteilii* AF064458 and *C. murliniae* AF025369 respectively. Sodium nitrate was the nitrogen of choice for both isolates, and at 1% and 0.5%, biosurfactant production by *P. monteilii* AF064458 and *C. murliniae* AF025369 respectively were improved. At a pH of 7.5, *P. monteilii* AF064458 gave high biosurfactant yield, while *C. murliniae* AF025369 stimulated an increase at pH of 8.0.The effect of agitation speed revealed that biosurfactant production in *P.monteilii* AF064458 and *C. murliniae* AF025369 was optimal at 200rpm.**Conclusions:** This study has shown that optimizing the fermentation conditions in mineral salt medium improved biosurfactant yield by *Pseudomonas monteilii* AF064458 and *Citrobacter murliniae* AF025369. Optimization of nutritional and physical parameters is recommended for substantially higher biosurfactant production by microorganisms.

Characterization of Phenolic Acid Decarboxylase (*padc*) from Lactic Acid Bacteria Isolated from Fermenting Mash (Moromi) of Awamori, Okinawan Traditional Distilled Beverage

Author Block:

K. Nakasone; Kindai Univ., Higashihiroshima, Japan

Abstract Body:

Awamori is traditional distilled beverage made from steamed Thai-Indica rice in Okinawa, Japan. For brewing the liquor, two microbes, local black-koji fungus *Aspergillus luchuensis* and awamori yeast *Saccharomyces cerevisiae*, are involved. After the mash fermenting (moromi) completed by the multiple parallel fermentation (simultaneous saccharification and ethanol production), the moromi is distilled under atmospheric pressure. One of unique flavors of awamori is characterized by vanillin generated by oxidation of 4-vinylguaiacol (4-VG). In the moromi fermentation, the microbial phenolic acid carboxylase (PAD) decarboxylate ferulic acid in cell wall of the rice with concomitant production of 4-VG. Thus, activity and function of the enzyme during the moromi fermentation are important for the awamori flavors. The microbial source(s) or origin(s) of the enzyme are still unclear and the gene was recently detected on the draft genome of *A. luchuensis*. Besides two microbes, importance of other microbes such as lactic acid bacteria as a contaminant in the moromi are suggested, because many awamori breweries are built as an open system from outside. In this study, several lactic acid bacteria from the awamori moromi were tried to isolate, in order to characterize biochemistry and function of PAD(s).At first, 10 milliliters of fermenting mashes (moromi) from an awamori brewery in Okinawa were collected and filtered. The concentrate on the filter was statically cultured at 30°C using liquid MRS medium containing 1% calcium carbonate. Single colony isolations on the solid MRS medium were repeated using the turbid cultures. Several genera of lactic acid bacteria such as *Lactococcus* and *Lactobacillus* were found and detected by fermentation test and 16SrDNA analyses. Then, these bacteria were cultured and the chromosomal DNA was purified. According to genome sequences of *Lactococcus* and *Lactobacillus* species, degenerate primers of the phenolic acid decarboxylase were designed and PCR was performed. After confirmation of nucleotide sequence of the gene, pColdI expression vectors for his-tagged protein, were constructed. These purified enzymes were also confirmed purity using SDS-PAGE and the biochemical analyses are being characterized.

Utilization of Lignocellulosic Waste (Plantain Peel) and Subsequent Generation of Organic Acids of Industrial Importance by *Streptomyces albus* strain DOB KF977551

Author Block:

O. M. Buraimoh, A. K. Ogunyemi, S. A. Boyejo, O. O. Amund, M. O. Ilori; Univ. of Lagos, Lagos, Nigeria

Abstract Body:

The global economy is faced with challenges of obtaining industrial raw materials in a sustainable manner. One way through which this could be addressed is the bioconversion of wastes generated in large quantities from agricultural activities into industrial raw materials. This warranted our study of the ability of a Streptomyces strain to utilize plantain peel as substrate for the production of organic acids of industrial importance. Growth was carried out in submerged fermentation for a period of 21days using Streptomyces albus strain DOB isolated from a tropical estuarine while plantain peel was the sole carbon source. The ability of the organism to grow on the peel was evaluated at intervals using a spectrophotometer (620 nm), changes in the pH of the medium was also monitored. After extraction, the analytes (1ml) including the uninoculated control was each injected into the GCMS to detect the by-products of fermentation. Increase in the optical density (up to 2.20 nm) showed that the organism utilized the plantain peel as a growth substrate. The pH dropped from 7.2 and fluctuated between 6.08 and 6.87 throughout the period of the experiment. The result of the GCMS showed that propionic, acetic, lactic, oxalic, nvaleric, isovaleric, cis -aconitic acid, nbutyric acid, trans -aconitic and iso-butyric acids were the by- products of fermentation of plantain peels by this strain. Organic acids are used as additives and preservatives in the food and pharmaceutical industries; hence, the biological production is significant because it allows the use of raw materials tagged as “wastes” and simultaneously removes wastes from the environment. Plantain peel appears to be an ideal substrate for microbial process for the production of organic acids.

Transformation of Acacetin during the Fermentation of Safflower Seed (*Carthamus tinctorius L.*) with *β*-Glucuronidase Producing Lactic Acid Bacteria

Author Block:

K. Lee, S-S. Lee; Natural Sci., Suwon-si, Korea, Republic of

Abstract Body:

This study was undertaken to investigate the possible application *β*-glucosidase producing lactic acid bacteria as a functional starter cultures to obtain the bioactive flavonoid, acacetin in fermented safflower seeds. Safflower seeds (*Carthamus tinctorius* L.) are used as traditional medicine for the treatment of osteoporosis and rheumatoid arthritis in Korea. In the present study, the influence of two types of lactic acid bacteria (*Lactobacillus acidophilus*, *Leuconostoc mesenteroides*) on antioxidant activities and acacetin contents of fermented safflower seeds was determined and compared with those of their unfermented safflower seeds. Safflower seeds fermented with *L. acidophilus* showed the highest antioxidant activity and the greatest increase in the contents of acacetin. The percentage of DPPH and ABTS in safflower seeds fermented with *L. acidophilus* increased from 59.48% and 48.16%, respectively, to 71.43% and 63.76 after 28 days. Results of the HPLC analysis indicated the change of phenolic compounds during the fermentation of safflower seeds with *L. acidophilus*. Acacetin which is a flavonoid compound in safflower seeds has anti-inflammatory, anti-cancer activity and were increased from 0.27 mg/g to 1.23 mg/g by *L. acidophilus* but composition of acacetin was not changed by *L. mesenteroides*. Transcriptional analysis showed that *β*-glucosidase (*gusA*) was expressed in *L. acidophilus* and was not expressed in *L. mesenteroides*. From the study, *L. mesenteroides* have less efficiency than *L. acidophilus*. These results demonstrated that *L.acidophilus* could be potentially used as functional starter to improve the antioxidant activity of safflower seeds.

New Function of Microbial Enzyme Involved in Dehydration Reaction

Author Block:

M. KOBAYASHI, M. Yamada, Y. Hashimoto, T. Kumano; Univ. of Tsukuba, Tsukuba, Japan

Abstract Body:

We have extensively studied microbial metabolism of toxic compounds with a triple bond between carbon and nitrogen, such as nitriles [R–CN]. In *Pseudomonas,* whose nitrile hydratase enzyme was previously used for the industrial acrylamide production and is now used for the production of 5-cyanovaleramide, we discovered the enzyme gene organization composed of seven genes and clarified the regulation mechanism of their gene expression.The nitrile-synthesizing enzyme is a unique enzyme, which catalyzes the dehydration of aldoxime [R-CH=N-OH] into nitrile [R-CN] even in an aqueous solution. This enzyme contains a heme as the prosthetic group. Unlike the utilization of H_2O_2 or O_2 as a mediator of the catalysis by other heme-containing enzymes, this enzyme is notable for the direct binding of a substrate to the heme ion. The ferrous enzyme, which contains a five-coordinated high-spin heme and a His residue as its proximal ligand, is the reactive form of the enzyme. Another histidine in the distal heme pocket was found to play a crucial role in the catalysis. We next clarified the crystal structure of the enzyme and its detailed reaction mechanism. We initially found catalase activity of the enzyme, when H_2O_2 was used as a substrate. We also determined kinetic parameters of this reaction.

C. C. Ezemba[1], V. N. Anakwenze[2], G. C. Anaukwu[3], C. E. Chukwujekwu[1], I. A. Ekwealor[4]; [1]Renaissance Univ., Ugbawka, Enugu. Nigeria, Enugu, Nigeria, [2]Nnamdi Azikiwe Univ., Awka Nigeria., Anambra, Nigeria, [3]Nnamdi Azikiwe Univ., Awka Nigeria, Awka, Nigeria, [4]Nnamdi Azikiwe Univ., Awka. Nigeria, Enugu, Nigeria

Abstract Body:

Background: Methionine is an α-protein dietary essential amino acid for human and other mammals for normal growth. Its deficiency has also been related to childhood rheumatic fever, muscle paralysis, hair loss, depression, schizophrenia, and Parkinson's liver deterioration. Methionine-producing bacteria characterized as *Bacillus cereus* RS16 based on 16s rRNA sequencing which was previously isolated from soil in Awka, Nigeria was screened for methionine production in submerged medium. **Method:** Corn Starch hydrolysate, and defatted groundnut meal were used as carbon and nitrogen sources respectively for methionine production. The influences of medium/fermenter volume, inoculum size, pH, agitation speed, growth stimulators, amino acid, antibiotics, bivalent metals, vitamins and fermentation time on methionine production were studied. **Result:** A 20% medium/fermenter volume ratio, 5% inoculum size, pH of 7.0 and agitation speed of 170rpm increased methionine yield. A 40g/l corn-starch hydrolysate and 20g/l defatted groundnut meal stimulated a methionine level of 2.66mg/ml. All growth stimulators at (0.1%w/v), DL-leucine (0.01%w/v), penicillin at all concentrations, Zn^{2+} (5.0mg/ml) and pyridoxine at 100.0µg/ml enhanced methionine accumulation by *Bacillus cereus* RS16. Methionine level of 3.79mg/ml was produced after 96h fermentation. **Conclusion:** The study has shown that methionine production by *B. cereus* RS16 is depended on medium composition and that agricultural products can be utilized as fermentation substrates.

Awka Nigeria, Awka, Nigeria

Abstract Body:

Background: L-methionine is an essential amino acids required by man and animal. They are used as food and feed supplement, pharmaceutical adjuvants, and are produed by fermentative process by bacteria and yeasts. Because agricultural products are rich in nutrients, cheap and economical, their use as fermentative substrates in methionine production was studied **Methods:** *Bacillus cereus* DS13, *Bacillus cereus* RS16, *Bacillus cereus* AS9 were used for methionine production. Shake flask experiments were conducted to examine the effects of 2% (w/v) starch hydrolysates of wheat, sorghum, cassava, cocoyam, yam, plantain, millet, corn, potato, rice and defatted plant proteins from pigeon pea, cowpea, bambaranut, and groundnut as carbon and nitrogen sources respectively for the production of methionine. **Results:** All *Bacillus* strains accumulated different methionine levels in their broth cultures: *Bacillus cereus* DS13, 2.32mg/ml with sorghum/groundnut: *Bacillus cereus* RS16, 2.22mg/ml with corn/groundnut and *Bacillus cereus* AS9, 1.78mg/ml with plaintain/bambaranut.**Conclusions:** This study has shown that agricultural products have great potential to be utilized in methionine production.

Viability And Thermal Resistance Of *bacillus Atrophaeus* Atcc 9372 Spores Cultivated In Orange'S Bagasse

Author Block:

E. H. Lenhardt, E. E. Santo, T. C. Vessoni Penna, **M. Ishii**; Univ. of São Paulo, São Paulo, Brazil

Abstract Body:

Background: Fruit production is of paramount importance to Brazil's economy, highlighting the cultivation of orange species. Regarding orange's juice manufacturing, this industrial process generates large amounts of residue waste (50% of fruit weight), rich in nutrients that could be used as substrate for microorganism cultivation. Spores of *Bacillus atrophaeus* ATCC 9372 are known as a bacteria resistant form and are used as producers of enzymes of industrial interest and as biological indicators to monitor and to validate sterilization cycles ensuring the sterility of medical articles. The aim of this work is to evaluate the viability and thermal resistance of *Bacillus* spores obtained using orange's bagasse, to be used as bioindicator to monitor sterilization processes.**Methods:** Surface oranges were rubbed, rinsed in tap water and immersed in a 1% peracetic acid solution for 60 minutes. The fruit was processed in a juice centrifuge to separate the bagasse, (pulp, peel and seeds, which was frozen at -18°C), from the juice. Cultivation media was prepared using from 1.5 g to 18.5 g of orange´s bagasse into from 50mL up to 130 mL of water, sterilized, filtered through gauze, inoculated with 0.1 g/L of *B. atrophaeus* ATCC 9372 spores and incubated into orbital shaker at 150 rpm / 37°C for 3 and 6 days. After this period, the culture was centrifuged (4000 rpm / 4°C / 25 minutes). The pH media, spores viability and thermal resistance, expressed in terms of D-values at 102°C were determined.**Results:** After 3 and 6 days of cultivation, using 10.0g of orange bagasse, viable spores achieved 5.0 x 10^7 CFU/mL (pH 7.8 (±0.01)) and 1.0 x 10^9 CFU/mL (pH 8.8 (±0.01)), respectively. The spores developed showed appropriate thermal resistance being D value = 1.32 minutes and D = 1.79 minutes for 10.0 g of bagasse after 3 and 6 days of cultivation, correspondingly. At standard media, TSB, after 6 days of cultivation, viable spores achieved 1.0 x 10^6 spores/mL (pH 8.75 (±0.05)) and D value = 1.0 min, being less resistant compared to orange's bagasse media ones.**Conclusions:** The thermal resistance of *Bacillus* spores suggest that the use of orange bagasse corresponds to a small cost-effective media and an ecologically friendly initiative to obtain bioindicators to be applied for industrial and healthcare purposes.

***n*-Acetyl-D-Glucosamine as an Advanced Feedstock for Biocatalytic Conversion to Triacylglycerol by *Rhodococcus opacus* Pd630, Towards Sustainable Biodiesel Production**

Author Block:

J. Palmer, M. Phou, C. Brigham; Univ. of Massachusetts Dartmouth, North Dartmouth, MA

Abstract Body:

Rhodococcus opacus strain PD630 has demonstrated the ability to accumulate triacylglycerol (TAG) as a carbon storage molecule when in nutrient limiting conditions. Based on broad substrate tolerability and high cell density culturing capacity, *R. opacus* PD630 has become a model oleaginous prokaryotic species for TAG accumulation. TAG may be converted into fatty acid methyl esters (FAMEs) and burned as diesel fuel. Here we demonstrate predicted relevant fuel properties of FAMEs (cetane number and lower heating value) derived from *R. opacus* PD630 grown in a defined media containing the amino sugar, *N*-acetyl-D-glucosamine (NAG), as the sole carbon source, based on previously developed models. NAG is a primary component of chitin, which has recently become a polymer of interest for industrial applications, as it is a nutrient rich waste product disposed of in mass quantities from the seafood/fishery industry. Additionally, we demonstrate the ability for *R. opacus* PD630 to achieve flask culture cell densities, when grown in defined media with NAG, more than 3X greater than when grown on other refined sugars (glucose, fructose, and sucrose) with the same starting conditions. This characteristic suggests that chitin and its monomeric subunit, NAG, hold great potential for being an ideal feedstock for industrial biodiesel production and *R. opacus* PD630 holds promising biocatalytic characteristics.

Enhanced Viability of Microencapsulated Probiotic Bacteria in Alginate and Chitosan Microbeads During Storage and Simulated Digestion

Author Block:

T. W. Yeung, I. J. Arroyo-Maya, E. F. Üçok, K. A. Tiani, D. J. McClements, D. A. Sela; Univ. of Massachusetts Amherst, Amherst, MA

Abstract Body:

Probiotic microorganisms are incorporated in foods and other applications to modulate the function of one's microbiome to impact health. However, maintaining viability of live cells during storage and gastrointestinal transit remains an obstacle for nutritional interventions. Accordingly, encapsulating lactococcal and bifidobacterial cells within food-grade hydrogel biopolymers was investigated to mitigate sensitivity to environmental stresses. Calcium alginate microbeads were formed by dripping a microbe-alginate mixture into a calcium solution, and were confirmed to envelop cells via microscopy. Temporal cell viability was evaluated by culture-based approaches. Encapsulating the facultative anaerobe *Lactococcus lactis* subsp. *cremoris* prolonged survival during aerobic storage, improving viability by 3 log CFU in comparison to free cells. Whereas, encapsulating obligate anaerobes *Bifidobacterium longum* subsp. *infantis* and *B. longum* subsp. *longum* strains showed little difference in viability over time between encapsulated and free cells. Indeed overall survival of bifidobacteria strains was low, decreasing by up to 10 log CFU in 14 days, suggesting that oxygen diffusion within the beads is limiting. An outer coating of chitosan changed the physicochemical properties as confirmed by increased zeta potential. However *B. longum* viability was not prolonged appreciably with the secondary coat. Encapsulated microbeads were subjected to simulated salivary, gastric, and intestinal fluids *in vitro*. Encapsulation maintained cellular viability in the salivary phase. In contrast, viability was significantly reduced when exposed to the low pH conditions of the gastric, as well as the modeled intestinal phase. Hydrogel beads have potential for improving the stability and efficacy of specific probiotics in various food products. Future studies optimizing encapsulated cell preparations based on inherent traits will enable colonic delivery more efficient than conventional practices.

Genetic Instability of *Shigella flexneri* from a Foodborne Outbreak in Hawaii

Author Block:

C. GRIM[1], R. Y. Kanenaka[2], K. A. Lampel[1]; [1]Food and Drug Admin., Laurel, MD, [2]Hawaii State Dept. of Hlth., Pearl City, HI

Abstract Body:

Background: A foodborne outbreak caused by *Shigella flexneri* affected over 270 people in Hawaii in 1996. Epidemiological data indicated that poi, contaminated by an infected preparer, was the transmission vector. Pulsed-Field Gel Electrophoresis (PFGE) data showed that most of the patient isolates were indistinguishable from G106, an isolate from the poi preparer, indicating a single source outbreak. However, PFGE patterns of some isolates differed slightly from G106.**Methods:** To resolve these genetic differences, genomic DNA was extracted from 14 *Shigella* poi isolates and sequenced on a MiSeq (Illumina). Reads were trimmed and de-novo assembled with CLC Genomics Workbench. For SNP based analysis, the CFSAN SNP pipeline was used to produce a SNP matrix by mapping unprocessed reads on the reference genome of *Shigella flexneri* 2a strain 301 (GenBank NC_004337.2/NC_004851.1). Phylogeny was calculated and visualized using Mega, version 6.06. Genomes were annotated with RAST and comparative genomics was performed using the SEED viewer.**Results:** A total of 9,697 SNPs were identified between the 14 poi isolates and the reference genome. In general, most SNPs, compared to the reference genome, were shared by all poi outbreak isolates. However, closer examination of the "clonal" poi outbreak group revealed a significant number of SNP variations between isolates. Comparative genomics also revealed an unusually high number of disparate genomic regions between isolates, with the majority of these being flanked by insertion sequences (IS). Many of these genomic regions encoded putative stress response or resistance operons.**Conclusions:** The genomes of *Shigella* isolates associated with this foodborne outbreak attributed to poi exhibited a high degree of genetic instability, apparently attributable to the mechanism of IS elements. All isolates formed a tight phylogenetic cluster, compared to the reference genome used; however, this high degree of genomic instability within an outbreak cluster may have a significant impact on future epidemiological investigations involving *Shigella*. Variations in the PFGE profiles and genomic differences indicate that this outbreak was caused by a strain of *S. flexneri* that had undergone relatively rapid changes in its genome and plasmid during either the outbreak or isolation.

Whole Genome Analysis of a Predominant *Escherichia coli* O157:H7 in Animals Reveals Unique Genetic Features That May Confer Persistency in Hosts

Author Block:

C. Lee[1], L. Teng[1], D. Park[2], K. C. Jeong[1]; [1]Univ. of Florida, Gainesville, FL, [2]Keymyung Univ., Daegu, Korea, Republic of

Abstract Body:

Shiga toxin-producing *Escherichia coli* (STEC) O157:H7 is an important foodborne pathogen that causes outbreaks of hemorrhagic colitis and hemolytic uremic syndrome. Cattle are a major asymptomatic reservoir of STEC O157 which primarily colonizes the terminal recto-anal junction. Persistent STEC O157 strains found in animals and on farms are presumably well adapted to hosts and environments and are responsible for a large part of O157 outbreaks. These environmentally persistent isolates can potentially convert cattle to become bacterial super-shedders, secreting O157 at a rate of more than 10^4 CFU/g of feces. Previous studies have revealed that an *E. coli* O157:H7 subtype strain (FRIK2455) was predominant on a farm while other clonal variants were rarely isolated (FRIK2069 and FRIK2533). However, genetic factors that may explain its predominance in cattle are not understood. In this study, we conducted whole genome sequencing using the PacBio sequencing technique to identify genetic factors that may explain predominance of FRIK2455 in cattle. By conducting comparative genome analysis of closed-genomes, we found that these strains share similar genetic composition and structure of chromosomes, but distinct features in plasmids. Only the predominant strain FRIK2455 carries a plasmid, p35K that encodes a type IV secretion system (T4SS) that may provide an advantage for survival in hosts and environments by enhancing colonization of this pathogen.

Stress-Induced Regulatory Mutations Generate Biofilm Diversity in an *Escherichia coli* O157:H7 Population

Author Block:

G. A. UHLICH, C-Y. Chen, B. J. Cottrell, L-H. Nguyen; ERRC, WYNDMOOR, PA

Abstract Body:

Background: Expression of *Escherichia coli* major biofilm components, curli fimbriae and cellulose, require the CsgD transcription factor. A complex regulatory network allows environmental control of *csgD* transcription and biofilm formation. However, most serotype O157:H7 strains contain prophage insertions in the *csgD* regulator, *mlrA*, or mutations in other regulators that restrict *csgD* expression. These barriers can be circumvented by certain compensating mutations that restore higher *csgD* expression. One mechanism is via *csgD* promoter mutations that switch sigma factor utilization. Variants utilizing either *rpoD* or mutated *rpoS*, and showing strong or weak curli/biofilm expression, respectively, have been identified in glycerol freezer stocks of a foodborne outbreak strain. In this study we used WGS and RNA-seq to study genotypic alterations accumulated during storage stress and their effect on CsgD-dependent phenotypes. **Methods:** Variants 43894OW (RpoS-dependent, curli-) and 43894OR (RpoD-dependent, curli+), isolated from a freezer stock prepared from an ATCC 43894 culture (aka CDC EDL932), were subjected to WGS and RNA-seq using an Illumina platform. Curli expression and biofilm formation were assayed using Congo red (CR) dye affinity and crystal violet dye retention, respectively. Gene deletions were constructed by Red ET recombination. Protein fusions were constructed in plasmid pSE380. **Results:** Enhanced expression ($p<0.05$) of *csgD*-dependent biofilm components and regulators accompanying stronger biofilm and CR-binding phenotypes was observed in RpoD-dependent strain 43894OR compared to 43894OW. A duplicated 13-kb chromosomal region was found in 43894OW that resulted in significantly higher *hnr* expression. Hnr can speed RpoS degradation in stationary-phase and a recombinant Hnr further repressed biofilm and CR phenotypes in a strain with normal RpoS-CsgD regulation (intact *mlrA* and WT *rpoS*). **Conclusion:** Mutations emerging during stressful conditions can have significant and opposing effects on CsgD-dependent phenotypes, creating individuals with phenotypic presentations that diverge from the parent population. Such individuals would increase population fitness for survival under extreme conditions.

Whole Genome Sequence Analysis Of Shiga Toxin Producing *e.Coli* O103:H2 Associated With Diarrhea In White Tailed Deer

Author Block:

D. S. S. Wijetunge[1], A. Sebastian[2], I. Albert[2], S. Kariyawasam[1]; [1]Pennsylvania State Univ., State College, PA, [2]Bioinformatics Consulting Ctr, Pennsylvania State Univ., University Park, PA

Abstract Body:

Shiga Toxin Producing *E. coli* (STEC) is one of the major causes of foodborne infections that leads to approximately 2,801,000 acute illnesses per year worldwide. Although *E. coli* O157:H7 has been the predominant cause of STEC infection, the Foodborne Diseases Active Surveillance Network (FoodNet) has reported a recent increase in non-O157 STEC illnesses since 2000. Approximately, 83% of non-O157 STEC outbreaks are associated with six serogroups, including *E. coli* O103. As with O157 STEC, common sources for non-O157 STEC infections are cattle and other ruminants. The objective of the present study was to analyze the whole genome of STEC strain PSUO103 (O103:H2 serotype), which was isolated from a white-tailed deer with severe diarrhea to study its zoonotic potential. Genome sequencing was performed using both Ion-Torrent PGM and PacBio sequencing technologies followed by Rapid Annotation using Subsystem Technology. Analysis of the genome revealed it consists of a circular chromosome of 5.449 Mb in size and a 73 kbp plasmid. Both the chromosome and plasmid of PSUO103 displayed a high degree of similarity (95% coverage with 99% similarity at the nucleotide level) to the genome of *E. coli* O103:H2 str. 12009 that was isolated from a human patient with hemorrhagic diarrhea in Japan in 2001. A total of 68 genomic islands were detected in PSUO103 chromosome, which included islands encoding the locus of enterocyte effacement and Shiga-toxin 1. The zoonotic potential of STEC PSUO103 strain was evaluated by its ability to bind two human colonic epithelial cell lines (Caco-2 and CCD841_CoN) and produce Shiga toxins as determined by Vero cell cytotoxicity assay.

Transcriptomic Analysis of *Salmonella enterica* Forc_015, a Clinical Pathogen Isolated from Human Blood, in Contact with Cabbage

Author Block:

S. Kim[1], H. Kim[2], H. Yoon[1]; [1]Ajou Univ., Suwon-si, Korea, Republic of, [2]Dankook Univ., Cheonan-si, Korea, Republic of

Abstract Body:

FORC_015 is a rod-shaped,facultative anaerobic, Gram-negative bacterium isolated from the blood of an infected patient in Korea. The complete genome sequence is released in NCBI NZ_CP011365. Recently, an increasing number of reports have shown that *Salmonella* survives and persists inside raw vegetables as well as animal hosts. To gain insight into the systematic gene regulation of *Salmonella* in contact with raw vegetables, cabbage in a M9 medium broth was inoculated with FORC_015 and the bacterial mRNA was analyzed using RNA-Seq technology. Sorting out genes with expression changes of three-fold or more by the contact with cabbage showed 114 genes up-regulated and 106 genes down-regulated. To understand genes whose expression is controlled for the adaptation to raw vegetables, genes increased or decreased fairly as an operon were chosen. Genes of *nar* operon (nitrate reductase) and *cit* operon (citrate lysase) were up-regulated, while genes of *thi* operon (thiamine biosynthesis) and *sit* operon (iron transport) were down-regulated. *Salmonella* mutant strains lacking each operon were constructed and their growth rates were compared in the presence and absence of cabbage. Except Δ*thi* mutant, all mutant strains showed comparable fitness to that of wild type *Salmonella* regardless of the presence of cabbage. However, the Δ*thi* mutant whose growth was significantly attenuated in a M9 medium condition was complemented by the addition of cabbage in the medium, indicating that vegetables like cabbage are exploited as a good source of vitamin B1 by *Salmonella*. These results suggest that the inhibition of thiamine biosynthesis in *Salmonella* and the abolishment of thiamine uptake by *Salmonella* may be considered as promising control measures against *Salmonella* infection via raw vegetables. Key words: *Salmonella enterica*, Vegetable, Virulence

Wgs Analysis of Antimicrobial-Resistant *Salmonella* from Animal Feed and Pet Food

Author Block:

K. Domesle[1], C. Li[1], Q. Yang[1], X. Li[2], B. Ge[1]; [1]U.S. Food and Drug Admin., Ctr. for Vet. Med., Office of Res., Laurel, MD, [2]U.S. Food and Drug Admin., Ctr. for Vet. Med., Office of Surveillance and Compliance, Rockville, MD

Abstract Body:

The prevalence of antimicrobial resistance genes among *Salmonella* isolates recovered from animal feed and pet food commodities is not well documented. In this study, 47 antimicrobial-resistant *Salmonella* isolates were selected from over 700 *Salmonella* recovered by the U.S. Food and Drug Administration between 2004 and 2012 from animal feed and pet food samples. The isolates were selected based on their unique phenotypic resistance, and further characterized for the presence of antimicrobial resistance genes by whole genome sequencing and queried against an in-house antimicrobial resistance database. The majority (76.6%) of isolates were recovered from pet food, primarily dog food, and comprised 29 domestic and 18 imported samples. Twenty-four *Salmonella* serovars were represented, with Typhimurium and group B monophasic representing 25.5% and 8.5% of selected isolates, respectively. Phenotypic resistance was most common to tetracycline (65.9%) and aminoglycosides (52.2%), followed by cephems (19.1%), folate pathway inhibitors (17.8%), β-lactams (15.6%), phenicols (14.9%), and quinolones (13.0%). Multidrug resistance (resistant to ≥ 3 antimicrobial classes) was observed in 16 (34.0%) isolates, all except two were recovered from pet food. One *Salmonella* Agona isolate from dog food and one *Salmonella* Uganda from canola meal, both from imported samples, were resistant to 7 and 6 classes of antimicrobials, respectively. With WGS, tetracycline resistance genes *tetA*, *tetB*, *tetC*, *tetD*, and *tetG* and aminoglycoside resistance genes *aph(6)-Ic*, *aph(6)-Id*, *aph(3'')-Ib*, *aph(3')-Ia*, *aph(3')-Id*, *aph(3')-II*, among others, were detected. The *sul1* and *sul2* genes accounted for sulfonamide resistance whereas $bla_{\text{CMY-2}}$, $bla_{\text{TEM-1}}$, $bla_{\text{carB-2}}$, bla_{OXA}, and bla_{TEM} were among the β-lactam resistance genes found. The agreements between phenotypic and genotypic determination of resistance at the antimicrobial level ranged from 53.3% for folate pathway inhibitors to 85.1% for phenicols and the agreement was 17.0% at the isolate level. In summary, diverse antimicrobial resistance genes were present in *Salmonella* serovars from animal feed and pet food and WGS effectively provided in-depth characterization of resistance genes among these isolates.

Genome-Wide Analysis Reveals *Salmonella enterica* Genes Involved in Proliferation within Tomatoes (An Alternative Host) with Implications for Human Health

Author Block:

M. H. de Moraes[1], P. Desai[2], D. R. Perez[1], S. Porwollik[2], W. Chu[2], R. Canals[2], M. McClelland[2], M. Teplitski[1]; [1]Univ. of Florida, Gainesville, FL, [2]Univ. of California, Irvine, Irvine, CA

Abstract Body:

The increasing number of salmonellosis outbreaks linked to tomatoes is a major concern for public health. Non-typhoidal *Salmonella* is capable of reaching high cell numbers, up to 10^7 colony forming units (CFU) per tomato fruit, making them a vehicle that allows the pathogen to re-infect the preferred animal hosts. Despite its importance for public health, the genetic mechanisms involved in the interactions of human enteric pathogens with alternate hosts, such as edible plants, remain largely unknown. In this study, a high-density transposon library of *S. enterica* Typhimurium ATCC 14028 was screened to identify loci involved in persistence within tomatoes. We identified 1245 loci disruption of which led to reduced fitness within tomatoes (FDR < 0.1). Competitive fitness assays using isogenic mutants confirmed screening results. Mutants for biosynthesis of lipopolysaccharide core and O-antigen had reduced fitness. Lipopolysaccharide is required for *Salmonella* virulence in animals, indicating that an overlap of colonization mechanisms in animals and plants may benefit *Salmonella* when using tomatoes as an alternative host. The global nitrogen regulator *glnG* had a major role in the *Salmonella*-tomato interaction; its deletion led to a severe defect in proliferation within fruits ($\log_2$[CI]= -3.54). Auxotrophic mutants for arginine, glutamine, leucine, valine, isoleucine, methionine, serine, threonine and tryptophan had decreased fitness within tomatoes, and *in vivo* reporters confirmed that these pathways are also highly expressed within tomatoes. Moreover, tomato genotype influenced amino acid requirements; *Salmonella* auxotrophic mutants for glutamine, leucine, valine, isoleucine, methionine and serine were less fit in *rin* tomato mutants, known to differentially accumulate amino acids during ripening. The nitrogen metabolism genes identified in our screening were within the core genomes of *Enterobacteriaceae,* suggesting that adaptations in this clade are related to nutritional requirements when adopting plants as hosts.

Rna-Seq Data Reveals Sigma H-Dependent Regulation of Competence Genes in *Listeria monocytogenes*

Author Block:

Y. Liu, R. H. Orsi, K. J. Boor, M. Wiedmann, V. Guariglia-Oropeza; Cornell Univ., Ithaca, NY

Abstract Body:

Background: *Listeria monocytogenes*, the foodborne pathogen which causes serious infection listeriosis, not only is a public health concern but also remains a problem in food industry. Among the four alternative σ factors of *Listeria monocytogenes*, σ^B remains the best understood and it has been shown to control a large regulon and play important roles in stress response and virulence. The function of σ^H, however, has not yet been well defined.**Method:** An *L. monocytogenes* strain with deletions of all 4 alternative σ factor genes (Δ*BCHL*) was used as the background strain, which was further modified to overexpress *sigH* (Δ*BCHL::*P_{rha}*-sigH*). A new bio-informatics approach was applied to compare normalized RNA-seq coverage (NRC), between Δ*BCHL::*P_{rha}*-sigH* and a Δ*BCHL* control, using sliding windows of 51 nt along the whole genome rather than comparing NRC calculated only for annotated genes as BaySeq does.**Results:** With this novel sliding window method, we identified 6 transcription units (TUs) that are transcribed from σ^H-dependent promoters and five of which are newly identified. Interestingly, among them, three are operons encoding competence genes (*comGABCDEFG*, *comEABC*, *coiA*). While these promoters were highly conserved in *L. monocytogenes*, none of them were found in all *Listeria* spp.**Conclusion:** Our data indicate that a number of *L. monocytogenes* competence genes are regulated by σ^H. This regulation is conserved in the pathogenic strains of *L. monocytogenes*, but not in other non-pathogenic *Listeria* strains, suggesting a possible novel role of σ^H-dependent competence genes in *L. monocytogenes* virulence. Additionally, the sliding window approach described here could also give more insights into RNA-seq data, particularly for genes that are transcribed from multiple promoter elements only some of which show differential transcription.

Evaluation of a 16s rRNA Amplicon Sequencing Protocol for the Identification of Bacteria in Environmental Swabs

Author Block:

A. A. Rodriguez[1], J. R. White[2], C. L. Randell[1], D. A. Sela[3]; [1]U.S. FDA, Winchester, MA, [2]Resphera BioSci.s, Baltimore, MD, [3]Univ. of Massachusetts, Amherst, MA

Abstract Body:

FDA routinely collects environmental swabs from food manufacturing facilities. These are analyzed for the presence of foodborne pathogens by cultivation methods. The analysis involves enrichment and isolation of the organism of interest. Furthermore, a separate analysis is required for each pathogen. 16SRrNA amplicon sequencing allows simultaneous identification of bacteria in a mixed community without prior enrichment or isolation. Our goal was to evaluate this technique as an alternative to cultivation methods. Two mock bacterial communities were prepared encompassing 12 genera and including foodborne pathogens *Listeria monocytogenes, Salmonella enterica, Escherichia coli* and *Staphylococcus aureus.* The first community consisted of a mixture of DNA extracted from 15 strains. The second consisted of a mixture of broth cultures from 10 strains. The later was spread onto stainless steel surfaces, allowed to dry, and swabbed, at which point the DNA was extracted. Dual-indexed DNA libraries targeting regions V3 and V4 of the 16S rRNA gene were prepared and sequenced on an Illumina MiSeq for 500 cycles. The resulting reads were analyzed using four bioinformatic pipelines 1) MiSeq Reporter, 2) Resphera Insight, 3) QIIME with UCLUST and 4) QIIME with RDP. All the pipelines tested correctly identified the genus of all bacteria present in the mock communities. Some foodborne pathogens were identified to the species level as follows: MiSeq Reporter - *S. aureus* and *S. enterica*; Resphera Insight- *S. enterica* and *E. coli*; QIIME with UCLUST- *S. aureus;* and QIIME with RDP- *S. aureus* and *E. coli*. None of the pipelines was able to speciate *L. monocytogenes*, moreover, QIIME with RDP misidentified it as *L. seeligeri*. The protocol evaluated permitted genus-level identification of mixed bacterial communities extracted from swabs without prior enrichment. We were able to accurately identify species *S. aureus, E. coli* and *S. enterica,* pathogens of relevance to the food industry. No one pipeline tested was able to speciate all bacteria. This is possibly due to limitations in the diversity of regions V3 and V4. Alternative primer sets targeting other variable regions will next be evaluated in an attempt to improve species identification.

Do Dna Extraction Methods Affect Shotgun Metagenomic Library Generation and Sequencing Output of Spice Microbiomes?

Author Block:

L. Ewing[1], G. Gopinath[1], N. Addy[2], D. Hanes[1], J. Jean-Gilles Beaubrun[1]; [1]FDA, Laurel, MD, [2]Oak Ridge Inst. for Sci. and Technology, Oak Ridge, TN

Abstract Body:

Next Generation Sequencing (NGS) is a critically useful tool for answering a variety of scientific questions. Currently we are using shotgun metagenomic sequencing to investigate foodborne pathogens in spices. Spices are difficult matrices to analyze because their essential oils contain antimicrobial properties that can inhibit detection methods. Previous studies using NGS to analyze leafy greens were successful using Qiacube (Qiagen) extracted DNA. However, spice samples did not generate quality results with the same consistency. Quality DNA is essential for generating libraries that can be sequenced and, in turn, affects NGS data. It's possible that physical and chemical properties of spices affect the purity of DNA which could interfere with the biochemistry of NGS, so we designed a study to compare the effects of three DNA extraction methods. Spices were enriched following a modification of the BAM using corn oil as an additive to the primary enrichment broth in an attempt to neutralize antimicrobial properties. Samples were collected throughout the enrichment process. DNA was extracted using the Qiacube, PowerPlant Pro DNA Isolation Kit (Mo Bio) and the MagNA Pure Compact (Roche). Libraries were prepared using Illumina's Nextera kit and run on the MiSeq; they were quantified using Qubit (Invitrogen) and the Agilent Bioanalyzer. NGS data was analyzed using CLC Bio's Genomic Workbench and Metaphlan2. Quality of the sequencing data was evaluated based on average length, total length and number of contigs and N50. The quality of the NGS data and metagenomics profiles were comparable for samples using all three DNA extraction methods. However, the MoBio samples exhibited the highest rate of samples that successfully produced quality libraries suitable for sequencing, 90%, versus 85% for MagNA Pure Compact and 81% for Qiacube. The results of this study suggest that using a MoBio DNA extraction method, which separates spice debris by pelleting and contains additional methods for removal of inhibitors, may be beneficial for metagenomics-based detection of pathogens in spice samples. An optimized laboratory workflow for pathogen detection in spices will allow for maximum quality and consistent results in samples that may be limited in number, as the case may be with food outbreak samples.

First Detection and Identification of *Candidatus* Neoehrlichia mikurensis in Korea

Author Block:

D-M. Kim, P. Jha, N. Yun, C-M. Kim; Chosun Univ. Coll. of Med., Gwang-ju, Korea, Republic of

Abstract Body:

Background: *Candidatus* Neoehrlichia mikurensis (CNM; family Anaplasmataceae) is an emerging tick-borne pathogen causing a systemic infecton mostly in persons with underlying hematologic or autoimmune diseases. The aims of this study were to identify CNM in small mammals in Republic of Korea (ROK).**Methods:** We investigated the presence of CNM in small mammals captured in south-western part of ROK, which was screened for CNM by molecular methods. Samples were initially screened by PCR targeting the *groEL* gene, and confirmed by PCR targeting the CNM 16S rRNA gene. For positive samples, the amplified fragments were sequenced.**Results:** 28.57 % of the investigated mammals were positive for CNM-DNA. All of the captured animals were identified as striped field mouse (*Apodemus agrarius).***Conclusions:** The presence of this pathogen in the investigated areas in these rodents points towards the need for more specific investigation on its role as human pathogens.

Detection of *Salmonella spp.* in Peruvian Guinea Pigs at First Parturition by Pcr Multiplex

Author Block:

A. M. Chero, G. Marcelo, G. Diaz, R. Rosadio & L. Maturrano; Univ. Natl. Mayor de San Marcos (UNMSM), Lima, Peru

Abstract Body:

Background: The production of guinea pigs in Peru was originated in the Andes of the country. This species is traditionally consumed by Peruvian population, besides of being an economic activity. Salmonellosis is the most important bacterial disease in this production, generating high rates of morbility and mortality. There are over 2500 serotypes of *Salmonella* spp., of which *Salmonella* Typhimurium have been reported more frequently in guinea pigs in Peru in animals without clinical signs of disease (Perez, 1975; Ortega, 2009; Morales, 2012), followed by *Salmonella* Enteritidis in another countries (Fish *et al*, 1968, Bartholomew *et al*, 2014). The risk of isolating *Salmonella* spp. of asymptomatic animals consists in the introduction of these in farms without presence of this bacteria, generating the disease because of a stress event, and the possibility of transmission to humans by direct contact or foodborne. For this reason, the aim of the present study was to identify the most frequent serotypes (Typhimurium or Enteritidis), isolated through microbiological standardized protocols. **Materials and methods:** We evaluated the presence of *Salmonella* spp. in 272 rectal swabs from guinea pigs without evidence of clinical signs, after their first parturition, from a commercial farm in Lima, Peru. The microbiologic method used is based on laboratory protocols according to the ISO-6579 (2002). DNA was isolates and analyzed by PCR Multiplex, in order to detect *inv*A, *prot*6E and *fli*C genes; which are specific for *Salmonella* spp., *Salmonella* Enteritidis and *Salmonella* Typhimurium, respectively, according to Jamshidi (2009). **Results:** At microbiological methods, eight of all animals evaluated were positive a *Salmonella* spp. Strains isolated were analyzed by PCR multiplex; all of them amplified *inv*A gene, belonging to the genus *Salmonella*. Seven isolates amplified *fli*C gene, belonging Typhimurium serotype. The remaining isolated was identified only as *Salmonella* spp. and Enteritidis serovar was no detecting. **Conclusion:** In this study, 2.94% of asymptomatic carrier guinea pigs at first parturition were detected in a farm that did not present outbreak of salmonellosis four years before. The predominant serovar was Typhimurium, we did not find Enteritidis and one isolate belongs to genus Salmonella, but no Typhimurium or Enteritidis.

Fungal Infection and Mycotoxin Contamination of Vietnamese Coffee Beans

Author Block:

T. Dao[1], L. Phan[1], H. Tran[2], M. Eeckhout[3], F. Devlieghere[4]; [1]Ho Chi Minh city Univ. of Food Industry, Ho Chi Minh city, Viet Nam, [2]Cai Lan Oils & Fats Industries Co., Ltd, Ho Chi Minh city, Viet Nam, [3]Lab. for applied mycology, Univ. Ghent, Gent city, Belgium, [4]Lab. of Food Microbiol. and Food Preservation, Univ. Ghent, Gent city, Belgium

Abstract Body:

Background: The estimated loss of agricultural products due to mold contamination in Vietnam is approximately 20-25% per year including reduced productivity and product quality. Mycotoxin such as aflatoxins, ochratoxins and fumonisins produced by molds are major concerns. Nowadays, Vietnam is the second biggest coffee producer in the world. Coffee is one of the most popular drinks of the Vietnamese people and has been exported to USA and EU countries. Therefore, it is important to have knowledge on the mold contamination and identification on Vietnamese coffee beans in order to improve the quality of Vietnamese coffee. **Methods:** Samples of coffee beans were collected from different regions of Vietnam (central highlands, Northern and Southern provinces⋯). In total, 80 samples of coffee beans were analyzed. Mold isolation from coffee beans was performed by direct plating on Dichloran Rose Bengal Chloramphenicol (DRBC) agar and identification was performed by DNA sequencing. **Results:** This study showed that 80% of the coffee samples were positive for *Aspergillus* sp. such as: *Aspergillus fumigatus*, *A. flavus*, *A. niger*, *A. oryzae* and *A. terreus*. The diversity of the mold population was correlated with geographical coffee origin. *Aspergillus niger*, *A. flavus* were more frequently detected in coffee bean samples from Southern area of Vietnam. HPLC analysis revealed that *A. flavus* strains were able to produce Aflatoxin AB1. **Conclusion:** This research has confirmed the biodiversity of molds from different regions in Vietnam. *A. flavus* was the dominant species infecting Vietnamese coffee beans. *A. flavus* is capable to produce Aflatoxin AB1, this mold was detected in 70% of the coffee bean samples.1

Microbial Load in Hard Corals of Burma Nella- Andaman Islands

Author Block:

K. Revathi, Ph.D, V. Gunasekaran; Ethiraj Coll., Chennai, India

Abstract Body:

Background: Microbial communities associated with the healthy corals play a major role in production of nutrition and also maintaining the health by producing antibiotics in coral animals. All healthy corals contains large population of algae, bacteria, archea and these microbes provide benefits to their host by various mechanisms including photosynthesis, nitrogen fixation and infection protection. Coral microbiology is an emerging field, driven largely by a desire to understand, and ultimately prevent, the world destruction coral reef. **Methods:** In this study five species of hard corals (Acropora aspera, Favia matthai, Goniastrea retiformis, Porites annae, Porites solida) from Burma Nella in Andaman were studied for microbial load.**Results:** The bacterial population ranged from 12.8 x 103 to 2.80 x 103 CFU/ml. Porites solida was registered maximum microbial load and Porites annae gave minimum microbial load. Altogether, 6 genera and 7 species viz. Aeromonas hydrophila, Bacillus megaterium, Bacillus subtilis, Enterobacterium sp, Flavobacterium hibernum, Pseudomonas aeruginosa, and Vibrio communis were identified from these five corals. Among them, the Pseudomonas aeruginosa was most abundant bacteria found in all coral samples followed by Vibrio communis.**Conclusions:** The aim of this study is to known the association of microbes in healthy corals and provide a theoretical reference for better protection and maintaining the coral's biodiversity.

Absolute Quantification of Viable *Lactobacillus acidophilus* Ncfm® and *Bifidobacterium animalis* s*ubsp*. *lactis* bl-04™ Using Strain-Specific Digital Pcr

Author Block:

S. J. Z. Hansen, W. Morovic; DuPont, Madison, WI

Abstract Body:

Total cell count (TCC) is the industry-accepted reference method for probiotic enumeration. However, it has a wide variation of 25-30% and cannot always differentiate between similar strains commonly found within blended products. Alternatively, Digital PCR (dPCR) is a technique that can quantify singular DNA targets through the detection of TaqMan® probe fluorescence. The objective of this work was to develop an absolute enumeration method utilizing strain-specific dPCR that produces results that improves the enumeration range of TCC. Optimization of the method included the use of Propidium Monoazide (PMA), a dye that inhibits the amplification of DNA in dead and damaged cells, and mechanical disruption. This creates a strategy to prevent amplification of DNA from non-viable cells as well as ensure all healthy cells are sampled. These treatments were applied to cell suspensions of freeze-dried *Lactobacillus acidophilus* NCFM® and *Bifidobacterium animalis* subsp. *lactis* BL-04™ and quantified with the chip-based Life Technologies' Quantstudio® 3D Digital PCR system. Statistical analysis of the reproducibility and repeatability between the TCC and dPCR results validated the method for quantifying probiotic cultures, giving consistent readings within 12% variation, well within the acceptable range of TCC. In all, the use of dPCR for the enumeration of probiotics not only allows results consistent with TCC, but also provides a solution for strain-specific enumeration that is not currently available for multi strain products.

Characterization of the Contaminant Bacterial Communities in Fed-Batch and Continuous Fermentation Process for Ethanol Production

Author Block:

M. L. Bonatelli, M. C. Quecine, A. P. Bini, C. A. Labate; ESALQ/USP, Piracicaba, Brazil

Abstract Body:

Brazil is the largest sugarcane ethanol producer in the world and ethanol demand has increased as it is considered a sustainable alternative to fossil fuel. During the fermentation process, that may operate either in fed-batch or continuous mode, bacterial contamination is responsible for significant economic losses. Thus, we compared the profile of the bacterial communities from two distilleries in Brazil, each operating a different fermentation processes. Bacterial communities were accessed through Illumina culture-independent 16S rDNA gene sequencing and qPCR was used to quantify total bacteria. Both distilleries showed similar bacterial density 5,05 ± 0,14 Log CFU/mL; however, 16S rDNA sequencing showed differences between the two distilleries. It was reported 219 genera belonging to 12 different phyla, several of them that have never been described in this environment, but 91% up to 99% of sequences were affiliated to genus *Lactobacillus* in the samples. Alpha diversity only showed a correlation through the fermentation tanks in continuous mode. Beta diversity clearly separated distilleries and the operational taxonomic units that were differentially represented, belonged mainly to *Lactobacillus*, where several of them were unique to distillery with continuous mode, whereas others from the genera *Weissella* were more abundant in fed-batch mode. *Pediococcus*, *Acetobacter* and *Anaerosporobacter* were more abundant in continuous mode. Predictive functional gene was made using PICRUSt and reinforced clustering within the distilleries. It also revealed that several classes of genes, as carbohydrate metabolism and membrane transport, mainly related to fermentation process, were significantly different between the distilleries. Our data strongly suggests that bacterial communities are distinct between distilleries, it may be related to fermentation process operation and future works should focus on looking for specific control method to each distillery.

Combining the Use of a Novel Substrate, Sorghum Bran, with Strain Improvement to Produce High Yields of Itaconic Acid

Author Block:

A. M. Ahmed El-Imam[1], C. Du[2], P. S. Dyer[1]; [1]Univ. of Nottingham, NOTTINGHAM, United Kingdom, [2]Univ. of Huddersfield, Huddersfield, United Kingdom

Abstract Body:

Itaconic acid (IA) is a bulk chemical produced by submerged fermentation of sugars by *Aspergillus terreus*. It could potentially replace many petroleum-based monomers in a many industrial applications. However, the cost of sugars makes its use uneconomical. Several approaches are being utilised to decrease the cost of IA production and these include attempts to increase yield, improve fermentation strains and utilise cheaper raw materials; many of which are promising in improving itaconic acid production economics. The present work combines two such strategies. Firstly, IA was produced from a novel substrate, sorghum bran (SB), which is the waste accumulated from the processing of *Sorghum bicolor* grains. To this end, SB composition and suitability for IA production was investigated, and then pretreatment conditions optimised to obtain a sugar-rich fermentable liquor. Secondly, strain improvement was attempted. *Aspergillus terreus* strains (n=45) were screened on SB hydrolysate for IA production. The most promising strains were then subjected to two strain improvement techniques. Mutagenesis was carried out by UV irradiation of the spores of strains 49-5 and 49-22. Alternatively, mating types of the strains were determined and sexual crossing undertaken where possible. Novel strains obtained via both methods are being tested for IA output. The SB contained about 53% residual starch, 20% protein and varying amounts of minerals, and thus showed potential for IA production. Screening showed yields from 0.1-2.6 g/L on SB hydrolysate. Following UV irradiation, a mutant of 49-22 showed a **6-fold** increase in yields relative to parents at 16.4 g/L of IA. It was observed that 28 strains were *MAT 1-1* while 18 were of *MAT 1-2* mating types. Sexual crossing yielded large numbers of cleistothecia (sexual reproductive structures of *A. terreus*) containing mature ascospores. Work is currently underway to verify clonality of the progeny by molecular markers, and their IA yields. This is the first report of itaconic acid production from sorghum bran, and also the first reported attempt to use sexual crossing to improve yields from *A. terreus*. These results could have significant impact on the economics of renewable itaconic acid production and consequently reduce dependence on petroleum-based monomers

Characterizing and Quantifying Bacterial Populations Associated with Nutrient Removal in Full-scale Sequencing Batch Reactors

Author Block:

J. T. Johnston, S. F. Behrens, T. M. LaPara; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

The bioreactors of municipal wastewater treatment plants are designed to rapidly metabolize nutrients to prevent ecological harm when treated wastewater is released to the environment. Despite the reliance on microbes, relatively little is known regarding the types and quantities of microorganisms that reside in full-scale wastewater treatment bioreactors. The goal of the present study was to track the microbial community composition in full-scale sequencing batch reactors using deep sequencing (Illumina MiSeq) of PCR-amplified 16S rRNA gene fragments and quantitative PCR targeting, functional genes associated with specific nutrient removal activities. These results were then statistically correlated to plant performance data. Results suggest complex but dynamic bacterial communities but stable functional community for ammonia-oxidizing bacteria (AOB) and ammonia-oxidizing archaea (AOA). These results suggest that tracking specific bacterial populations by qPCR can become a useful tool for monitoring wastewater treatment bioreactors.

Development and Validation of a Species-Specific Multiplex Pcr Protocol for the Identification of Commercial Probiotic Products

Author Block:

B. J. Zabel, W. Morovic, B. Stahl; DuPont Nutrition and Hlth., Madison, WI

Abstract Body:

The Dietary Supplements industry has made large strides in product quality and safety under regulatory entities such as FDA, EFSA, and HealthCanada, however molecular methods still lag behind requirements. Recent reports have shown that label claims do not always describe the contents of dietary supplements, including probiotic products (Mills *et al.* 2015). In order to identify multiple bacterial species in products, we developed an end-point, multiplex PCR method that identifies 20 common species and sub-species of probiotic products.We collected whole genome sequences from public and proprietary strains of common probiotic species of the genera: *Lactobacillus, Bifidobacterium, Lactococcus, Streptococcus, and Pediococcus*. Utilizing polymorphism in the glucose-6-phosphate isomerase gene, a single copy core housekeeping gene, we were able to design primers targeting various amplicon sizes leading to an assay of four reactions that detect 20 species and sub-species.To validate these results, we tested the multiplex PCR against controls and determined the optimum detection limit of each to be 1E5 CFU/mL. Then, we obtained 20 various commercial formulations to compare with the method.We processed these samples with the MoBio PowerSoil gDNA extraction kit and were able to remove the inhibitors and identify the samples, all of which amplified well.Preliminary results show that all species claimed on the labels were detected. However, six of the products have additional bacteria not noted on the label. The amplicon strengths seemed to be affected by the concentration of bacteria in the product, but this could not be confirmed because formulations were not always present on the label. This highlights the need for a quantitative method for multi-strain blends.In conclusion, the molecular method we developed can detect up to 20 different species and sub-species common in probiotic products. When used with commercial samples, we showed that the contents to do not always match the label claim. Highlighting the need for oversight of regulatory testing on probiotic dietary supplements, to ensure label accuracy and customer confidence.

Direct Capture and Expression of the Didemnin Anti-Cancer Agents from the Marine Bacterium *Tistrella mobilis*

Author Block:

J. Zhang, Bradley S. Moore; Univ. of California, San Diego, La Jolla, CA

Abstract Body:

The cyclic depsipeptide didemnin B was the first marine natural product to enter clinical trials as a chemotherapeutic agent. Although the compound and several analogs were originally isolated from tunicates, it was recently discovered that two species of free-living marine bacteria, *Tistrella mobilis* from the Red Sea and *Tistrella bauzanesis* from the Pacific Ocean, also produce didemnins. To investigate the biosynthesis and unique post-synthetase activation mechanism of these compounds, the 75-kb biosynthetic gene cluster was directly captured from *Tistrella mobilis* KA081020-065 using transformation-associated recombination (TAR) in yeast. Heterologous expression and genetic manipulation of the pathway provides a mechanism for didemnin B biosynthesis, as well as a proposed route to the natural analogue aplidine (dehydrodidemnin B), a drug with orphan designation in the EU.

Diversity of Novel Alkaline Protease Producing Bacteria from Chilika Lake

Author Block:

A. Narayan Panda, S. Mishra, L. Ray, T. K. Adhya, M. Suar, V. Raina; Sch. of Biotechnology, .Bhubaneswar, India

Abstract Body:

Chilika lake is the largest brackish water lake in India situated in the east coast of Odisha. The lake is a biodiversity hotspot & is a storehouse of industrially important marine microorganisms. Enzymes from marine or brackish environment have unique properties & have proven industrial applications. Alkaline proteases are known active ingredients of the commercial detergents & have wide application in leather & tanning industries. Culture-based isolation of alkaline protease producing bacteria from different stations & identification by biochemical & molecular methods. Microbial identification & characterization by using polyphasic approach. 30 different sampling sites from the lake were investigated for the isolation of alkaline proteases. 13 isolates showing highest zone in plate assay within a pH range of 9-11. By using casein as a substrate at pH 10, three bacterial isolates i.e KGS4, KGW1 & PKS7 were characterized by polyphasic taxonomy. The preliminary phylogenetic analysis based on 16SrRNA sequence & BLAST analysis showed that closest phylogenetic neighbors of KGS4, KGW1, CHW3, & PKS7 were *Bacillus stratosphericus* 41KF2a, *Halobacillus trueperi* SL-5 & *Rheinheimera aquimaris* SW-353, respectively. The 16SrRNA sequence similarities were found to be 99.5%, 99.1%, & 98.58%, respectively. The isolated strains showed alkaline protease activity at pH10 & were morphologically & biochemically distinct from their closest taxonomic neighbors which may be considered as a novel feature. The alkaline protease activities as measured by activity assay of strains KGS4, KGW1& PKS7 were 4.1U/ml, 3.8U/ml, 2.2U/ml respectively, at pH 10. PCR amplification of *subtilisin e* (EMI14709) gene for alkaline protease was detected in KGS4. The isolated strains showed alkaline protease activity at pH10 & were morphologically & biochemically distinct from their closest taxonomic neighbors which may be considered as a novel feature. On the basis of phenotypic, chemotaxonomic properties, phylogenetic analysis, strain KGW1^T KGS4^T & PKS7 should be placed in the genus Halobacillus, Bacillus & Rheinheimera as novel species, for which the *Halobacillus marinus* sp. nov. , *Bacillus kharajalensis* sp. nov. *Rheinheimera pleomorphicus sp. nov*. were proposed. The type strains were KGW1^T (= DSM 29522=KCTC 33609) , KGS4^T (=DSM 29521=KCTC 33610) & PKS7^T (=KCTC 42365)

Genome Analysis and Comparative Genomics of Two *escherichia Coli* isolates Associated with Salpingo-Peritonitis in Commercial Layer Hens

Author Block:

K. H. E. M. Karunathilake, D. S. S. Wijetunge, A. Sebastian, I. Albert, S. Kariyawasam; Pennsylvania State Univ., University Park, PA

Abstract Body:

Egg peritonitis in laying hens is a major cause of morbidity and mortality leading to significant economic losses to the table-egg industry worldwide . Unlike other forms of colibacillosis, egg peritonitis and associated salpingitis (salpingo-peritonitis) is restricted to adult hens in egg production . Objective of the present study was to identify novel virulence traits of *E. coli* associated with salpingo-peritonitis using the whole genome sequencing approach. To accomplish this objective, we have sequenced two *E. coli* strains isolated from the ovaries and oviducts of two laying hens with egg peritonitis. These two *E. coli* strains designated PSUO2 (O2 serogroup) and PSUO78 (O78 serogroup) were sequenced and assembled using PacBio sequencing technology and genomes were annotated using the NCBI prokaryotic annotation pipeline. Both sequences were analyzed and compared with the genomes of five *E. coli* strains isolated from avian colibacillosis with the orthology defined by >70% identity and >70% coverage. Around 400 accessory genes, including, putative adhesins, autotransporters, and heme utilization systems that might be involved in pathogenesis of layer salpigo-peritonitis were identified in the two sequenced genomes.

Isolation, Screening and Optimization of Medium Composition for Protease Production by *Bacillus sp*

Author Block:

C. FLORES-FERNANDEZ, L. Alejandro Paredes, A. Zavaleta Pesantes; Univ. Natl. Mayor de San Marcos, Lima, Peru

Abstract Body:

Background: *Bacillus* is isolated from different environments and has been widely reported as proteases producer, the most important enzymes in the industrial market. Nowadays, studies are aimed at finding microorganisms from extreme environments that produce proteases with peculiar properties and optimizing the production of these for subsequent application in the industry. In this study, a strain of *Bacillus sp*. with proteolytic activity was isolated and medium for protease production were optimized. **Methods:** The soil samples were collected from Pilluana Salterns in San Martin, Peru. For the isolation, samples were plated in nutrient agar plates with 5 % NaCl and incubated at 37 °C for 24 h. Screening of protease producing bacteria was carried out with crude extract produced by each strain on nutrient agar plates with gelatin, skim milk, casein, and proteins from leguminous as, Cicer arietinum, Pisum sativum and Glycine max (1 % w/v). Enzyme activity was visualized as clear zones due to hydrolysis of substrates. The strain with the highest activity was identified by 16S RNA gene sequencing. Plackett-Burman design was employed to find out the optimal medium constituents to enhance protease production. Five factors (glycerol, galactose, yeast extract, bacteriological peptone and NaCl) were evaluated in 12 experiments. Each factor was tested at two levels, high (+) and low (−). Minitab package version 15 was used. **Results:** A total of 47 strains were isolated, 10 were identified as protease producers and the strain with the highest activity was identified as Bacillus sp. based on 16S rRNA gene analysis. The diameters of zone of hydrolysis for this strain were 20, 18, 17 and 16 mm for gelatin, casein, skim milk and proteins from legumes, respectively. Plackett-Burman design revealed that galactose (12, 5 g / L) and yeast extract (9 g / L) significantly influenced the protease production ($p < 0,05$). The enhancement of protease from 139,52 U/mL to 337,49 U / mL was achieved with the optimization. **Conclusions:** *Bacillus sp*. isolated from Pilluana Salterns in San Martin, Peru produces an exoprotease that hydrolyze proteins from various sources. Plackett-Burman design allowed optimizing medium composition in order to increase protease production for the potential industrial applications.

Metall (and Metalloid)-Binding of Different Metallophores from Bacteria and Fungi

Author Block:

M. Mehnert[1], G. Retamal M.[2], T. Heine[1], R. Schwabe[1], M. Schlömann[1], G. Levicán J.[2], D. Tischler[1]; [1]Technical Univ. Bergakademie, Freiberg, Germany, [2]Univ. de Santiago de Chile, Santiago, Chile

Abstract Body:

Background: Under iron-restricted conditions many bacteria and fungi produce metal chelating molecules called metallophores for scavenging metal ions from the environment. These compounds possess a high affinity and selectivity for ferric iron, but some of them are able to effectively bind other metals and metalloids as well. They find application in environmental and medical sector. In order to identify metallophores, which are able to bind strategically important metals we screened numerous bacteria and fungi for metallophore production and metal-affinity. **Methods:** A general and widely used method for metallophore detection is a colorimetric assay based on the utilization of chrome azurol S (CAS) [1]. We used a low phosphate minimal growth medium and a liquid CAS assay variant. The test has been optimized regarding to different metals and metalloids, ion concentrations and pH values in order have an applicative and useful screening method for different types of microorganisms. **Results:** We established the test for Ga, Al, As and V in microtiter plates and calibrate these CAS assay solutions as well as the available solutions for iron [2] and copper [3] with desferrioxamine B (DFOB) to calculate DFOB-siderophore-equivalents. Using these assay variants, we screened more than 35 stains of different bacteria and fungi for metallophores and their affinity to Fe, Al, V, As, Ga and Cu ions. **Conclusions:** The CAS assay with different metal solutions in microtiter plates was found to be a rapid and easy-to-perform method to test culture supernatants of different strains for metallophores and their affinity to different ions. The screening of various strains showed that the siderophores differ in their metal binding specificity. Indeed we determined, that the metallophore of A. niger bind Cupper and Vanadium much more effectively than other strains.

Microorganisms for Industrial Antimicrobial Biosurfactant Production, a Review

Author Block:

D. SOLAIMAN, R. Ashby; ERRC, ARS, USDA, Wyndmoor, PA

Abstract Body:

There is a demand in the consumer product industry to address the emerging antibiotic resistance issue especially with regard to the cleaning products. Natural products such as glycolipid biosurfactants with antimicrobial activity synthesized by microorganisms could provide environmentally friendly bioproducts to fill this industrial demand. Accordingly, researchers had developed and applied screening methods such as colorimetric plate assay and nucleic-acid-based metagenomic screening to identify microorganisms capable of producing biosurfactants. Various antimicrobial assay methods were then applied to assay the antimicrobial activity of these biosurfactants. Fermentation system is constantly refined to lower the production costs of these biomaterials to improve their commercial viability. In this review presentation, emphasis will be placed on the antimicrobial sophorolipid and rhamnolipid biosurfactants with regard to their fermentative production and antimicrobial property.

Resistance to Antibiotics and Lead of Bacteria Isolated from Sediments of St. Clair River

Author Block:

R. Gismondi, M. Fenner, D. Patel, S. M. Tiquia-Arashiro; Univ. of Michigan-Dearborn, Dearborn, MI

Abstract Body:

Bacteria are generally the first organisms affected by the increased presence of toxic compounds in the aquatic environments including antibiotics and heavy metals. The purpose of this study is to determine natural susceptibility levels of bacterial isolates to Pb and antibiotics. Two enrichment experiments (LB and R2A broths) containing 10 g of sediments and increasing concentrations of Pb(NO3)2 were carried out to isolate Pb-resistant strains. Cells that grew on enrichments containing the highest Pb concentrations (1500 mg/L for LB and 1250 mg/L for R2A) were isolated and characterized for their antibiotic resistance using eight different antibiotics. The results showed that the majority of the LB strains were resistant to chloramphenicol (80% of the isolates), erythromycin (71%), novobiocin (100%), penicillin G (100%) and tetracycline (73%). For the R2A strains, the majority were resistant to erythromycin (98% of isolates), neomycin (81%), novobiocin (100%), and penicillin G (100%). However, LB strains showed sensitivity to streptomycin (98% of isolates) while the R2A strains showed sensitivity to both streptomycin (75%) and chloramphenicol (72%). In general, Pb-resistant strains isolated from Saint Clair River sediments showed natural resistance to a variety of antibiotics. This result suggests that the combined expression of antibiotic resistance and metal tolerance is caused by selection resulting from the metals present in the environment. Bioremediation requires organisms that are tolerant to an array of toxins. As such, Pb-resistant strains isolated in this study could be successful candidates for bioremediation of Pb-contaminated sites in a more economical way in comparison to current chemical remediation methods.

Optimized Production Conditions of Thermpohilic CMCase by a Novel "*Bacillus* TLW-3" Strain, Isolated from Local Oven Ash of Karachi

Author Block:

T. K. Awan, W. -. -. -. Asad, -, S. A. -. -. Rasool; Karachi Univ., Karachi, Pakistan

Abstract Body:

Cellulases have been reported as the third largest single industrial enzyme worldwide being employed in textile industries, paper recycling, detergent industry and food processing industries. A growing interest in the cellulases is obvious because of their utility in transportation i.e. fuel production, the economy driver of a country. For the production of extensively diversified cellulases, microorganisms (both fungi and bacteria) have been extensively exploited. Varieties of ecological niches were explored for the isolation of cellulolytic microorganisms. However, there have been scarce report on the hot oven ash cellulolytic bacterial flora. In this regard the newly isolated 37 *Bacillus* strains ("*Bacillus* TLW-1 to *Bacillus* TLW-37") from the local hot oven ash were screened for CMCase (carboxymethyl cellulase) production ability by plate screening method. Accordingly, 26 isolates could produce CMCase and, were subjected to submerged fermentation. Crude extract was obtained and assayed for CMCase titer by DNS (dinitrosalicylic acid) method. "*Bacillus* TLW-3" that shown the highest IU/ml/min was selected for further study. The enzyme production conditions and growth conditions were optimized for the highest CMCase yield. The "*Bacillus* TLW-3" showed the highest growth and enzyme production at 50ºC, pH 7 and after 72 hour of incubation at 150rpm. Moreever, the organisms showed higher enzymatic yield when grown on complex defined media as compared to minimal salt media. Studies on the different carbon and nitrogen sources effect on enzyme production revealed that CMC (1%), yeast extract (0.5%) and peptone (1%) significantly increased the CMCase yield compared to other tested sources. Tween-20, Tween-80 and EDTA acted as the inhibitors for the enzyme production. Furthermore, enzyme production regulation is not influenced by catabolite repression. The present study holds the conviction that the reported organism could directly be applied for the thermophilic cellulase production.

Optimization of Pectinase Production from Indigenously Isolated Yeast Strain Using Response Surface Methodology

Author Block:

A. Ahmed; Karachi Univ., Karachi, Pakistan

Abstract Body:

Pectinases are hydrolases that degrade pectin molecules present in primary cell-wall and middle lamella of fruits and vegetables. In fruit-juice production, the presence of pectin may cause problem during the extraction, filtration and clarification by creating turbidity and viscosity. Pectinases have long been used to increase the juice yield and reduce the turbidity and viscosity. Though, several organisms are able to produce pectinases including plants, filamentous fungi, bacteria and some yeasts. Yeasts have a great potential to produce industrial enzymes and they offer an alternative source. Yeasts have many advantages over filamentous-fungi as they are unicellular, growth is simple, growth medium does not require an inducer and they usually don't produce undesirable pectinesterases. This study was conducted to isolate, screen and optimize indigenously isolated yeast strains for pectinase production. Different samples were used for isolation of yeast strain. Almost 30 strains were isolated. These isolated strains as well as some strains from departmental culture collection were qualitatively and quantitatively screened for pectinase production. The qualitative screening was carried out on mineral salt agar medium using ruthenium red. Our results showed that 48 strains out of 127 strains were pectinolytic. These 48 strains were quantitatively screened by performing enzyme assays based on determination of reducing sugar (galacturonic acid) using dinitrosalicylic acid. One strain, AA15, producing significant titer of pectinase was selected for further studies. Response surface methodology was employed for the optimization of fermentation conditions. Initial pH, inoculum size and substrate concentration were found to be the significant factors using Plackett-Burman design.The optimum fermentation conditions were determined by using Box-Behnken design in RSM. Inoculum size 3%, substrate concentration 0.75% and the initial pH 5.3 were determined as optimum conditions. The strain yielded 0.250 IU/ml pectinase activity under optimized conditions. It provides a merit to study this strain further as, yeasts generally do not produce the pectin methyl esterase which results in release of toxic alcohols so they have advantage over filamentous fungi therefore, it is worthwhile to explore the potential of this strain.

Potential Use of Dehydrogenase Activity as a Marker of Microbial Activity in Lake St. Clair and St. Clair River Sediments

Author Block:

R. Gismondi, M. Fenner, D. Patel, A. Oest, N. Bowman, D. Azzopardi, A. Alsaffar, S. M. Tiquia-Arashiro; Univ. of Michigan-Dearborn, Dearborn, MI

Abstract Body:

Dehydrogenase activity based on the reduction of 2,3,5-triphenyltetrazolium chloride (TTC) to red-colored formazan (TPF), was used in this study as a method to determine microbial activity from river and lake sediments. Three sites were selected from St Claire River (SC1, SC2, SC3) and three from Lake St. Clair (LC1, LC2, LC3). Bacterial and fungal counts and physico-chemical assays were carried out over three consecutive seasons to characterize the microbial and phyico-chemical properties of the sediments. Incubated sediments containing TTC (1 ml) and distilled water (2.5 ml) were extracted with methanol and the absorbance (485 nm) was used to determine the sediments' dehydrogenase activity. Sediments from sites LC2 and SC2 had little activity (0.0007-0.031 ug/TPFg) throughout spring, summer and fall seasons, which also corresponded to low bacterial count at these sites. Site LC1 had high activity only in spring (0.936 ug/TPF g). Sediments from LC3, SC1 and SC3 showed higher activities compared to LC1, LC2 and SC2 in summer, spring and fall. Dehydrogenase activity was correlated with fungal count, TOC and pH of the sediments. High dehydrogenase activity was reported for SC1 and SC3 sediments, which correlated with sediments having the highest overall bacterial and fungal counts. This trend was not consistent with sediments collected in Fall (SC3) and Spring (SC1), because dehydrogenase activity then correlated only with fungal counts, not with bacterial counts. The data indicate that dehydrogenase activity is at best a weak indicator of microbial activity in Lake St. Clair and the St. Clair River sediments.

Polyhydroxyalkanoates Production by Native Strains Isolated from Northeast Mexico

Author Block:

J. Villarreal-Chiu[1], O. López-Ayala[1], M. Salinas Santander[2], M. Garza-González[1], E. Blanco-Gámez[1]; [1]Univ. Autónoma de Nuevo León, San Nicolas de los Garza, Mexico, [2]Univ. Autónoma de Coahuila, Saltillo, Mexico

Abstract Body:

Background: Polyhydroxyalkanoates (PHA) are biopolymers synthesized by microorganisms as reserve materials for carbon and energy when cells are exposed to inorganic nutrient limitation coupled with an excess of carbon source. The composition and properties of PHA depend on the metabolic routes present in the microorganism as well as the monomers that are supplied to the cell.**Methods:** An initial bioinformatic study was carried out using a set of amino acidic templates representing the four distinct classes of PHA synthases to estimate their distribution in bacteria. 60 native bacteria isolated from northeast Mexico were tested under nutritional stress conditions using phosphorus and nitrogen-depleted minimal media enriched with acetate as carbon source.**Results:** The distribution of PHA synthase genes over the sequenced bacterial database contained on NCBI reached nearly 26% (868 de 3260). Analysis of the flanking regions of each homologue suggested that most of PHA synthases of class II (92%), which is related to the production of medium-chain length PHA, are controlled by the HTH-type transcriptional regulator *acrR*. Expression of *acrR* is increased under general stress conditions. 49 out of 60 native bacteria tested were confirmed as PHA producers when supplied with acetate. Four representatives bacteria were tested with 10 different nutrient-depleted agro-industrial residues supplied as carbon and energy source. Results indicated that all 4 native bacteria were capable of producing PHA at times ranging from 6 to 13 days with diverse monomer compositions, including hydroxybutyric and hydroxyvalerate acids.**Conclusions:** It is important to find new ways to decrease the cost of PHA production for industrial purposes. The use of agrodindustrial residues as carbon source successfully produced hydroxybutyric-hydroxyvalerate co-polymer.

Production of Bioactive Secondary Metabolites from Alkaliphilic Actinomycetes Against Various Multi Drug Resistant (MDR) Pathogens

Author Block:

S. Aslam, I. Sajid; Univ. of the Punjab, Lahore, Pakistan, Lahore, Pakistan

Abstract Body:

Background: The search for novel therapeutic agents for use in the pharmaceutical industry is driven by the need to combat the increase in the incidence of infection due to antibiotic resistant pathogens. Among the producers of commercially important metabolites, actinomycetes isolated from extreme environment are of prime importance as prolific producers of novel antibiotics having diverse biological activities. The present study was designed to screen the alkaliphilic actinomycetes for their antimicrobial potential against MDR bacterial pathogens.**Methods:** In the present study, forty different actinomycetes were isolated from the water and mud samples collected from a saline Kallar Kahar lake. The isolates exhibit significant tolerance to alkaline conditions and grow well at pH 9-11. The morphological, biochemical and genetic characterization of these strains was performed to identify them. The selected strains were cultivated on small scale, the resulting culture broth was freeze dried and the residue was extracted with ethyl acetate. In biological screening the activity of the extracts was determined against MRSA, *Pseudomonas aeruginosa*, *Proteus vulgaris*, *K. pnuemoniae*, *E. coli*, *Enterobacter* spp., and *Acinetobacter baumanii*. In chemical screening the crude extracts were analyzed by TLC and HPLC-MS.**Results:** The current study revealed that majority of the actinomycete strains (90%) was belonging to the genera *Streptomyces*. Many lake actinomycetes showing remarkable antimicrobial activities against MDR bacterial pathogens. Among selected strains, $KL_1$4, $KL_2$1, $KL_3$2, $KL_3$7, $KL_4$1, $KL_6$3, $KL_7$2, $KL_7$3, $KL_8$1, $KL_9$3, $KL_9$6, $KL_9$8 and KL_{11}6 were found to be most biologically active as they exhibited promising activity against all the test strains of multi drug resistant pathogens. In thin layer chromatographic analysis of the crude extracts, appearance of various coloured bands indicating a unique pattern of different bioactive metabolites. HPLC-UV chromatograms of each crude extract of the isolates showed a number of different peaks at various retention times, which was also an indication of the presence of many valuable antimicrobial compounds.**Conclusions:** Alkaliphilic actinomycetes are an important resource of bioactive compounds, and can prove to be a goldmine of novel secondary metabolites in drug discovery.

Recovery & Characterization of Polyhydroxybutyrate Biopolymer Produced by *Bacillus cereus* Isolate P83

Author Block:

N. Elsayed, K. Aboshanab, M. Yassien, N. Hassouna; Faculty of pharmacy- Ain shams univerisity, cairo, Egypt

Abstract Body:

Background: Polyhydroxyalkanoates (PHA) biopolymers offer a valuable alternative to synthetic plastics in our daily life. Also, they are biocompatible and biodegradable giving rise to different applications in medical field. This study aimed at testing PHA production using *Bacillus cereus* isolate P83 in a laboratory 14L fermentor, studying different approaches of recovery and characterization of produced polymer. **Methods:** PHA production was tested using mineral salt medium containing 0.7% corn oil and 0.1 g/L ammonium chloride as carbon and nitrogen sources, respectively at 28°C, 200 rpm, 1 vvm and under uncontrolled pH. Various approaches of recovery of PHA were investigated using sodium hypochlorite, chloroform, dispersion of both of them and sonication. These approaches were evaluated by testing amount of PHA produced, molecular weight of polymer and its polydisperisty value. Statistical analysis was done using Graph Pad instat program. Characterization was done using transmission electron microscope, gel permeation chromatography, thin layer chromatography, IR and NMR spectroscopy. Appropriate universal heterologous primers were designed and used for PCR amplification followed by DNA sequencing of genes coded for PHA synthase enzyme and R subunit. **Results:** About 49% PHA per dry weight was produced after 24 h of incubation. Recovery using chloroform resulted in higher molecular weight of polymer ($2.15*10^4$ g/mole) and lowest polydisperisity (1.15). Characterization techniques revealed polymer identity which is Polyhydroxybutyrate (PHB). Melting point of the polymer was 180 °C. IR analysis confirmed the presence of key functional groups namely OH group at 3448 cm^{-1}, CH group at 2923 cm^{-1} and carbonyl at 1735 cm^{-1}. NMR analysis showed the resonance absorbance of CH_3 at 1.91ppm, CH at 4.52 ppm and CH_2 at 4.52 ppm. Analysis of PHA synthase (PhaC) and PhaR subunit PCR products indicated class IV PHA synthase. **Conclusion:** *Bacillus cereus* isolate P83 is a candidate for commercial production of PHB polymer due to cheap carbon source, high growth rate, high production level and comparable molecular weight of polymer with low polydispersity value. The low polydisperisty value extends use of PHB polymer in biomedicine.

Screening for Linear Plasmids in Actinomycetes Isolated From the Great Salt Plains of Oklahoma

Author Block:

C. Cornell, M. K. Fakhr; The Univ. of Tulsa, Tulsa, OK

Abstract Body:

One of the unique features of actinomycetes, especially the genus *Streptomyces*, other than the presence of a linear chromosome, is the linear extrachromosomal material seen in many of those microorganisms. These linear plasmids have a size range of 12 kb to upward of 600 kb, and are often termed as mega-plasmids. While many of the genes involved in secondary metabolite production reside in clusters on the chromosome, several studies have identified biosynthetic clusters on the large linear plasmids that produce important secondary metabolites including antibiotics. Due to the large size of the extrachromosomal DNA, most plasmid isolation kits and traditional gel electrophoresis do not allow separation of the plasmid(s) and chromosome. Pulse Field Gel Electrophoresis (PFGE) can be used to separate DNA fragments up to several mega-bases. There is a lack of large scale plasmid screening studies done using PFGE, therefore we developed a protocol by using several existing methods. PFGE was used to screen 176 actionmycete isolates collected from the Great Salt Plains of Oklahoma for the presence of plasmids. To determine the topology of the smaller plasmids present, the plasmids were treated with S1 nuclease to linearize any circular plasmids and ran against an untreated sample for comparison using PFGE. From the 176 strains screened, 78 showed the presence of plasmids, about 44% of the total sample number. Several of the strains contained more than one plasmid accounting for a total of 109 separate plasmids. Ten of the samples showed extrachromosomal DNA larger than 200 kb falling into the category of mega-plasmids. Based on the subset of samples treated with S1 nuclease to determine topology, all plasmids examined appeared to be linear. In conclusion, PFGE facilitated the detection of plasmids in different actinomycete strains found in the unique terrestrial environment of the Great Salt Plains of Oklahoma, with the majority of the plasmids being linear ranging from 54.7 kb up to 400 kb. Further studies are currently underway to molecularly characterize the large linear plasmids through next generation sequencing. DNA sequence will help in molecularly characterizing these large plasmids and in identifying the prospective encoded genes of secondary metabolites production and/or stress adaptation.

Systematic Analyses of Transcriptome and Translatome Revealed the Regulation of Energy Conservation Metabolism in *Clostridium ljungdahlii*

Author Block:

J-N. Kim, M. M. Al-Bassam, J. K. Jiu, K. Zengler; Univ. of California San Diego, La Jolla, CA

Abstract Body:

The homoacetogen *Clostridium ljungdahlii* is an anaerobic bacterium that ferments sugars as well as other organic compounds. Additionally, the organism grows on carbon dioxide (CO_2) /hydrogen (H_2) and carbon monoxide (CO) (i.e. syngas). Syngas fermentation makes *C. ljungdahlii* an interesting microbial production platform for the production of commodity chemicals from syngas. In order to harness the full biosynthetic potential, it is important to understand the regulatory networks that orchestrate energy conservation in *C. ljungdahlii* and their response to autotrophic and heterotrophic conditions. We thus have integrated genome-scale measurements of the transcriptome and translatome at nucleotide resolution of *C. ljungdahlii*. ChIP-exo and transcription start site profiling techniques were used to determine RNA polymerase binding sites and elucidate transcription units and detailed promoter architectures. Integrating RNA-seq and ribosome profiling data revealed the translational efficiency of genes that are involved in energy conservation metabolism such as the Wood-Ljungdahl pathway under autotropic growth conditions. Overall, the multiomics approach provides insight into the regulation of energy metabolism of *C. ljungdahlii* between autotropic and heterotropic growth. These findings will enable the development of *C. ljungdahlii* as a chassis organism for commodity chemical production from cheap and renewable sources.

The Preservation Challenge Test Method Using Pool Inoculum Compatible with ISO11930

Author Block:

S. Hamada, H. Araki, H. Anan, N. Shigemune, M. Hasumi; Kao Corp., Tochigi, Japan

Abstract Body:

Background: Different preservation challenge test methods are commonly available in the cosmetic industry. As test inoculum, either pure or mixed cultures may be used. A challenge test method using pure culture is in the International Standard ISO11930. Pure culture challenge, although more time-consuming, will yield specific data on each microorganism employed. Mixed-culture challenge, on the other hand, can be used to obtain rapid pass-or-fail decisions on preservative adequacy and reduce the workload. However, antagonism among organisms may occur. In this study, we studied the antagonism among bacterial test strains to balance out the difference between pure and mixed cultures. With pool inoculum we constructed the bacterial challenge test method which is compatible with ISO11930 method.**Methods:**As test strains, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Escherichia coli* which are used in ISO 11930, and *Serratia marcescens*, *Burkholderia cepacia*, *Klebsiella pneumonia* which are known as contaminants of cosmetics, were used. The cell number in single and pooled inoculum was adjusted to 10^8 CFU/ml and viable bacteria were counted every few hours after preparation to confirm whether antagonism occurred or not. The challenge tests were conducted on 109 products including skin care, hair care and personal care products. The initial inoculum of approximately 10^8 CFU/ml was inoculated into 20g aliquots of each product formulation. At 7, 14 and 28 days post-inoculation, 0.1g aliquots were withdrawn from the inoculated samples to determine the recovery of viable test strains. Based on the results, the criterion of preservative efficacy compatible with ISO11930 was determined.**Results:**The viable cells in pooled cell suspension did not decrease within 24 hours after preparation. It suggested that pooled strains did not compete to kill each other. The log reduction observed in testing by our method tended to be more rapid than by ISO method, which might be due to antagonism. Based on the test results, we found that 4log reduction of pooled strains within 7day by our method met the preservative efficacy of the criterion B in ISO11930, 3log reduction of all 3 single strains within 14days.**Conclusions:**We investigated challenge test method using bacterial pool inoculum. With our method, the workload can be reduced and we can evaluate the product has preservative efficacy ISO11930 requires.

Temperature Effects on Distributed Metabolisms of Partial Nitritation/Anammox (Pn/A) Reactor

Author Block:

A. S. Bhattacharjee[1], S. Wu[1], B. Dutilh[2], R. Goel[1]; [1]Univ. of Utah, Salt Lake City, UT, [2]Utrecht Univ., Utrecht, Netherlands

Abstract Body:

Background: Mitigation of Nitrogen (N) from wastewater is necessary because of the environmental impact of ammonia leading to eutrophication in the receiving bodies. The combination of partial nitritation & anammox (PN/A) process brought in an innovative biotechnological revolution in energy-efficient process with reduced greenhouse gas emissions for N removal from wastewater. PN process provides nitrite, which mainly acts as an electron acceptor for Anammox (AMX) process, wherein ammonia is oxidized directly to N_2 gas. Most PN/A reactors are maintained at mesophilic temperatures, despite the fact that AMX bacteria in natural ecosystems have been found to thrive below 10^{o}C, indicating the possibility of PN-AMX to be metabolically active even at low temperatures. In this study, we investigated the temperature effect by subjecting a pilot scale PN/A reactor to different gradients, as specific metabolic pathways underlying remains poorly understood. **Method:** To gain insight into the key interactions between PN-AMX, metagenome & metatranscriptomes were generated from biomass collected from a 9-L PN/A reactor, fed with reject water from anaerobically digested sludge. For investigating the temperature effect on PN/A metabolism, it was exposed to temperature gradients of 35, 21 & 13°C. Biomass was collected at each gradient post acclimatization period, wherein RNA & DNA were extracted to generate high throughput sequencing data. Briefly, DNA sequences were assembled into contigs using Omega & subsequently binned into genomes. RNA-Seq data were assembled into transcripts using trinity. **Results:** 11 near-complete genomes were recovered, 3 of which, *Planctomycete* sps., *Anaerolinea* sps. & *Ignavibacterium* sps. were estimated to be >90% complete based on single-copy gene analysis. Furthermore, from the transcriptomes generated we observed a significant down regulation of transcripts in case of low temperatures along with a 3 fold decrease in abundance of genes being expressed between gradients of 35 to 13°C. **Conclusions:** Low temperatures were found to drastically affect the distributed metabolism of the PN & AMX. Furthermore, metabolic pathways inferred from genome, & transcriptome annotations indicated that reactor organisms were metabolically versatile & exhibited novel opportunities for metabolic-cooperation**.**

Using Microbial Populations in Concrete as Bio Indicators of Alkali-Silica Reaction

Author Block:

A. Treglia, J. Maresca; Univ. of Delaware, Newark, DE

Abstract Body:

Concrete is one of the world's most widely-used building materials and is the most used material in the world in terms of volume. In many areas, the alkali-silica reaction (ASR) damages concrete, reducing its lifespan. This reaction causes internal cracking in concrete that leads to deteriorating structural health and may result in structural failure. There are no current methods to detect ASR at an early stage before the reaction has occurred, but there are some options for mitigation, including limiting the alkali content of the concrete mix, and limiting or prohibiting the use of reactive aggregates. Here, we present a method for extraction of DNA directly from concrete, resulting in 9-900 ng DNA per g of concrete. Further, we use 16S amplicon sequencing to show that samples collected from inside concrete may have more than 2000 bacterial species, primarily Actinobacteria, and these species are not uniformly distributed inside the samples. We hypothesize that the changes in the chemical and physical properties of concrete over time will be reflected in the microbial populations, and use a three-year time series to test this hypothesis. To assess changes in microbial populations in ASR-affected concrete as damage progresses, we prepared concrete test cylinders using highly reactive materials provided by the Delaware Department of Transportation, and prepared parallel cylinders using the standard DelDOT ASR mitigation procedure, which replaces 50% of the cement powder with fly ash. These cylinders were placed outside to weather in the spring of 2013; since then, 1 cylinder from each series has been brought inside every 6 weeks for analysis of microbial population and assessment of ASR damage. This work demonstrates the feasibility of identifying microbes that can be used as bio-indicators for early diagnosis of structural problems in concrete.

Evolution of Bacteriophage T7 on Genetic Codes Expanded with Nonstandard 21st Amino Acids

Author Block:

M. J. Hammerling, D. E. Deatherage, **J. E. Barrick**; The Univ. of Texas at Austin, Austin, TX

Abstract Body:

The genetic code for translating DNA information in genomes into protein sequences has remained fixed for most of the history of life on Earth. Thus, while limited computational analysis of the organization of the code has been possible, it has been difficult to determine the extent to which the chemical alphabet consisting of the standard 20 amino acids is optimal for biochemistry and evolution versus an alternative set of amino acid side chains. We have begun to address this fundamental question by taking advantage of recently developed synthetic biology tools that enable the amber stop codon (TAG) to be efficiently recoded to incorporate a variety of nonstandard amino acids (nsAAs). We passaged 576 populations of a hypermutator T7 bacteriophage on nonevolving *Escherichia coli* hosts with the amber stop codon recoded to 3-iodotyrosine, 3-nitrotyrosine, 4-azidophenylalanine, 5-hydroxytryptophan, *o*-(2-nitrobenzyl)-tyrosine, or tyrosine (as a canonical control). After 1000 hours of continuous evolution as plaques in soft agar, we sequenced all of these populations to compare how their genomes and proteomes evolved with each different genetic code. In the resulting dataset of >100,000 amino acid substitutions and >1,000 amber substitutions, we are able to quantify the relative tolerance for neutral substitutions to each nsAA within the T7 proteome and also to find specific sites in proteins with statistical signatures that indicate that some nsAA substitutions improve phage fitness in unique ways. In particular, we observe sites in the T7 RNA polymerase and tail fiber proteins where substitutions of specific nsAAs occurred in parallel across many different populations. Our results illustrate how expanding the genetic code increases the evolvability of an organism, both by making new amino acid substitutions possible by converting a nonsense codon to a sense codon and by adding the potential for encoding proteins with a 21st amino acid that has a novel side chain.

Methanogenic Paraffin Biodegradation Proceeds Via Alkane Addition To Fumarate By "*smithella*" Spp. Mediated By A Syntrophic Coupling With Hydrogenotrophic Methanogens

Author Block:

C. R. Marks[1], B. Wawrik[1], I. A. Davidova[1], M. J. McInerney[1], S. Pruitt[2], K. E. Duncan[1], J. M. Suflita[1], A. V. Callaghan[1]; [1]Univ. of Oklahoma, Norman, OK, [2]Oglethorpe Univ., Atlanta, GA

Abstract Body:

Background: Anaerobic biodegradation of recalcitrant and water-insoluble substrates, such as paraffins, poses unique metabolic challenges for microorganisms. We investigated the activation mechanism(s) and requisite organisms involved in the methanogenic mineralization of long chain *n*-paraffins.**Methods:**An anaerobic consortium that mineralizes long chain *n*-alkanes (C_{28}-C_{50}) under methanogenic conditions was enriched from San Diego Bay sediment. The phylogenetic composition and metabolic potential of the microbial community were interrogated via metagenomics and comparative analyses of binned draft *"Smithella"* genomes. Alkane activation by addition to fumarate was investigated via RT-PCR analysis of the catalytic subunit of alkylsuccinate synthase (*assA*).**Results:**Analysis of 16S rRNA genes indicated the dominance of Syntrophobacterales and Methanomicrobiales. Draft genomes were assembled of dominant community members belonging to the bacterial genus *Smithella* and the archaeal genera *Methanoculleus* and *Methanosaeta*. Five contigs encoding *assA* genotypes were detected in the metagenome, and mRNA transcripts for these genes, including a homolog binned within the *"Smithella"* sp. SDB genome scaffold, were detected via RT-PCR. Genomic analysis revealed a membrane-bound FeS oxidoreductase and putative formate dehydrogenases and hydrogenases within the "*Smithella*" sp. SDB scaffold.**Conclusions:**Metabolic reconstruction, transcript analyses, and comparison with genome scaffolds of uncultivated *n*-alkane degrading *"Smithella"* spp. suggest that syntrophically growing *"Smithella"* spp. activate *n*-paraffins by 'fumarate addition' and may achieve reverse electron transfer by coupling the reoxidation of ETF_{red} to a membrane-bound FeS oxidoreductase functioning as an ETF:menaquinone oxidoreductase. Subsequent electron transfer could proceed via a periplasmic formate dehydrogenase and/or hydrogenase, allowing energetic coupling to hydrogenotrophic methanogens such as *Methanoculleus*. These data provide fundamental insight into the energy conservation mechanisms that regulate interspecies interactions pertinent to methanogenic alkane mineralization.

A Long-chain Paraffin-degrading Consortium and the Potential for Steel Corrosion Under Defined Redox Conditions

Author Block:

I. A. Davidova, R. Liang, K. Duncan, B. Wawrik, J. Suflita; The Univ. of Oklahoma, Norman, OK

Abstract Body:

An archaeal and bacterial consortium was enriched for almost a decade in the absence of sulfate for its ability to mineralize large molecular weight paraffin hydrocarbons ($\geq C_{25}H_{52}$) to stoiciometrically expected amounts of methane. Molecular analysis of the consortium revealed predominant deltaproteobacterial families, including the *Syntrophaceae* that are incapable of reducing sulfate, as well as typical sulfate reducing taxa including, *Desulfobacteraceae, Desulfovibrionacea and Desulfobulbaceae.* Upon amendment, the consortium was able to reduce sulfate when $C_{28}H_{58}$ served as an electron donor. After three transfers, sulfate reduction far exceeded methanogenesis in either the absence or presence of the paraffin. The corrosivity of the consortium to carbon steel was evaluated by measurement of coupon weight loss, dissolved iron concentration and profilometry as a function of both electron donor (i.e. elemental iron or paraffin) and acceptor (sulfate) status. The mild steel corrosion rate increased from 1.2 ± 0.3 mpy (milli-inch per year) up to 9.6 ± 0.8 mpy when sulfate was available to the microorganisms. Other measures of corrosion were similarly increased in the presence of sulfate. When cultivated with iron as a potential electron donor, sequencing of 16S rRNA gene amplicons revealed that 69.9% of bacterial reads were affiliated with *Desulfobulbus* and 15.6% were classified as *Desulfovibrio.* Apparently, sulfate-reducing bacteria were capable of direct electron withdrawal from iron and to catalyze corrosion in the absence of any organic substrate. Efforts are underway to isolate the requisite organism(s).

High Frequency of *Thermodesulfovibrio* spp. and *Anaerolineaceae* in Association with *Methanoculleus* spp. in a Long-Term Incubation of *n*-Alkanes-Degrading Methanogenic Enrichment Culture

Author Block:

B. Liang[1], B-Z. Mu[1], **J-D. Gu**[2]; [1]East China Univ. of Sci. and Technology, Shanghai, China, [2]The Univ. of Hong Kong, Hong Kong, China

Abstract Body:

Background: Alkanes are quantitatively the most significant components of petroleum hydrocarbons and they were considered hard-biodegradable in the absence of oxygen, nitrate or sulphate in petroleum reservoirs for a long time. Stable consotium obtained through enrichment culturing with long-term stability for methanogenic alkane degradation can eliminate the inactive members to larege extent so that the essential ones can be promoted. **Methods**: a methanogenic alkanes degrading consortium was established after enrichment culturing and long-term of incubation amended with mixture of n-alkanes as the sole sources of carbon and energy. The succession of microbial community and potential functional genes were analyzed using PCR and clone libraries coupling with quantitative PCR analysis in this study. Both degradation intermediates and product methane were also quantified. **Results**: A net increase of methane as the end product was detected in the headspace of the alkanes amendment enrichment cultures through hydrogenotrophic methanogenesis pathway; degradation intermediate metabolites including octadecanoate, hexadecanoate, isocaprylate, butyrate, isobutyrate, propionate, acetate and formate were measured in the liquid cultures. The composition of microbial community shifted through the enrichment transfer and a stable methanogenic alkanes-degrading microbial consortium was formed. **Conclusions**:Bacterial and archaeal 16S rRNA clone libraries and *mcrA* functional gene clone library analysis showed that bacteria of *Thermodesulfovibrio* (49.4%) and *Anaerolineaceae* (33.3%) syntrophically cooperated with the archaeal *Methanoculleus* (100%) as the dominant members performing the alkane degradation and methanogenesis. The presence of *assA* functional genes encoding the alkylsuccinate synthase α-subunit indicated that fumarate addition mechanism should be involved in the initial activation of alkanes.

Microbial Reduction of Co_2 and the Dominant Pathway of Methanogenesis in Production Water from High Temperature Oil Reservoirs Amended with C^{13} Labelled Bicarbonate

Author Block:

G-C. Yang[1], J-D. Gu[2], **B-Z. Mu**[1]; [1]East China Univ. of Sci. and Technology, Shanghai, China, [2]The Univ. of Hong Kong, Hong Kong, China

Abstract Body:

Background: The oil reservoirs are special ecosystem, which are natural anaerobic bioreactor with the potential ability to convert CO2 to methane with unique microorganisms. The objectives of this study were to assess the potential of bioconversion of CO2 to methane with indigenous microorganisms from oil reservoirs under microcosm conditions.**Methods:** The microcosm study was conducted with amendment of different concentrations of C13 labelled bicarbonate (0~90 mM) and ethanol to investigate microbial CO2 reduction to methane using the production water from high temperature oil reservoirs as inoculum.**Results:** Higher amounts of methane were detected in the treatments with higher bicarbonate addition, but little methane in the treatment without bicarbonate, indicating that bicarbonate was an important substrate for methanogenesis in the testing systems. The stable isotopic data showed that bicarbonate were converted to methane by methnogens through the CO2-reducing methanogenesis. The bicarbonate and ethanol addition impacted the microbial community differently. The dominant bacterial group in the initial inoculum and control treatment was Thermodesulfovibrio, but the majority in the treatments of bicarbonate additions was Synergistetes. The prevalent archaea also changed from Methanosarcinales in the inoculum to Methanobacteriales in all the amended treatments. **Conclusions:** The results showed that the dominant pathway for ethanol-driven CO_2 fixation in the microcosms was through the conversion of ethanol to acetate linked with syntrophic acetate oxidation and CO_2-reducing methanogenesis. These results suggest microbial CO_2 conversion and alternative biochemical pathways of methanogenesis in the presence of bicarbonate and ethanol in oil reservoirs.

Metagenomic Characterization of Soil Microbiota in Polluted Mangrove Swamp Using Bioinformatic Approach

Author Block:

C. C. NWANKWO, G. C. OKPOKWASILI, C. J. OGUGBUE; Univ. OF PORT HARCOURT, PORT HARCOURT, Nigeria

Abstract Body:

The quest for insights into soil microbial diversity using the metagenomics approach has emerged as a veritable tool for ecological study since majority of the microbes cannot be cultured in the laboratory using traditional techniques. Microbial population studies in the crude oil polluted Niger Delta ecosystem have relied mainly on traditional techniques rather than the metagenomics approach. In this study, a population-based understanding of the ecology of bioremediation was undertaken by investigating the diversity of microbial population and the patterns of their responses to hydrocarbon pollution and interactions in the mangrove swamp. Taxonomic study of three georeferenced crude oil contaminated swamps with known pollution history(Cawthornne Channel II, Bodo West and Bille) and three pristine sites with no pollution history were studied using Next Generation Sequencing technique to determine the nucleotide sequences of all microorganisms present in the swamp sample using the Genome sequencer 454 or Illumina, data sets generated were analyzed using bioinformatics. Results show that the polluted swamps had 23 bacterial classes whereas, 20 bacterial classes in the unpolluted swamp. In the polluted swamp samples, 6 classes had relative abundance greater than 2%; No-hits or potential novel bacteria (49.08%); Beta proteobacteria (30.78%); Gamma Proteobacteria (4.9 %); Uncultured bacteria (4.85%); Actinobacteria (3.29%) and Gamma proteobacteria (2.72%). On the other hand, 6 bacterial classes obtained in unpolluted swamps had a relative abundance greater than 2%: Bacilli (25.5%), No hits (24.3%), Beta proteobacteria (16.12%), Uncultured bacteria (12.83%), Actinobacteria (11.34%) and Alpha-proteobacteria (2.83%). Hierarchical clustering analysis based on overall patterns of variation showed distinct microbial communities in relation to geographical locations and this spatial species distribution was attributed to the monitored geochemical parameters of polluted swamps. The findings of this study have established that geochemical parameters influence the frequency, variability and microbial compositions in the different crude oil contaminated and pristine sites studied. Effective bioremediation strategies in the mangrove ecosystem will depend on the knowledge and manipulation of these geochemical parameters.

Population Dynamics And Community Composition Of Ammonia Oxidizers And Relationships With Nitrification Rates In Salt Marshes After The Macondo Oil Spill

Author Block:

A. E. Bernhard[1], R. Sheffer[1], J. Marton[2], B. Roberts[2], A. Giblin[3]; [1]Connecticut Coll., New London, CT, [2]Louisiana Universities Marine Consortium, Chauvin, LA, [3]The Ecosystems Ctr., Woods Hole, MA

Abstract Body:

The recent oil spill in the Gulf of Mexico had significant effects on microbial communities in the Gulf, but impacts on nitrifying communities in adjacent salt marshes has not been investigated. We studied persistent effects of oil on ammonia-oxidizing archaeal (AOA) and bacterial (AOB) communities and their relationship to nitrification rates and soil properties in Louisiana marshes impacted by the Deepwater Horizon oil spill. Sediments were collected at oiled and unoiled sites from Louisiana coastal marshes in July 2012, two years after the spill, and analyzed for community differences based on ammonia monooxygenase genes (*amo*A). TRFLP analysis of bacterial and archaeal *amo*A genes and DNA sequence analyses revealed significantly different AOA and AOB communities among the three regions, but few differences were found between oiled and unoiled sites. Community composition of nitrifiers was best explained by differences in soil moisture and nitrogen content. Despite the lack of significant oil effects on overall community composition, we identified differences in correlations of individual populations with potential nitrification rates between oiled and unoiled sites that help explain previously published correlation patterns. Our results suggest that exposure to oil, even two years post-spill, has led to subtle changes in population dynamics. How, or if, these changes may impact ecosystem function in the marshes, however, remains uncertain.

Dominance of the Genus, *Bacillus* in Soil Spiked with Polycyclic Aromatic Hydrocarbons

Author Block:

H. M. RAJI[1], J. B. AMEH[1], S. A. ADO[1], S. E. YAKUBU[1], G. WEBSTER[2], A. J. WEIGHTMAN[2]; [1]AHMADU BELLO Univ., ZARIA, ZARIA, Nigeria, [2]CARDIFF Univ., CARDIFF, United Kingdom

Abstract Body:

Soils contaminated with petroleum products are usually inhabited by bacteria and fungi adapted to the use of these hydrocarbons for their metabolic needs. Polycyclic aromatic hydrocarbons (PAHs) have the potential to be toxic and carcinogenic to living organisms, and they are persistent pollutants in soils, sediments and the aquatic environment. In this study, soil was obtained from a site close to a stream receiving petroleum refinery effluent, and spiked with PAHs. The possible effect of these hydrocarbons on the diversity of bacteria in the soil sampled was determined using phylogenetics and Shannon diversity index. Genomic DNA was extracted from soil at two depths from the site and the bacterial 16S rRNA gene analysed by PCR-DGGE, prominent bands were excised and sequenced. The Shannon diversity index was determined based on the presence and number of prominent bands on the DGGE profile. Similarity searches on the NCBI database revealed that all the 16S rRNA sequences from the study site were closely related to the genus, *Bacillus* (96%-100%). *Bacillus* species have been known to degrade many pollutants in the environment including PAHs, however there is no apparent reason for the selective dominance of this genus in the soil sampled. The soils spiked with PAHs had more prominent bands on DGGE gel than those samples not spiked with the PAHs, and they also produced better PCR amplicons. The soil sampled from a depth of up to 40cm had slightly more bacterial species than the soil sampled between 17 - 20 cm, with respect to the PAH treatments, the sample spiked with chrysene had significantly more bacterial species compared to the control and the soils spiked with either phenanthrene or benzo[a]pyrene.**Methods:**Extraction of genomic DNA, PCR-DGGE analysis of 16S rRNA gene, Determination of Shannon diversity index, Phylogenetic analysis of 16S rRNA sequences**Results:**The genus, *Bacillus* was the only phylum identified in the site based on similarity searches on the NCBI website. Majority of the 16S rRNA sequences identified were in the soil spiked with chrysene. The Shannon diversity index was found to be 2.4424**Conclusion:**The presence of pollutants such as PAHs in the soil could affect the diversity of bacterial species in such environments.

Microbial Response to Crude Oil Contamination of Freshwater Stream

Author Block:

J. A. SHENGE; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

The impact of crude oil contamination emanating from oil exploration activities in Nigeria is devastating, affecting mostly aquatic lives, however, the effects on fish and other large aquatic forms are frequently studied, while the microbial population are less studied hence, underrepresented. We conducted microbial examination of freshwater samples in culture before and after contamination with crude oil and monitored for four weeks.Crude oil-free freshwater sample (temperature 26^{o} C; pH 7.0) was collected from upstream and downstream ends of Gbelede stream located at the University of Ibadan. Bacterial isolation was done using a Plate Count Agar and modified nutrient agar enriched with 1ml of crude oil to encourage the isolation of petroleum hydrocarbon degraders, at a dilution factor of 10^{-1} to 10^{-6} , total number of colonies were expressed as colony forming units per ml (Cfu/ml). Thereafter, stream was impacted with 500ml of Forcados crude oil obtained from Shell Petroleum Development Company, collection of contaminated sample was made daily at two hours interval, four times a day, for four weeks.Six bacterial species (*Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa, Enterococcus faecalis, Bacillus subtilis, and Streptococcus sp*) were isolated from uncontaminated freshwater samples (control). Four (66.6%); *Staphylococcus aureus, Escherichia coli*; *Enterococcus faecalis* and *Streptococcus sp,* were eliminated at 2hr (1.2m) after contamination, microbial population increased at 4hr, 6hr, and 8hrs at distances of 2.4m, 3.6m and 4.8m respectively. 2 (33.3%); *Pseudomonas aeruginosa and Bacillus subtilis* were proliferating suggesting that *P. aeruginosa and B. subtilis* are`petroleum hydrocarbon utilizers.Our results show that microbial species of a freshwater decreases with crude oil contamination, while oil utilizers among the species thrive under same condition. This study has pointed out the need for regular microbial examination and environmental impact assessment of freshwater, to understand microbial dynamics, preserve their population and prevent environmental degradation .This may help to identify hydrocarbon utilizers, their ability to degrade crude oil and exact microbes to introduce to utilize crude oil and clean up polluted freshwater environment.

Purification and Characterization of a Solvent, Surfactant and Oxidizing Agent Tolerant Protease from *Bacillus cereus* Isolated from the Gulf of Khambhat, India

Author Block:

K. N. Shah[1], K. H. Mody[2]; [1]Gujarat Energy Res. and Management Inst., Gandhinagar, India, [2]Central Salt and Marine Chemicals Res. Inst., Bhavnagar, India

Abstract Body:

Twenty-eight organic solvent tolerant bacteria were isolated from crude oil contaminated samples, out of which, AK1871 isolate produced a solvent, detergent and oxidizing agent tolerant serine alkaline protease. Based on the morphological and biochemical characteristics, FAME analysis as well as 16S rRNA gene sequence, the isolate is identified as *Bacillus cereus*. A 58-fold purification of protease was achieved by a three-step purification procedure. This protease is active over a broad range of pH (6.0-9.0, optimum at 8.0); and temperature from 40 °C to 70 °C (optimum at 60 °C). Li^{+}, Ba^{2+}, K^{+}, Mg^{2+} and Mn^{2+} did not affect, while heavy metals like Cr^{3+}, Hg^{2+} and Cu^{2+} inactivated the enzyme. It is stable in the presence of non-ionic detergents (Triton X-100 and Tween 80), and oxidizing and bleaching agents (hydrogen peroxide). The protease exhibited noteworthy stability and activation in the presence of organic solvents with log *P* values equal to or more than 2.0. This protease could be used in detergent formulations, enzymatic peptide synthesis, biotransformation reactions and in the formulation of antifouling agent.Keywords: Organic solvent stable bacteria, *Bacillus cereus*, Organic solvent stable protease, Serine alkaline protease.

Microbial Community Structure in Mining and Drilling Impacted Appalachian Stream Sediments

Author Block:

L. J. Bird[1], T. Kondratyuk[2], K. H. Nealson[1], J. F. Stolz[2]; [1]Univ. of Southern California, Los Angeles, CA, [2]Duquesne Univ., Pittsburgh, PA

Abstract Body:

Drilling for natural gas has increased in the Appalachian region in recent years, particularly in West Virginia and Pennsylvania. Along with runoff from coal mining in the region, this boom in fossil fuel extraction activity has the ability to impact local waterways through small leaks and accidental spills of drilling fluids. We hypothesize that inputs from fossil fuel activity into nearby streams may impact the microbial community structure of freshwater sediments in the region. We used 16S rDNA sequencing to conduct microbial community structure analysis of 75 sites in West Virginia and Pennsylvania in the fossil fuel extraction zones. The sites are divided into un-impacted, impacted by mine drainage, impacted by drilling activity, or impacted by both mining and drilling. Sequencing results were combined with a variety of water quality parameters using correspondence analysis to determine the correlation between community differences among the collected sediments and water pH, ion concentrations, metal concentrations, and site history. We here report the correlations between community structure and diversity and aquatic chemistry parameters.

Culture Dependent Analysis of Bacterial Diversity Associated with Processed Salads

Author Block:

A. Bano; Univ. of the punjab, lahore, Pakistan

Abstract Body:

The main objective of the present study was to evaluate the biosafety of the raw-eaten fresh salad by exploring the general microbial diversity. For this purpose, more than hundred bacterial strains were isolated from the fresh salad of different localities in Lahore, Pakistan, by using variety of selective and enriched media. 16S rRNA gene sequencing showed the presence of bacterial strains belong to the genera of *Bacillus, Staphylococcus, Proteus, Macrococcus, Haemophilus, Escherichia, Citrobacter, Enterobacter, Salmonella, Shigella, Klebsiella* and *Acinetobacter.* Antibiotic susceptibility pattern against different antibiotics showed that majority of the strains were resistant against amoxicillin and ampicillin. Strains were also evaluated for biofilm formation, swarming motility, slime production and virulence inhibition. Maximum biofilm production in monocultures was observed by the strains *B. cereus* C35, *M. caseolyticus* C96, *S. saprophyticus* Ms99, *B. pumilis* C49, *K. pneumonia* Mc910. In the presence of carbon sources, *S. saprophyticus* Ms99 and *M. caseolyticus* C96 showed significant biofilm formation at 1 % and 3 % fructose, over control. Similarly, *H. influenza* C410 gave promising results at 3 % lactose. *P. mirabilis* L21 and *P. mirabilis* B33 were strongly positive for swarming motility; whereas *En. cloacae* E47, *B. cytotoxicus* B33, and *P. mirabilis* E11 were intermediate for slime production. In conclusion, fresh salads from different localities of Lahore were inhabited by different bacterial genera. Human potential pathogen like *E. coli* was isolated from salad which indicated fecal contamination. Some potential human pathogens such as *En. cloacae, K. pneumoniaea, B. cereus, S. dysentriae, H. influenza, S. saprophyticus* were also identified that make the biosafety of salad sources questionable. They can cause harmful health effects in their consumers.

Microbial Characterization of Pombe Samples Implicated in 75 Deaths in Mozambique, 2015

Author Block:

J. L. Brzezinski; United States Food and Drug Admin., Cincinnati, OH

Abstract Body:

In January, 2015, at least 75 people died and 177 were hospitalized following the consumption of a traditional beer called pombe in the village of Chitima in the Tete province of Mozambique. The symptoms included diarrhea, muscle aches, vertigo, nausea, dizziness, convulsions, aggression, agitation, and hallucinations. Deaths were preceded by coma and cardiovascular arrest. The cause of the illnesses and deaths were unknown. During the course of the investigation into this event, samples of the pombe and corn flour were obtained, and subjected to a battery of chemical and microbiological testing. The pombe and corn flour were enriched in trypticase soy broth and plated to a variety of selective and non-selective media, yielding a variety of bacteria and fungi, including *Bacillus, Pediococcus, Candida, Enterobacter* and *Rhizopus* species. After the identification of the bacterial toxin, bongkrekic acid, in the pombe and corn flour samples, targeted analysis revealed the presence of *Burkholderia gladioli*, the organism which produces this toxin, in the corn flour starting material. The symptoms of bongkrekic acid poisoning are consistent with those observed in the sickened patients. The identification of this organism was confirmed using 16S rDNA sequencing, and *in vitro* toxin production experiments determined that this strain is capable of producing bongkrekic acid. Taken together, these results suggest that the deaths in this case were caused by fatal bongkrekic acid intoxication, caused by contamination of the corn flour with *B. gladioli*. Foodborne bongkrekic acid poisoning had previously been reported in both China and Indonesia; this is the first reported incidence of bongkrekic acid poisoning in Africa.

Analysis of Aflatoxin Content of Groundnut Cakes Sold in Ekiti State, Nigeria

Author Block:

R. I. Aboloma, Fajilade T.O and Oyebode J.A; The Federal Polytechnic, Ado-Ekiti, Nigeria

Abstract Body:

Ground nut cake(Kuli Kuli) is a fried product made from ground nut. It is a delicacy or snack which is consumed as an accompaniment to many foods. Ground nut has been implicated in mycotoxin contamination of food and feed stuff so it is thought that its use in production of kuli kuli could lead to contamination. Aflatoxin is a toxic metabolite produced by the mold *Aspergillus flavus* on the substrate which it grows. This toxin has been implicated in many disease conditions like hepatotoxicity, immune suppression, stunting in children etc. The present work was therefore undertaken to ascertain the safety or otherwise of Kuli kuli sold in the study area. Samples of Kuli Kuli were collected randomly from sellers in the 3 agricultural zones of the state. Samples were collected randomly from sellers in the 3 zones. They were then analysed for Aflatoxins B1, B2, G1, G2 using standard methods. The data obtained were subjected to statistical analysis of variance and means were separated using Duncan Multiple Range Test. The results showed that there was significant difference ($p<0.05$) in the values of Aflatoxin types in the kuli kuli samples. The levels of Aflatoxin B1 in all but one sample were higher than 20ppm which is the permissible level in food. There was no significant difference in Aflatoxin contents of Kuli Kuil from the 3 agricultural zones. It was concluded that Kuli Kuli produced and sold in Ekiti state is not fit for human and animal consumption. It was recommended that the food regulation agency(NAFDAC) should standardise production of Kuli kuli to ensure food safety.

Bacteriological Quality of Street Vended Foods in Ado-Ekiti, Ekiti State, Nigeria

Author Block:

R. I. Aboloma, T. O. Fajilade; The Federal Polytechnic, Ado-Ekiti, Nigeria

Abstract Body:

Unregulated food vending in public places has become a common practice in Ado-Ekiti with attendant increase in food borne diseases. This research was therefore undertaken to understand the role of food vendors in transmission of food borne bacterial pathogens. Samples of street vended foods were examined for presence of pathogens. These foods were randomly bought from fifty (50) food vendors as soon as they were prepared ready for sale in major public places like motor parks, markets and street corners. In the laboratory, the samples were stored in the refrigerator at 4°C until needed for analysis. Each of the food samples was cultured on Nutrient, Mackonkey and Deoxycholate Citrate agar, incubated at 37°C for 24 hours. The demographic data of the vendors were also obtained via questionnaires. The results obtained showed that many genera of bacteria contaminated the foods beyond acceptable levels. The most frequently occurring bacteria in order of occurrence were *Staphylococcus aureus*(90%),*Enterobacter aerogenes*(85%) *Bacillus cereus*(66%), *Escherichia coli*(54%), *Pseudomonas aeroginosa*(30%) *Salmonella* sp(18%), *Serratia marcescens* (10%). It was therefore concluded that with extra care most of these pathogens will be prevented from contaminating foods. Education of Food vendors on proper food handling methods was finally recommended.Keywords: Food, Bacteriological, Street-Vended

The First Detection of Florfenicol-Resistant Gene in Shiga-Like Toxin Producing *Escherichia coli* Isolated from Pork in Korea

Author Block:

J-S. Moon; Animal and Plant, Quarantine Agency, Anyang-si,Gyeonggi-do, Kosovo, Republic of

Abstract Body:

Background: Florfenicol is fluorinated derivative of chloramphenicol and represent highly protein inhibitors of bacterial protein biosynthesis. It is used in veterinary medicine or feed additives for pigs in Korea. The transfer of antibiotic resistance gene among the bacterial strains has become a problem worldwide, so drug resistant bacterial phenotypes should be identified. In this study, antimicrobial resistance and resistance gene were investigated for *Escherichia coli* (*E. coli*), especially shiga-like toxin producing *E. coli (*STEC) isolated from pork in Korea. **Methods:** We monitored 301 pork samples in slaughter houses and retail markets, and isolated 50 strains of *E. coli*. Among these isolates, six isolates resulted in STEC. Minimum inhibitory concentration (MIC) on six strains was performed for 14 antibiotics, ampicillin, amoxicillin/clavulanic Acid, cefoxitin, ceftiofur, cephalothin, florfenicol, ciprofloxacin, colistin, gentamicin, nalidixic acid, neomycin, streptomycin, tetracycline and trimethoprim/Sulphamethoxazole, and three strains showed high MIC to florfenicol and chloramphenicol (64 ug/mL). PCR was conducted to detect the florfenicol resistant gene (*floR*) and the chloramphenicol resistant gene (*cat*). **Results:** All of 3 strains contained the *floR*, while none of them had the *cat*. These PCR products were sequenced and aligned to obtain homology with other available genes in reference GenBank. A BLAST search showed that they contained sequences with homology to the *floR* gene of *E. coli* or *Salmonella enteric* serovar Heidelberg. **Conclusions:** This is the first report to detect *floR* gene in STEC isolated from slaughtered pigs in Korea. These results suggest that some STEC isolates in Korea carry florfenicol resistant gene and transfer this gene to other bacterial strains.

Shiga Toxin (*stx*) Gene Analysis and Verotoxigenic Potentials of *Escherichia coli* Isolated from 'Bobozi'- Indigenous Nigerian Ready-To-Eat Fermented Cassava Chips

Author Block:

S. A. Enabulele[1], E. O. Daniel[1], R. O. Ohenhen[2]; [1]Benson Idahosa Univ., Benin City, Nigeria, [2]Ambrose Alli Univ., Ekpoma, Nigeria

Abstract Body:

Background: Many strains of *E. coli* have been identified as food borne pathogens inducing serious gastrointestinal diseases and even causing death in humans. Among these are those referred to as Shiga or Vero toxin producing *E. coli*. Bobozi is an Indigenous Nigerian ready to eat snack food made from cassava and is widely consumed in most parts of the country. The objective of this study was to Isolate and Identify *E. coli* from Bobozi, analyze their Shiga toxin (*stx*) gene profile and thereafter determine their verotoxin capabilities.**Methods:** A total of 248 samples of Bobozi were purchased from hawkers in the metropolis of Benin City, Edo state, Nigeria. Isolation and Identification was done using standard microbiological methods. Analysis for the presence of Shiga toxin (*stx1* and *stx2*) genes was done using PCR technique and for their verotoxigenic potentials using tissue culture assay on Vero cells.**Results:** Result of the investigation reveals that of the total 248 samples collected, 107(43.15%) had *E. coli* isolated from them. Total number of *E. coli* isolated from the 107 samples was 386. Shiga toxin gene analysis of the isolates reveal that 169(43.78%) had *stx1* gene alone, 112 (29.02%) had *stx2* gene alone, 3(0.78%) had both *stx 1* and *stx 2* genes while 102 (26.42%) had none of the two genes. Tissue culture assay on Vero cells indicate that there is a strong relationship between the presence of *stx* genes and their degree of cytotoxic effect on vero cells as over 80% isolates without the genes exhibited weak cytotoxic effect whereas over 80% of those with the genes exhibited more than strong cytotoxic effect.**Conclusions:** The findings from this study provide evidence of the presence of Shiga toxin producing *E. coli* in our food system and this can be of serious health challenge especially as Bobozi is a Ready to eat food that is consumed without further processing. It is recommended therefore that more measures be taken in monitoring the processing and sale of such food products to prevent potential food borne disease outbreak.

Characterization of Shiga Toxin-Producing *Escherichia coli* Isolates from Retail Meats in Korea

Author Block:

J. B. Lee, D. Han, H. T. Lee, J. W. Yoon; Coll. of Vet. Med. & Inst. of Vet. Sci., Kangwon Natl. Univ., Chuncheon, Korea, Republic of

Abstract Body:

Shiga toxin-producing *Escherichia coli* (STEC) is a zoonotic bacterial pathogen causing hemorrhagic colitis and a life-threatening hemolytic uremic syndrome. Consumption of raw or undercooked meat is the most common route of transmission of STEC. Recently, we isolated 7 STEC strains carrying one or both Shiga toxin genes (*stx1* or *stx2*) from 434 retail meat samples in Korea. Here, the seven STEC isolates were further characterized in terms of their serotypes, virulence potentials, and phylogenetic relatedness. We showed that all the STEC isolates belonged into the 4 different serotypes; O91:H14 (3 strains), O91:H21 (1), O121:H10 (2), and Ont:H20 (1). The two STEC O91:H14 isolates were non-motile although they had a functional copy of the *fliC* gene encoding the H antigen. The PCR analyses revealed that none of them carried the *eae*, *tir*, and *espB* genes, implying the absence of the LEE pathogenicity island encoding the Type 3 secretion system. Instead, the 2 STEC O91:H14 isolates had the *subAB* toxin genes with both *saa* and *iha* genes, previously known as the alternative adhesins for STEC. The STEC O91:H21 and Ont:H20 isolates possessed the *cdt-V* toxin gene encoding the cytolethal distending toxin. As expected, all the STEC isolates harbored plasmids of various sizes, but only 4 STEC isolates were PCR positive to the STEC O157:H7 pO157-encoded *ehxA*, *espP*, or *katP* genes required for full virulence of STEC. Notably, the L-glutamate-induced acid tolerance phenotypes of the STEC isolates were varied depending on the expression of GadA although no significant differences were observed in the RpoS-induced acid resistance. Both antibiogram and PFGE analyses demonstrated that all the STEC isolates were susceptible to the antimicrobials evaluated and one possible clonal set was identified between the two STEC O91:H14 isolates. Our results demonstrated the recent prevalence of STEC isolates among retail meats in Korea as well as their genetic and phenotypic properties. Further study might be needed to elucidate the *in vivo* virulence of the STEC isolates.

Prevalence of *Salmonella, Escherichia coli* O157 and Listeria monocytogenes Contamination of Chickens and Quails Eggs in Lagos State, Nigeria

Author Block:

O. O. Ishola, T. Olubade; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: The prevalence of Salmonella, Escherichia coli O157 and Listeria monocytogenes contamination in chickens and quail eggs from commercial farms and sold in markets in Lagos state, Nigeria was investigated. **Methods**: total of 510 eggs (240 chicken and 270 quail eggs) were randomly selected from 10 farms and 10 markets from the five Administrative Areas. Isolation of Salmonella, E. coli O157 and L. monocytogenes was done from enrichment samples using standard cultural and biochemical procedures. Antibiotics profiling, total aerobic counts and coliform counts were done using standard methods. **Results:**The chicken eggs had prevalence of 100% each for Salmonella, E. coli O157 and L. monocytogenes. The quail eggs sampled had prevalence of 100% each for Salmonella and E. coli O157 but with a prevalence of 61.8% for L. monocytogenes. Mean total aerobic count (Log CFU/ml) and mean total coliform count (Log CFU/ml) for the chicken eggs were 6.79 and 6.54, respectively. The mean total aerobic count for quail eggs from the farms was 6.67 while from the markets was 6.69. The mean coliform count (Log CFU/ml) from quail eggs from the farm was 6.30 while from the markets was 6.42. All the Salmonella and E. coli isolates were highly sensitive to Ofloxacin and Nalixic acid but resistant to Cotrimoxazole and Tetracycline. All the Listeria isolates were highly sensitive to Gentamycin and resistant to Cotrimoxazole. **Conclusions:** This study suggests that eggs from these farms and offered for sale in these markets were harbouring Salmonella, E. coli and Listeria. Poultry and personal hygiene should be improved to control these zoonotic pathogens of poultry and eggs.

Isolation and Characterization of Antimicrobial Resistant Non-Typhoidal *Salmonella enterica* Serovars from Imported Food Products

Author Block:

D. Bae, O. Kweon, A. A. Khan; U.S. FDA/Nat'l. Ctr. for Toxicol. Res., Jefferson, AR

Abstract Body:

Background: Unlike mild gastroenteritis by non-typhoidal *Salmonella* (NTS) infection, severe systemic infections including bacteremia or meningitis, can occur in immunocompromised persons. Fluoroquinolones and β-lactams are widely used to treat the life-threatening systemic infections. However, the emergence of multidrug resistant strains is a global health concern. The objective of this study was to determine antimicrobial resistance in 110 NTS isolates from food products imported into the US during the period from 2011 to 2013. **Methods:** One hundred ten NTS were isolated from a variety of imported food products (n = 3,840). The disk diffusion agar and the microdilution assays were performed for antimicrobial susceptibility testing using 10 antimicrobials. A combination of PCR, DNA sequencing, and plasmid analyses were performed to characterize antimicrobial resistance determinants. **Results:** Twenty-three out of 110 *S. enterica* isolates were resistant to various antimicrobial classes including β-lactam, aminoglycoside, phenicol, glycopeptide, sulfonamide, trimethoprim, and/or fluoroquinolone antimicrobials. Twelve of the isolates were multi-drug resistant strains. Antimicrobial resistance determinants, including *bla*$_{\text{TEM-1}}$, *bla*$_{\text{CTX-M-9}}$, *bla*$_{\text{OXA-1}}$, *tetA, tetB, tetD, dfrA1, dfrV, dhfrI, dhfrXII, drf17, aadA1, aadA2, aadA5, orfC, qnrS* and mutations of *gyrA* and *parC* were detected in one or more antimicrobial resistant NTS isolates. Plasmid profiles showed that 12 of the 23 antimicrobial resistant strains harbored plasmids having incompatibility groups IncFIB, IncHI1, IncI1, IncN, IncW, and IncX. **Conclusions:** Our study indicates that imported foods contaminated with multidrug resistant NTS may contribute to the spread of antimicrobial resistance genes and potentially compromise the therapeutic activity of antimicrobials. In addition, the data generated from the integrated research approaches reported in this study could be useful for investigations of foodborne illness outbreaks linked to domestic and international food facilities.

***Campylobacter jejuni* Contamination of Raw Bovine Milk in Oyo State, Nigeria**

Author Block:

O. I. Olatoye, A. Ogunsemoyin; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Dairy development and commercialization in Nigeria from local herds require microbial safety evaluation. This study determined the prevalence and antibiotic susceptibility of Campylobacter species isolated from milk of dairy herds in Oyo State. **Methods:** Bulk raw milk samples (n=300) were aseptically collected into Amies transport medium fromthree milk collection centres during June to September 2014. These were cultured for campylobacter and characterised using standard methods and further tested to commonly used antibiotics by breakpoint method.**Results:** Campylobacter species were isolated from 264 samples (88.0%) prevalence) comprising 349 strains of Campylobacter spp, out of which 70 (20.1%) were confirmed to be Campylobacter jejuni. The isolates were 100.0% resistance to nalidixic acid, gentamicin, erythromycin and 38.0% resistance to enrofloxacin.**Conclusions:** The high prevalence obtained couldresult from milking of mastitic cows, unhygienic milk handling andtransportation, while antibiotic resistance could be due tounregulated drug use in dairy herds. Hygienic milking, dairyproduction and processing education will ensure milk safety while Consumption of raw/improperly pasteurized milk should be discouraged.

Antimicrobial Resistance and Molecular Characterization of *Campylobacter coli* in Ceca and Carcass of Poultry in Lebanon

Author Block:

S. Fadlallah[1], R. Hajj[2], Z. Nasser[3], N. Ghosn[3], W. Ammar[3], **G. M. Matar**[1]; [1]American Univ. of Beirut, Beirut, Lebanon, [2]Lebanese Agriculture Res. Inst., Fanar, Lebanon, [3]Ministry of Hlth., Beirut, Lebanon

Abstract Body:

Background: *Campylobacter* is the primary bacterial cause of human intestinal infections worldwide; poultry products being the main source of contamination. This study assessed the prevalence of *Campylobacter* spp. in chicken carcass and ceca collected at two slaughterhouses in Lebanon, determining their antimicrobial resistance profiles and detecting genomic diversity within the species. **Methods:** Fifty one *Campylobacter* positive isolates (carcass: 13 and caeca: 38) were obtained from the Lebanese Agriculture Research Institute (LARI) through the Ministry of Health (MOH). *Campylobacter* isolates were identified biochemically according to the standard ISO 10272: 2006. Species identification was confirmed by the 16 S rRNA gene sequence analysis. Antimicrobial susceptibility testing (AST) was performed using a wide range of β lactam agents and tetracycline. PCR detection of the bla_{OXA-61} and *tet(0)* genes in resistant and susceptible isolates to ampicillin and tetracycline respectively was determined. Genomic diversity of the isolates was determined using Random Amplified Polymorphic (RAPD) and BIONUMERICS analysis. **Results:** Sequencing revealed that all tested isolates were *Campylobacter coli*. AST showed resistance in the isolates to cephalothin and aztreonam (100%), cefamandol and cefoxitin (98%), tetracycline (94%), ampicillin (49%), amoxicillin (46%), piperacillin (45%), carbenicillin (36%), ticarcillin (20%), ceftazdime (17%), cefotaxime (8%) and amoxdicillin-clavulanic acid (2%). All ampicillin-resistant isolates and 84% of the ampicillin-sensitive ones carried the bla_{OXA-61} gene. All tetracycline-resistant isolates were positive for the *tet* (O) gene with 96% encoded on plasmids. The tetracycline sensitive isolates were negative for the *tet* (O) gene. RAPD analysis revealed 9 distinct clusters with a minimum percentage of 43.5% genomic similarity. **Conclusion**: This study emphasizes the importance of surveillance in identifying and controling commonly circulating food borne pathogens and calls out for implementation of food safety measures.

Prevalence and Antibiotics Resistance *Campylobacter jejuni* in Retail Chickens in Oyo State, Nigeria

Author Block:

A. Ogunsemoyin, O. Olatoye, J. Y. Adeseko; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Increasing demand and production of animal protein in Nigeria require safety assessment of associated food borne pathogens for consumer protection. Unhygienic handling of chickens during processing is a common practice at retail markets and poultry slaughter slabs in Nigeria with possibility of foodborne pathogen contamination including Campylobacter. Published data on Campylobacter in poultry meat in Nigeria are scanty. **Methods:** In this study, Campylobacter jejuni were isolated from chicken samples obtained from retail markets in Ibadan to determine the prevalence and antibiotic susceptibility using Campylobacter standard culture technique. **Results:** Out of 252 chicken samples collected, Campylobacter jejuni was isolated in 242 (96.0% prevalence) samples. Susceptibility test indicated that the isolates were 100.0% resistance to nalidixic acid, gentamicin, and erythromycin and resistance of 38.0%, 46.0%, 50.0% and 58.0% to enrofloxacin, chloramphenicol, streptomycin and tetracycline respectively. **Conclusions:** Food safety risk could result from direct contamination and cross contamination of carcasses during evisceration and unhygienic rinsing of multiple carcasses from different farms. While the high resistance to commonly used antibiotics could be due to unregulated misuse of veterinary drugs commonly practiced in Nigerian poultry production. Prudence use of antibiotics in poultry, hygienic handling and thorough cooking of poultry products will ensure food safety.

A Naturally Occurring MutY Mutation Promotes the Emergence of Spontaneous Oxidative Stress Resistant Mutants in *Campylobacter jejuni*

Author Block:

L. Dai, Q. Zhang; Iowa State Univ., Ames, IA

Abstract Body:

Campylobacter jejuni is a leading cause of foodborne illnesses worldwide. As a microaerophilic organism, *C. jejuni* has to defend against the oxidative stress encountered both in the host and in the environment. Recently we identified a *C. jejuni* mutator isolate CMT, with a naturally occurring mutation in MutY, promoting the emergence of antibiotic-resistant mutants. We also observed CMT conferred reduced susceptibility to oxidant treatment, but the underlying mechanisms remains unclear. This study was aimed to determine how CMT contributes to oxidative stress resistance in *C. jejuni*. *C. jejuni* isolates were assayed for oxidative stress susceptibility to a mixture of paraquat and H_2O_2. Spontaneous oxidative stress resistant (OX^R) mutants were subjected to qRT-PCR and sequencing for mutations in oxidative stress related genes. Site-specific reversion and EMSA were conducted to link the OX^R phenotype with *perR* mutations in *C. jejuni*. A promoter-reporter fusion P_{katA}-*cat* was utilized to determine spontaneous OX^R mutation frequencies of *C. jejuni* isolates. Results showed that CMT was more resistant to oxidant treatment than the wild-type *C. jejuni* isolate. Disk inhibition assay revealed the presence of spontaneous OX^R mutants in *C. jejuni* which are highly resistant to oxidant treatment. Notably, CMT demonstrated a spontaneous OX^R mutation frequency that was >100-fold higher than that of the wild-type strain. Transcription of *katA* and *ahpC* genes were significantly upregulated in these OX^R mutants, with over 500-fold increase for *katA* compared with that in the wild type. Sequencing results revealed that all *C. jejuni* OX^R mutants carried mutations in the transcriptional regulator gene *perR*. In the CMT background all *perR* mutations were G→T or C→A transversion, while in the wild-type background *perR* mutations were short (1~2 bp) deletions or insertions. Site-specific reversion and EMSA proved that the identified *perR* mutations were responsible for the OX^R phenotype. The mutator phenotype caused by a *mutY* mutation increases the loss-of-function mutation rate of *perR*, which results in the malfunction of PerR and the derepression of PerR-controlled oxidative stress defense genes, thereby promoting the emergence of OX^R mutants in *Campylobacter*.

Molecular Analysis and Toxigenic Potential of *Vibrio cholerae* Isolated from Hilsha Fish (*Tenualosa ilisha)*, Bangladesh

Author Block:

Z. Hossain[1], I. Farhana[1], S. Tulsiani[2], P. Jensen[2], A. Begum[1]; [1]Univ. of Dhaka, Bangladesh, Dhaka, Bangladesh, [2]Univ. of Copenhagen, Copenhagen, Denmark

Abstract Body:

Exposure to contaminated fish may upsurge the virulent strains of *Vibrio cholerae*, the deadly human pathogen in the households of rural and urban Bangladesh. Since *V. cholerae* spreading was reported from the Bay of Bengal, this study hypothesized that Hilsha (*Tenualosa ilisha)*, a marine and fresh water fish may serve as a transmission vehicle of potential emerging epidemic causing strains.We studied 9 toxigenic *V. cholerae* strains isolated from Hilsha fish including 6 *V. cholerae* O1 and 3 non O1/O139 serogroups for virulence associated genotype and their pathogenic potential on animal model and human cancer cell line. The study also analyzed clonality by genetic fingerprinting and *rpoB* gene sequencing.The *V. cholerae* O1 strains possessed diverse virulence genes but lacked some major toxin genes like *ctxA*, *tcp* etc. The non O1/O139 strains harbored genes for type III (T3SS) and type VI secretion systems (T6SS). Eight of the nine strains showed survivality up to 10% sodium chloride in broth culture which indicates their coastal origin. All nine isolates were able to accumulate fluid in rabbit ileal loops. Cell free culture supernatant of three O1 and two non O1 strains caused distinctive cell death in established HeLa cell line. Diverse polymorphic patterns were revealed in Random amplified polymorphic DNA (RAPD) fingerprinting except two non O1 isolates (I-49d and I-52a) showed considerable correlation in band patterns. Similar restriction fragment length polymorphism (RFLP) profile of *groEL*-I of *V. cholerae* chromosome 1 in all strains indicated homogeneity in species level. Hierarchical cluster analysis by β subunit of RNA polymerase gene (*rpoB*) sequencing showed that theses isolates did not cluster together and also distinct from clinical and environmental toxigenic strains.Our results indicate the indigenous *V. cholerae* strains associated with Hilsha fish possesses considerable virulence potentiality despite being quite diverse from current epidemic strains. In a cholera epidemic-prone region like Bangladesh, surveillance research on this fish species is vital to control the evolution of outbreak strains of *V. cholerae.*

Detection and Molecular Characterization of *Vibrio parahaemolyticus* in the Clam *Phacoides pectinatus* and the Oyster *Crassostrea rhizophorae* from the Southwest Coast of Puerto Rico

Author Block:

K. E. Correa-Velez, H. M. Nieves-Rosado, M. Chaparro-Serrano, C. Rios-Velazquez; Univ. of Puerto Rico at Mayaguez, Mayaguez, PR

Abstract Body:

Bivalves such as clams and oysters are filtering mollusks that inhabit aquatic environments. These filter feeder organisms can accumulate bacterial species such as *Vibrio parahaemolyticus*. Recently, the Centers for Disease Control and Prevention estimated a higher incidence (7,880 cases/year) of *Vibrio* infections, where approximately 2,800 cases were associated with *V. parahaemolyticus*. The Food and Drug Administration (FDA) recognized this bacterium as leading cause of human gastroenteritis associated with seafood consumption. In Puerto Rico, there are no laws or regulatory agencies that assess bivalve quality for sale. Therefore, the Island does not have statistics on foodborne disease incidence caused by consumption of raw bivalves. This research sought the detection of *V. parahaemolyticus* in both raw bivalves consumed in PR, and established the potential of pathogenicity of the isolates. This study used standardized tests including molecular protocols established by the FDA in the Bacteriological Analytical Manual for the detection of *V. parahaemolyticus* strains in oyster and clam samples from the southwest coast. The enrichment on alkaline peptone water, the selection of *Vibrio* on Thiosulfate Citrate Bile Salts Sucrose and differentiation of species based on growth in different concentrations of NaCl were performed as standardized test. Finally, molecular analysis involved the use of Multiplex PCR to detect the presence of *V. parahaemolyticus* pathogenic associated genes. After 4 seasonal samplings, 58 strains of presumptive *V. parahaemolyticus* were isolated, where 36% were able to grow at 3%, 6% and 8% of NaCl. Also, 64% of the isolates grew in 10% of NaCl. Based on species specific marker amplicon, and the absence of pathogenic genes signal, 90% of the isolates in the study are *V. parahaemolyticus* and none of them are potentially pathogenic. This study has demonstrated the absence of pathogenicity markers in *V. parahaemolyticus* isolated from mollusk samples from the southwest coast of PR. Comparisons with isolates from patients with diarrhea associated to bivalve consumption will provide more information on potential foodborne disease associated to raw shellfish consumption from these waters.

Publishing Title:

Evaluating the "Hot" Oyster: A Healthy Oyster Containing Elevated Levels of *Vibrio parahaemolyticus*

Author Block:

S. L. Klein, C. R. Lovell; Univ. of South Carolina, Columbia, SC

Abstract Body:

Outbreaks of the pandemic, emergent human pathogen *Vibrio parahaemolyticus* are increasing in size and frequency, and are occurring at higher latitudes. The United States Food and Drug Administration (FDA) estimates that there are approximately 4,500 cases of *V. parahaemolyticus* gastroenteritis per year in the United States; however, this could be a significant underestimate, as most cases are self-limiting and do not require hospitalization. Symptoms of *V. parahaemolyticus* gastroenteritis occur 24 to 72 h after ingestion of raw or undercooked seafood, usually oysters. Constant monitoring of *V. parahaemolyticus* densities within oysters is required due to recent *V. parahaemolyticus* outbreaks at locations usually considered to be too cold for *V. parahaemolyticus* (i.e.: Alaska, Chile, and the Baltic Sea). Relatively little is known regarding *V. parahaemolyticus* loads in individual oysters as monitoring protocols usually entail homogenizing several oysters together prior to analysis.A total of 110 oysters were harvested from two sampling sites, one a site of commercial oyster harvest (Whale Branch in Beaufort, SC) and the other a pristine comparison site (North Inlet in Georgetown, SC). The majority of oysters sampled (98%) contained levels of presumptive *V. parahaemolyticus* deemed safe for consumption by the FDA. However, two oysters from these sites contained presumptive *V. parahaemolyticus* densities that exceeded “safe levels” established by the FDA. After dissections, it was determined that the two “hot” oysters contained densities of presumptive *V. parahaemolyticus* within the gills that were approximately 100-fold higher than the average. Current FDA protocols for detection of *V. parahaemolyticus* require homogenizing a dozen oysters together, which might result in dilution of *V. parahaemolyticus* from the “hot” oysters to acceptable levels. *V. parahaemolyticus* gastroenteritis due to ingestion of the relatively rare “hot” oyster could explain why *V. parahaemolyticus* gastroenteritis is an illness that is sporadic and somewhat difficult to predict.

Identification of Synergistic Antimicrobial Combinations to Control *Listeria monocytogenes* in an Acidified Broth System

Author Block:

S. M. Kozak, D. J. D'Amico; Univ. of Connecticut, Storrs, CT

Abstract Body:

Effective approaches using antimicrobials to reduce *Listeria monocytogenes* levels in ready-to-eat (RTE) foods and prevent pathogen growth have been identified. However, concerns with approved usage levels, cost, development of resistance, and negative sensorial changes can limit these applications. The identification of combinations of antimicrobials to produce additive or synergistic effects is desirable in an effort to limit usage levels without diminishing inhibitory or bactericidal effects. A broth micro-dilution assay was utilized to identify minimum inhibitory (MIC) and bactericidal concentrations (MBC) of antimicrobials when used alone or in binary combinations against an eight-strain cocktail of *L. monocytogenes* in growth media adjusted to pH 5.5. When applied singly, lauric arginate (LAE) and hydrogen peroxide (HP) were observed to have the lowest MICs at 10 and 50 ppm, respectively. Similarly, LAE, HP, and ε-polylysine (EPL) had the lowest MBCs at 20, 100, and 300 ppm, respectively. A total of six combinations resulted in reduced MICs while three combinations resulted in reduced MBCs. Fractional inhibitory and bactericidal concentration indices (FIC_I and FBC_I) from combination antimicrobial treatments were calculated to characterize these antimicrobial interactions. Of the four inhibitory combinations, the interaction of acidified calcium sulfate with lactic acid (ACSL)- octanoic acid (OA) was identified as synergistic ($FIC_I = 0.52$) while dihydroxybenzoic acid (DHBA)-LAE ($FIC_I = 0.67$) and ACSL-OA ($FIC_I = 0.62$) were moderately synergistic. The remaining interactions of ACSL-EPL, EPL-OA, and ACSL-HP were additive in the inhibition of *L. monocytogenes*. The bactericidal interactions of EPL- sodium octanoate (SO) ($FBC_I = 0.23$), ACSL-SO ($FBC_I = 0.19$), and HP-EPL ($FBC_I = 0.58$) were also identified as synergistic. In the present study the most effective inhibitory combination of ACSL-OA reduced the assay pH from 5.5 to 5.03 while a pH of 5.09 was noted for ACSL-SO. Reductions in pH resulting from antimicrobial combinations must be considered in future applications. Additional studies are necessary to identify the mechanisms of action for the combined treatments. The efficacy of antimicrobial combinations must also be determined when used as surface treatments and in the reformulation of RTE foods.

Lyngby, Denmark, [2]Federal Univ. of Goiás, Goiania, Brazil, [3]Univ. of São Paulo, Pirassununga, Brazil, [4]Univ. of São Paulo, Ribeirão Preto, Brazil

Abstract Body:

Staphylococcus aureus is one of the most common food-borne pathogenic bacteria and enterotoxigenic strains can cause food poisoning due to the production of heat-stable enterotoxins. *S. aureus* can contaminate several foods including dairy products. This is a challenge in the Brazilian dairy industry where soft cheese as Minas cheese, produced from either raw or pasteurized milk, is widely consumed and mainly produced in small dairy plants. The aim of this study was to evaluate the contamination rate of *S. aureus* in Minas cheese production plants and investigate if the contamination was caused by persistent clones or repeated introduction of new clones. Also we assessed the potential health risk of isolates. Five dairy plants were sampled during 8 months (421 samples in total). Using phenotypic tests and 16S rRNA gene sequencing, *S. aureus* (n=66) was found in 4 of 5 of the dairy plants. The contamination rate varied from 0% to 63.3% depending on the processing plant and the sampling date. Multi-Locus Sequence Typing was used to type and assess potential persisting Sequence Types (ST). Seven known ST (ST1, ST5, ST30, ST97, ST126, ST188 and ST398) were identified. Three new ST were identified and all belong to Clonal Complex (CC) 1 which was the dominant CC in the investigated dairy plants. However, there was no indication of reoccurring ST in the plants. The isolates were screened for resistance to 11 antibiotics recommended for control of *S. aureus* using the disk diffusion method. Only 16 isolates (24.2%) were resistant and only to 1 to 4 antibiotics. However, all of the isolates were methicillin sensitive *S. aureus* and presumptive non-vancomycin resistant. Despite a low level of antibiotic resistance of those isolates, the frequent isolation of CC1 strains, known to be an epidemic CC, indicates a potential risk for human health suggesting that surveillance of *S. aureus* should be improved.

Vancomycin Non-Susceptibility and Co-Existing Virulence Determinants in *Enterococcus faecalis* Isolated from Traditionally Processed Fish Products of India

Author Block:

K. Biswas, S. R. Joshi; North Eastern Hill Univ., Shillong, India

Abstract Body:

Background: Fermented foods are frequently consumed in different parts of Northeast India. These are often reported to act as reservoir of pathogenic organisms that disseminate within the community complicating the treatment option. *Enterococcus faecalis* are often responsible for contamination of food products. The current study dealt with investigation of glycopeptide non susceptible enterococci found in traditionally processed foods and their co-existing virulence determinants.**Methods:** Susceptibility testing was performed for a total of 46 *E. faecalis* isolates obtained from fermented fish samples. Minimum inhibitory concentrations (MIC) of vancomycin was determined by the agar dilution method. PCR assays were performed targeting various vancomycin resistance genes and 6 virulence determinants (*efaAfs, cpd, esp, agg, cylA,* and *gelE*). Plasmids were isolated and purified from *vanA, vanC$_1$, esp* and *gelE* harbouring isolates. Transformation by heat shock method was carried out to assess plasmid transfer.**Results:** 82.6% (n=38) of *E. faecalis* isolates showed MIC of vancomycin at 124 µg/ml while 17.3% (n=8) of the isolates showed MIC of less than 4 µg/ml. Molecular characterization revealed presence of *vanA* (n=33), *vanB* (n=7), *vanC$_1$* (n=4) and *vanC$_{2/3}$* (n=2). Two of the isolates showed the presence of all the four resistance genes. *gelE, agg* and *esp* were present in 17, 13 and 5 isolates respectively. *cpd* and *efaAfs* was found in all the isolates whereas *cyl* could not be detected. *vanA, vanC$_1$, esp* and *gelE* were detected in plasmid DNA and these genes could be horizontally transferred from the host to *E. coli* DH5α. PCR analysis also yielded positive results for the presence of these genes on the plasmids of the transformants.**Conclusions:** The simultaneous occurrence of virulence determinants and vancomycin resistance genes in enterococci from the traditionally fermented fish products consumed in Northeast India pose a potential threat of transmission of these risk factors to humans through the food chain. This study, the first of its kind, highlights the importance of *E. faecalis* as a reservoir of resistance and virulence genes and their potential transfer to humans through consumption. Overall, these findings reopen the issue of food safety of enterococci prevalent in traditionally processed products.

Evaluating the Extraction Efficiency of Food Borne Pathogens on Automated Homogenizer Platforms

Author Block:

S. Garrett, J. Atwood, B. Easparro; Omni Intl., Kennesaw, GA

Abstract Body:

There is an ever increasing demand for food and beverage manufacturers to adhere to rigorous food safety regulations. As part of the global need for safe food, food and beverage manufacturers test their products for the presence of food borne pathogens. While safety regulations describe what pathogens should be controlled through testing there is no predefined method of sample preparation or detection. Typically, the first step in a food borne pathogen detection study is the disaggregation of the food product or the washing of the sample to release bacteria from the food surface using a Stomacher. While the later method is great for large masses of food stuffs, some researchers may require small amounts of product for analysis. Bead mill homogenizers, as well as rotor-stator homogenizers, can be used to aid in the sample preparation process. Processing can be completed in less than one minute while maintaining bacterial cell and analyte integrity. Depending on the pathogen of interest and the food matrix, the downstream results, including sensitivity can vary greatly based on the sample preparation method chosen. With this is mind, we analyzed two sample preparation techniques on commonly contaminated foods. Meat and spinach samples were inoculated with known levels of recombinant *Escherichia coli* expressing Green Fluorescent Protein. The inoculated samples were processed on a bead mill homogenizer and an automated rotor-stator homogenizer. The homogenates were grown on nutrient agar and the proportion of viable cell recovery was quantified. Limit of detections were determined by lysis of recovered homogenates, DNA purification and PCR amplification. It was determined that both homogenization techniques were able to process food samples for the extraction of live cells and plasmid DNA. The processing efficiency can deliver a 76% cell recovery with a PCR detection limit to $1x10^{-5}$ CFUs/ml. A linear relationship was demonstrated between the number of CFUs to intensity of DNA amplified via PCR. A detection limit of 10^{-5} CFUs is comparable to some food testing methods; however the vigorous processing of bead mill and rotor stator technology has the potential to eliminate the standard pre-enrichment step needed for the detection of food pathogens.

Hyperspectral Images and Differences During Growth of *Salmonella enterica* Typhimurium Chemotypes

Author Block:

R. D. Riggs, K. Wade, I-H. Chen, J. M. Barbaree; Auburn Univ., Auburn, AL

Abstract Body:

BackgroundHyperspectral imaging (HSI) is currently being utilized in a variety of research and is being utilized for detection purposes. Eady and group used HSI to differentiate serotypes of *Salmonella* at various time points in order to characterize the surface chemistries of each of the serotypes.[1] Salmonella is an organism of particular interest in the food industry considering it is estimated to cause illness in 1 million people in the United States annually with symptoms of fever, severe cramping and diarrhea.**Methods**In this study we used the Cytoviva hyperspectral imaging system to elicit the individual hyperspectral profiles produced by *S. enterica* serotype Typhimurium lipopolysaccharide mutants at one hour post stationary phase, or 9 hours, and at 18 hours post inoculation. All organisms were cultured in Luria-Bertani (LB) broth, pelleted at 10,000x rpm and washed in 1x PBS buffer prior to imaging. 0.8 μL of each sample was transferred to a poly-l-lysine coated slide for immobilization and topped with a glass cover slip.Data is collected by the pushbroom approach during which an image is generated that contains both hyperspectral and spatial data by moving the sample pixel line by pixel line to generate distinct profiles for each specimen. The use of a patented enhanced darkfield condenser in conjunction with high resolution optical and hyperspectral imaging creates spectral profiles based upon the unique surface chemistries of each chemotype. The hyperspectral profiles of five cells were composed from each image through the ENVI software.**Results**All of the rough mutants were compared to the wild type and differences in the wavelength at which peak intensity of reflectance of the light were not seen at 1-hour post stationary phase as expected. However, differences in the overall hyperspectral curves produced by each were seen. Significance between chemotypes was noted at 18 hours when comparing one mutant to the smooth wild type through statistical analysis.**Conclusion**In conclusion, the Cytoviva HSI system was not capable of detecting differences in the lipopolysaccharide mutants of *S.* enterica Typhimurium at 9 hours; yet significance can be seen as early as the 18-hour time point.

Microwave Cell Lysis and Dna Fragmentation of *Listeria monocytogenes*

Author Block:

T. Santaus, C. Geddes; Univ. of Maryland, Baltimore County, Baltimore, MD

Abstract Body:

The central hypothesis being addressed, is *can microwaves effectively and efficiently lyse cells of Listeria monocytogenes, and what is the effect on DNA fragmentation size (distribution) post heating.* Listeria monocytogenes is of particular interest because it is a deadly food borne bacterial pathogen with a mortality of 20-30% of those who get infected. People with a compromised immune system and pregnant women are more likely to suffer the effects of Listeriosis.[1] The Listeria bacterium can grow under extreme conditions such as low pH and high temperatures. Places that are most likely to transmit the bacterium are food processing plants. Once Listeria is contracted in the human body, it can cross in to the blood, through the blood brain barrier, and into the cerebral spinal fluid.[2] Most of the common DNA extraction and detection methods are slow, costly, and require multiple steps for cell lysis, DNA fragmentation and purification.The method used includes a standard Frigidaire 900 W microwave, a custom slide holder, and microscope slides equipped with an isolator for the sample and metallic microwave focusing geometries, optimized to condense microwaves into a small sample volume. A sample is heated at a specific power and time to lyse the cells and fragment the genomic DNA. Post lysis, a Varian Absorption Spectrometer and a Fluoromax 4P are used to analyze the annealing process of the DNA. Ethidium bromide and SYBR gold™ are the fluorescent molecules being used to study the changes in [*ss*DNA], as compared to [*ds*DNA] over a period of 3 hours. Both standard Gel electrophoresis and high resolution micro-gel techniques are used to determine the fragmentation patterns and distributions observed from microwave-based lysing.In this study we demonstrate that *Listeria monocytogenes* DNA can be efficiently and rapidly extracted and fragmented using metal microwave focusing lysing triangles and a conventional microwave. Post microwave lysis, solution DNA readily anneals forming *ds*DNA observed by an increase in ethidium bromide fluorescence. Our microwave based lysing approach[2] has the particular advantages in that it can fragment the Listeria genome to much smaller DNA fragments, which is ideal for rapid detection using the MAMEF (Microwave-Accelerated Metal-Enhanced Fluorescence) platform[3], as well as the potential for combining cell lysing and DNA fragmentation into one rapid and low cost step.

Pcr Time Real for Detection of *Salmonella* spp. and *Listeria monocytogenes* in Food of Markets of Guadalajara, México

Author Block:

Y. Lugo-Melchor[1], I. Higuera-Ciapara[1], M. Renteria-Ledezma[1], M. Novoa-Palazuelos[2]; [1]Centro de Investigación y Asistencia en Tecnología y Diseño del Estado de Jalisco, Guadalajara, Mexico, [2]Inst. Tecnológico y de Estudios Superiores de Occidente, Tlaquepaque, Mexico

Abstract Body:

Background: Foodborne diseases, caused by pathogenic microorganisms, are a major public health problem worldwide. In Mexico, the detection of food pathogens in routine laboratories is still mostly based upon traditional microbiological methods. Thus, the availability of reliable, rapid and accepted test systems to detect the presence or absence becomes increasingly important for the agricultural and food industry. Real-time PCR (RT-PCR) is currently used for the diagnosis of infectious agents, and there are reports of the application of RT-PCR for the direct detection of *Salmonella* spp. and *Listeria monocytogenes*. The aim of this study was to use RT-PCR for Detection of *Salmonella* spp. and *Listeria monocytogenes* in food of markets of Guadalajara, México.**Methods:** A total of seventy-four different samples of food from markets was evaluated for *Salmonella* and forty samples for *Listeria monocytogenes* using a commercial kit of RT-PCR. The results were confirmed by traditional methods based on the Mexican official standard.**Results:** Different types of samples as meat, sausage, vegetable and dairy products was analyzed. Only 1.35% (1/74) of the samples was positive for *Salmonella* spp. In case of *Listeria monocytogenes*, all samples showed absence of the pathogen.**Conclusions:** The findings of this study indicated the presence of several *Salmonella* spp. in food of the markets is a risk for health for consumers. The study showed that RT-PCR is a valuable alternative to determine Salmonella spp. in foods for their specifity and sensibility.

Comparison of Immunomagnetic Separation Beads for Detection of Non-O157:H7 Shiga Toxin-Producing *Escherichia coli* in Complex Matrices

Author Block:

A. L. Kraft[1], W. L. Shelver[2], J. Sherwood[1], T. M. Bergholz[1]; [1]North Dakota State Univ., Fargo, ND, [2]USDA, Fargo, ND

Abstract Body:

An emerging concern in public health and food safety in the United States involves the need to accurately and efficiently detect six serotypes of Shiga toxin producing *Escherichia coli*, which include O26, O45, O103, O111, O121, and O145. Since these non-O157:H7 adulterants thrive in the GI tract of cattle, it is necessary to use reliable detection methods that will work effectively in various matrices such as cattle feces, ground beef and fresh produce, which can be exposed to these pathogens by fecal contamination. Immunomagnetic separation (IMS) used in conjunction with culture based methods has been a useful technique in the detection of pathogens. However, an assessment has not been performed on the extent that matrices or normal flora influence recovery of isolates of each serotype by IMS. Initially, samples of sterile phosphate buffered saline (PBS) were inoculated with a 1cfu/ml concentration mixture of isolates representing the six serogroups. After a 6h incubation at 37C, the samples were mixed with three different commercially available IMS beads and plated on eosin methylene blue agar with vancomycin, cefsulodin and cefixime (EMB-VCC). Three suspect *E. coli* colonies were selected from the EMB-VCC and multiplex PCR was used to determine the serotype. Next, IMS was used in samples of sterile feces in order to gauge the effects of a matrix. To evaluate the beads further by adding competing flora, IMS was performed with non-sterile fecal samples. Three replicates were performed for each bead type, STEC serogroup, and sample type. The most consistent results came from one IMS bead manufacturer with 100% correct identification for four serogroups in PBS and >88.9% correct identification in five serogroups in sterile feces. Conversely, rates of false positives rose for some serogroups in samples that had competing normal flora and a complex matrix such as for the O103 serogroup rising from 10%, 5.3%, and 10% in sterile feces to 21.7%, 40%, and 50%, respectively, in non-sterile feces for the three IMS bead manufacturers. These results suggest that matrix and IMS bead type markedly influence the ability to accurately recover these six serogroups. More research on specific sample preparation should be done to improve the efficacy of recovery of these serogroups with IMS from various matrices.

Using Multiplex-PCR to Detect Virulence Factor Genes from *vibrio Parahaemolyticus* Isolates from the Oyster *crassostrea Rhizophorae* from Puerto Rico

Author Block:

H. M. Nieves-Rosado, K. E. Correa-Velez, M. Chaparro, C. Rios-Velazquez; Univ. of Puerto Rico, Mayagüez, Puerto Rico

Abstract Body:

The detection of pathogens in food involves the use of diverse culture dependent and independent approaches such as selective-differential media, serological methods and molecular techniques. The Food and Drug Administration (FDA) has recommended the use of PCR, DNA hybridization and a modified version of PCR, known as Multiplex-PCR. This technique involves the use of more than one set of primers to amplify different DNA sequences simultaneously in one polymerase chain reaction. Recently, reports for the Center for Disease Control and Prevention indicate that the outbreaks of *V. parahaemolyticus* increases 52% compared with 2006-2008 incidences. In Puerto Rico, there are no regulatory agencies that control the handling and quality conditions for selling raw shellfish such as oysters. Detection of pathogenic strains of *V. parahaemolyticus* from environmental samples can allow us to potentially predict and compare outbreaks in PR with other countries and will develop awareness to local population about the health issues that can potentially be caused by eating raw seafood. Our goal is to determine the pathogenic levels of *V. parahaemolyticus* isolates from the oyster *Crassostrea rhizophorae* from the southwest coast of PR. DNA extractions were performed from presumptive *V. parahaemolyticus* strains previously isolated using TCBS media. The extracted DNA was processed following standardized multiplex-PCR protocol recommended by the FDA in the Bacteriological Analytical Manual. Multiplex PCR was performed for the amplification of *tdh* (270bp) and *trh* (500bp) genes associated with pathogenic activity; and *tlh* (450bp) a specie specific marker. *V. parahaemolyticus* O4:K12 strain 48057 (NR-21990) ATCC® was used as a positive control. From the analysis of a total of 9 isolates, all of them resulted positive to *V. parahaemolyticus* based on the presence of a *tlh* gene amplicon and none of them resulted to be pathogenic due to the absence of a *tdh* and *trh* amplicons by modified electrophoresis in a 3% agarose gel. While the isolates analyzed in this study lack pathogenic activity and do not represent a risk to population, future monitory is necessary using this molecular techniques to detect the pathogenic levels of any *V. parahaemolyticus* isolated from the coasts of PR.

Immunomagnetic Separation Combined with Multiplex Polymerase Chain Reaction for Rapid Detection of *Salmonella* in Chicken Meat

Author Block:

B. Liu, C. Lei, A. Zhang, R. Xiang, H. Wang; Animal Disease Prevention and Food Safety Key Lab. of Sichuan Province, Coll. of Life Sci., Sichuan Univ., Chengdu, China

Abstract Body:

Background: Foodborne salmonellosis poses a threat to human health worldwide. The most common human nontyphoidal salmonellosis is caused by *S.* Typhimurium and *S.* Enteritidis, both of which are frequently found in contaminated meat. However many methods used to identify them are labor-intensive and time-consuming. Here we developed a method based on immunomagnetic separation combined with multiplex polymerase chain reaction (IMS-mPCR) for rapid detection of *Salmonella* and differentiation of *S.* Typhimurium and *S.* Enteritidis in chicken meat. **Methods:** The immunomagnetic beads (IMBs) were synthesized by immobilizing *Salmonella* polyclonal antibody onto the surface of the amino-silane modified Fe_3O_4 nanoparticles. Three pairs of primers targeting *S.* Typhimurium, *S.* Enteritidis and *Salmonella enterica* were designed for mPCR. The optimization of immunomagnetic separation system was performed. The sensitivity and specificity of the IMS-mPCR and the direct PCR were conducted. Both standard culture method and the IMS-mPCR procedure were used to detect *Salmonella* in 157 chicken meat samples. **Results:** When 150μL of IMBs (10 mg/ml) mixed with 1ml of samples to incubate for 30 min, the immunocapture efficiency was greater than 95%.The detection limit of IMS-mPCR was 10^1 CFU/g of *Salmonella* in chicken meat , which is significantly lower than that of the direct PCR (1×10^4CFU/g). Compared with standard culture method, the coincidence rates of the IMS-mPCR procedure for detecting *S.* Typhimurium, *S.* Enteritidis and *Salmonella enterica* were 99.4%, 98.1% and 98.1% respectively, but the latter only took less than 5 hours.Fig. 1. The flow chart for the detection of *Salmonella* by IMS-mPCR.

Evaluation of a Novel PCR Based System for the Detection of *Salmonella* spp. in a Variety of Food and Environmental Samples

Author Block:

H. P. Dwivedi, P. Chablain*, B. Nahlik, G. Devulder*, J. Mills, S. Bailey, R. Johnson; bioMerieux, Inc., Hazelwood, MO

Abstract Body:

Background: GENE-UP® is a novel PCR based molecular system for as early as same day detection of *Salmonella* in 25g and 375g samples using a very simplified workflow. The performance of GENE-UP molecular system for the detection of *Salmonella* was evaluated against USDA-FSIS reference methods in a variety of food and environmental matrices.**Methods:** The matrices including fresh raw ground beef (25g and 375g samples), fresh raw chicken breast, fresh raw fish, creamy peanut butter, vanilla ice cream, dry pet food (all 25g samples) and stainless steel (sponges) were separately inoculated using different *Salmonella enterica* strains as per AOAC guidelines and analyzed using GENE-UP method. The alternate method results were compared to the USDA-FSIS methods for *Salmonella* (MLG -4.08). The probability of detection (POD) analyses were conducted to compare the method performances.**Results:** All the samples were analyzed at three inoculation levels (un-inoculated, low, high). For samples with low contamination levels (n=20/ matrix), the difference in POD for confirmed alternate and reference methods (measured as $dPOD_C$ values) along with 95% confidence interval were -0.15 (-0.41,0.14) for 25g beef samples and -0.15 (-0.41,0.15) for 375g beef samples; 0.15 (-0.15, 0.41) for raw chicken breast; 0.05 (-0.24, 0.33) for raw fish; 0.15 (-0.13, 0.40) for creamy peanut butter; 0.10 (-0.19, 0.37) for vanilla ice cream; 0.15 (-0.15, 0.41) for dry pet food; and 0.05 (-0.23, 0.33) for stainless steel surface samples. As the confidence interval of all dPOD values contained zero, no statistically significant difference was observed between the alternate and reference methods. For all un-inoculated (n=5/ matrix) and high contamination level (n=5/ matrix) samples, $dPOD_{C\sim}$ values were 0, indicating no statistical difference between the candidate and reference methods.**Conclusion:** No statistical difference was found in the performance of GENE-UP *Salmonella* assay against the USDA reference method. The GENE-UP method offers a significant savings in terms of time and improved convenience when compared to the reference methods. It utilizes a simple one step enrichment, giving same day presumptive results for raw beef samples and next day results for processed food and environmental samples.

Multi-Laboratory Validation of Abrin Detection Method in Foods

Author Block:

A. Minor, Z. Kuhl, B. Keavey; WVDA, Charleston, WV

Abstract Body:

Background: Abrin is an extremely potent bio-toxin produced from the seed of the tropical plant *Abrus precatorius*, commonly found in the southern U.S. and the Caribbean. Abrin toxin inhibits the synthesis of proteins in the cells of an exposed individual, causing severe illness and cell death. Due to the lethality and ease of accessibility, a screening method for the detection of abrin toxin in foods is necessary for biodefense purposes. This study's objective was to provide a multi-laboratory validated method, combining an optimized extraction and commercially available ELISA kit for the detection of abrin toxin in foods. **Methods:** Five participating Food Emergency Response Network / FSIS/ Cooperative Agreement Laboratories analyzed 3 sets, consisting of 18 x 5 g samples for abrin detection in hot dogs, liquid eggs, and liquid infant formula. Samples were homogenized with GBS and the toxins were extracted via centrifugation. Following extraction, the aqueous layers were analyzed in accordance with the ELISA manufacturer's instructions. The validation incorporated replicate sets in three fortification levels and analyzed in duplicate.**Results:**

	Specificity	Sensitivity (Low Fortification)	Sensitivity (High Fortification)	Test Efficiency
Hot Dogs	100% (48/48)	88% (42/48)	100% (48/48)	95.8% (138/144)
Liquid Eggs	100% (48/48)	58% (28/48)	96% (46/48)	84.7% (122/144)
Infant Formula	100% (48/48)	19% (9/48)	96% (46/48)	69.4% (100/144)

Conclusions: The sensitivity for the detection of abrin in all food matrices analyzed, at the high fortification levels, by all participating laboratories was 96% or greater. Low fortification levels were near the LOD for each food, and exhibited a much lower recovery rate. All foods analyzed demonstrated 0 false positives and a specificity of 100%. The data from this multi-laboratory study suggests that the optimized extraction procedure, combined with the ELISA detection assay, may offer a suitable method for the detection of abrin toxin ina variety of foods.

A Novel Nanotechnology-Based Antimicrobial Platform Using Engineered Water Nanostructures for Food Safety Applications

Author Block:

M. Eleftheriadou[1], G. Pyrgiotakis[2], C. de Freitas Cirenza[2], P. Demokritou[2]; [1]European Univ. Cyprus, Nicosia, Cyprus, [2]Harvard Univ., Boston, MA

Abstract Body:

BACKGROUND: Microbial contamination is a leading cause of foodborne illnesses in the US each year[1] with the cost exceeding 15.6 billion USD.[2] There is a need for novel, antimicrobial interventions with the potential to be applied throughout the Farm-to-Fork chain for enhanced safety assurance. A chemical free, nanotechnology-based, antimicrobial platform using Engineered Water Nanostructures (EWNS), produced by electrospraying water, was recently developed. EWNS have high surface charge, are loaded with reactive oxygen species (ROS) and can interact with and inactivate an array of microorganisms of public health significance by causing damage to the cell envelope (Fig 1d). **METHODS:** EWNS were synthesized by concurrently electrospraying and ionizing highly purified water in a lab based EWNs generation system (Fig 1a, b). Characterization of EWNS properties (charge, size and ROS content) was performed using state-of-the art analytical methods[3] (Fig 1c). Microbial inactivation potential was evaluated using food related microorganisms (*E. coli, Salmonella enterica, Listeria innocua, Mycobacterium parafortuitum* and S*accharomyces cerevisiae),* spot inoculated on organic grape tomatoes. **RESULTS:** Microbial reductions were found to be microorganism dependent and ranged between 1.0 to 3.8 logs after only 45 mins of exposure to an EWNS aerosol dose of 40,000 #/cm^3. *E.coli* and *L. innocua* exhibited close to 4 log reductions, *S. enterica* a 2 log reduction while Mycobacterium and Saccharomyces showed a 1 log reduction (Fig 1e). **CONCLUSION:** This novel, low cost, antimicrobial platform is chemical-free, has low environmental impact, is easy to use and leaves no residues in the final food product.

Comparative Characterization of Botulinum Neurotoxin Subtypes F1 and F7 Featuring Differential Substrate Recognition and Cleavage Mechanisms

Author Block:

J. Guo[1], E. Chan[2], S. Chen[2]; [1]Hong Kong PolyU Shen Zhen Res. Inst., Shenzhen, China, [2]The Hong Kong Polytechnic Univ., Hong Kong, Hong Kong

Abstract Body:

Introduction: BoNT/F7, one of the seven subtypes of botulinum neurotoxin type F (F1 to F7)[1], is the second-most divergent subtype of this group. Despite sharing >60% identity with BoNT/F1 at both holotoxin and enzymatic domain levels, it requires an N-terminal extended peptide for efficient substrate cleavage[2], suggesting its unique substrate recognition mechanism but which remain to be elucidated. In order to probe the basis of discrepancy between the molecular mechanisms employed by BoNT/F1[3] and /F7 in recognizing substrate VAMP2, we dissected the substrate recognition mechanism utilized by BoNT/F7 in detail and compared it with that of BoNT/F1.**Method:** LC/F7 and VAMP2 were constructed and purified as previously reported[4]. LC/F7-VAMP2 complex structure was modeled and the possible interacting residues between LC/F7 and VAMP2 were predicted and further proved by performing linear velocity assays and enzyme kinetic analysis.**Results and Significance:** Our data revealed that VAMP2 (20-65) was likely a minimally effective substrate for LC/F7. LC/F7 recognized VAMP2 in a unique way, which differed significantly from that of LC/F1, although both share similar substrate binding and hydrolysis mode. LC/F7 utilizes distinct pockets for specific substrate binding and recognition in particular for the B1, B2 and S2 sites recognitions. Our findings provide insights into the distinct substrate recognition features of BoNT subtypes and useful information for therapy development for BoNT/F. This study also broadens our understanding of the general functional mechanisms of BoNTs and provides essential background knowledge for future development of antitoxins and novel approaches for detecting different subtypes of BoNTs.1.B. L. Hu[1], L. M. Ma[2], S. Zheng[3], H. Wang[1], E. W. Brown[1], T. S. Hammack[1], G. Zhang[1]; [1]U.S. Food & Drug Admin. (FDA), College Park, MD, [2]Oklahoma State Univ., Stillwater, OK, [3]Northeast Agricultural Univ., Harbin, China

Abstract Body:

Loop-mediated isothermal amplification (LAMP) is a novel simple detection technology that amplifies DNA with high speed, efficiency, and specificity under isothermal conditions. The objective of this study was to evaluate the effectiveness of 3M Molecular Detection Assay (MDA) *Salmonella* and ANSR *Salmonella* methods for detecting *Salmonella* from egg products in comparison with Food and Drug Administration (FDA) Bacteriological Analytical Manual (BAM) culture method and a modified culture method. Two *Salmonella* ser. Enteritidis (18579, PT4; CDC_2010K_1441, PT8), one *Salmonella* ser. Heidelberg (607310-1), and one *Salmonella* ser. Typhimurium (0723) isolates were used in this study. Seven wet egg products (e.g., liquid egg yolk, egg nog, etc.) and thirteen dry egg products (e.g., egg rolls cookies, macaroni & cheese, egg matzos, egg yolk powder, etc.) were inoculated with these strains individually at 1-5 CFU/25g. One set of sample processing followed FDA BAM procedures [with Lactose broth as preenrichment broth]. Another set of samples were processed using Buffered Peptone Water (BPW) as preenrichment broth as instructed by the two LAMP detection kits. The 3M and ANSR LAMP assays were 100% in agreement with their BPW based culture method results. The number of *Salmonella* positive test portions (80 tested), identified with the BAM, 3M, and ANSR methods were, 63, 61 and 59, respectively. In conclusion, both the 3M MDA and ANSR LAMP *Salmonella* methods were as effective as their BPW based culture method for the detection of *Salmonella* from egg products. These sensitive LAMP assays could be used as rapid detection tools for *Salmonella* in egg products when BPW was used as preenrichment broth.

Development of a Novel Loop-mediated Isothermal Amplification (Lamp) Assay for the Detection of *Salmonella* ser. Enteritidis

Author Block:

L. Hu[1], L. M. Ma[2], S. Zheng[3], T. S. Hammack[1], E. W. Brown[1], G. Zhang[1]; [1]U.S. Food & Drug Admin. (FDA), College Park, MD, [2]Oklahoma State Univ., Stillwater, OK, [3]Northeast Agricultural Univ., Harbin, China

Abstract Body:

Loop-mediated isothermal amplification (LAMP) is a novel simple detection technology that amplifies DNA with high speed, efficiency, and specificity under isothermal conditions. The objective of this study was to develop a new LAMP assay for the detection of *Salmonella* ser. Enteritidis (SE) from foods. Prot6E gene encoding fimbrial biosynthesis protein was the target for detection. PrimerExplorer V4 software was used to design primers. Eight sets of primers were selected and evaluated for their effectiveness in detecting SE using isothermal master mix (OptiGene, UK), with SE isolates SE12 (Phage Type 14b), 18579 (PT4), and CDC_2010K_1441 (PT8). Ratio of outer and inner primers, amount of DNA template per reaction, reaction temperature and time were optimized using the 3 SE isolates described above. The following primers were determined to be effective in detecting SE: F3 5′-GTGAGGGCGAGGTTTGAAC-3′, B3 5′-GGTCATGGTCGGGTATTCGA-3′, FIP 5′-TCCTCCACTGACAGGATTCCCAAAGTGGAGCAGCTGAGCA-3′, BIP 5′-CAAACTGAACGTTTGGCTGCCTGCAGTGACTGGCATCAAGAA-3′. Inclusivity test using 24 SE isolates was 100% positive. Twenty four non-SE *Salmonella* isolates (24 serotypes) and 20 non-*Salmonella* isolates (10 species) were tested for exclusivity. They were 100% negative. More isolates will be tested. And effectiveness of these primers in detecting SE from egg products is being investigated. These preliminary data showed that the newly designed LAMP assay could be a rapid molecular tool for detecting SE.

Charbohydrate-Active Enzymes from the Zygomycete *Lichtheimia ramosa* Strain h71D

Author Block:

M. Alvarez-Zúñiga[1], J. Ayala-Sumuano[2], C. Cano-Ramírez[1], M. Hidalgo-Lara[1]; [1]Centro de Investigación y Estudios Avanzados del Inst. Politécnico Natl., Distrito Federal, Mexico, [2]Univ. Natl. Autónoma de México, Querétaro, Mexico

Abstract Body:

Background: The phylum Zygomycota is a primitive and early diverging group of fungi that contains approximately 1% of the described species of true fungi (~900 described species). Zygomycetes surround us in our daily life, not only as agents of disease, but also as starters of fermentation in the preparation of food products, and as pioneer degraders in food spoilage. Since many members grow easily in axenic culture and show an impressive morphology, they have been subject of studies since the mid nineteenth century. However, Zygomycetes have been scarcely investigated both genetically and genomically. Fungi produce a variety of carbohydrate activity enzymes (CAZymes) for the degradation of plant polysaccharide materials to facilitate infection and/or gain nutrition. In our working group we are interested in the study of industrial enzymes. **Methodology:** The fungal strain H71D isolated from sugarcane bagasse was chosen because its ability to grow on a wide range of temperatures (heat-tolerant, with optimum growth temperature of 37°C) and present lignocellulosic activity. H71D was identified both morphologically and molecularly (ITS, and secondary structure of the ITS2) as *Lichtheimia ramosa*. The genome of *L. ramosa* was sequenced by Illumina HiSeq 2000 100bp pair-end. **Results:** DNA sequencing resulted in 57,199,250 raw reads. Filtered reads were assembled using SOAPdenovo2 resulting in a draft genome of a 15,915 scaffolds with a N50 size of 4,560, the GC content is 40% and 26,228 predicted protein-coding genes, which were analyzed with Cazymes Analysis Toolkit (CAT). CAZymes annotation resulted in 1160 glycoside transferases (GT), 613 glycoside hydrolases (GH), 322 carbohydrate esterases (CE), 198 carbohydrate-binding modules (CBM), and 146 auxiliary activities (AA). **Conclusion:** The *L. ramosa* genome encodes a collection of CAZymes different of that of other filamentous fungi like ascomycetes and basidiomycetes, *e.g.*, the *L. ramosa* genome encodes higher number of GT than GH compared to ascomycetes (*H. jecorina, C. globusum*, etc) and basidiomycetes (*U. maydis, P. chrysosporium*, etc), suggesting that zygomycetes present different strategies for polysaccharide degradation.

Complete Genome Sequence of *Weissella jogaejeotgali* FOL01^{T}, Isolated from Traditional Korean Fermented Seafood

Author Block:

H-J. Ku, J-H. Lee; Inst. of Life Sci. and Resources, Kyung Hee Univ., Yongin-si, Korea, Republic of

Abstract Body:

Weissella is recognized as lactic acid bacteria and potential probiotics for promoting host health. Most recently, a novel species, *W. jogaejeotgali*, was reported. To understand genomic features of this new species, *W. jogaejeotgali* FOL01^{T} (= KCCM 43128^{T} = JCM 30580^{T}) was isolated from a jogaejeotgal, a traditional Korean fermented salted calm and its genome was completely sequenced and analyzed. The genome sequence of FOL01^{T} was determined using a SMRT® Technology PacBio RS II and analyzed using various bioinformatic programs including GeneMarkS, RAST, BLAST, InterProScan, and JSpecies. The genome consists of a circular chromosome consists of 2,114,163-bp with the GC content of 38.85% and a plasmid pFOL01 consists of 35,341-bp with the GC content of 39.14%. The chromosome has 2,016 open reading frame (ORF), 75 tRNA genes, 8 rRNA operons, and two additional 5S rRNA genes. Among the predicted ORFs, 1,583 ORFs were annotated to encode functional proteins (78.52%) and 433 ORFs were predicted to encode hypothetical proteins (21.48%). pFOL01 were predicted 51 ORFs, containing MobC and RepB genes for plasmid mobilization and replication. 16S rRNA sequence analysis and multilocus sequence typing (MLST) of FOL01^{T} showed that *W. thailandensis* is closely related, probably evolved from a common ancestor. Metabolic pathway analysis revealed that FOL01^{T} utilize heterofermentative sugar fermentation for energy production. In addition, osmotic stress response-related ORFs encoding proline/glycine betaine ABC transport were detected for adaptation in high-salt fermented foods. This is the first report for genome information of a newly identified *W. jogaejeotgali* providing its physiological and genomic properties for further understanding in its role in the fermented foods.

Identification of Background Flora in Ice Cream Associated with a Listeriosis Outbreak

Author Block:

C. J. GRIM, L. S. Burall, A. R. Datta; Food and Drug Admin., Laurel, MD

Abstract Body:

Recently, an outbreak of listeriosis was linked to ice cream products manufactured by a firm with plants in two different states. Enumeration of products from a single line linked to a cluster of illnesses in Kansas indicated that the *Listeria monocytogenes* (*Lm*) contamination had been present at a fairly consistent level for at least nine months. During enumeration work, direct plating of a portion of the samples on RAPID'*L.Mono*™ (RLM) agar, yielded a diverse range of colony phenotypes that did not match any of the typical *Listeria* phenotypes. The level of background flora observed varied and while it was not quantified, it generally appeared to exceed *Lm*. Subsequently, ice cream samples were plated on RLM and incubated at 5°C, room temperature and 37°C. Twenty colonies representing ten general colony phenotypes inconsistent with *Lm* were isolated for characterization via whole genome sequencing. The colonies were presumptively identified by comparing 16S RNA sequences to the NCBI and the Ribosomal Database Project (release 11) databases. The colonies were identified as matching 16S RNA sequences from *Bacillus paralicheniformis, Brevundimonas sp.*, two different *Microbacterium sp.*, isolates, *Microbacterium testaceum, Rhodococcus sp., Sanguibacter keddieii* and *Staphylococcus pasteuri*. We compared the draft genomes of the non-Lm organisms using tetramer frequency and found that, while multiple isolates matched to the same 16S RNA reference sequence, none appeared to have clonal relationships with each other or their reference strains' sequences. Evaluation of the non-*Lm* isolates demonstrated a broad diversity with Gram positive genera present from three different Orders, as well as a Gram negative isolate. Many of the species identified are typically associated with environmental sources, such as plants, soil, and water, as well as industrial settings, and are also known to grow in cold and various other stress conditions, overlapping some of *Lm* growth characteristics. Metagenomic sequencing of the microbiome of the ice cream samples confirmed our culture-based isolations, but revealed even greater diversity. This study helps to more clearly define the complicated nature of the background flora associated with a contaminated food production line that may affect the survival of the pathogen in the facility and the subsequent detection and enumeration of Lm in the samples.

Characterizing Methicillin Resistance in Methicillin Resistant *Staphylococcus aureus* of Swine

Author Block:

C. M. Logue, T. Cavender, D. W. Nielsen, N. Lima Barbieri; Iowa State Univ., Ames, IA

Abstract Body:

Background: Methicillin-associated resistance in *S. aureus* is encoded by the *mecA* gene, carried on the staphylococcal cassette chromosome *mec* (*SCCmec*) resulting in an altered penicillin binding protein (PBB) and reduced susceptibility to the β-lactam antibiotics including penicillin. Until now, detection of *mecA* or PBP was considered an indicator of methicillin resistance and confirmation of MRSA. Recently, new strains of MRSA resistant to methicillin but negative for *mecA* and PBP have been recognized. **Methods:** This study examined the prevalence of *mecA* and *mec* variants in a collection of MRSA and non-MRSA from swine and pork meat. Isolates examined were identified as methicillin resistant on media containing oxacillin. A total of 598 *S. aureus* and non-*S. aureus* strains from production swine at lairage and slaughter and 65 isolates recovered from retail pork were examined for *mec* genes including *mecA*, $mecA_{LGA251}$, *mecA1* and *mecC1* using PCR. Isolates were also subtyped for *SCCmec* using a multiplex PCR. **Results:** Overall most isolates identified as methicillin resistant were positive for the *mecA* gene (n = 521) however, a small collection (n=22) were identified as $mecA_{LGA251}$ positive, but they could not be confirmed as *mecC* using standard primers. Further typing using *mecA1* primers detected this variant in four isolates of both *S. aureus* and non-*aureus* species. Subtyping *mecA* positive isolates using the *SCCmec* typing scheme found the most common subtypes detected included II, IV and VI. A significant number could not be assigned to a subtype using the current scheme and will require further analysis. **Conclusions:** While the emerging *mecC* variant has not been detected in MRSA and non-MRSA of swine to date, our data suggests that there are other emerging novel variants of *mecA* and *mecA1* that would appear to be common. These novel variants may also be a source of, or recipient of resistance and could potentially pose a threat to animal or human health.

Food Plants are a More Efficient Reservoir Than Food Animals for Human Infections with *Salmonella* Newport

Author Block:

M. Yue, S. C. Rankin, D. M. Schifferli; Univ. of Pennsylvania Sch. of Vet. Med., Philadelphia, PA

Abstract Body:

Salmonella enterica remains the leading cause of bacterial foodborne diseases in the U.S. For the last 15 years, serovar Newport (*S.* Newport) has ranked among the three most frequent serovar for human infections. In a retrospective survey by the CDC, 14,811 non-human Newport isolates from 1968 to 2011, approximately half of the clinical isolates were of bovine origin, while nearly one third of the non-clinical strains were food plant and environmental isolates. These findings prompted an accentuated surveillance on bovines to better control the incidence of human infections with *S.* Newport. Surprisingly, our analysis of the 97 *S.* Newport outbreaks with confirmed sources of infection that occurred between 1998 and 2014 indicated that contaminated food plants (53%) were significantly more often the cause than products of land animal origins (32%). A minimum spanning tree based on multilocus sequence typing (MLST) separated 1,787 isolates in three clades that coincided with the origins of isolation (human, animal and environment). The constructed tree indicated that isolates of human origin were more directly related to environmental strains than to animal isolates ($P<0.01$). Moreover, a phylogenomic analysis of 1050 available *S.* Newport genomes clearly grouped over 90% of the land animal genomes together as a distinct cluster. In contrast, both the human and food plant isolates were randomly distributed among clades to the exclusion of the land animal clades, suggesting a greater role of plants than animals for *S.* Newport infections in humans. The environmental and aquatic isolates took an intermediary distribution by preferential associations with some specific clades. Finally, an extensive analysis of the antibiotic resistance profiles for 3,497 *S.* Newport isolates similarly separated human and plant strains from animal isolates of *S.* Newport. Taken together, our findings suggests that Newport joins an increasing number of food plant-associated *Salmonella* serovars that cause foodborne infections in humans. The relative trend in recent years of salmonellosis outbreaks due to food plants calls for improved surveillance methods.

Novel Locus Mediating Metal Homeostasis in Listeria Monocytogenes

Author Block:

C. Parsons, S. Kathariou; North Carolina State Univ., Raleigh, NC

Abstract Body:

p *Listeria monocytogenes* is a ubiquitous facultative intracellular pathogen responsible for listeriosis, a severe foodborne illness in humans and other animals. One key element to *Listeria*'s survival in the environment is its ability to tolerate frequently high levels of heavy metals, especially cadmium and arsenic. Sequestration of essential metals or challenging with toxic metals are two mechanisms used by host organisms to combat infection. To better understand the functional role that genes associated with heavy metal homeostasis play in *Listeria*, a *mariner*-based mutant library was created for the cadmium and arsenic-resistant serotype 4b strain F8027 (originally isolated from celery) and screened for loss of heavy metal resistance. Four mutants with impaired tolerance to cadmium were isolated. Of those, two were found to have transposon insertions in a large chromosomal island harbored by F8027. For one of these mutants, E2G4, the transposon insertion localized to the intergenic space between two oppositely transcribed genes LMOSA_2450 (annotated as wall-anchored protein with the LPXTG motif) and LMOSA_2460-2470 (hypothetical proteins). While E2G4 was initially identified by its reduced tolerance to cadmium, this mutant also had reduced tolerance to zinc. Tolerance to arsenic and copper, as well as an array of antibiotics was not impacted. Genetic complementation of E2G4 with the LMOSA_2460-2470 cassette cloned into the integration vector pPL2 restored the cadmium resistance phenotype, while complementation with LMOSA_2450 restored the resistance to zinc. Consistent with the heavy metal resistance phenotype, this mutant was tested for growth on the surface of cantaloupe and biofilm formation, with no perceived inhibition. Virulence assessments were conducted in a *Galleria mellonella* model with no significant impact on virulence. Since LMOSA_ 2470 is co-transcribed with LMOSA_2460, they are in the process of being cloned individually to ascertain their specific contributions to the phenotype. Additionally, a deletion of LMOSA_2450 is also in progress to better understand what role this wall-associated protein may play in heavy metal tolerance and possibly virulence of *L. monocytogenes*. Quantitative real time PCR is also being pursued to assess potential induction of these genes in the presence of cadmium and zinc.

Antimicrobiobial Resistance of Staphylococci Isolated from Bovine Mastitis in Argentina

Author Block:

M. E. Srednik[1], M. Archambault[2], L. Barnech[1], E. R. Gentilini[1]; [1]Univ. de Buenos Aires, Buenos Aires, Argentina, [2]Université de Montreal, St-Hyacinthe, QC, Canada

Abstract Body:

Background: Bovine mastitis causes important economic losses in the dairy industry. *Staphylococcus aureus* and coagulase-negative staphylococci (CNS) are commonly isolated from bovine mastitis. β-lactams and macrolides-lincosamides (ML) antibiotics are frequently used in intrammamary therapy. CNS can be considered reservoir of antimicrobial resistance genes. The genes *mec*A and *mec*C both confer resistance to all β-lactams antimicrobials. **Methods:** Eighty *S. aureus* and ninety CNS isolates from bovine mastitis milk samples from different farms in Argentina, were tested by disk diffusion test for susceptibility to penicillin, oxacillin, cefoxitin, erythromycin and clindamycin, and also were tested by PCR for the presence of resistance genes for β-lactams (*bla*Z, *mec*A and *mec*C genes) and ML (*erm*A, *erm*B, *erm*C, *mef*A, *msr*A, *mph*C and *lnu*A genes).**Results:** *S. aureus* resistance to β-lactams in Argentina is 23.1%. Among 80 *S. aureus* isolates, 32 (40%) were positive to *bla*Z gene and 15 (18.75%) to ML genes: *erm*B and *mef*A (4 isolates), *erm*B (2 isolates) *mef*A (2 isolates), *erm*B, *erm*C and *mef*A (1 isolate), *erm*A, *erm*B, *erm*C and *mef*A (1 isolate), *erm*B, *mef*A, *lnu*A and *msr*A (1 isolate), *erm*C, *erm*B *and lnu*A (1 isolate) and *erm*A (1 isolate). Among 90 CNS isolates, 12 (13.3%), 4 (4.4%), and 1 (1.1%) were positive for *bla*Z, *mec*A and *mec*C genes, respectively. Only in one isolate we found both, *bla*Z and *mec*A genes, and 6 (6.7%) were positive to ML genes: *erm*C (1 isolate), *erm*B and *erm*C (2 isolates), *erm*B, *erm*C and *mph*C (1 isolate), *mph*C (1 isolate), and *mph*C and *mrs*A (1 isolate). The recently described *mec*C gene has been detected by PCR in a few CNS of animal origin only around Europe. We describes for the first time a *mec*C positive isolate of CNS from bovine mastitis in Argentina. Identification of mastitis pathogens is important for selecting appropriate antimicrobial therapy. Reservoirs of antimicrobial resistance genes are potential threat to public health.**Conclusions:**The presence of a methicillin resistant (MR) CNS isolates in this study emphasize the importance of identification of CNS and its antibiotic susceptibility when an intramammary infection is present. Detection of MR should consider the inclusion of *mec*C gene because of the potential risk of lateral transfer of this gene between staphylococcal species.

Abstract Body:

Background: A multicenter study was performed to evaluate the accuracy of a revised formulation of vancomycin on a MicroScan Dried Gram Positive MIC (MSDGP) Panel when compared to CLSI broth microdilution reference panels.**Methods:** For efficacy, MSDCP panels were evaluated at four sites with 947 clinical isolates. For reproducibility, a subset of 11 organisms was tested on MSDGP panels at each site. MSDGP panels were inoculated using both turbidity and Prompt™* inoculation methods. Frozen reference panels, prepared according to ISO/CLSI methodology, were inoculated using the turbidity inoculation method. All panels were incubated at 35 ±2ºC and visually read. Frozen reference panels were read and reported at 24 hours for all organisms. Read times for the MSDGP panels were 18 hours for all species. FDA/CLSI breakpoints (µg/ml) were used for interpretation of MIC results.**Results:** When compared to frozen reference panel results, essential and categorical agreements for isolates tested in Efficacy are as follows:

Y. R. Kang[1], D. R. Chung[1], S. H. Kim[1], Y. E. Ha[2], C-I. Kang[2], K. R. Peck[2], J-H. Song[1]; [1]Asia Pacific Fndn. for Infectious Diseases, Seoul, Korea, Republic of, [2]Samsung Med. Ctr., Sungkyunkwan Univ. Sch. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: High MIC of vancomycin in methicillin-resistant *Staphylococcus aureus* (MRSA) has been considered as one of the causes of vancomycin treatment failure. Among methicillin-susceptible *S. aureus* (MSSA), however, strains with high vancomycin MICs are often found. We characterized 71 MSSA blood isolates with high vancomycin MICs. **Methods:** Vancomycin susceptible MSSA with vancomycin MIC ≥ 1 mg/L was selected among the *S. aureus* collection from the previous nationwide surveillance study on bacteremia in Korea during the periods 2006-2007 and 2012-2013. MSSA isolates with vancomycin MIC < 1 mg/L were randomly selected in the ratio of 1:1 as the control. Isolates were characterized by *spa* typing, multilocus sequence typing (MLST), *agr* group and the distribution of 7 staphylococcal enterotoxin (SE) genes. The presence of hVISA was screened by Etest and growth on brain heart infusion agar with 4 mg/L vancomycin (BHIV4). hVISA was confirmed by using a modified PAP-AUC method.**Results:** Among 242 MSSA isolates, a total of 71 isolates (29.3%) with vancomycin MIC ≥ 1 mg/L were identified. A total of 25 *spa* types and 10 STs were identified. The most predominant clonal type was ST6-t207 (14.1%). In control group, 31 *spa* types and 21 different STs were identified with distribution of ST188-t189 (14.1%). All *agr* types were represented in the isolates of MSSA with high vancomycin MIC : 63.4% were *agr*-group I, 5.6% *agr*-group II, 26.8% *agr*-group III and 4.2% were non-typable (NT). The control strains were grouped as *agr*-group I (52.1%), *agr*-group II (15.5%), *agr* group III (29.6%), *agr* group IV (1.4%) and 1.4% were NT. SEI was the predominant enterotoxins in both MSSA with high vancomycin MIC (45.1%) and MSSA with low vancomycin MIC (55%). Six isolates were positive by hVISA screening, however none of those were not hVISA by confirmation test.**Conclusions:** We investigated the molecular characteristics of MSSA blood isolates with high vancomycin MICs. ST6-t207 was frequently found in MSSA with high vancomycin MICs compared to MSSA with low vancomycin MICs, of which ST188-t189 was predominant. Multiple combinations of enterotoxin genes were seen in both groups. No hVISA was detected among tested isolates.

Genetic Alteration Responsible for Reduced Vancomycin Susceptibility in *Staphylococcus aureus* of Sequence Type 72

Author Block:

J. Y. Baek[1], D. R. Chung[2], S. H. Kim[1], S-J. Yang[3], C-I. Kang[2], K. S. Ko[4], K. R. Peck[2], J. H. Song[1]; [1]Asia Pacific Fndn. for Infectious Diseases, Seoul, Korea, Republic of, [2]Samsung Med. Ctr., Sungkyunkwan Univ. Sch. of Med., Seoul, Korea, Republic of, [3]Sch. of Bioresources and BioSci., Chung-Ang Univ., Anseong, Korea, Republic of, [4]Samsung BioMed. Res. Inst., Sungkyunkwan Univ. Sch. of Med., Suwon, Korea, Republic of

Abstract Body:

Background: Previously, we reported the first case of vancomycin treatment failure due to development of vancomycin intermediate resistance in a patient with community genotype ST72-methicillin-resistant *Staphylococcus aureus* (MRSA)- SCC*mec* IV infection. We obtained two isogenic MRSA isolates from the bacteremia patient who experienced treatment failure with vancomycin and rifampin. We investigated the genetic alteration that confers to vancomycin resistance by tracking the mutations in these strains using whole genome sequencing (WGS). **Methods:** To identify the genetic changes that confer vancomycin intermediate resistant *S. aureus* (VISA) phenotype, WGS of vancomycin-susceptible and intermediate resistant *S. aureus* isolates (VSSA303 and VISA072, respectively) was completed. The mutations between two isolates were introduced into VSSA303 to test the effect of mutation on VISA phenotype. The strains were tested for antimicrobial susceptibilities, population analysis under the curve (PAP/AUC) and transmission electron microscopy (EM). **Results:** Five non-synonymous mutations were identified by genome sequence data, which included *agrC* (K389stop), *dprA* (G196C), *rpoB* (H481Y), *vraR* (E127K), and a gene encoding a UDP-N-acetylmuramoylpentapeptide-glycine glycyltransferase (F92C). Introduction of the *vraR* (E127K) mutation was accompanied by increase of vancomycin MIC, and acquisition of hetero-VISA phenotype confirmed by PAP/AUC, which are partially responsible for vancomycin resistance. EM of strains with mutated *vraR* showed increased cell wall thickness. **Conclusion:** We identified 5 alleles that were potentially associated with VISA phenotype developed in clinical MRSA strain of the ST72 background. The presence of a unique mutation in the *vraR* gene (E127K) may contribute to vancomycin resistance, which is supported by cell wall thickness and PAP analysis. Further studies are needed to elucidate the molecular effects of these genetic changes which confer or partially contribute to resistance.

Trends in Antimicrobial Resistance of *Streptococcus pyogenes* and Its Association with *emm* Types

Author Block:

T. ABRAHAM, S. Sistla; Jawaharlal Inst. of Postgraduate Med. Ed. and Res., Puducherry, India

Abstract Body:

Background: In Penicillin allergic patients, macrolides and tetracyclines are the most common antibiotics employed for the treatment of streptococcal infections. A decline in the resistance rate of these antibiotics has been observed in different parts of the world. The present study was undertaken to evaluate the antibiotic resistance pattern, molecular basis of resistance and its association with *emm* types among *Streptococcus pyogenes* isolates in Pondicherry, India**Methods:**One hundred and seventy three *Streptococcus pyogenes* isolates were characterized by antimicrobial susceptibility, resistance genotype, macrolide resistance phenotype (using double- disc test) and *emm* genotyping (M typing)**Results:**All the isolates were susceptible to penicillin and vancomycin. Erythromycin resistance was found in 51.4%, with MIC_{50} &MIC_{90} of ≥256 μg ml^{-1}. Inducible phenotype was common (iMLS, 67.4%, 60 strains) followed by the M phenotype (32.5%, 29 strains). Among these isolates, 65.1% harboured *erm*B and 32.5% *mef*A as sole macrolide resistance gene, whereas presence of *erm*B plus *mef*A (2.2%) was also observed. Of the erythromycin resistant strains, 42.6% were invasive. The prevalent *emm* types among resistant strains were *emm* 63 (11.2%), *emm* 44 (6.7%), *emm* 42 (5.6%), and *emm* 75.3, *emm* 82, *emm* 85, *emm* 92, *emm* 111.1(4.4% each). Statistically significant association was observed between *emm* 63, *emm* 44 and erythromycin resistance (P-value < 0.05). Tetracycline resistance was found in 59.5%, with MIC_{50} &MIC_{90} of 24 μg ml^{-1} and 32 μg ml^{-1} respectively. Among these isolates, 96.1% were positive for *tet*M, 2.9% were positive for *tet*O and one strain positive for both *tet*M and *tet*O. Of these tetracycline resistant strains, 23.4% were invasive. . The prevalent *emm* types among resistant strains were *emm* 63 (9.7%), *emm* 44 (5.8%), *emm* 92 (4.8%), and *emm* 75.3, *emm* 82.1, *emm* 85, *emm* 106 (3.8% each). Statistically significant association was not observed between emm types and tetracycline resistance.**Conclusion:**Erythromycin and tetracycline resistance continues to exist at high levels in Pondicherry, may be attributed to the over prescription and use of these antibiotics. This study suggests that the variation in antibiotic resistance among *Streptococcus pyogenes* is, with a few exceptions independent of *emm* type distribution

Intestinal Colonization of VanA Genotype Vancomycin-Resistant E*nterococcus faecium* in Western Nepal

Author Block:

S. Hosuru Subramanya[1], N. Kishor Sharan[1], B. Prasad Baral[1], N. Nayak[1], I. Bairy[2], S. Gokhale[1]; [1]Manipal Coll. of Med. Sci., Pokhara, Nepal, [2]Melaka Manipal Med. Coll., Manipal, India

Abstract Body:

Background: The gastrointestinal colonization by multi drug resistant *Enterococcus* has been increasing worldwide. The present study was dedicated to determine the rate of fecal carriage of multi drug resistant *Enterococcus* spp. in hospitalized patients and in individuals living in the community and to determine the predominant vancomycin resistance genotype in western Nepal.**Materials and Methods:** A cross sectional study was conducted. Stool specimens were collected from 141 community subjects and 129 hospitalized patients. Isolates were identified by conventional methods and Vitek based identification parameters. Antibiotic susceptibility testing was performed using Kirby-Bauer disk diffusion method. The Minimum inhibitory concentration [MIC] for vancomycin was determined by both E-test strips and micro broth dilution method. Genotypic characterization of VRE was performed by multiplex PCR assays targeting VanA, VanB and VanC genes.**Results:** Out of a total 270 study subjects, 142 (52.59%) yielded *Enterococci* spp. amongst these, 99 (69.71%) were from community subjects and 43(30.28%) were from hospitalized patients. Of these 142; 58 (40.84%) were *E faecalis,* 46 (32.39%) *E faecium* and 38 (26.76) were other *Enterococcus* species. The ampicillin resistance that was as high as 80.98% was quite alarming. A total of 47 (33.1%) out of 142 *Enterococci* were MDR. 31 (72.1%) of 43 hospitalizes individuals were colonised with MDR *Enteroccocci*, as compared to only 16 (16.2%) of 99 community individuals ($\chi^2 = 42.35$; $p < 0.001$).The overall prevalence rate of fecal VRE colonization was 6.33% (9/142). Whereas, 18.6% (8/43) of the hospitalised patients were colonised with VRE, only 1 (1.01%) out of 99 community subjects was colonised with VRE ($\chi^2=15.63$; $p< 0.001$). Quantification of VRE from 9 of the colonized patients showed that the colony counts ranged between 10^2 to 10^5 CFU/g of stool. All 9 VRE isolates were found to be *E faecium* and positive for *vanA* genotype, no *vanB or vanC* genotypes were found.**Conclusion:** High rate of colonization by MDR *Enterococcus* and VRE is alarming. Further studies are warranted to elucidate the origin and the epidemiology of vancomycin resistance in this geographical area.

Publishing Title:

Activity of Ceftaroline Tested Against Different Clonotypes of Methicillin-Resistant *Staphylococcus aureus* Collected from Two Nationwide Studies in Spain

Author Block:

E. Cercenado[1], A. Vindel[2], O. Cuevas[1], M. Marín[1], F. Román[2], E. Bouza[1], Staphylococcus Study Group; [1]Hosp. Gen. Univ.rio Gregorio Marañón, Madrid, Spain, [2]Inst. de Salud Carlos III, Majadahonda, Spain

Abstract Body:

Background: Ceftaroline (CPT) is a new cephalosporin active against methicillin-resistant *Staphylococcus aureus* (MRSA). Previous studies have demonstrated variable activity of CPT against different MRSA clonotypes and geographical differences regarding CPT MICs due to high prevalence of clonotypes ST228, ST239, and ST247. We evaluate the in vitro activity of CPT tested against MRSA isolates from different clonotypes collected in Spain. **Methods:** A total of 311 MRSA isolates collected in two nationwide prevalence studies performed in Spain in 2010 (152 isolates) and in 2014 (159 isolates) were studied. The presence of the *mecA* gene was determined by PCR. CPT susceptibility testing was performed by the gradient diffusion (GD) method (epsilon test, Liofilchem, Italy). CLSI and EUCAST breakpoints were applied for CPT (susceptible ≤1 mg/L). *S. aureus* ATCC 29213 and *E. faecalis* ATCC 29212 were used as control strains. Molecular characterization was achieved by SCC*mec* typing, *spa* typing, BURP, and MLST.**Results:** Among the 311 MRSA isolates, 212 corresponded to clonal complex (CC) 5 (ST5, ST125, ST225, ST146, and ST228), 38 to CC8 (ST8), 31 to CC22 (ST22), 9 to CC30 (ST36, ST30), 8 to CC398 (ST398), 5 to CC1 (ST1), 4 to ST72, 2 to ST273, 1 to ST146, and 1 to ST45. A total of 297 isolates (95.5%) carried SCC*mec* type IV (with its variants), 7 SCC*mec*II, 6 SCC*mec*V, and 1 SCC*mec* I. CPT inhibited 98% of isolates at an MIC of ≤1 mg/L, with MIC50/90 values of 0.38/1 mg/L. Only one isolate belonged to clonotype ST228. Comparative CPT activity (MIC, mg/L) against the different clones is shown in the table.**Conclusions:** This study shows potent in vitro activity of CPT against all MRSA clonotypes isolated in Spain with no differences in activity against isolates belonging to different CC. The very low frequency or absence of ST228, ST239, and ST247 in our country could determine a higher activity of CPT against MRSA.

Clonal complex (No. isolates)	**CPT MIC50**	**CPT MIC90**	**Range**

Antimicrobial Susceptibility Testing of Outbreak Associated *Listeria monocytogenes*, 1983-2015

Author Block:

C. Smith[1], J. Chen[1], Z. Kucerova[2], K. Jackson[2], K. Roache[3], C. Scheel[2]; [1]IHRC, Inc., Atlanta, GA, [2]Ctr.s for Disease Control & Prevention, Atlanta, GA, [3]ORISE, Oak Ridge, TN

Abstract Body:

Listeria monocytogenes is a bacterial foodborne pathogen causing an estimated 1600 cases of invasive listeriosis infections annually in the United States. Exposure to *L. monocytogenes* typically occurs through consumption of contaminated foods. Among foodborne illnesses, listeriosis has the highest mortality rate of around 20%. Treatment for invasive listeriosis consists of antibiotic therapy, usually an aminopenicillin and gentamicin or trimethoprim-sulfamethoxazole for patients with a β-lactam allergy. Antibiotic resistance is a growing concern with many enteric pathogens; however, little resistance has been shown in *L. monocytogenes*. In this study, 152 *L. monocytogenes* isolates representing over 90 different outbreaks from 1983-2015, were selected for antimicrobial susceptibility testing. Broth microdilution using the Thermo Scientific Sensititre™ Gram positive susceptibility panel comprised of 17 antimicrobials was performed and then interpreted using Clinical Laboratory Standards Institute (CLSI) M45 or European Committee of Antimicrobial Susceptibility Testing (EUCAST) criteria. No resistance to ampicillin, erythromycin or trimethoprim-sulfamethoxazole was detected, and gentamicin MICs were all ≤4 μg/mL. Seven isolates (5%) showed tetracycline MICs >16 μg/mL; the other 145 showed tetracycline MICs ≤4 μg/mL. Whole genome sequencing confirmed that all isolates with high tetracycline MICs possessed the *tetM* gene. Antimicrobial susceptibility should continue to be monitored in *L. monocytogenes* to identify changing trends in antimicrobial susceptibility.

Reference Lab. INEI-ANLIS, Buenos Aires, Argentina

Abstract Body:

The emergence of MRSA in horses, pet animals and productive livestock has risen worldwide. Colonized horses may transmit MRSA to other horses and people. We evaluated the MRSA nasal colonization in horses from Argentina, characterized the resistance profile and the clonal relation between isolates**Methods:** During May, September and October of 2015, 96 healthy thoroughbreds horses belonging to the La Plata Race track were screened for MRSA. Swabs were taken from nasal vestibulum and plated on chromogenic agar (CHROMagar™ MRSA). Nine suspicious strains were confirmed as *S. aureus* by conventional tests. Antibiotic susceptibility were done by disk diffusion test (CLSI M100S25). D-test was performed to evaluate inducible or constitutive MLSb-phenotype. Detection of macrolide resistance genes *ermA* and *msrA*, *mecA* and PVL were performed by PCR, SCC*mec* type was determined by multiplex PCR, and molecular typing by *Sma*I PFGE and MLST**Results:** Nine strains were resistant to cefoxitin and *mecA* positive. The prevalence of MRSA was 9.4% (9/96). All were susceptible to ceftaroline, gentamicin, ciprofloxacin, tetracycline, chloramphenicol, trimethoprim-sulfamethoxazol, rifampin, teicoplanin, linezolid and nitrofurantoin, but seven (78%) were resistant to erythromycin and clindamycin. All MRSA isolates carried the SCC*mec*IV. Two clonal types were observed by PFGE. Most of them (7/9) belonged to clonal type A the already described ST5-SCC*mec*IV responsible of the emergence of community associated MRSA in human infections in our country between 2000-08. All MRSA ST5-SCC*mec*IV were PVL negative, showed inducible MLSb phenotype, carried the *erm*A gene and were negative to *msrA* gene. Isolates from clone B (2/9) were PVL positive and belonged to ST30-SCC*mec*IV (South West Pacific clone), responsible for the half of the CA-MRSA infections in humans in our country nowadays**Conclusions:** This is the first study of prevalence of nasal MRSA colonization in healthy horses from Argentina. All the strains belonged to ST5-SCC*mec*IV or ST30-SCC*mec*IV, the two dominant community-associated clones in Argentina

In Vitro* Activity of Tigecycline and Minocycline Against Vanm-type Vancomycin-resistant *Enterococcus faecium

Author Block:

C. Chen, Y. Guo, F. Hu, X. Xu; Huashan Hosp., Fudan Univ., Shanghai, China

Abstract Body:

Background: Vancomycin-resistant enterococci (VRE) have become one of the most important nosocomial pathogens worldwide due to limited adequate treatment options and increasing occurrence of high-level resistance to most antimicrobial drugs. Tigecycline is one of the last-line treatment options left to combat multidrug-resistant bacteria including VRE. In previous study, we found that VanM is the most prevalent genotype in vancomycin-resistant *Enterococcus faecium* (VREm) in Shanghai. Most VanM-type VREm isolates were susceptible to doxycycline, but their susceptibilities to two other tetracycline antibiotics minomycline and tigecycline remain unknown. In this study, we investigated the in vitro activity of minocycline and tigecycline against VanM-type VREm and to provide guidance for clinical treatment on VRE infections. **Methods:** Forty five VREm clinical strains were obtained from hospitals in Shanghai between 2006 and 2014. Species and vancomycin resistance genotype were identified by PCR and sequencing. Minimal inhibitory concentrations (MICs) of ten antimicrobial agents (vancomycin, teicoplanin, tigecycline minocyline, linezolid, ampicillin, erythromycin, levofloxacin, gentamicin, and rifampicin) were determined by agar dilution or broth microdilution.**Results:** All the 45 isolates were VanM-type vancomycin-resistant *Enterococcus faecium,* and all of them were resistant to vancomycin with high MICs of 128 to >256 mg/L, 71.1% of the strains were resistant to teicoplanin. No isolates were resistant to tigecycline. The resistance rates to minocycline, gentamycin and rifampicin were 15.6%, 64.4% and 82.2%, respectively. Almost all isolates showed resistance to levofloxacin (100%) and ampicillin (97.8%).**Conclusions:** Though minocycline resistant VREm strains emerged, tigecycline exhibit excellent *in vitro* activity against these VanM-type VREm isolates. Tigecycline can be a promising treatment option for VRE infections.**Table 1. MICs of 10 antimicrobial agents against VanM-type VREm isolates (mg/L)**

Antimicrobial agents	**VanM-type VREfm(n=45)**

Ceftaroline Activity Against *S. aureus* Clinical Isolates from Argentina: Association with Different Mrsa Clonal Types

Author Block:

A. Corso[1], P. Gagetti[1], P. Ceriana[1], C. Lucero[1], A. Egea[2], D. Barcudi[2], Grupo S. aureus Argentina, J. Bocco[2], C. Sola[2]; [1]Antimicrobial Div. Natl. Reference Lab. INEI-ANLIS "Dr. Malbran", Buenos Aires, Argentina, [2]Dept Bioq Clin. FCQ, UNCordoba, CIBICI-CONICET., Cordoba, Argentina

Abstract Body:

MRSA is an increasing problem worldwide, both in hospitals (healthcare-associated-HA) and in the community (community-associated-CA). In a previous study, we demonstrated that higher rates of MRSA were mainly associated with the spread of two CA-MRSA clones ST5-IV (32%) and ST30-IV (32%) and one HA-associated ST5-I Cordobes/Chilean (19%) (*Egea et al.* Int J Med Microbiol 2014; 304:1086-99). The aim of the present study was to evaluate in the same collection. ceftaroline (CPT) susceptibility and its association with the different MRSA clonal types **Methods**: 591 consecutive *S. aureus* clinical isolates were collected in 66 hospitals from 20 provinces and BA City in Argentina, 322 were MRSA (54.5%). Susceptibility to CPT was performed by agar dilution and interpreted according to CLSI M100-S25. The 322 MRSA isolates (231 CA and 91 HA) were previously studied by SCC*mec*, spa-typing, PVL, PFGE and MLST by standard procedures **Results:** The prevalence of intermediate (I) resistance to CPT (MIC 2mg/L) was 6.4% (38/591) for *S. aureus*, $MIC_{50/90}$ 0.25/1 mg/L, range 0.06-2 mg/L. All MSSA isolates were susceptible to CPT with $MIC_{50/90}$ 0.25 mg/L, range 0.06-0.25 mg/L. Among MRSA, 11.8% (38/322) were CPT-I. CPT resistant isolates were not detected ($MIC \geq 4$ mg/L). The susceptibility profiles of CA and HA-MRSA clones are shown in Table. **Conclusions:** CA-MRSA isolates were CPT susceptible independently of the clone involved. In contrast, in HA-MRSA isolates, CPT susceptibility was strongly associated to the clonal type, being ST5-I

Cordobes/Chilean the main clone associated with CPT-I isolates

Isolation, Identification and Differentiation of *Staphylococcal* Isolates from the Patients of Wound Infections

Author Block:

T. Ijaz[1], **M. Afzal**[2], N. Ijaz[3]; [1]Mayo Hosp.,King Edward Med. Univ., Lahore, Pakistan, [2]Shalamar Med. and Dental Coll., Lahore, Pakistan, [3]CMH Med. and Dental Coll., Lahore, Pakistan

Abstract Body:

Background: *Staphylococcus species* are the notorious pathogens causing serious infections. They also have acquired resistance against a wide range of the antibiotics. Methicillin Resistant *Staph. aureus* (MRSA)and Methicillin Resistant *Staph, epidermidis* (MRSE) are becoming more prevalent in current scenario and thus difficult to treat. **Objective:** The present study was designed to investigate the prevalence of Staphylococcus among the infected wounds, burns and the surgical sites and further, to evaluate the frequency of the Staphylococcus spp on the basis of Methicillin resistance. Antimicrobial assay was also performed against other available antibiotics of different groups including, Penicillins, Cephalosporins, Quinolones, Aminoglycocides, beta-lactamase inhibitors, Tetracyclines, Carbapenems, Macrolides, lincosamides and others antistaphylococcal drugs. **Methods:** A total of 200 pus and burn wound samples were taken and were processed in the Microbiology laboratory at Mayo hospital Lahore, Pakistan. Isolation, identification and differentiation of the *Staphylococcus* species were performed according to the standard protocol. (Monica Cheesebrough, 2006).**Results:** From a total of 200 pus samples, *Staphylococcus spp* were observed to be 43.1% among the positive cultures. Staphylococci were isolated from 49 (62.8%) of the pus samples and 29 (37.2%) from the burn wound swabs. MRSA was found to be dominating among the staphylococcal isolates, with the overall rate of 53.8%. This increased percentage of Methicillin Resistance was also observed among the cases of Staph. epidermidis. Risk factors associated with such increased rate of antibiotic resistance among the infected individuals were the irrational use of the antibiotics and the inadequacies in the alertness among the infected patients. Antibiogram assay showed variable resistance pattern, however, Carbapenems, Aminoglycosides, Linezolids and Vancocins were found superiors as compared to others. ($P<0.05$) **Conclusion:** *Staph. aureus* was found to be prevalent 66.6% among the other staphylococcal isolates, however, *Staph. epidermidis* MRSE established more resistance i.e. 57.6% as compared to MRSA that was 53.8% along with other antibiotics as well.

Phenotypic and Genetic Diversity of Nasopharyngeal *Streptococcus pneumoniae* Isolates from Children at the Age of Six Weeks and Nine Months from Selected Health Centres of Addis Ababa, Ethiopia

Author Block:

W. T. Sime; Armauer Hansen Res. Inst., Addis Ababa, Ethiopia

Abstract Body:

Background: *Streptococcus pneumoniae* (Pneumococcus) among the most important human pathogens, with high morbidity and mortality rates. Nasopharyngeal colonisation is the necessary first step in the pathogenesis of associated invasive pnuemococcal diseases. Ethiopia, introduced the ten-valent pneumococal conjugate vaccine (PCV110) since October, 2011 without adequate baseline information on epidemiological factors for subsequent impact assessment. The aim of this study was to determine phenotypic and genotypic diversity nasopharyngeal isolates of *Streptococcus pneumoniae*.**Method**: A total of 789 newborn babies were enrolled at the age of six weeks when they came for the first PCV10 vaccine, and 206 were re-sampled at the age of nine months and 201 at two years after final dose of PCV10. Nasopharyngeal swabs were taken for bacteriological analysis before vaccination at the age of six weeks, and after completion at the age of nine months and two years. Isolates were tested for 13 commonly used antibiotics by disc diffusion method and those isolates that showed resistance for penicillin and erythromycin the minimum inhibition concentration were determined by E-test A total of 325 pneumococcal isolates were serotyped and characterized by Pulsed Field Gel Electrophoresis and 12 isolates were analyzed by multilocus sequence typing.**Results**: The carriage rate of *Streptococcus pneumoniae* at the age of six weeks, nine months and two years was 26.6%, 56.8% and 47.6% respectively. A total of 59 serotypes of *S. pneumoniae* were identified from 325 isolates, and 6A, 11A, 15B, 23F,15A and 19F dominated in decreasing order. The proportion of serotypes covered by PCV10 vaccine among the isolates at 6 weeks and 9 months were 20.2% and 11.1% respectively. Molecular typing further showed a presence of high genetic diversity.The antibiotic test indicated that resistance rates were ranging from 4.3% for chloramphenicol to 27.7% for Trimethoprim/sulfamethoxazole.**Conclusion**: This study highlights the presence of very diverse serotypes in the country, and PFGE and MLST result indicates case of a possible capsular switching event. This work were conducted in Addis Ababa only, it is necessary to scale up the investigation to other part of the country and include clinical cases to have a complete picture.

Utilization of Sensititre(C) to Evaluate Antibiotic Susceptibilities of *Aerococcus* Species

Author Block:

K. L. J. Smith, S. R. Petry, D. J. Hardy; Univ. of Rochester, Rochester, NY

Abstract Body:

Aerococcus species are being identified with increasing frequency in urine cultures, but it is unclear if this is due to improved identification technologies or to a better recognition of the bacterium as a urinary tract pathogen. From October to December 2015, we observed that ~1% of positive urine cultures included *Aerococcus urinae* and in 55% of cases it was the only organism present. Recently, CLSI has approved antimicrobial susceptibility testing guidelines and interpretive breakpoints for *Aerococcus* species. In the present study, we compared standard broth microdilution MIC determinations to MICs identified using commercially available Sensititre© MIC Susceptibility plates recommended for *Streptococcus pneumoniae*. Sensititre© plates were selected for comparison to manual broth microdilution plates due to the excellent overlap of drugs between the antibiotics on the plate and those with CLSI interpretive breakpoints for *Aerococcus* species; Ciprofloxacin is the only drug with CLSI interpretive breakpoints not included in Sensititre© plates. To date, 22 clinical isolates have been tested by manual broth microdilution and Sensititre© with few significant discrepancies. Major discrepancies were described as changes in interpretation between the methods from sensitive to resistant or vice versa and are as follows: Penicillin - 4.5%, Cextriaxone - 5%, and Levofloxacin - 10.5%. When utilizing Sensititre© alone, all isolates were susceptible to Meropenem, Linezolid, and Vancomycin and most were susceptible to Tetracycline (93%), Cextriaxone (93%), Cefotaxime (96%), and Penicillin (96%); for Trimethoprim/Sulfamethoxazole 75% were susceptible and 25% were intermediate. The only appreciable resistance was to Levofloxacin (25% resistant). In conclusion, susceptibility testing of *Aerococcus* species using commercially available Sensititre© microdilution plates may enhance ease of testing, increase clinical treatment options, and assist in efficiently gaining insight into the susceptibility patterns of these strains in the clinical laboratory.

Kinetic of Eosinophil Count and Correlation with Effective Antibiotic Treatment

Author Block:

S. Makhloufi, A. Dinh, R. Calin, O. Senard, J. Salomon, **B. Davido**; Hosp. Raymond Poincaré, Garches, France

Abstract Body:

Background: Eosinophil count has been in the center of debates for decades as a criterion of SIRS (Systemic Inflammatory Response Syndrome). Furthermore, some authors claimed that a cut-off value<40 to 50/mm3 could help physician in the diagnosis of sepsis.Our present work evaluates the kinetic of eosinophil count according to antibiotic treatment and its correlation with patient's response. **Methods:** We gathered prospectively all data of patients hospitalized with sepsis + eosinopenia (<100/mm^3) on day (D) 0 confirmed by microbiology (i.e. blood culture, urinalysis etc.)Patients were divided in 2 groups:- Number 1: effective antibiotic treatment since day 0 (D0)- Number 2: delayed effective antibiotic treatment after D1We compared temperature, leukocyte count and C - reactive protein (CRP) during the first 5 days of hospitalization.**Results:** Mean age and comorbidities were not significantly different between both groups.We noted 17 urinary tract infections, 11 bloodstream infections, 8 pneumonias, 5 skin and soft tissue infections and 4 digestive tract infections.

	Day	Group number 1 (n=30)	Group number 2 (n=15)	P-value (alpha=5%)
Mean temperature (°C)	0	38.8±1	38.5±1	Non-significant (NS)
	1	38.7±1	38.2±1	NS
	3	37.8±1	37.7±1	NS
	5	37.5±1	37.2±1	NS
Mean value of polymorphonuclear neutrophils (PMN) count (/mm^3)	0	10475±7000	7440±3800	NS
	1	9900±5000	7550±4100	NS
	3	6450±3580	3210±1580	<0.0001
	5	6680±3150	4000±2230	NS
Mean value of eosinophil count (/mm^3)	0	9±8	7±12	NS
	1	44±21	9±15	<0.0001

	3	110±61	140±94	NS
	5	166±100	130±78	NS
Mean value of CRP (mg/L)	0	220±110	105±70	0.0006
	1	245±120	145±120	NS
	3	120±60	79±80	NS
	5	70±50	44±34	NS

Table 1: data characteristics of studied patientsStatistical analysis showed a significantly higher eosinophil count at D1 ($p<0.0001$) in the group Number 1, meanwhile CRP and PMN were comparable. (Table 1).However, CRP was significantly lower at D0 in group Number 2, which may explain why physician in charge delayed the antibiotic therapy. PMN count was significantly lower at D3 in group Number 2, which may also be consecutive to a delayed antibiotic treatment.Clinical outcome was favourable in all cases after an effective antibiotic regimen.**Conclusions:** Kinetic of eosinophil count appears to normalize faster than CRP and PMN if patient is under the appropriate antibiotic therapy. Resolution of eosinopenia seems to predict a quick recovery.

Plasma Neutrophil Gelatinase-Associated Lipocalin (NGAL) as a Predictor of Acute Kidney Injury in Patients Treated with Colistin

Author Block:

J. LEE, S. PARK, J. Eom, J- . Park, Y-S. Ju; Kangdong Scred Heart Hosp., Hallym Med. Coll., seoul, Korea, Republic of

Abstract Body:

Background: We hypothesized that plasma neutrophil gelatinase-associated lipocalin (NGAL) would be an early biomarker for acute kidney injury (AKI) in patients treated with colistin. **Methods:** We performed a prospective cohort study in patients receiving colistin. All 109 patients aged ≥20 years who received intravenous colistin from March 1, 2014 to November 30, 2015 were eligible for the cohort and 23 patients were enrolled. The primary outcome was AKI which was defined according to a Kidney Disease: Improving Global Outcomes (KDIGO) criterion. We measured the serum creatinine at baseline and daily after initiation of colistin up to day 7. We collected blood samples at baseline and 8 hours after the beginning of colistin therapy, every 8 hour for the third day, and then every 12 hour for 4 days for measuring NGAL.**Results:** We studied 23 patients with a mean age was 61.3 ± 16.1 years, and 65.2% were males. At the baseline, plasma NGAL level was 233.0 ± 135.4 ng/mL. Overall, 13/23 (56.5%) patients fulfilled an AKI definition. The mean duration of colistin therapy before the onset of AKI was 78.15 ± 30.49 hours. Based on the primary outcome, we classified patients into those with and without AKI. There was no statistically significant difference (*P*=0.218) in baseline NGAL levels between patients with AKI (264.0 ± 167.3 ng/Ml) and patients without AKI (192.7 ± 65.3 ng/mL). The amount of NGAL in plasma at 64 hours after colistin treatment was the most powerful predictor of AKI. For concentration in plasma of NGAL at 64 hour, the AUC curve was 0.840 (95% [CI], 0.672 to 1.000; *P*=0.006), sensitivity was 76.9%, and specificity was 80.0% for a cutoff value of 288 ng/mL. **Conclusions:** In the current study, plasma NGAL is a powerful immediate early biomarker for AKI, preceding any increase in serum creatinine by 12-28 hours. Plasma NGAL represents sensitive and specific predictive early biomarkers for AKI in patient treated colistin.

Hyperferritinemia As A Marker For Severe Fever With Thrombocytopenia Syndrome

Author Block:

U. KIM, **B-s. Kim**, S. Kim, S. Kang, H-C. Jang, K-H. Park, S. Jung; Chonnam Natl. Univ. of Med. Sch., Gwangju, Korea, Republic of

Abstract Body:

Background: Eversince the first identification in China in 2009, severe fever with thrombocytopenia syndrome(SFTS) is an emerging infectious disease in many rural areas of Asia. Its increasing prevalence and overall mortality as high as 46% puts emphasis on early diagnosis of SFTS to prevent both transmission and mortality of the disease. Our aim was to determine biomarker that can help early diagnosis of SFTS in emergency setting before the confirmed diagnosis with PCR sequencing.**Methods:** Patients aged 18 years or older with serologically confirmed SFTS or microbiologically confirmed community-onset bacteremia with thrombocytopenia (blood platelet count $\leq 130{,}000/mm^2$) at presentation between June 2013 and August 2015 were included from two tertiary university hospitals in Republic of Korea. Data on age, gender, residence, and medical history, clinical manifestations on admission and laboratory test results were collected by a retrospective review of electric medical records.**Results:** From June 2013 to August 2015, data of 9 SFTS and 62 bacteremia with thrombocytopenia were collected. In laboratory findings, white blood cell count and absolute neutrophil count were significantly lower in SFTS group. SFTS group had significantly higher serum level of aspartate aminotransferase (AST), lactate dehydrogenase (LDH), creatine kinase (CK), ferritin. Inflammatory markers such as C-reactive protein (CRP), procalcitonin and fibrinogen were lower in SFTS group. Calculated AUC of AST, LDH, CK, ferritin were above 0.5, indicating high discriminative power of the biomarkers. Among these markers, serum ferritin had an AUC of 1.0. In addition, the optimal cut off value of ferritin was 3835.9 ng/ml with a sensitivity of 100% and specificity of 100%.**Conclusion:** This study highlights the importance of serum level of ferritin as a diagnostic tool in differentiating SFTS from bacteremia.Table 1. Comparison of basal characteristics and laboratory findings in patients with SFTS and bacteremia with thrombocytopenia.

Publishing Title:

Utility of Procalcitonin in Oncology Patients with Bacteremia

Author Block:

D. Y. C. Yii, **W. H. L. LEE**, Y. Liew, S. S. L. Tang, A. L. Kwa; SINGAPORE GENERAL Hosp., SINGAPORE, Singapore

Abstract Body:

Background: Diagnosis of bacterial infections in oncology patients can be challenging as symptoms are often non-specific. Procalcitonin (PCT) may be a useful biomarker in such cases. We aim to determine the diagnostic value of PCT in early identification of oncology patients with bloodstream infections (BSI).**Methods:** This is a retrospective study of all adult oncology patients with ≥1 PCT level done during their hospital admission between January 2013 and December 2014. BSI was defined as any clinically significant bacterial growth in blood cultures taken at symptom presentation or start of antibiotics. We evaluated the median of biomarkers measured at this point, using cutoffs of PCT 0.5mcg/L and CRP 50mg/L as research supports increased likelihood of bacterial infection above these values. Patients were placed in the control group if the physician deemed sepsis unlikely based on clinical and microbiological data.**Results:** A total of 258 patients were included - 107 with BSI and 151 in the control group. Baseline PCT levels were significantly higher in those with BSI (2.0mcg/L vs 0.12mcg/L, $p<0.001$). Of note, 80 (75%) patients with BSI but only 8 (5%) controls had PCT≥0.5mcg/L (, $p<0.001$). CRP levels were also more likely to be elevated in patients with BSI - 64 (75%) had CRP>50mg/L vs 52 (50%) in patients with no infection ($p<0.001$); median CRP in BSI group was 125mg/L (IQR 50-194) vs. 49mg/L (IQR 17-85) in the controls ($p<0.001$). There was no statistically significant difference in PCT levels by type of causative pathogen. In distinguishing BSI from no infection, the area under ROC curve was 0.92 (95% CI 0.88-0.96, $p<0.001$) for PCT and 0.72 (95% CI 0.64-0.79, $p<0.001$) for CRP. Optimal cutoffs were PCT 0.28mcg/L, with 87% sensitivity and 81% specificity; and CRP 76mg/L which had 65% sensitivity and 71% specificity. In comparison, values of PCT 0.5mcg/L had 75% sensitivity and 95% specificity, and CRP 50mg/L showed 75% sensitivity and 51% specificity.**Conclusions:** These findings support the use of PCT over CRP for detection of BSI in oncology patients, given its superior specificity.

Clinical Significance of Low $Cd4^+/Cd8^+$ Ratio in Patients with Immune Thrombocytopenic Purpura: A Single Centre Study

Author Block:

A. Arshad, S. N. Mukry, M. Saud, I. shamim, T. S. Shamsi; Natl. Inst. of Blood Diseases and Bone Marrow Transplatation, Karachi, Pakistan

Abstract Body:

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune clinical syndrome in which decreased number of circulating platelets leads to epistaxis, bruises and bleeding. The T cells play an important role in the pathogenesis of ITP. CD4 co-receptor assists the T cell receptor in communicating with an antigen presenting B-cells resulting in development of clones of plasma cells secreting antibodies against the platelets glycoprotein as antigens. Decrease in the helper and cytotoxic T cells ratio is generally observed in immune conditions like ITP.**Methods:** A total of 50 ITP patients and 30 healthy volunteers were included in this study as control. Informed consent was taken from all the patients. About 21 were male while 29 were females. Complete blood count was performed on automated hemo-analyzer XN-1000 and morphological examination of blood was done in duplicate by two different microscopists. The $CD4^+/CD8^+$ ratio was determined by BD Tri-testCD4 FITC/ CD8 PE/ CD3 PerCP (Cat Number: 340298) antibody cocktail using BD FACS Calibur flow-cytometer. The data was acquired and analyzed by using Multiset version 3.0. Mean platelet count and $CD4^+/CD8^+$ were calculated using SPSS version 17. **Results:** Out of total 50 patients, 21(42%) were males and 29 (58%) were females. The mean age of the patients was 35 years (range : 3-80 years).Platelet anisocytosis and decreased platelet count was observed. The mean platelet count was 28.2x103/µl and 328x103/ µl for ITP patients and controls respectively. The mean CD4/CD8 ratio was 0.8 in patients while it was $\geq$1.09 in controls. It was observed that patients with low CD4/CD8 ratio ($\leq$ 0.3) exhibited poor treatment response. Prolonged thrombocytopenia was observed in these patients. **Conclusions:** In ITP,T-cell plays an important role in pathogenesis. In the present study decreased platelet count and low CD4/CD8 ratio were observed. This decreased ratio can be use as a marker in evaluating the immune-suppressive drug's efficacy/ response in ITP patients. More studies are needed to confirm significant involvement of T-cell in pathogenesis of ITP.

A Comparison of Two Assays for Quantification of Hepatitis B Surface Antigen in Patients with Chronic Hepatitis B

Author Block:

T. Adilistya, N. Indrasari; Dr. Cipto Mangunkusumo Hosp., Jakarta Pusat, Indonesia

Abstract Body:

Background: Serum hepatitis B surface antigen (HBsAg) levels correlate with hepatitis B virus intrahepatic covalently closed circular (ccc) DNA and may be useful to predict treatment response. Currently there are two commercial platforms available for HBsAg quantification in clinical practice: the Roche HBsAg QT and Architect HBsAg Quant. This study aimed to compare the results of both assays. **Methods:** HBsAg levels were measured in 50 serum samples from chronic hepatitis B patients and subsequently analysed for HBsAg levels using both assays.**Results:** Correlation between Roche and Architect results was high ($r=0.989$, $p<0.05$). By Bland Altman analysis, agreement between two assays was close (mean difference between Roche and Architect 0.001 log IU/mL, limit of agreement -0.20 log IU/mL (95% CI: -0.25 - -0.15) to 0.21 log IU/mL (95% CI: 0.15-0.26). There were 2 (4%) samples with far agreement (difference 0.42 and 0.30 log IU/mL). This discrepancy is hypothesized to be caused by HBsAg mutants.**Conclusions:** There is a high correlation and close agreement between quantitative HBsAg measurement by Roche and Architect. Clinical prediction rules derived from data from one platform can be applied on another. Both assays can be used interchangeably in clinical practice.

Identification of Novel Diagnostic Antigens for Human Granulocytic Anaplasmosis

Author Block:

M. He, W. Xu, L. Zhang, Y. Li, S. Wu, R. Huang, **H. Niu**; Soochow Univ., Suzhou, China

Abstract Body:

Human granulocytic anaplasmosis (HGA), an emerging tick-borne infectious disease is caused by a gram-negative obligatory intracellular bacterium, *Anaplasma phagocytophilum*. HGA is accompanied by fever, chills, headache, myalgia, malaise, leucopenia, thrombocytopenia, and elevation of hepatic aminotransferase activity. Because the clinical manifestation is not specific, the diagnosis of HGA is highly depends on the laboratory tests. *A. phagocytophilum*-infected cell-based indirect immunofluorescence assay (IFA) is the standard method to serologically assist diagnosis of HGA, but the interpretation of result relies on the well-trained clinical laboratory personnel. The enzyme-linked immunosorbent assay (ELISA) is an alternative serological test for detection of *A. phagocytophilum* infection by providing convenience and accuracy, but the peptide antigen derived from *A. phagocytophilum* outer membrane protein P44 offers lower sensitivity of detection in current ELISA kit compared to IFA. In this study, we attempted to identify new protein antigens aiming to increase the sensitivity of ELISA for detection of *A. phagocytophilum* infection. Genes encoding 24 *Anaplasma*-specific proteins were amplified by PCR, cloned into prokaryotic expression vector pET28a(+) and expressed in *E. coli*. Recombinant proteins were purified with Nickel affinity chromatography, and subjected to western blot analysis using human serum against *A. phagocytophilum* as primary antibody. Comparable to P44, 6 proteins were found to strongly react with the positive serum. Further study showed 2 of them reacted with sera which are positive for *A. phagocytophilum*, but negative for P44 in western blot analysis. Here these two proteins are named as *A. phagocytophilum* antigen 1 (Apa-1) and 2 (Apa-2), respectively. ELISA with peptides derived from Apa-1 and Apa-2 was found to have high sensitivity of detection. Furthermore, besides reacting with sera, which contain anti-P44 antibody, the peptides also reacted with sera, which contain anti-*A. phagocytophilum* antibody, but no detectable anti-P44 antibody. Taken together, we identified novel *A. phagocytophilum* antigens, which may increase the sensitivity of ELISA in assisting diagnosis of HGA.

Detection of Antibodies to *Borrelia Garinii* and *Borrelia Afzelii* by Immunoblot

Author Block:

D. Granger[1], F. Strle[2], E. S. Theel[1]; [1]Mayo Clinic, Rochester, MN, [2]Univ. Med. Ctr., Ljubljana, Slovenia

Abstract Body:

Lyme disease (LD) occurs following infection with a *Borrelia burgdorferi* (*Bb*) sensu lato complex member. Certain complex members, including *B. afzelii* (*Ba*) and *B. garinii* (*Bg*), are geographically confined in Europe, while *Bb* is endemic in both Europe and the United States (US). LD diagnostic assays in the US target antibodies specific to the *Bb* and may not detect antibodies to *Ba* or *Bg*, possibly leading to missed diagnoses among travelers who acquired LD abroad. Currently no US reference laboratory offers testing specific to *Ba* or *Bg*. We evaluated the *Borrelia* ViraStrip IgM and IgG (Viramed Biotech AG, Planegg, Germany) immunoblots for detection of antibodies to *Ba* and *Bg* from patients with culture confirmed infection in comparison to the US two-tiered algorithm (TTA) for LD.Thirty serum samples from patients with culture confirmed *Ba* (n=23) or *Bg* (n=7) infections were tested by the C6 ELISA (Immunetics Inc., MA, USA) and the US *Borrelia* B31 and European *Borrelia* IgM/IgG ViraStrip immunoblots (Viramed Biotech AG, Planegg, Germany). European blot specificity was evaluated using 20 C6 ELISA negative samples, 50 donor samples from a US LD endemic region, 49 samples seropositive for *Bb*, and 61 samples positive for antibodies to other infectious agents.The C6 ELISA was positive in 93% (28/30) of the *Ba* and *Bg* culture confirmed serum samples. The B31 IgM/IgG blots were positive in 47% (14/30) of cases compared to 87% (26/30) by the European IgM/IgG blots. Of the 20 C6-negative samples and 50 donor samples, the European IgM/IgG blots had a specificity of 95% and 90%, respectively. The European IgM and IgG blots were positive in 63% (12/19) and 97% (29/30) of samples previously seropositive for IgM and IgG by the B31 assays, respectively. Finally, the European IgM and IgG blots were positive in 2/10 CMV IgM and 1/5 *Anaplasma* positive (C6 negative) specimens, respectively.The current assays used for the LD TTA in the US are specific to *Bb* and this study confirms that these assays are not sensitive enough to detect antibodies to the European species associated with LD, including *Ba* and *Bg*. As international travel increases, the need has arisen for US reference laboratories to offer serologic assays specific to these LD agents to ensure that LD diagnoses are not missed.

Publishing Title:

A Comparative Analysis of Indoleamine 2,3-Dioxygenase Activity in Plasma of Cystic Fibrosis Patients with and without Exacerbation

Author Block:

M. Betancourt, **E. Manavathu**, C. Forseen, J. Vazquez; Med. Coll. of Georgia/Augusta Univ., Augusta, GA

Abstract Body:

Background: Indoleamine 2,3-dioxygenase (IDO) catalyzes the conversion of tryptophan (T) to kynurenine (K). Elevated levels of IDO have been detected in association with respiratory diseases, including cystic fibrosis (CF). The increased levels of IDO modulates the immune response against microbial pathogens in chronic infections, including respiratory diseases such as CF. Since active infection in CF patients is associated with exacerbation (EXBN) we hypothesized that elevated levels of IDO would be detected in the plasma of CF patients during an EXBN. We therefore examined the level of IDO activity by determining the relative amounts of K and T in plasma of CF patients with and without EXBN. **Methods:** Heparinized blood was collected from control (CONT) and EXBN CF patients. Plasma was collected, treated with trichloroacetic acid, centrifuged and the clear supernatant was used to determine K and T levels. K and T were separated on a C18 RP column (4.5 mm x 150 mm) using a Shimadzu HPLC system (mobile phase: 15 mM acetic acid-sodium acetate (pH 4.0) with 2.7% acetonitrile, 1.0 ml/min). HPLC grade K, T and 3-nitro-L-tyrosine were used as external and internal standards. K (360 nm) and T (278 nm) were detected using a UV detector. The K and T levels were determined from standard curves. The K/T ratio which represents the relative activity of IDO was calculated from the K and T levels for each patient. **Results:** Detectable levels of K and T were observed in 14 patients each in the CONT and EXBN groups. The mean K levels in the CONT and the EXBN patients were 1.29±0.17 µM (range 1.01-1.70 µM) and 1.47±0.55 µM (range 1.02-3.08 µM), respectively. Similarly, the mean T levels in the CONT and the EXBN patients were 21.38±5.72 µM (range 12.60-36.34 µM) and 17.38±6.72 µM (range 6.55-30.03 µM), respectively. The mean K/T ratio for the CONT and the EXBN patients were 0.0359±0.0115 (range 0.0213-0.0585) and 0.0556±0.0341 (range 0.0221-0.1346), respectively. A comparison of the K/T ratio for the CONT and the EXBN patients showed that it is significantly higher (p=0.0504) in the EXBN patients. **Conclusions:** The K/T ratio which represents the relative activity of IDO was significantly higher in CF patients with EXBN compared to non-EXBN patients. The plasma level IDO activity has the potential to be used as a biomarker for the onset of EXBN in CF patients.

Evaluation Of Ehrlichiosis In Northeastern Oklahoma Canines

Author Block:

J. M. Corley, D. E. Kirk, S. A. Ruskoski; Northeastern Oklahoma State Univ., Broken Arrow, OK

Abstract Body:

Background: Certain *Ehrlichia* species can be found in ticks which can cause world-wide ehrlichiosis in humans and other mammals. The lone star tick is the primary host for the bacteria. *Ehrlichia* spp. reproduces in mammalian leukocytes. In ticks, organisms remain dormant in the salivary glands until transferred to secondary hosts, such as canines, during feeding. The purpose of this study was to evaluate exposure to *Ehrlichia* spp. in Northeast Oklahoma canines currently exhibiting tick-borne disease symptoms, such as lethargy, anorexia, fever, and depression.**Materials:** Local veterinary hospitals supplied 51 blood samples from canines exhibiting tick-borne disease symptoms between September 2014 and September 2015. Sera were tested for antibodies to *Ehrlichia* spp. using an indirect immunofluorescent antibody assay (IFA). DNA was extracted from EDTA-treated whole blood from positive IFA samples and end-point polymerase chain reaction (PCR) was employed to confirm the presence of the organism.**Results:** Antibody testing revealed that 33 (65%) canines had positive titers to *Ehrlichia* spp. From the positive IFA samples, 17 (52%) tested positive for the *Ehrlichia* spp. DNA while 16 (48%) were negative.**Conclusion:** These data support the conclusion that while symptomatic canines may test positive for antibodies to *Ehrlichia* spp., it does not necessarily indicate a current infection with the organism.

Development of Elisa Kit for Serological Diagnostics of the Ruminants' Bluetongue

Author Block:

S. Nychyk, M. Sytiuk, V. Spyrydonov, G. Kovalenko; Inst. of Vet. Med. of the NAAS, Kyiv, Ukraine

Abstract Body:

Bluetongue virus (BTV) belongs to genus *Orbivirus* family *Reoviridae* consisting of 24 serotypes (BTV 1-24). The virus has small (diameter - 90 nm) icosahedral capsid containing segmented genome with 10 segments of double stranded RNA. Each segment encodes a different viral protein. The internal capsid layer consists of 5 structural proteins: 3 minor (VP1, VP4, VP6) and 2 major (VP3, VP7). The external capsid layer includes 2 major proteins (VP2, VP5). VP2 antigen determines serotype diversity of BTV, and VP7 antigen is responsible for serotype specificity. Therefore, VP7 is an appropriate protein for bluetongue diagnostics in ruminants. In our previous work, we produced transgenic tobacco plants expressing functional recombinant virus-specific capsid antigen VP7 that we used as a part of the developed ELISA kit for BTV antibody detection in serum samples.As of today, no bluetongue cases have been registered in Ukraine, but it should be taken into account that several outbreaks of this disease were observed a year ago in Europe, namely in France, Germany and Poland. BTV serotypes 6 and 8 were detected in Europe. That was the reason that we had performed validation of a developed ELISA kit with the use of reference samples and panels from animals experimentally infected with BTV serotypes 6 and 8 (Friedrich Loeffler Institute).For the validation of ELISA specificity and reproducibility, 19 positive and 89 negative sera were analyzed in triplicate. The average optical density (OD_{450}) of the positive samples was 1.150±0.488 and for the negative ones - 0.04±0.01.As a result of the experiments, it has been shown that the developed ELISA is characterized by high sensitivity, specificity and reproducibility. The developed ELISA kit has been recommended for use by the State Veterinary and Phytosanitary Service of Ukraine to monitor the spread of ruminants' bluetongue throughout Ukraine.

Use of Recombinant *Salmonella* Flagellar Hook Protein (Flgk) for Detection of Anti-*Salmonella* Antibodies in Chickens by Automated Capillary Immunoassay

Author Block:

H-Y. Yeh[1], A. Acosta[2], K. Serrano[2], R. J. Buhr[1]; [1]USDA/ARS/PMSPRU, Athens, GA, [2]Univ. of Puerto Rico, Mayaguez, PR

Abstract Body:

Background: Conventional immunoblot assays are a very useful tool for specific protein identification, but are tedious, labor-intensive and time-consuming. An automated capillary electrophoresis-based immunoblot assay called "Simple Western" has recently been developed that enables protein separation, blotting and detection in an automatic manner. This technology has been used by pharmaceutical industries to identify and characterize biophamarceutical products. However, this technology has not been used in clinical diagnosis. The flagellar hook protein **(**FlgK) is required for flagellar filament formation, plays a role in intestinal inflammation, and is the most immune-reactive flagellar protein. Therefore, it is a potential target for host immune response. In this communication, we evaluated whether the Simple Western system could be used to detect *Salmonella* FlgK antibodies from chicken sera. **Methods**: The recombinant *Salmonella* FlgK (rFlgK) protein was cloned, expressed and purified using commercial kits. Chickens were immunized with rFlgK emulsified in Freund's incomplete adjuvant at the ages of one and three weeks. Appropriate controls were included. Immunoblot analyses were performed in two ways: (1) conventional Western blot analysis, and (2) Simple Western immunoblot analysis according to the manufacturer's instructions. Chicken sera were collected from field. **Results**: The rFlgK protein reacted strongly to sera from the immunized chickens by both conventional Western blot and Simple Western analysis. Sera from un-immunized chickens and commercial specific pathogen free chickens did not react rFlgK. Further, we tested 66 individual chicken sera collected from a single flock raised similar to commercial conditions, and observed 63 out of 66 sera reacted at various degrees to the rFlgK protein by both methods. **Conclusion**: The *Salmonella* FlgK protein was expressed in and purified from the *E. coli* expression system. This protein induced strong immune response in chickens. The Simple Western immunoassay was successfully used for detection of antibodies against *Salmonella* rFlgK from chicken sera. These results provide a rational for further evaluation of the Simple Western immunoassay as a tool using *Salmonella* rFlgK in *Salmonella* outbreak investigation.

Recovery of Four Healthcare Associated Organisms from Hospital Surfaces Using Sponge Sticks

Author Block:

H. Houston, L. J. Rose, R. West-Deadwyler, J. A. Noble-Wang; CDC, Atlanta, GA

Abstract Body:

As healthcare-associated infections (HAI) become an increasing concern, we need a better understanding of the environmental reservoirs and the role of fomites in transmission. Collecting surface samples during HAI investigations or evaluation of cleaning and disinfection procedures is common, but no standard sampling protocol exists and little is known about the recovery efficiency of the sampling tools. We investigated the efficiency of the Sponge Stick (3M™), in recovering *Acinetobacter baumannii* (AB), *Clostridium difficile* (CD), carbapenem-resistant *Klebsiella pneumoniae* (KPC), and vancomycin-resistant *Enterococcus faecalis* (VRE) from three healthcare surface types (steel, laminate, and acrylic). Surfaces (50 in^2) were inoculated with each organism suspended in phosphate buffer (BB) or Artificial Test Soil (ATS) ($n \geq 6$ for each variable) to simulate body fluids, and allowed to dry before being sampled with a Sponge Stick. The organisms were eluted from the Sponge Stick, cultured and percent recovery (%R) was calculated. We compared: 1) %R of organisms in BB spread evenly across the surfaces to those suspended in ATS; 2) %R of inocula uniformly spread to a 4 cm^2 "hot spot" on the surface; and 3) %R of 10^4 and 10^6 CFU evenly spread and as a "hot spot." When spread evenly, %R was significantly higher if cells were suspended in ATS matrix ($p<0.005$). The highest %R for each organism (in ATS) was: CD from acrylic (58.9, SD 12.7), VRE "hot spot" on steel (62.8, SD 9.7), KPC spread on steel (8.9, SD 3.9) and AB spread on acrylic (21.5, SD 9.9). The lowest %R for each (all spread evenly in BB) was: CD on steel (26.3, SD 9.6), VRE on acrylic (3.2, SD 8.8), KPC on acrylic (0.3, SD 0.3), and AB on acrylic (6.9, SD 2.2).The %R was generally higher for VRE and AB as "hot spots" as compared to the spread inocula on surfaces ($p<0.0005$) except AB on acrylic ($p>0.05$). When comparing inoculum levels, %R was higher for 10^4 from steel ($p<0.05$), but no difference was seen from acrylic. The %R varied with organism, surface, matrix and deposition method. Additional studies are needed to investigate the role of cell and surface characteristics in attachment, sampling and recovery. The low %R for some organisms suggests current sampling and culture methods may not serve as a true indicator of bioburden and therefore underestimate the potential for transmission involving surfaces.

Trend of *Clostridium difficile* Infections by Onset Settings: A Multicenter Study

Author Block:

Y. P. Tabak[1], **C. A. DeRyke**[2], V. Gupta[1], X. Sun[1], R. S. Johannes[1], S. W. Marcella[2]; [1]Becton, Dickinson & Company, Franklin Lakes, NJ, [2]Merck & Co. Inc., Rahway, NJ

Abstract Body:

Background: A historically hospital-onset infection, C. *difficile* infection (CDI) may be increasingly community-onset. We sought to examine the trend of CDI by onset settings. **Methods:** We analyzed automated clinical data in 154 USA hospitals from 1/1/2008 to 9/30/2015. A CDI case was defined as a positive result of C. *difficile* toxin or molecular assay of a stool specimen obtained from a patient without a positive assay in the previous 8 weeks. Cases were classified based on the positive specimen collection time and setting: **a) Community-onset-community-associated**: in an outpatient setting or ≤3 calendar days after hospital admission AND no overnight hospital stay in the prior 12 weeks; **b) Community-onset-hospital-associated**: in an outpatient setting or ≤3 calendar days after hospital admission AND with overnight hospital stay in the prior 12 weeks; **c) Hospital-onset**: >3 calendar days after hospital admission.**Results:** From 2008 to 2015 (2015 cases annualized), the total number of CDI cases increased from 14,686 to 25,273 (72% increase, $p<0.01$). Setting specific rates were: community-onset-community-associated, from 6,586 to 13,975 (112%); community-onset-hospital-associated, from 4,545 to 6,524 (44%); hospital-onset, from 3,555 to 4,775 (34%) (all $p<0.01$). The community-onset-community-associated cases accounted for half of overall cases and proportionately increased from 45% in 2008 to 55% in 2015 ($p<0.01$). The combined community onset cases with or without prior hospital stay accounted for 81% of all cases in 2015. **Conclusions:** The overall CDI cases increased significantly over time for all three settings. The community-onset cases accounted for vast majority of all CDI cases and increased in proportion over time.

Molecular Epidemiological Analysis of *Clostridium difficile* Pcr Ribotype 018 Isolates from a University Hospital Over 5 Years

Author Block:

M-R. Seo, J. Kim, J. Kang, **H. Pai**; Med Coll Hanyang Univ., Seoul, Korea, Republic of

Abstract Body:

Background: *Clostridium difficile* PCR ribotype 018 (RT018) is the most prevalent strain in Korea, Japan and Italy. RT018 was known to be highly resistant to antibiotics. Objective of this study was to analyze a change of clonality and minimum inhibitory concentration (MIC) of antibiotics among annual isolates of RT018 from 2009 to 2013 in a tertiary hospital.**Methods:** A total of 207 *C. difficile* RT018 isolates were obtained from patients at the Hanyang Univeristy Hospital from January 2009 to December 2013. Multilocus variable-number tandem repeat analysis (MLVA) using six selected *C. difficle* repeat (CDR) loci was performed. The susceptibility of these isolates to clindamycin (CLI), moxifloxacin (MOX), metronidazole (MET), vancomycin (VAN), rifaximin (RFX) and piperacillin/tazobactam (PTZ) was determined.**Results:** Minimum-spanning-tree analysis of the MLVA data from 207 RT018 strains identified 78 MLVA types: 21 in 2009, 27 in 2010, 22 in 2011, 23 in 2012 and 10 types in 2013. The 78 MLVA types of RT018 isoates were categorized into 6 clonal complexes containg 2 or more isolates. The largest cluster, CC-I was composed of 51 MLVA types from 148 isolates (71.5%), and distributed in: 83.8% (31/37) in 2009, 93.3% (56/60) in 2010, 42.2% (19/45) in 2011, 59.6% (31/52) in 2012 and 84.6% (11/13) in 2013. CC-II composed of 10 MLVA types from 36 isolates distributed mostly in 2011: 0 in 2009, 3.3% (2/60) in 2010, 51.1% (23/45) in 2011, , 21.2% (11/52) in 2012 and 0 in 2013. Among 207 RT018 isolates, resistance rates to CLI and MOX were 97.6% and 98.6% respectively, while 1.4% presented VAN resistance. All strains were susceptible to MET or PTZ, with MIC_{90} values of 0.094 and 16ug/ml. Resistance rate to RFX was 8.2% ($MIC_{50,}$ 0.0038 and MIC_{90}, 0.5ug/ml). Comparing the MIC value of each antibiotic among annual isolates of RT018, MICs of CLI, MOX, PTZ, RFX and MET increased during 5 years (*P* for trend: <0.0001, <0.0001, <0.0001, <0.0001, and 0.006).**Conclusions:** MLVA types of RT018 changed over the years in a hospital, and several antibiotics' MICs of annual isolates increased.

Abstract Body:

Background: *Clostridium difficile* is an important cause of antibiotic-associated diarrhea and one of the most common healthcare-associated infections among children. This study investigated the molecular epidemiology and antimicrobial susceptibility of *C. difficile* infecting children.**Methods:** From January 2012 to October 2015, we analyzed 25 non-repetitive *C. difficile* strains isolated from children under eighteen years old who suffered diarrhea in the medical hospital of Tokyo Medical and Dental University. Multilocus sequence typing for molecular epidemiology and multiplex PCR for detecting the toxin genes were performed. The minimum inhibitory concentrations of antibiotics were determined by the agar dilution method.**Results:** The incidence of *C. difficile* infection in children <18 years was 1.58 cases per 1,000 in-patients. The most common risk factors were immunosuppression (96.0%), use of antibiotics (92.0%), use of proton pump inhibitors and/or histamine-2 receptor antagonists (40.0%). The clinical course was mild in most cases; however, 60% of the cases experienced recurrence despite metronidazole treatment. Nineteen toxigenic strains (76.0%) (including eleven *tcdA*-positive, *tcdB*-positive, and *cdtA/cdtB*-negative strains ($A^+B^+CDT^-$) and eight $A^+B^-CDT^-$ strains) and six (24.0%) non-toxigenic strains were classified into eleven and four sequence types, respectively. Of these, sequence type (ST) 109 (20.0%) was the most predominant. Antibiotic susceptibility rates to clindamycin, vancomycin, and metronidazole were 8, 92, and 100%, respectively.**Conclusions:** The role of *C. difficile* infection in immunocompromised children, including those with malignancies, hematopoietic stem cell transplants, and other humoral and cellular immunodeficiencies, has been increasingly recognized. In addition, the recurrence rates among these patients were higher than expected. Continuous surveillance for antibiotic susceptibility of *C. difficile* is very important for the administration of the appropriate antimicrobial therapy.

Impact of Presence of Malignancy and Exposure to Chemotherapy on Clinical and Microbiological Characteristics of *Clostridium difficile* Infection

Author Block:

M. Chung, J. Kim, **J. Kang**, H. Pai; Med Coll Hanyang Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Purpose of the study was to investigate the impact of malignancy and chemotherapy on clinical and microbiological characteristics of *Clostridium difficile* infection (CDI).**Methods:** We performed a retrospective study with the patients of CDI from February 2009 through January 2013. CDI patient with history of malignancy within 5 years was defined as cancer group. Among the cancer group, patient who received chemotherapy within 2 months was regarded as chemotherapy group. Characteristics of patients were compared between the groups according to presence of malignancy and exposure to chemotherapy.**Results:** Of 580 patients with CDI, 159 cases (27.4%) belonged to cancer group and 421 (72.6%) to non-cancer group, and 69 of 159 cases were in subgroup of chemotherapy. More patients in cancer group were hospitalized within prior 2 months (P<0.001). Leukocytosis was more common in non-cancer group (P = 0.034), and infection by PCR ribotype 017 strains occurred more frequently in cancer group with marginal significance (P =0.07). Recurrence rate was higher in cancer group than non-cancer group (20.4% vs. 9.5%, P =0.005), and the presence of malignancy was consistently a significant risk factor for recurrence of CDI in multivariate logistic regression (OR=2.665, 95% CI 1.343-5.289, P =0.005). Age significantly contributed to recurrence of CDI as well (OR=1.032, 95% CI 1.004-1.060, P =0.026). However, chemotherapy did not effect on clinical course of CDI significantly.**Conclusions:** Malignancy and old age were independent risk factors for recurrence of CDI. Cancer patients require careful observation for recurrence after treatment of CDI.

Publishing Title:

Risk Factors for *Clostridium difficile* Infection in Patients with HIV

Author Block:

H. Imlay, D. R. Kaul, K. Rao; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: *Clostridium difficile* infection (CDI) is a healthcare-associated infection resulting in significant morbidity. Immunosuppression is a significant risk factor for both acquisition of CDI and adverse outcomes. However, the epidemiology of CDI in HIV-infected patients has been little studied in the era of antiretroviral therapy (ART). This study's goal was to identify the risk factors, including HIV-specific ones, for acquisition of CDI in HIV-infected patients.
Methods: A retrospective, propensity score-matched case/control study design was employed, with patients selected from our institution's outpatient HIV clinic. CDI cases were defined as having positive stool testing for either the toxin(s) A/B or the *tcdB* gene plus an appropriate clinical presentation. The propensity score was generated via multiple logistic regression from year of HIV diagnosis, age at first contact, duration of follow up, gender, and initial CD4 count. Chart review extracted variables.**Results:** The 46 cases included were matched up to 1:4 by propensity scores to a total 180 controls. The final model is presented in Table 1. Adjusting for covariates, including age, prior antibiotic treatment was a significant predictor of CDI (odds ratio [OR] 13, 95% confidence interval [CI] 3.49-48.8, *P* <.001) as was number of hospital admissions in the preceding year (OR 4.02, CI 1.81-8.94, *P* <.001). Neither PPI use nor low CD4 count (<200 cells/µL) were independent predictors of CDI, but if both were present an interaction existed that conferred a significantly increased risk of CDI in the multivariable model (OR 15.17, CI 1.31-175.9, *P* = .021).**Conclusions:** As in the general population, frequent hospitalizations and exposure to antimicrobials are independent predictors of CDI acquisition in patients with HIV. Intriguingly, the HIV-specific risk factor of a low CD4 count combined with PPI use significantly increased the risk of CDI and, as potentially modifiable characteristics, these present targets for preventative interventions in future studies.

Table 1. Multivariable model for acquisition of *Clostridium difficile* infection with HIV

Variable	**β coefficient ± standard error**	***P***
Exposure to antimicrobials	2.57 ± 0.67	<.001
Number of hospitalizations in the preceeding year	1.39 ± 0.41	.001
Exposure to proton pump inhibitors (PPIs)	−0.74 ± 0.88	.4
CD4 count <200 cells/µL	−0.87 ± 0.97	.369
CD4 <200 cells/µL + PPI exposure	3.46 ± 1.67	.039

Multi-laboratory Evaluation of Storage Conditions and Stability of Purified Spore Suspensions of *Clostridium difficile*

Author Block:

J. A. HASAN, K. M. Japal, R. M. Pines; US Environmental Protection Agency, FT. MEADE, MD

Abstract Body:

The US Environmental Protection Agency (EPA) regulates antimicrobial pesticides including products with claims for use against spores of *Clostridium difficile* on hard non-porous surfaces. ASTM Standard Test Method (E2839-11) is recommended for production of *C. difficile* spores for use in efficacy testing. The method does not currently specify storage conditions for spore suspensions. Six laboratories participated in a study to evaluate two storage conditions over a twelve week period; spore suspensions stored at -80°C, and, spores dried on test carriers and stored under desiccation at room temperature (RT). The log densities (LD) of the spore suspensions on control carriers and the log reduction (LR) values of the spores when exposed to laboratory grade sodium hypochlorite (NaOCl) at 5,000 ppm, 2,500 ppm and 1,500 ppm available chlorine were evaluated every two weeks over a twelve week period. The OECD Quantitative Method (ASTM E2197-11) was used to measure the LD and LR values for control and treated carriers, respectively. For four of the six labs, the LD values of control carriers inoculated with spores and stored in a desiccator at RT dropped below the required minimum of six logs of spores per carrier necessary to evaluate the LR values for the NaOCl treatments. The LD values of control carriers inoculated with spores stored at -80°C demonstrated stable counts across all labs over the 12 week period ($p = 0.797$). Spores stored at -80°C and exposed to the NaOCl solutions exhibited low variability for the 5,000 ppm and 1,500 ppm treatments, but higher variability for the 2500 ppm treatment over the study period. The mean LR values for all three treatments are statistically significantly different ($p \leq 0.010$) indicating the responsiveness of the OECD method at each point in time. The trends of the mean LR were not statistically significantly different across treatments ($p \geq 0.577$), suggesting the suitability and stability of the spores when stored at -80°C. EPA will utilize the data in considering whether to modify the guidance used for developing efficacy data for antimicrobial products against *C. difficile.*

Effect of Testing Methods with Real-Time Clinical Surveillance Tools in Patients with *Clostridium difficile* Infections

Author Block:

H. Burgess, **M. Cooper**, R. Burks, D. Smith, A. Nelson, S. Fraker, J. Kramer; HCA Corporate, Nashville, TN

Abstract Body:

Background: Despite effective antibiotic therapy, *Clostridium difficile* infections (CDIs) are associated with a high rate of mortality. Moreover, patients who survive the disease can experience high morbidity and be left with debilitating effects. The utilization of polymerase chain reaction and nucleic acid amplification tests (PCR/NAAT) for diagnostic testing has been suggested as an opportunity for antimicrobial stewardship programs to improve antimicrobial use and clinical outcomes in patients with CDIs. Additionally, real-time clinical surveillance tools (RTCSTs) can be utilized to alert pharmacists to opportunities for intervention. The aim of this study was to determine the impact of PCR/NAAT and RTCST compared to conventional CDI testing and RTCST on time to appropriate antimicrobial therapy. **Methods:** This retrospective study looked at patients treated at one of 83 hospitals from November 1, 2014 through June 30, 2015 who had RTCST alerts for a positive *C. difficile* test who had not been started on therapy prior to the result being reported as positive. The primary outcome was frequency of appropriate antimicrobial therapy administration within 4 hours of RTCST alert activation. 2-sample t-tests, Chi-square tests, and Mann-Whitney-Wilcoxon tests were used for statistical analysis of the data. **Results:** 1748 patients were included in the analysis. For the primary outcome, 41.9% of patients in the PCR/NAAT group received an appropriate medication within 4 hours of RTCST activation, compared with 27.4% in the conventional group ($p<0.001$). In those patients who received appropriate therapy within 4 hours, time from collection to results was significantly shorter in the PCR/NAAT group when compared to the conventional group, resulting in faster time to therapy (6.6 hours vs. 16.1 hours, respectively [$p<0.001$]). When looking at the group as a whole and comparing PCR/NAAT and conventional testing, no differences were found in length of stay or mortality. **Conclusions:** RDT testing shows benefit over conventional diagnostic testing in patients with CDIs. In this study, it led to faster diagnostic results which, in turn, resulted in earlier administration of appropriate antimicrobial therapy.

In Vitro Activities Of Fidaxomicin, Op-1118, And Surotomycin Against Ribotype 027 (Nap1/Bl) *clostridium Difficile* Isolated From Canadian Patents: Can-Diff 2013-2015

Author Block:

J. Karlowsky[1], H. Adam[1], Z. Narrandes[2], G. Golding[3], K. Nichol[1], T. Kosowan[3], M. Baxter[2], N. Laing[2], D. Hoban[1], G. G. ZHANEL[2], CARA; [1]Diagnostic Services Manitoba, Winnipeg, MB, Canada, [2]Univ. of Manitoba, Winnipeg, MB, Canada, [3]Natl. Microbiol. Lab., Winnipeg, MB, Canada

Abstract Body:

Background: Clinical microbiology laboratories do not routinely culture toxin-positive (TP) stool specimens for *C. difficile* (CD), or perform antimicrobial susceptibility testing (AST) or ribotyping on TP-CD isolates. Therefore, periodic assessments are informative. The current study determined genotypes and the in vitro activities of 6 routinely tested anti-anaerobic agents as well as the oral narrow-spectrum macrocyclic antimicrobial, fidaxomicin, its active metabolite OP-1118, and surotomycin, an oral cyclic lipopeptide against TP-CD isolates collected in Canada from 2013 to 2015.**Methods:** To date, 983 isolates of CD have been cultured from TP stool specimens using CDMN agar. Each isolate's identity was confirmed by accepted laboratory methods. AST was performed using the agar dilution method (CLSI, M11-A9, 2015). The presence of *tcdA* (toxin A), *tcdB* (toxin B), *tcdC* (negative regulator of toxin production) and *cdtB* (binary toxin) were determined by PCR methods. Genotyping was performed by an accepted PCR ribotyping method.**Results:** >99.9% of CD were susceptible to metronidazole, amoxicillin-clavulanate, and tigecycline; isolate susceptibilities to clindamycin (4.8%), ceftriaxone (11.9%), and moxifloxacin (66.7%) were lower. MIC ranges/MIC_{90}s (µg/mL) were ≤0.015-1/0.5, 0.25-32/16, 0.12-8/2, and ≤0.25-4/2, respectively, for fidaxomicin, OP-1118, surotomycin, and vancomycin. 027 (25.7% of isolates), 014 (8.5%), 020 (5.9%), and 106 (5.3%) were the most common ribotypes identified. Ribotype 027 accounted for 15.3, 27.9, and 34.7% of isolates from western Canada (BC, Alberta, Manitoba), Ontario, and eastern Canada (Quebec, Nova Scotia), respectively, as well as 18.1, 22.9, and 40.2% of isolates from patients aged ≤64, 65-79, and ≥80 years. Isolates of ribotype 027 had higher MIC_{90}s for moxifloxacin and vancomycin (>32 and 2 µg/ml), respectively, than other ribotypes (2-16 and 1 µg/ml).**Conclusion:** Fidaxomicin, OP-1118, and surotomycin demonstrated potent in vitro activity against all genotypes of TP-CD including ribotype 027 (NAP1/BI).

***In Vitro* Activity of Vancomycin (VA), Metronidazole (ME), Clindamycin (CL), Moxifloxacin (MX), Fidaxomicin (FX), and Rifaximin (RX) Against *Clostridium difficile* (CD) Isolates Recovered from Patients Enrolled in a Global Clinical Trial of Actoxumab and Bezlotoxumab**

Author Block:

D. M. Citron[1], E. J. C. Goldstein[1], S. Sambol[2], M. H. Wilcox[3], M. Dorr[4]; [1]R.M. Alden Res. Lab., Culver City, CA, [2]VA Med. Ctr., Hines, IL, [3]Leeds Inst. of BioMed. and Clinical Sci., Leeds, United Kingdom, [4]Merck & Co., Kenilworth, NJ

Abstract Body:

Background: MODIFY I and II were global clinical trials of actoxumab and bezlotoxumab (+ standard of care) for prevention of recurrent CD infection, conducted over 3 years (2012-15) at 382 sites in 30 countries in N. and S. America, Europe, Asia, and including Israel and S. Africa. **Methods**: CD positive samples came from 297 (93.6 %) of 317 study sites that sent specimens and yielded 1776 unique Visit 1 isolates. Susceptibility testing was performed with 6 antimicrobial agents using an agar dilution method. Isolates were also shipped to two laboratories for REA and ribotyping (RT). **Results**: 42.8% of isolates came from US, while Spain had 7.8%, Canada 7.5%, Poland and Israel each 4.1%, Japan 3.7%, Czech Republic 3.6%, and Italy 3.1%. The remaining countries each had &lt3% of the total. Decreased susceptibility to VA (MIC 4-8 µg/ml) was seen in 144/1776 isolates (8.1%), predominantly from USA and Israel. The most common RTs were 027 and 137, corresponding to REA groups BI and BN, respectively. Resistance to MX (MIC &gt2µg/ml) was also present in 88.2% of these (127/144), isolates. Decreased susceptibility to ME (MIC 4-8 µg/ml) was found in 46/1776 strains (2.6%), which also showed resistance to MX (95.7%) and were recovered largely from sites in Chile, Poland, and USA, mostly RTs 027 and 001 (REA groups BI and J, respectively). RX resistance (MIC &gt32µg/ml) was seen in 12.9% of isolates overall; over half of these (116/229) were RT 027, mostly from the US, and Poland and almost half the isolates (26/53) from Italy were RX-resistant with RTs 356 and 018 (REA group W) predominating. Two strains with FI MIC &gt8 µg/ml were found, one each from US and France. **Conclusions:** Worldwide resistance of CD is increasing. RT 027 strains are multi-resistant, including decreased susceptibility to VA (22.8%) and ME (6.2%), and resistant to MX (89.1%) and RX (35.8%); other highly resistant RTs include 137 (Israel) and 001 (Europe and S. America). 99.9% of the isolates were susceptible to FI at &lt2 µg/ml. New therapies to improve outcomes are needed for this increasingly problematic pathogen.

Genotypes and Antifungal Susceptibility of *Cryptococcus neoformans* Species Complex Causing Invasive Diseases in China: Predominance of *C. neoformans* var. *Grubii* Sequence Type 5, and Emergence of Isolates Non-Susceptible to Fluc

Author Block:

M. Xiao[1], X. Fan[1], S. Chen[2], F. Kong[2], H. Wang[1], Y-C. Xu[1]; [1]Peking Union Med. Coll. Hosp., Beijing, China, [2]Westmead Hosp., Westmead, Australia

Abstract Body:

Background: There are limited data on cryptococcosis in China. Here we investigated the nationwide genetic structure and antifungal susceptibility of the *Cryptococcus neoformans* species complex over a five-year period.**Methods:** A total of 312 *C. neoformans* species complex isolates from patients with cryptococcosis collected from 10 hospitals from August 2009 to July 2014 in China were studied. The isolates were identified by sequencing of the rDNA internal transcribed spacer (ITS) region, and multilocus sequence typing was used for genotyping of the species complex. The ability of two MALDI-TOF MS systems to identify *C. neoformans* complex isolates were also evaluated. *In vitro* susceptibility to six antifungal drugs was determined by the Sensititre YeastOne method.**Results:** Of 312 isolates, 211 (67.6%) were isolated from cerebrospinal fluid (CSF), followed by blood cultures (n = 74, 23.7%). *C. neoformans* was the most common species (n = 305, 97.8%), of which *C. neoformans* var. *grubii* sequence type (ST) 5 were predominant (n = 272, 89.2%), followed by ST31 (n = 31, 6.1%), while other *C. neoformans* var. *grubii* STs (n = 12 in all, 3.9%) and *C. neoformans* var. *neoformans* (n = 2, 0.7%) were rare. Molecular serotyping found all *C. neoformans* var. *grubii* were serotype A, and the two *C. neoformans* var. *neoformans* isolates were serotype AD heterozygote. *C. gattii* were also less common (n = 7, 2.2%). Two MALDI-TOF MS showed good capacity in identifying *C. neoformans* var. *grubii* and var. *neoformans* isolates (>99%) but less satisfying in identifying *C. gattii* (Bruker Biotyper 71.4%, Vitek MS, 0%). Amongst *C. neoformans* var. *grubii* isolates, the proportion of fluconazole non-wild-type isolates were significantly higher in the fourth year (23.9%) comparing to previous three years (0-2.1%), including five fluconazole highly non-susceptible isolates (minimum inhibitory concentrations ≥ 32 mg/L) that all belonged to *C. neoformans* ST5.**Conclusions:** In summary, *C. neoformans* var. *grubii* ST5 was the most predominant in China. The emergence of fluconazole highly non-susceptible isolates and their geographic difference warrant continuous surveillance.

Evaluation of *In Vitro* Amphotericin B and Triazole Activity Against *Coccidioides* species from United States Institutions

Author Block:

G. Thompson, III[1], B. M. Barker[2], N. P. Wiederhold[3]; [1]UC-Davis, Sacramento, CA, [2]Tgen, Flagstaff, AZ, [3]UTHSCSA, San Antonio, TX

Abstract Body:

Background: Large scale testing of *Coccidioides* isolates to define population susceptibility has not previously been performed, nor has the frequency of clinical isolates with elevated amphotericin B (AMB) or triazole MICs been evaluated. **Methods:** *Coccidioides* isolates ($n \geq 380$) submitted to the UT Health Science Center Fungus Testing Laboratory were queried for AMB, fluconazole (FLC), itraconazole (ITC), posaconazole (PSC), and voriconazole (VRC) MICs. Isolates from across the United States were included in this assessment. Antifungal susceptibility testing was performed by broth macrodilution according to the CLSI M38-A2 standard. The MIC range, MIC50, MIC90, and geometric mean (GM) MIC values were determined, and differences in GM MIC values were assessed for significance by ANOVA with Tukey's post-test for multiple comparisons.**Results:** Of the antifungals evaluated, VRC had the most potent *in vitro* activity. The VRC GM MIC (0.106 μg/ml) was significantly lower than that observed for AMB (0.243 μg/ml), FLC (7.586 μg/ml), and ITC (0.244 μg/ml) ($p < 0.0001$ for all comparisons). The PSC GM MIC (0.140 μg/ml) was similar to that of VRC, and was significantly lower than that of AMB, FLC, and ITC ($p < 0.0001$). Interestingly, there was a wide range of potency for each antifungal with several isolates having elevated MIC values for FLC (MIC $\geq$ 16 μg/ml; 37.2% of isolates), ITC ($\geq$ 2 μg/ml; 1.0%), PSC ($\geq$ 1 μg/ml; 1.1%), and VRC ($\geq$ 2 μg/ml; 1.2%), AMB ($\geq$ 2 μg/ml; 2.8%).**Conclusions:** Mould active triazoles exhibited low MICs for the majority of isolates tested with MICs likely to confer clinical resistance uncommon. However elevated fluconazole MICs were commonplace. Further work focusing on patient outcomes and the molecular mechanisms responsible for elevated triazole MICs should be performed as resistance and clinical failure remain uncharacterized in coccidioidomycosis.

Development of a Risk Score for Fluconazole Failure among Patients with Invasive Candidiasis

Author Block:

L. Ostrosky-Zeichner[1], **R. Harrington**[2], N. Azie[2], H. Yang[3], N. Li[3], J. Zhao[3], V. Koo[3], E. Wu[3]; [1]UTHlth., Houston, TX, [2]Astellas, Northbrook, IL, [3]Analysis Group, Boston, MA

Abstract Body:

Background: Resistance to fluconazole (FLU) has become a growing concern. We developed a prediction model to identify patients with invasive candidiasis (IC) at high risk of failing FLU. **Methods:** Adult patients with IC (defined by positive microbiology blood culture) who received FLU during hospitalization were selected from Cerner Health Facts database (2005-2013). FLU failure was defined as switching from or adding other antifungal to FLU, a positive culture for *Candida* ≥ 10 days after FLU initiation, or death during hospitalization. Patients were randomly split into modeling and validation samples (2:1 ratio). A least absolute shrinkage and selection operator regression was used to select predictors for estimating individual risk of FLU failure. The list of potential predictors evaluated included patient demographics, *Candida* species, initiation of FLU before positive culture and after admission, co-morbidities, procedures, and treatments during the period from 6-month before admission to initiation of FLU. The performance of the selected prediction model was evaluated using the validation sample.**Results:** A total of 987 patients were identified, including 488 with FLU failure and 499 without failure. The final prediction model for FLU failure was composed of 9 risk factors: days to start FLU from admission, *C. glabrata* infection, *C. krusei* infection, hematological malignancies, venous thromboembolism (VTE), enteral nutrition, use of non-operative intubation or irrigation, use of mechanical ventilation, and use of other antifungals. All factors, except VTE, were associated with a higher risk of FLU failure. The c-statistic of the model was 0.65. Model performance using a predicted risk score threshold ranging from 0.3 to 0.7 to define FLU failure was summarized in Table 1.**Conclusion:** The prediction model could identify patients with a high risk of FLU failure, illustrating the potential value and feasibility of personalizing IC treatment.**Table 1.** Model performance

Threshold	**Sensitivity**	**Specificity**	**Positive Predictive Value**	**Negative Predictive Value**
0.3	0.97	0.17	0.53	0.85
0.4	0.78	0.42	0.57	0.66

Publishing Title:

Echinocandin (Ec) Agent-Specific Spontaneous and *fks* Mutation Rates in *Candida glabrata* (Cg)

Author Block:

R. K. Shields, M. H. Nguyen, E. G. Press, C. J. Clancy; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: EC resistance in Cg is mediated by point mutations in *FKS1* and *FKS2* hot spots (HS). Our objective was to measure spontaneous (SMR) and *FKS* mutation rates among Cg exposed to anidulafungin (ANF), caspofungin (CSP), and micafungin (MCF). **Methods:** 20 *FKS* wild-type (WT) Cg with varying EC MICs from pts w/ or w/o prior EC exposure were selected. SMR was calculated as ratio of Cg on SDA plates w/ or w/o ECs at 3x MIC. Minimum fungicidal (MFC) and mutation prevention concentrations (MPC) were the lowest EC concentrations inhibiting ≥99% and 100% of Cg, respectively. MICs and *FKS* genotypes were determined for colonies growing at ≥MFC for each EC. **Results:** Median ANF, CSP, and MCF MICs were 0.06 (range: 0.03 - 0.12), 0.12 (0.03 - 1), and 0.03 (0.015 - 0.03), respectively. Corresponding median MFC/MPCs were 0.25/0.5, 1/2, and 0.06/0.06, respectively. CSP MFCs and MPCs were higher than other ECs (P<0.0001 for each). Median Cg SMRs in ascending order were 3.1E-9 (0 to 1.1E-7), 3.5E-7 (2.7E-8 to 3.9E-6), and 1.0E-5 (5.3E-7 to 3.5E-3) for MCF, ANF, and CSP, respectively (P<0.0001). SMR did not vary by CSP MIC or prior EC exposure. 159, 74, and 14 strains growing at ≥MFC of CSP, ANF, and MCF, respectively, were collected; 20% had no change in MIC compared to parent strains. Among the remaining 80%, CSP, ANF, and MCF MICs were increased by ≥2-fold in 89%, 60%, and 44%, respectively. All strains selected on MCF-agar had increased MICs to all agents; however, strains selected on ANF or CSF-agar demonstrated agent-specific MIC increases (P<0.004). 33% of MFC mutants (41% of mutants w/ ≥2-fold MIC increase) had *FKS* mutations. *FKS* mutations were detected among 30%, 30%, and 86% of strains recovered on CSP, ANF, and MCF-containing agar, respectively (P<0.001). 78%, 16%, and 6% of *FKS* mutations were in FKS2-HS1, FKS2-HS2, and FKS1-HS1, respectively. Mutations at S629 (FKS1) or S663 (FKS2) were more common among strains exposed to ANF or MCF (26%) compared to CSP (4%; P=0.006). 3% of MFC mutant strains had ≥4-fold MICs to all agents, but no *FKS* mutations. **Conclusions:** MFC and MPC are highest for CSP. Across agents, SMR and *FKS* mutations are inversely related. In rank order, SMR are CSP>ANF>MCF; however, the percentage of mutant strains harboring *FKS* HS mutations was MCF>ANF>CSP. *FKS* mutations also differ by EC. A small, meaningful % of strains demonstrate increased MICs to all ECs, but do not harbor *FKS* HS mutations.

Publishing Title:

In Vitro Antifungal Activity of Echinocandins Against 198 *Candida* spp Strains

Author Block:

N. Kiraz; Istanbul Univ. Cerrahpasa Faculty of Med., Istanbul, Turkey

Abstract Body:

Background: The echinocandins anidulafungin (ANF), caspofungin (CSF), micafungin (MCF) represent a new antifungal group with potent activity against *Candida* species. A commercially prepared dried colorimetric microdilution panel (Sensititre YeastOne, TREK Diagnostic Systems, Cleveland, OH, USA) is able to determine the susceptibility of echinocandins and demonstrated excellent corelation with the reference method M27-A3 from the Clinical Laboratory Standards Institute (CLSI). Resistance rates were determined by recently revised CLSI antifungal breakpoints. The aim of this study is to evaluate the *in vitro* activity of ANF, CSF and MCF against clinically significant *Candida* strains by YeastOne colorimetric microdilution panel.**Methods:** Isolates were checked of purity and were identified by classical morphological tests including germtube formation in human serum at 37°C for 3 h, blastoconidia, pseudohyphae, truehyphae and chlamydoconidia formation on corn meal agar-Tween 80, integrating with the results of chromogenic agar (CHROMagar, HiMedia, India) and of API 20C AUX kit (Bio Mérieux, France). Identification kit procedure and colorimetric microdilution tests were performed according to the manufacturer's instructions. Quality control was ensured by testing CLSI-recommended strains *C. parapsilosis* ATCC 22019 and *C. krusei* ATCC 6258.**Results:** Among 198 Candida isolates, 112 were C. albicans, 11 were C. glabrata, 45 were C. parapsilosis, 14 were C. tropicalis, seven C. krusei, three of each C. kefyr and C. lusitaniae, two C. guilliermondii, and one C. pelluculosa. Regarding to the MIC values obtained, resistance to ANF was observed in one C. albicans, two C. tropicalis, five C. parapsilosis strains; resistance to CSF was observed in one C. albicans and one C. parapsilosis strains; and resistance to MCF was observed in two C. albicans, one C. tropicalis and fiveC. Parapsilosis strains. There remaining strains were in vitro susceptible to all echinocandins tested.**Conclusions:** Based on newly established breakpoints for species-specific interpretive criteria, the results of this study affirmed that echinocandins exhibit excellent activity against the *Candida* secies most frequently involved in human infections.

Publishing Title:

World-Wide Epidemiology of FKS Mutations in Candida: A Systematic Review of the Literature

Author Block:

M. Al Obaidi[1], D. Thye[2], L. Ostrosky-Zeichner[1]; [1]UTHlth., Houston, TX, [2]Cidara, San Diego, CA

Abstract Body:

Background: Echinocandins are the agents of choice for treatment of candidemia. Echinocandin failures and FKS mutations are being reported more frequently. We describe the world-wide epidemiology of FKS mutations.**Methods:** We performed a systematic review of the literature from 2006-2015 using Pubmed. We included publications in English with the following keywords: FKS candida, FKS1, and FKS2, excluding duplicate isolates by screening for any publication with overlapping sources, including the SENTRY database. Data at the individual strain level were collated and descriptive statistics were performed.**Results:** We found 54 publications that met criteria reporting 535 *Candida* isolates with FKS mutations. The number of reported isolates fluctuated throughout the years with a peak in 2014. *C. glabrata* dominated the number of reported FKS mutations with 326 (60.9%) isolates (68% FKS2 and 32% FKS1), followed by *C. albicans* with 71 (13.27%), *C. krusei* 14 (2.6%), *C. tropicalis* 12 (2.2%), *C. kefyr* 5(0.9%), *C. lusitaniae* 4(0.7%), *C. parapsilosis* 4(0.7%), *C. orthopsilosis* 3(0.56%), and *C. dubliniensis* 2 (0.37%). All non-glabrata isolates had only FKS1 mutations. North America accounted for the highest proportion of the reported isolates with a total of 252 (47%), with Europe reporting 111 (20.7%) isolates. Only 20/535 (3.7%) isolates harbored a heterozygous mutation. 282/535 (52.7%) of the reported mutations were within the classic hotspot regions (96.8% HS1 and 3.19% HS2). Amino Acid substitutions analysis showed S663 was the commonest with 137/535 (33.7% of *C. glabrata* isolates). S629P was the second most frequent substitution seen in 35 *C. glabrata* isolates and 1 *C. albicans*. **Conclusions:** Our study is limited by publication and search strategy bias; nevertheless, our systematic review confirmed an increasing number of isolates with FKS mutations being reported in the literature since 2006. Most mutations are being reported in North America and Europe with *C. glabrata* and *C. albicans* accounting for the majority of strains. FKS2 mutations are seen exclusively in *C. glabrata*. Most mutations are homozygous and the high frequency of certain amino acid substitutions may indicate clonal/regional spread. Continued surveillance of these epidemiological trends is warranted as echinocandin use extends.

Incidence, Clinical Characteristics And Sensitivity Profile Of Candidemia In A Teaching Hospital Located In The Southeast Of Brazil

Author Block:

H. M. S. Canela[1], M. E. S. Ferreira[1], B. Cardoso[1], R. Martinez[2], L. H. Vitali[2]; [1]Sch. of Pharmaceutical Sci. of Ribeirão Preto, Ribeirão Preto, Brazil, [2]Clinical Hosp. of Ribeirão Preto Med. Sch., Ribeirão Preto, Brazil

Abstract Body:

Background: *Candida* spp. are the seventh leading cause of nosocomial bloodstream infections in Brazil and are related to high mortality rates. Therefore, the aim of this work was to characterize 79 bloodstream isolates of *C. albicans*, *C. glabrata*, *C. orthopsilosis*, *C. parapsilosis* and *C. tropicalis* from patients of a Brazilian hospital. **Methods:** The Minimal Inhibitory Concentration (MIC) of amphotericin B, fluconazole and voriconazole was determined by broth microdilution CLSI guidelines. The clinical characteristics were analyzed using patients files.**Results:** *C. albicans* was the predominant species (44%), followed by *C. glabrata* (19%), *C. tropicalis* (19%), *C. parapsilosis* (14%) and *C. orthopsilosis* (4%). Amphotericin B mean MIC was 0.85 (±0.31). Since CLSI has no breakpoints for this drug, the results were not classified in resistant or susceptible. All *C. glabrata* isolates were susceptible dose-dependent to fluconazole. One *C. albicans* isolate was susceptible dose-dependent to voriconazole. One *C. albicans* isolate showed high MIC values against fluconazole (512 μg/mL) and voriconazole (128 μg/mL). The incidence was 1.52 per 1,000 admissions and the mortality rate was 52%. *C. glabrata* (73%) showed the highest mortality rate, followed by *C. tropicalis* (53%), *C. albicans* (49%), *C. parapsilosis* (36%) and *C. orthopsilosis* (33%). The majority of the patients was male (57%) and the mean age was 42 (±27), however, the mean age of *C. orthopsilosis* patients was significantly lower (0.58±0.32). Patients were hospitalized on medical units (42%), Intensive Care Units (ICU) (34%) and surgery units (24%). Though, all *C. orthopsilosis* patients belonged to ICU and most of *C. glabrata* (47%) and *C. parapsilosis* (45%) were hospitalized in surgery units. The main risk factor was antibiotic therapy (86%), followed by urinary catheter (68%), central venous access (60%), surgeries (54%), parenteral nutrition (42%) and neutropenia (14%). Solid cancer was the main underlying disease (28%), followed by diabetes (23%), gastrointestinal diseases (20%) and liver diseases (15%).**Conclusions:** These results are useful to bring a better comprehension of candidemia in the studied hospital.

Publishing Title:

Prevalence,Clinical Relevance, and Azole Resistance of Cryptic *Aspergillus* Section *Fumigati* Isolates: A 2000-2013 Survey in a Montreal Hospital

Author Block:

M. Parent-Michaud[1], L. de Repentigny[1], S. F. Dufresne[2]; [1]Univ. of Montreal, Montreal, QC, Canada, [2]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada

Abstract Body:

Cryptic species of *Aspergillus* section *Fumigati* are an emerging cause of invasive aspergillosis, and are of growing concern because many isolates display intrinsic *in vitro* resistance to triazole antifungals, associated with treatment failure. However, the prevalence of these cryptic species can vary widely across institutions, due to varying methods in detection/identification, different patient populations, and differing strategies in antifungal prophylaxis. We therefore conducted a retrospective survey of 1183 stored clinical isolates of *Aspergillus fumigatus*, collected from 2000 to 2013 at Maisonneuve-Rosemont Hospital. The isolates were cultured on Sabouraud-dextrose agar, and Czapek-Dox agar, to ascertain their macroscopic and microscopic morphology, and thermotolerance was determined at 49^{o}C. Twenty-one atypical isolates (delayed sporulation and/or no growth at 49^{o}C) were further identified by sequencing of the β-tubulin gene, yielding *A. fumigatus* (N=9; 9 patients), *Aspergillus turcosus* (N=4; 4 Pts.), *Neosartorya pseudofischeri* (N=7; 1 Pt.), and *Neosartorya hiratsukae* (N=1; 1 Pt.). Antifungal susceptibility to itraconazole, voriconazole and posaconazole was determined using the CLSI M38-A2 broth microdilution procedure. *Aspergillus* isolates were considered resistant if they showed an MIC above the epidemiological cutoff values (ECVs) for *A. fumigatus*: >1 µg/ml for itraconazole and voriconazole, and >0.25 µg/ml for posaconazole. All seven *N. pseudofischeri* isolates were resistant to voriconazole (MIC=4 µg/ml), while the two *A. turcosus* isolates also showed reduced susceptibility (MIC=2 µg/ml). *Cyp51A* gene sequencing of these isolates is underway. Review of medical records revealed that all four *A. turcosus* isolates were associated with airway colonization, that *N. hiratsukae* caused chronic cavitary aspergillosis, and that *N. pseudofischeri* was the cause of disseminated pulmonary, nasal sinus and cerebral aspergillosis in an allogeneic hematopoietic stem cell transplant recipient. These findings confirm the overall low prevalence (1%) of cryptic species of *Aspergillus* section *Fumigati* among clinical isolates, but also emphasize the need for active surveillance of these emerging resistant species.

Abstract Body:

Background: Isavuconazole (Astellas Pharma US, Inc., Northbrook, IL) is a triazole antifungal that is currently approved for use in the treatment of invasive mucormycosis and aspergillosis. A multi-site evaluation was undertaken to determine the performance of the Thermo Scientific™ Sensititre® YeastOne® susceptibility system (Thermo Fisher Scientific, Cleveland, OH) with Isavuconazole (ISA) compared to the CLSI M27 and ISO16256 (2012)(E) Broth Microdilution Methods (BMD).**Materials and Methods:** 400 clinical (100 per site) and 100 challenge strains along with 10 reproducibility isolates of *Candida* spp. were tested at 4 sites comparing the performance of ISA on the Sensititre YeastOne plate with CLSI and ISO BMD. The range tested for ISA was 0.004-8ug/ml. CLSI quality control (QC) organisms were tested daily and were within the CLSI expected QC ranges. **Results:** Clinical isolate comparisons of the Sensititre YeastOne plate to the CLSI and ISO BMD resulted in 99% and 92% essential agreement (EA) +/- 2 $\log_2$ dilutions. Challenge isolates resulted in 99% and 89% EA +/- 2 $\log_2$ dilutions. YeastOne modal reproducibility MICs +/- 2 fold dilutions between sites for ISA resulted in 98.6% agreement at 24 hours. **Conclusions:** This evaluation indicates that the Sensititre YeastOne plate with ISA is equivalent to the CLSI and ISO BMD and is a potential method for susceptibility testing of ISA.

Evaluation of the Sensititre Yo-9 Plate for Antifungal Drug Susceptibility Testing of Molds

Author Block:

R. C. WALCHAK, A. Abbenyi, A. A. Milone, N. L. Wengenack; Mayo Clinic Rochester, Rochester, MN

Abstract Body:

Background: The performance of the commercially available Sensititre YeastOne YO-9 plate (ThermoFisher/Trek Diagnostics) was compared with the broth dilution reference method (CLSI M38-A) performed at a reference laboratory in order to evaluate the potential utility of the YO-9 plate for mold antifungal susceptibility testing.**Methods:** Well-characterized clinical isolates of molds including *Aspergillus* spp. and *Fusarium* spp. were tested in parallel using both the reference method and the YO-9 plate against 9 antifungal drugs including several azoles, amphotericin B, and three echinocandins. The MIC or MEC for each drug were determined by following the guidelines in the CLSI M38-A document.**Results:** The agreement between the reference laboratory and the YO-9 plate was 98.9% using an essential agreement acceptance range of +/- 2 doubling dilutions. There was a single discordant fluconazole result for a *Fusarium* sp. isolate.**Conclusions:** The Sensititre YeastOne plate compared favorably with the reference method in terms of essential agreement for each drug tested across a variety of mold genera and species. Using the Sensititre YeastOne plates also provides a simplified workflow compared with the reference method for implementation into a clinical laboratory.

Comparison of Copan THIOL Broth to F.A.B and THIO W/O Indicator Broths for the Enrichment of Aerobic, Anaerobic Bacteria and Fungi

Author Block:

R. Paroni, L. Conter, S. Castriciano; Copan Italia, Brescia, Italy

Abstract Body:

Background: Different enriched broths, currently available on the market, are used for the cultivation of facultative and obligatory anaerobic microorganisms present in clinical specimens. Copan developed the THIOL, an enrichment broth that contains Vitamin K and Hemin as growth supplement for many fastidious anaerobic bacteria. THIOL, (T1) a ready to use LBM device, contains 4 ml broth in a PET tube with a cap with a plastic sealant to maintain anaerobic conditions during incubation. The objective of this study was to compare the Copan THIOL broth to LABM F.A.B (T2) and THIO W/O indicator (T3) broths for the enrichment of anaerobes and aerobes and fungi. **Methods:** In this comparison study 6 anaerobic ATCC strains (*B. Fragilis*, *B. Vulgatus, P. ana*, *P. mel*, *C. perfrigens*, and *C.difficile*) and 9 aerobic including 2 fungi, (*E.faecalis* 12022, *P.auroginosa* 27853 and 27853, *Salmonella* 14028, *Shigella sonnei* 9290, *C.albicans* 10211 and 24433, S.*aureus* 6538, 29213 and 25923, *E.coli* 25922) were used to inoculate the T1, T2 and T3 for enrichment. A 0.5McFarland dilution, made with fresh culture of each strain, was used to prepared countable dilutions of 25-250ufc /100 ul for the anaerobes and $10^{4,}$ 10^{5} dilutions for the aerobes and used for testing. Ten tubes were inoculated with 400ul of each strain; one for T0, 2 for T24, and T48h, vortexed and incubated at 35°C. Aliquots of 100ul from T0 tubes was plated on Blood agar plates and incubated at 35°C for 24/48H. Same procedure was followed for 24 and 48h incubations. Culture and turbidity results were recoded.**Results:** The T0 results for the 3 broths were compared toT24 and T48 incubations. The anaerobic strains growth was present only at T0,in T2 and T3 broths and no growth or turbidity after 24 and 48h, while for the T1 the growth and turbidity incremented from countable to TNTC. In the aerobic strains only a few colonies were present at T0 for both dilutions used for all 3 media and an exponential growth of TNTC and turbidity was present at both 24 and 48h.**Conclusions:** The results demonstrated that the Copan THIOL supports both anaerobic and aerobic bacteria growth confirmed by the turbidity compared to the no growth with the F.A.B. and THIO W/O indicator broths. Copan THIOL can be used for anaerobic and aerobic bacteria and fungi growth with manual and WASP™ and WASPLab™ automation broth inoculation and culture streaking.

A System-Wide Initiative to Increase Blood Culture Volumes Correlates with Increased Positivity Rates

Author Block:

R. Khare, S. Juretschko; Northwell Hlth.Lab., Lake Success, NY

Abstract Body:

Background: Collection of adequate blood volume is highly associated with an increased yield of pathogens from blood cultures. Blood culture volumes from >260,000 bottles from 9 hospital sites were analyzed before and after implementation of a large-scale improvement initiative. **Methods:** Blood culture volumes and culture results were evaluated from aerobic bottles for a period of 12 months using the Becton Dickinson automatic blood volume monitoring system (BVMS), software version 6.60. **Results:** From January to June 2015, the average blood culture collection volume per bottle was 3.13 ml with an overall positivity rate of 3.7%. A system-wide initiative to increase blood culture collection volumes was implemented in July 2015. After a period of 6 months, 9 out of 9 hospitals achieved statistically significant increases in collection volume (range: 14-94%). The average volume increased to 4.36 ml, and the average positivity rate increased to 4.4%. In the post-implementation phase the rates of detection for potential contaminants and Gram negative bacilli increased, while detection rates of *S. aureus* and *Enterococcus* sp. remained constant. **Conclusions:** All hospital sites in this study showed small but significant increases in blood culture fill volumes. This correlated with an overall increase in blood culture positivity rate, although an increase in number of contaminants also occurred. Further education, monitoring and feedback needs to be performed to correctly collect an adequate volume of blood.

Evaluation Of The BD MAX™ Staphsr Assay For Detecting MSRA And MSSA in ESwab™ Collected Wound Samples

Author Block:

A. Gostnell, **S. Silbert**, C. Kubasek, R. Widen; Tampa Gen. Hosp., Tampa, FL

Abstract Body:

The BD MAX™ StaphSR assay performed on the BD MAX™ System is a FDA-cleared molecular test for detection of *S. aureus* (SA) DNA and MRSA DNA from nasal swab specimens collected from patients at risk of nasal colonization. This PCR based test can provide results in approximately 2.5 hours. The objective of this study was to evaluate the BD MAX StaphSR assay for the detection of SA and MRSA from ESwab (Copan Diagnostics Inc., USA) collected wound samples, and to compare the results to culture, our standard of care procedure. **Methods:** A total of 250 wound samples collected by ESwab were included in this study. Samples were submitted for traditional wound culture and after processed, residual ESwab samples were tested by PCR on the BD MAX System. Briefly, an aliquot of 200µL of the residual ESwab sample was transferred to the BD MAX Sample Buffer Tube. Extraction and multiplex PCR were performed on the BD MAX System, using the BD MAX StaphSR assay. Discrepant result samples were retested by an in-house *mecA*/*femA* real-time PCR assay and by the Xpert® MRSA/SA SSTI assay on the GeneXpert® System (Cepheid, Sunnyvale, CA). In addition, an enrichment culture was processed by inoculating 100µL of the remaining ESwab sample into TSB with 6.5% NaCl (BD Diagnostics). After incubation at 37°C for 24h, TSB was plated on CHROMagar *S. aureus* and CHROMagar MRSA II (BD Diagnostics) for another 24h at 35-37°C. Results from traditional and enrichment culture were combined and compared to PCR results. **Results:** Out of 250 samples tested, 194 were negative and 54 were positive for MRSA, and 159 were negative and 83 were positive for *S. aureus* by both PCR and culture methods. Nine samples had discrepant results between culture and PCR. Out of them, 5 were false positive for SA (Ct values ≥ 38) and 1 was false negative for MRSA by the BD MAX StaphSR PCR. **Conclusion:** The BD MAX StaphSR assay and culture displayed an excellent overall agreement for the detection of MRSA (99.2%) and SA (96.8%) from ESwab collected wound samples. Moreover, the BD MAX StaphSR assay has the ability to yield faster results than culture and can potentially facilitate earlier appropriate treatment for wound infections.

Prevalence and Impact of Blood Volume on the Recovery of True Pathogens and Contaminants from Pediatric Blood Cultures

Author Block:

J. Dien Bard, J. Mestas, J. Lee, P. Pannaraj; Children's Hosp. Los Angeles, Los Angeles, CA

Abstract Body:

Background: Blood volume remains the most critical variable that directly influences blood culture (BC) yield. Insufficient volume is an ongoing issue that is particularly prevalent in the pediatric setting. There are currently limited data on the optimal collection volume in children as most studies are devoted to the adult population. We sought to assess the prevalence and impact of adequate blood volume on blood culture positivity in a large pediatric hospital.**Methods:** A total of 4073 BacT/Alert Pediatric FAN BC bottles collected from pediatric patients were analyzed. Bottles were initially weighed in the microbiology lab prior to distribution and reweighed upon arrival back in the lab. The final BC weight was determined by subtracting the initial from final bottle weight plus 0.16 to account for bottle volume depletion. Blood volume > 1mL and < 5mL were defined as “adequate” whereas volume outside the range were considered “inadequate.” Blood volumes were compared between positive and negative culture results.**Results:** 406 (10%) blood cultures were positive; 313 (77%) Gram-positive, 73 (18%) Gram-negative, and 20 (4.9%) yeast. Probable contaminant organisms were recovered from 52% (215/406) of all positives. The mean blood volume was 2.2 mL and ranged from 0.2 to 12.0 mL. In total, 83.3% of BC were adequate in blood volume and there were no significant difference between adequate blood volume and BC positivity (83.5% neg vs 81.3% pos , p=0.261). Overall, positive BC had a lower mean blood volume compared to negative BC (2.02 mL vs 2.24 mL, p=0.005) and the proportion of positive BC decreased with each mL of blood obtained. Further removal of contaminants from the analysis resulted in no significant difference (2.3 mL vs 2.2 mL, p=0.465). BC growing true pathogens had a mean blood volume of 3.4 mL compared to contaminants at 2.2 mL (p=0.0008).**Conclusions:** In this study, the yield of positive BC in pediatric BC bottles inversely correlated with blood volume obtained. Although the mean difference was < 1mL, the findings were statistically significant. Removal of contaminants from the analysis resulted in no significant correlation between positive BC and blood volume. Low blood volume directly increases recovery rate of BC contaminants.

Current Pattern of Antibiotic Resistance in Clinical Isolates of *Acinetobacter baumannii* from Intensive Care Units of Tertiary Care Hospital

Author Block:

I. Bashir[1], I. Khan[2]; [1]Univ. of Karachi, Karachi, Pakistan, [2]SUNY Albany, Albany, NY

Abstract Body:

Purpose: To determine the pattern of antibiotic resistance in clinical isolates of *Acinetobacter baumannii* from ICU's of tertiary care hospital in Karachi.**Study Design:** A case control study.**Methods:** Three hundred and fifteen clinical isolates of *Acinetobacter baumannii* collected from different ICUs were evaluated during 1 year period. The isolates were identified by morphology, growth and biochemical characteristics, susceptibility to a panel of antimicrobial agents in disc diffusion assay and molecular characterization by PCR using *gltA* and *gyrB genes*.**Results:** 94% of *Acinetobacter* spp were detected as multi drug resistant (MDR) and sensitive to Polymixin B only. About 6% *Acinetobacter* spp were also MDR but sensitive to Polymixin B, Meropenem and Salbactum + Cefoperazone. All tested isolates exhibited differing resistance representation, as establish by medium incorporation-replica method, against different tested antibiotics, as follows: Amoxicillin-Calvulanic acid, Tazobactam, Ceftriaxone, Ceftazidime, Meropenem, Imipenem, Gentamicin, Amikacin, Chloramphenicol, Co-trimoxazole, Tobramycin, Salbactam, Cefoperazone, Gentamicin and Amikacin. All the isolates of *Acinetobacter baumannii* were PCR positive for *glt* A and gyrB.**Conclusions:** *Acinetobacter baumannii* is the most frequently isolated and alarming pathogen in the health care system specifically for the patients in intensive care units (ICUs). Its survival in hospital environment is because of tolerance the antibiotics and antiseptic pressures. Multi drug resistance made this pathogen the lethal pathogen of this century to infect debilitated patients. There is a strict need to monitor the surveillance of global clones at institutional and or intra-institutional level for accurate treatment, precise prevention and batter control.**Keywords:** Multidrug resistance (MDR), housekeeping genes

A New GN Broth for Selective Enrichment of Gram Negative Bacteria Especially *Salmonella* and *Shigella*

Author Block:

L. Conter, R. Botrugno, B. Massetti, S. Castriciano; Copan Italia, Brescia, Italy

Abstract Body:

Background: Selective enrichment broths are essential to enhance the isolation of some Gram Negative bacilli (G-) like *Salmonella* and *Shigella* (S&S), isolated from stool specimens, highly contaminated with enteric flora (EF) limiting the growth of other coliform G-. Copan is producing the GN broth (Hajna's formula) with an increased amount of mannitol to accelerate the growth of *S&S* and contains sodium citrate and deoxycholate to inhibit gram positive growth in the first 8h. GN broth, a Copan LBM device, is available in 12x80mm plastic tubes with 4ml broth, and can be used for manual and WASP™ automation broth inoculation and agar plating. The objective of this study was to validate the performance of the GN broth for the selective enrichment of SA and SH using clinical isolated strains **Methods:** In this validation study were used 171 clinical isolated strains of G- and G+ bacteria, *Salmonella* (29) and *Shigella (*23) strains were used. GN selectivity at 6-8h was tested with 11 *Proteus,* 7 *Bacteroides,* 16 *Enterobacter and* 19 *E.coli.* G+ strains were used for selective and inhibitory action of GN broth until 24h like 12 *S. aureus, 6 Bifidobacterium, 12 Lactobacillus, 19 E.Faecium and* 17 *E.faecalis.*From a fresh culture for each strain, a 0.5McFarland inoculum was prepared and diluted to a countable dilution of 25-250ufc/100ul. Aliquots of 100ul of each strain were inoculated in GN broth. All tubes were vortexed and 100ul were plated in appropriate agar plates. All tubes were incubated at 35°C and after 6-8 h the broths were checked for turbidity and 100ul were manually plated on appropriate agar plates and WASP™ automation plated with a 10ul loop. All GN broth were re-incubated at 35°C and at 24h incubation were plated manually and on the WASP™ as above and plates incubated at 35°C for 24h.**Results:** In the results obtained using the 52 isolates S&S after both 6-8h and 24h incubation turbidity was present in all GN broth tubes. The selectivity of the GN broth was confirmed by the inhibition of the 53 isolates of enteric coliform flora after 6-8h and 66 G+ bacteria after 24h incubation.**Conclusions:** The results obtained demonstrated that Copan GN broth enriches and supports the growth of *Salmonella* and *Shigella*; inhibits the growth up to 6-8h of EF and inhibits G+ growth up to 24h. GN broth can be used for the selective enrichment of stool specimens for the detection of S&S with manual and WASP™ automation.

A New Amies Medium +20% Glycerol Device for the Collection and Long Term Frozen Storage of Clinical Specimens for Bacteria Culture

Author Block:

R. Botrugno, L. Conter, B. Massetti, R. Paroni, S. Castriciano; Copan Italia, Brescia, Italy

Abstract Body:

Background: Research studies to monitor bacteria changes during infection due to vaccination and antibiotics require to freeze original specimens to culture bacteria at a later date. After requests from microbiologists, Copan developed a new LBM device, the Amies Liquid Medium+20%glycerol (ALMG), a tube with 1.0 ml medium and a regular FLOQSwab™, for the collection and frozen storage of clinical specimens for bacteria culture. The objective of this study was to validate the performance of the new Amies Liquid Medium+20%glycerol, for the isolation of bacteria after long term frozen storage at -20°C and -80°C using a panel of ATCC bacteria strains. **Method:** In this study these ATCC bacteria strains were used: *P.aeruginosa* (BAA-427) *S.pyogenes* (19615), *S. pneumoniae* (6305), *H. influenzae* (10211), *B. fragilis* (25285), *P. anaerobius* (27337), *P. acnes* (6919), *N. gonorrhoeae* (43069) MRSA (43300), *E.coli* (25922), *S.aureus* (6538). Starting from a 0.5McF dilution of fresh cultures for each strain, two dilutions were prepared, one with countable CFUs (200-500/100ul) and another with uncountable CFUs. Tubes of ALMG were inoculated with 100ul of each dilution per each strains and the swab was broken inside the tube. Two sets of 12 tubes for each bacteria and dilutions were prepared, one tube was used at zero time as baseline, and the other sets were stored at -80°C and -20°C; stability was tested monthly up to 1 year. At each storage time, 10ul of each tube inoculated with different bacteria was manually plated using a micropipette and spreaders and WASP automated plated using a 10ul loop on the appropriate agar plates. All plates were incubated for 24/48h at 35^0C at the appropriate conditions. CFUs were counted for each plate and results recorded for all culture plates. The results were expressed as percentage of recovery. **Results:** No loss of bacteria viability was detected with the new ALMG devices inoculated with all the bacteria strains when comparing the zero time CFUs counts to the CFUs counts obtained after one to six and nine months storage at -80°C and -20°C. **Conclusions:** The data obtained suggests that the new Copan ALMG device, supports the viability of a wide range of aerobic, anaerobic and fastidious bacteria and can be used for the collection, transport and long term frozen storage of specimens for clinical and research studies.

Validation of COPAN LIM Broth for the Detection of *Streptococcus* Type B

Author Block:

S. Castriciano, L. Conter, R. Paroni; Copan Italia, Brescia, Italy

Abstract Body:

Background: The CDC guidelines for screening for type B streptococcal colonization recommend the collection of vaginal/rectal swab in pregnant women at 35 to 37 weeks of gestation. After collection specimens are inoculated in an enrichment broth. Copan is producing the LIM broth, another LBM device, a tube with 2 ml of LIM broth for the enrichment of group B Streptococcus (GBS).The objectives of this study were to: 1) Compare the performance of the Copan LIM Broth to the BD for pre-enrichment of GBS. 2) Validate the LIM broth ability to support *S.agalactiae* growth during shelf life.**Methods:** In this validation the ATCC 12386 *of S.agalactiae* was used to compare the performance of the Copan LIM (Todd Hewitt+ CNA) broth to the BD Todd Hewitt (BDTH) broth. 3 lots of LIM at 6 and 1 month prior and 1 after expiry date were also tested for growth of SA. Starting from a fresh culture of *SA a* 0.5McF dilution (1.5 x 10^8 UFC/ml) was prepared in PBS. Serial dilutions were prepared up to a concentration of 10^2 UFC/ml. Five sets tubes of LIM and BDTH and the 3 different LIM lots of broths were inoculated with each SA dilution using a 1:10 inoculum ratio in order to obtain a final concentration of 10^1 UFC/ml for 0, 2, 4, 6, 8, 10, 12, 14, 16, 18 and 24 hours incubations at 35^0C. At zero time 100 ul of the T0 set were inoculated in triplicate on blood agar plates (BioMèrieux) as a baseline and repeated after each incubation time only 10 ul were inoculated as above. All plates were incubated at 35^0C for 24 hours, colonies were counted and recorded on an excel file.**Results:** The LIM broth had a log more growth of *S.agalactiae* than the BD Todd-Hewitt broth starting from 2 hours incubation time. No *S.agalactiae* difference was noted in the LIM at 6 and 1 month prior and 1 after expiry date. The LIM broth tubes are compatible with WASP™ automation and are safe to handle compared to the large glass tubes of the BD Todd-Hewitt broth , that are not suitable for automation and prone to bread if accidental dropped.**Conclusions:** Better *S.agalactiae* growth was detected with the Copan LIM broth compared to the BD Todd-Hewitt broth. LIM support S.*agalactiae* growth even after one month expiry date. The Copan LIM broth is suitable for the collection of clinical specimens for type B streptococcal colonization screening and compatible with both manual and WASP™ automation inoculation methods and is safe to handle.

Comparison of Recovery Rates of *Clostridium difficile* from Stool Using Chromogenic Agar versus a Classic Culture Method

Author Block:

S. Shannon, D. Gustafson, R. Segner, A. Ali, B. Schieffer, K. Boelman, J. Mandrekar, R. Patel; Mayo Clinic, Rochester, MN

Abstract Body:

Introduction: The goal of this study was to compare performance characteristics of a conventional medium, taurocholate, cycloserine, cefoxitin, fructose agar (TCCFA) with CHROMagar *C.difficile* (ChromAGAR Paris , France) for recovery of *C. difficile* from stool. **Methods:** 50 stool specimens in Cary Blair that were known to be *C. difficile* PCR positive were subcultured in parallel to CHROMagar and TCCFA agars. Specimens were plated directly to both selective agars without processing prior to inoculation, and incubated in anaerobe jars with anaerobiosis attained using an AnaeroPack anaerobic gas generating system (Mitsubishi Gas Chemical America, Inc. New York, NY). The CHROMagar medium was examined at 24 hours in accordance with the manufacturer's recommendation, and tested within 6 hours of examination. Identification was performed by MALDI-TOF mass spectrometry directly from the CHROMagar plate. TCCFA medium was examined at 48 (±6) hours, in accordance with standard protocols. Identification was performed by MALDI-TOF mass spectrometry directly from selective plates, except in circumstances where subculture was required for isolation of colonies resembling *C. difficile*. Sensitivities of the two tests were compared using McNemar's test and detection duration was compared using a log rank test.**Results:** CHROMagar media provided a 94% recovery rate of *C. difficile* on the first day of examination. Two specimens were positive on the first day, but were subcultured and identified on the second day. Three specimens did not yield *C. difficile* on CHROMagar media; *C. difficile* was recovered from one of the three specimens on TCCFA. Organisms other than *C. difficile* were not recovered on CHROMagar. TCCFA agar provided a 68% recovery rate of *C. difficile*, requiring up to 4 days of incubation and occasional subculture to yield final results. Non-*C. difficile* bacteria were isolated on TCCFA.**Conclusion:** For culture-based screening of stool for *C. difficile*, the CHROMagar medium was more sensitive than the TCCFA medium ($p=0.0008$), with faster detection ($p<0.0001$).

***Propionibacterium acnes* Detection Rates are Lower from Swab Specimens and Higher with Longer Incubation Duration**

Author Block:

A. O. Miller, J. DiPietro, J. P. Kleimeyer, O. A. Shonuga, M. W. Henry, F. Zodda, M. Klein, R. F. Warren, B. D. Brause; Hosp. for Special Surgery, New York, NY

Abstract Body:

Background: *Propionibacterium acnes* is increasingly recognized as a troublesome pathogen, and a common cause of indolent shoulder and spine hardware infections - as well as a problem in neurosurgical and cardiac surgical infections. Because the microbe typically requires at least 5 days to grow, and grows best in enriched anaerobic media, *P. acnes* infections are likely underdiagnosed. Proper collection methods and incubation times are not clear. We sought to identify optimal practices to detect *P. acnes.* **Methods:** Over a single two-month period, 1,039 consecutive anaerobic thioglycollate broth cultures from orthopedic surgery patients were observed for an extended duration (39 cultures for 28 days, and 1000 for 42 d). Samples were anonymized so that cultures positive after 10 d were not linkable to patients. Data on anatomic site and specimen type (SP Brand CultureSwab swab, solid tissue, or synovial fluid) were collected. Positive cultures were identified by turbidity, Gram stain, and biochemical identification.**Results:** In total, 34/1039 cultures grew *P. acnes*; 8/34 (23%) took more than 10 days to grow. Only 3 CultureSwab specimens yielded positive cultures, and these specimens grew after 15-21 days. All positive non-swab cultures (solid tissue and fluid cultures) grew in 14 days or less (n=31, range 3-14 days). No cultures (0/1039) grew *P. acnes* after 21 days. When multiple positive broth cultures with identical date, site, and type were grouped together and analyzed as if from a single patient, 6/18 (33%) of such patients had *P. acnes* isolates that took over 10 days to grow.**Conclusions:** Swab specimens lead to slower growth of *P. acnes* than direct tissue and fluid samples. Swab specimens are also probably less sensitive for *P. acnes* in a clinically significant manner, regardless of incubation time. A significant percentage of *P. acnes* infections may be missed when isolates are incubated for less than 10 d. In summary, swab cultures should be avoided, and anaerobic broth cultures should be incubated for 14 d, in cases where *P. acnes* is a pathogen of interest, such as surgical hardware infections.

The Importance of Gram Stained Smears in the Diagnosis of *Nocardia* Infections

Author Block:

S. Olmez[1], O. Tuncer[1], B. Altun[1], B. Sancak[1], N. Gursoy[2], B. Otlu[3], **B. Sener**[1]; [1]Hacettepe Univ., Ankara, Turkey, [2]Inonu Univ., Malatya, Turkey, [3]Malatya Univ., Malatya, Turkey

Abstract Body:

Background: Nocardiosis can be a cause of disease in patients with underlying risk factors such as immunosuppression, chronic lung disease and malignancies. The overall correlation between Gram staining of the clinical specimens and subsequent organism identified is usually fair to moderate. This study was aimed to emphasize the utility of the microscopic examination of Gram stained smears for the diagnosis of *Nocardia* infections.**Methods:** The study included cases whose specimens yielded isolation of *Nocardia* spp. between November 2014-December 2015 in a university hospital in Turkey. Following the examination of Gram stained smears, the incubation period of the cultures which yielded morphology consistent with *Nocardia* spp., were prolonged. The relevant colonies that grew in ≥72 h of incubation, were identified by standard microbiological methods. Species level identification of the *Nocardia* isolates was done by 16S rRNA sequence analysis and antimicrobial susceptibility testing by gradient strip method.**Results:** A total of 19 *Nocardia* spp. strains were isolated from 8 patients. Three cases exhibited repeated growth of *Nocardia* spp. up to a period of nine months. All of the *Nocardia* positive specimens revealed growth following prolonged incubation. The most frequently isolated species was *N.cyriacigeorgica,* identified in three cases. The other species identified were *N.asteroides, N.transvalensis/wallace, N.farcinicia, N.asciatica/arthritidis.* All of the isolates were found to be susceptible to amikacin, ceftriaxone, imipenem, linezolid and trimetoprim-sulphametoxazole. All *N.cyriacigeorgica* were resistant to ciprofloxacin and except one also to clarithromycin.**Conclusion:** Proactive suspicion of nocardiosis based on Gram stain results may aid to isolation of *Nocardia* spp. from routine cultures. Thus longer incubation with a preceeding Gram stained smear should be encouraged in clinical practice for the early diagnosis of nocardiosis. *N.cyriacigeorgica* is the most common and most antibiotic resistant species in the study population. Increasing information about the *Nocardia* species specific antimicrobial susceptibility profiles is necessary for the establishment of successful empirical treatment protocols.

Optoelectronic Detection of Bacterial Growth in Different Media Types

Author Block:

U. Aurbach[1], E. Michael[2], S. Lim[2], P. Rhodes[2], **H. Wisplinghoff**[3]; [1]Wisplinghoff Lab., Cologne, Germany, [2]Specific Technologies, Mountain View, CA, [3]Inst. for Med. Microbiol., Univ. of Cologne, Cologne, Germany

Abstract Body:

Background: Optoelectronic detection and identification of microorganisms based on an inexpensive, printed, disposable colorimetric sensor array (CSA) responsive to the volatiles emitted into the headspace of culture bottles during growth has been shown to have the potential to shorten time to result in blood cultures. Similarly, using sensors placed in the lids of blood agar plates, it has been possible to identify presence and species during growth on blood agar plates.**Methods:** This study was conducted to evaluate the reportedly faster time to detection exhibited by this paradigm to improve efficiency in routine clinical microbiology. A total of 20 clinically relevant bacteria including E. coli and other Enterobacteriaceae, P. aeruginosa and other non-fermenting gram-negatives, Enterococcus spp., Staphylococcus spp., and Streptococcus spp. were incubated at concentrations ranging from 10^2 to 10^6 on different selective and non-selective solid media. All samples were run in triplicate.**Results:** All bacteria could be identified on all media (if the bacterium was able to grow on the respective medium). Overall, time to positivity ranged from 4.2 to 11 hours, varying between different bacteria/media combinations. Sensitivity of species identification (monomicrobial cultures) at 1, 2 and 3 hours after initial detection of growth was as high as 99.4%. Accuracy varied between different bacteria/media combinations and could be improved by adaption of algorithms to the respective media.**Conclusions:** In our study, CSA-based optoelectronic detection could be adopted to be used largely independent of different types of solid media and seems to be a promising addition to the routine clinical microbiology laboratory with the potential to significantly shorten the time to positivity, time to negativity, and / or species identification.

Evaluation Of Oxyrase(R) Agar Media for Growth and Selection of Anaerobic Isolates

Author Block:

L. M. Koeth[1], J. DiFranco-Fisher[1], A. Windau[2]; [1]Lab. Specialists, Inc., Westlake, OH, [2]Microtech Lab., Inc., Westlake, OH

Abstract Body:

Background: Oxyrase® (Oxyrase, Inc., Mansfield, OH) is an enzyme system that removes dissolved oxygen from liquid, gas or semisolid products. Oxyrase® is included in agar media that are typically used to grow and select for anaerobic organisms. Oxyrase allows the plate to remain reduced on the bench up to 2 hours. This study was performed to evaluate the growth of anaerobic bacteria on Oxyrase Brucella and Oxyrase Schaedler agar plates compared to conventional media. Oxyrase selective media was also evaluated for growth of specific anaerobic organisms from mixed isolate cultures. **Methods:** The study isolates were stock strains from clinical sources that included various Gram-positive and Gram-negative aerobes and anaerobes. Within the anaerobe chamber, inocula were prepared and plated onto control media (Remel brucella agar w/5% sheep blood, hemin, vitamin K and Becton Dickinson tryptic soy agar with 5% sheep blood). In addition, inocula were plated onto Oxyrase media (Schaedler OxyPlate, Brucella OxyPRAS, BBE, KVL, AnaSelect and PEA) outside the anaerobe chamber. All plates were incubated under anaerobic conditions for 48 hours. Phase I consisted of single isolate cultures plated onto control media. Phase II consisted of 3 separate mixed isolate cultures (anaerobic and aerobic) plated onto various selective media. **Results:** As shown in the table, bacteria concentration was similar on all tested media. The colony sizes were also comparable. In Phase II, the selective media also showed good growth and selection/inhibition of specified organisms according to manufacturer specifications.

		CFU/mL Range		
Organism	n	Remel Brucella	Brucella OxyPRAS	Schaedler OxyPlate
Bacteroides spp.	4	2 - 5.4 x 10^7	8 x 10^7 - 2.6 x 10^8	1.8 x 10^7- 1.5 x 10^8
Clostridium spp.	3	1 x 10^6 - 9.9 x 10^7	7 x 10^6 - 7.6 x 10^7	1 x 10^6 - 1.5 x 10^7
Eubacterium lentum	1	3.8 x 10^8	4.4 x 10^8	2.1 x 10^8
Fusobacterium nucleatum	1	6.8 x 10^7	4.4 x 10^7	4.8 x 10^7
Peptostreptococcus spp.	2	4 x 10^6- 5 x 10^7	2.6 - 3.6 x 10^7	6 - 8.0 x 10^6
Prevotella spp.	2	1.6 x 10^8 - 3.1 x 10^8	1.4 - 2.1 x 10^8	1.9 x 10^{8*}

Propionibacterium acnes	1	2 x 10^6	1.2 x 10^7	1.4 x 10^7
*One isolate (*Prevotella bivia*) had no colonies on Schaedler OxyPlate after 48 hours incubation				

Conclusions: Count and size of colonies on the Schaedler OxyPlate and the Brucella OxyPRAS plate (inoculated aerobically and incubated anaerobically) were similar to control plates (inoculated and incubated anaerobically). The Oxyrase selective media (BBE, KVL, AnaSelect and PEA) allowed for growth of specified organisms.

Impact of Urine Gram Stain Order Availability on Utilization and Test Performance

Author Block:

A. BRYAN, N. G. Hoffman, B. T. Cookson; Univ. of Washington, Seattle, WA

Abstract Body:

The utility of urine Gram stain in addition to urine culture is unclear given rapid urinalysis, transport time, and empiric therapy. The laboratory can alter ordering practices by altering availability in computer-provider-order-entry (CPOE). To reduce over-utilization, urine Gram stains were eliminated from the urine culture panel and offered as a separate test in our inpatient and emergency department CPOE. In the year after the order changes, the portion of urine isolates with an associated Gram stain decreased from 50 to 2% for ED patients and inpatients and 38 to 30% ($p < 0.0001$) for outpatients. Isolates were considered more likely clinically significant if antimicrobial susceptibility testing (AST) was performed per protocol; possible urosepsis isolates were designated as those with the same organism isolated from the blood within 7 days. These sub-groups revealed decreases in the fraction of isolates accompanied by Gram stains: 40 to 16% for AST isolates and 65 to 14% for possible urosepsis. Separately ordered Gram stains accounted for a small fraction of the performed stains. Interestingly, Gram stain sensitivity for orders associated with a urine culture panel differed from independent orders. Isolate Gram results were counted as concordant if a urine stain from the same day appropriately identified the phenotype (GNRs, GPCs, GPRs, or yeast); allowing for multiple phenotypes to be observed by stain. Culture results that reported extensively mixed or Gram positive flora were excluded unless a specific isolate was reported. The sensitivity of Gram stains ordered with a culture panel was 51.4% (95% CI: 50.6 - 52.1%), while the sensitivity of separately ordered stains was 63.4% (95% CI: 57.3 - 69.2%) ($p < 0.0001$). When limiting separately ordered Gram stains to isolates where AST was performed, the sensitivity was 68% versus 35% for non-AST isolates ($p < 0.0001$). These results demonstrate the dramatic impact uncoupling urine culture and Gram stain orders panels can have to reduce over-utilization, as well as the greater sensitivity of Gram stains for organisms most likely to be of clinical significance. To prevent under-utilization and improve test performance, future work is needed to establish ordering practices that facilitate Gram stain ordering in populations where it is diagnostically useful and to elucidate pre-analytic factors that impact test performance.

Detection of *Clostridium difficile* Toxin in Patient Samples by Cell Culture Cytotoxicity Neutralization Assay (CCNA) Using Isolated Colonies of *C. difficile* versus Stool Samples

Author Block:

P. P. Patel, L. Edwards; Covance Central Lab Services, Indianapolis, IN

Abstract Body:

Background: Clostridium difficile toxin is a common cause of antibiotic associated diarrhea (AAD) and pseudomembranous colitis (PMC). The toxigenic culture method in which organisms are cultured and the stool is tested by the Cell Culture Cytotoxicity Neutralization assay (CCNA) remains the diagnostic "gold standard" for detection of toxigenic C difficile. The CCNA consists of two reactions - detection of toxin and toxin neutralization by the C.difficile antitoxin. The method is extremely sensitive and can detect toxin levels as low as 1 picogram. This testing should be performed using stool specimen filtrate however our evaluation shows that when a pure isolate of C.difficile is used as an alternative specimen, the sensitivity of the test is higher than the raw stool specimen.**Method:** Stool samples tested - preserved samples in Cary-Blair transport medium (stored ambient) and unpreserved samples (stored @ -70°C). Preserved stool from Cary-Blair medium was cultured anaerobically for growth of C.difficile. 27 stool cultures that yielded C. difficile were tested. Isolated colonies for these 27 samples along with C. difficile strains ATCC9689 (toxin producing) and ATCC700577 (non-toxin producing) were tested. 2 to 3 colonies of C. difficile isolate were inoculated into cooked meat broth and thioglycolate broth. CCNA using the Diagnostic Hybrids Cytotoxicity Assay was performed on both broth types after 48 hours of incubation (anaerobically). For the preserved samples that were positive by culture, the corresponding frozen stool sample was also tested for CCNA.**Results:** 9 out of the 27 unpreserved stool samples were cytotoxin-positive and 18 were negative on direct testing. Of the 27 C.difficile isolates; 22 confirmed cytotoxin production with both broths; 1 tested positive in the thioglycolate broth but was negative in cooked meat broth and frozen stool sample; remaining 4 were cytotoxin-negative. The ATCC strains performed as expected.**Conclusions:** A delay in transport of unpreserved stool samples can lead to degradation of toxin in samples leading to a false negative result. CCNA testing of C.difficile isolates from preserved stool samples (enriched in cooked meat broth or thioglycolate broth) provides better sensitivity than that obtained with direct testing of unpreserved stool samples.

Is There a Relationship between Bacteriology Report Time in the Morning and Length of Stay in Hospital after the Report?

Author Block:

K. H. RAND, M.D., S. G. Beal, G. Lipori; Univ. of Florida, GAINESVILLE, FL

Abstract Body:

Background: Physicians are under continuing pressure to discharge patients early to lower length of stay (LOS). Since decisions are often made on AM rounds, logically the sooner microbiology reports are available the sooner discharge decisions can be made.**Methods:**We studied the last bacteriology culture report times (BCRT) before discharge from 10/1/2014–9/30/2015 that were within 168 h (1 week) of a patient's actual time of discharge, assuming that after 1 week the BCRT would be unlikely to influence discharge plans. University HealthSystem Consortium (UHC) risk-adjusted expected LOS on admission was also included https://www.uhc.edu/26295. We calculated the mean LOS following the BCRT for each ½ h time period between 6 AM and 1PM (N=14), representing 94% of all results, and tested the relationship to LOS after BCRT for significance by correlation and t-test. http://graphpad.com/quickcalcs/ttest2/**Results:** As shown in Figure, for patients whose total LOS was less than 168 h (N=6,895), there was a highly significant positive linear relationship between the BCRT and LOS following the last report (r=0.8686, p = 0.000056): the later the report the longer the LOS after BCRT. For patients with total hospital LOS > 168 h (N=2,434), the LOS after BCRT was actually longer between 6 – 8 AM than between 8-10 AM; the 6–8 AM patients also had a higher UHC risk-adjusted expected LOS on admission than those reported later when divided into ½ h time cohorts (r= -.6494, p=0.01196, 2 tailed).**Conclusions:** We conclude that the relationship between BCRT and use of this information by physicians in discharging patients is complex, but for certain subgroups there is a strong relationship between an earlier report and earlier patient discharge.

Publishing Title:

Routine Tissue Culture vs. the Use of Blood Culture Bottles for Suspected Cases of PJI

Author Block:

E. J. Davis, S. E. Sharp; Kaiser Permanente - Northwest, Portland, OR

Abstract Body:

Background: The culturing of multiple tissue specimens is becoming the standard of care for patients suspected of having prosthetic joint infections (PJI). These specimens consisting of both aerobic and anaerobic cultures significantly increase the workload for the microbiology laboratory. We investigated the incubation of these tissue specimens in blood culture bottles in order to compare the results to those of routine culture.**Methods:** 37 patients with a total of 198 specimens (4-7 per patient) were routinely cultured and were also added to a set of blood culture bottles. The specimens consisted of tissues from 16 hips, 13 knees, 6 shoulders, 1 ankle and 1 elbow. All specimens were incubated aerobically and anaerobically for 14 days unless they were positive for growth before that time.**Results:** A total of 113 tissues (57%) and 11 patients (30%) had cultures that were negative for microbial growth after 14 days of incubation for all culture media. 10 patients (27%) showed growth only of a contaminating organism ($\leq$ 1 positive specimen). 16 patients (43%) showed potentially significant culture results ($\geq$ 2 positive specimens) in either the routine culture (94%) and/or the blood culture bottles (88%); 1 of these patients had a 2nd significant organism in routine cuture only. These 17 organisms consisted of: S.aureus (5), P.acnes (4), S.epidermidis (3), S.mitis (2), and 1 each of B.fragilis, S.lugdunensis, and F.magna. Of the 87 specimens from these 16 patients, the recovery of significant organisms per patient in blood culture bottles compared to culture was 75% and 63%, respectively. 11 of these 16 patients had the same organism cultured from both the routine media and the blood culture bottles. The remaining 5 patients had varying discordant results as shown in the table.

	Routine Culture	Blood Culture Bottles
1	5/5 NG	2/5 P.acnes
2	2/5 P.acnes	1/5 P.acnes; 1/5 Micrococcus
3	3/6 F.magna; 2/6 S.epidermidis	4/6 S.epidermidis
4	2/6 P.acnes; 1/6 CoNS	1/6 CoNS
5	1/6 S.aureus	5/6 S.aureus

Conclusions: This study shows that utilizing blood culture bottles in place of routine cultures is an acceptable method for culturing tissue specimens submitted from patients with suspected PJI.

This method would also save technologist time on the bench as approximately half of cultures remain negative and would not require manipulation of media.

Chromogenic Media is Selective and Differential but Not Specific for the Detection of Carbapenem-Resistant *Enterobacteriaceae*

Author Block:

C. Young, W. LeBar, M. Bachman, D. W. Newton; Univ. of Michigan Hlth. Syst., Ann Arbor, MI

Abstract Body:

Background: Infection preventionists request surveillance cultures in clinical care units when there is concern of carbapenemase-resistant *Enterobacteriacae* (CRE) colonization in their patient cohort. The CDC broth method is time consuming requiring 4 days while chromogenic media is now available. We evaluated the use of HardyCHROM CRE (H-CRE), MALDI identification and detection of resistance determinants using Verigene BC-GN directly from H-CRE.**Method:** Previously characterized *Enterobacteriaceae* were grown on MacConkey (Mac) and H-CRE, incubated in ambient air at 35C for 24 hours and evaluated for growth and color on H-CRE. In addition, perirectal swabs were obtained from ICU patients and inoculated on H-CRE. Organisms growing on H-CRE were identified by MALDI (Bruker) followed by direct isolate testing on Verigene BC-GN for resistance determinants (KPC, NDM, OXA, IMP, VIM, CTXM). MALDI scores from isolates recovered from Mac were compared to those obtained from isolated recovered from H-CRE.**Results:** Fifty well-characterized *Enterobacteriaceae* from clinical specimens were evaluated for growth on H-CRE. Of 32 confirmed CRE, 28 exhibited the appropriate color change on H-CRE (25 KPC, 2 NDM and 1 OXA) and 17 non-CRE were also chromogenic on H-CRE (16 *Enterobacter sp.* and 1 *Klebsiella sp*). In addition, there were 4 CRE which did not grow on H-CRE (3 KPC and 1 NDM). Results from 139 perirectal swabs demonstrated no growth (86), haze or pinpoint (33), cream (13) and chromogenic (7) colonies. The 7 chromogenic colonies were tested on Verigene which identified 3 *Acinetobacter sp.* and 1 each K. *pneumoniae, K. oxytoca, Escherichia coli* and *Citrobacter sp*. Of these, one KPC was detected in *Citrobacter sp.* Eighteen of twenty three isolates from Mac and 23/23 isolates from H-CRE had MALDI scores >2.0.**Conclusion:** We show that Hardy-CRE is a selective and differential media that can be used for surveillance cultures; however, it does appear to lack specificity. Direct identification of chromogenic colonies on Hardy CRE can be performed on Bruker MALDI followed by detection of resistance determinants with Verigene BC-GN. When the chromogenic colony is a genus/species not on Verigene, another method must be used to determine whether the isolate is CRE.

A Multicenter Assessment of Errors in Culture Reports

Author Block:

A. Harrington[1], L. Samuel[2], J-M. Balada-Llasat[3], R. Cavagnolo[4]; [1]Univ. of Illinois at Chicago, Chicago, IL, [2]Henry Ford Med. Ctr., Detroit, MI, [3]The Ohio State Univ. Wexner Med. Ctr., Columbus, OH, [4]MedFusion, Lewisville, TX

Abstract Body:

Background: Review of bacteriology culture work up is a standard daily practice in some clinical microbiology laboratories; however, there is a paucity of information regarding laboratory practices of review and error rates. Futhermore, because the practices are not standardized between laboratories a benchmark for error rates has never been established. The goal of this study was to describe and compare the culture review practices and error rates for four large laboratories affliliated with tertiary care academic medical centers. **Methods:** Aerobic bacteriology culture reports from sterile sites including joint fluids, tissues, cerebrospinal fluids (CSF), body fluids and aspirates were evaluated based on the current review practices and standard operating procedures specified by each individual laboratory. Laboratories that did not currently practice a process of secondary review implemented it for the purposes of this study. **Results:** A total of 2304 laboratory reports were reviewed, with an overall positivity rate of 19% for all sites. Two-hundred and sixteen (9%) errors were found, with 149 (65%) being characterized as clerical errors and 67 (35%) being characterized as technical errors. Overall, technical errors were more likely to have a clinical impact on patient care. **Conclusions:** Establishing a benchmark error rate for culture review is a challenging process due to variability in laboratory practices. A process of secondary culture review is a resource intensive but useful tool for uncovering systematic laboratory error and for routine quality control review of daily processes.

Publishing Title:

Application of Eubacterial Molecular Detection to Clinical Routine

Author Block:

A. E. Budding[1], M. Hoogewerf[1], C. M. J. E. Vandenbroucke-Grauls[1], P. H. M. Savelkoul[2]; [1]VU Univ. Med. center, Amsterdam, Netherlands, [2]Maastricht Univ. Med. center, Maastricht, Netherlands

Abstract Body:

Background: The past decade has seen an increasing application of molecular techniques -most notably qPCR- for the detection of bacterial pathogens in clinical samples. Advantages of qPCR over culture are its speed and the ability to detect species when culture cannot. However, qPCR is typically directed at specific species. Thus, anything that is not explicitly searched for will be missed. Universal PCR followed by sequencing is an alternative. However, this significantly increases cost, complexity and turnaround time. Here we investigated the application of a rapid universal bacterial molecular assay, IS-pro, to clinical practice in 220 patient samples.**Methods:** IS-pro is a fully automated and internally controlled eubacterial assay based on the detection and categorization of 16S-23S Interspace regions, that are specific for each microbial species. IS-pro was performed on 220 clinical samples from a range of bodily locations that are normally sterile (pleural cavity, joints, liver abscesses etc). Results were compared to culture and clinical records.**Results:** Of the 220 samples that were analysed, 30% of samples that were negative by culture were positive by IS-pro. Species found included many common pathogens, such as *Staphylococcus aureus*, *Streptococcus pyogenes* and *Escherichia coli*, but also many species less established as pathogens, such as *Faecalibacterium prausnitzii* and *Ailstipes putredinis*. The finding of cultivable species with IS-pro while culture was negative could often -but not always- be explained by administration of antibiotics prior to sampling. The species that were less well established as pathogens were often species that were refractory to standard culture techniques. These species commonly derived from endogenous microbiota.**Conclusions:** Here we demonstrate that the application of a broad range molecular detection technique, IS-pro, can be of great benefit to clinical diagnostics. We conclude that 1. IS-pro can very often detect pathogens when culture cannot (30% of culture negative samples). 2. Not only uncultivable, but also common pathogens that are missed by culture are detected by IS-pro. 3. Additionally detected species are highly clinically relevant: IS-pro results often guided clinical decisions.

I. Martin, B. Opene, T. Tekle, J-A. Miller, K. Carroll, A. Milstone, P. Simner; The Johns Hopkins Med. Inst.s, Baltimore, MD

Abstract Body:

Background: This study evaluated the performance of the Check-Direct CPE assay (CA)—a multiplex PCR assay for detection of carbapenemase genes (CG) (*bla*$_{KPC}$, *bla*$_{NDM}$, *bla*$_{OXA-48-like}$, *bla*$_{VIM}$)—directly from rectal swabs in comparison to the CDC broth enrichment method (CDCM) in detecting carbapenemase-producing organisms (CPO).**Methods:** 213 remnant VRE surveillance rectal ESwabs from 191 inpatients and 10 characterized isolates containing CG were included in this study. The CA was performed using 25 µl of ESwab broth on the BD MAX instrument. The CDCM was performed using a 10µg ertapenem disk for selection. ID and AST of isolates were performed with the BD Phoenix and MALDI-TOF MS. CG production was confirmed by the CarbaNP and Check-MDR CT103 XL assays.**Results:**

Specimen Type:	**Remnant VRE surveillance rectal ESwabs (N=213)**		**Previously Characterized Isolates (N=10)**
Method:	**CDCM**	**CA**	**CDCM and CA**
Number of swabs (%)			
Turbid Broths	168 (78.9)	NA	10 (100)
GNB Recovery	83 (39.0)		10 (100)
CRO Recovery	13 (6.1) 6 *S. maltophilia* 4 *E. cloacae* *2 P. aeruginosa* *1 K. pneumoniae*		10 (100)
CPO Recovery	2 (0.9) 1 KPC-producing *E. cloacae* 1 KPC *K. pneumoniae*		10 (100)
CG positive direct from ESwab broth	NA	10 (4.7) 7 *bla*$_{KPC}$ 2 *bla*$_{VIM}$	3 *bla*$_{KPC}$ 3 *bla*$_{OXA-48-like}$

		1 *bla*$_{\text{OXA-48-like}}$	2 *bla*$_{\text{VIM}}$ 2 *bla*$_{\text{NDM}}$
Other Considerations			
Hands-on-time	30 - 45 mins	5 mins	
TAT	24 hrs - 5 days	3 hrs	
Costs	$1 - 15	~$50	
NA: not applicable; GNB: Gram-negative bacilli; CRO: carbapenem resistant organism			

Of the 10 CG detected by CA, only 2 (20%) were recovered by CDCM. Discrepant analysis recovered 4 additional CPOs (data not shown). Failure to recover these CPOs by CDCM was due to the overgrowth of meropenem susceptible *P. aeruginosa*. No growth was observed by the CDCM method or by discrepant analysis for 2 *bla*$_{\text{VIM}}$ (Ct 39.7 & 40.8), 1 *bla*$_{\text{KPC}}$ (Ct 40.5) & 1 *bla*$_{\text{OXA-48-like}}$ (Ct 40.6).**Conclusions:** The CA is more sensitive for detection of CPO than the CDCM. However, the significance of results with Ct values > 35 requires further evaluation. The advantage of greater sensitivity and more rapid TAT of the CA is mired by its high cost. The CDCM yielded many turbid broths which were negative for CRO. However, CDCM was able to detect many non-carbapenemase-producing CRO.

Publishing Title:

Comparison of chromid CPS Elite Media to Conventional Culture Media for Urine Specimens

Author Block:

M. Wallace[1], M. Yarbrough[1], C. Marshall[2], E. Mathias[2], C-A. Burnham[1]; [1]Washington Univ. Sch. of Med., St. Louis, MO, [2]bioMérieux, Inc., Hazelwood, MO

Abstract Body:

Objective: Urine specimens are among the most common sample submitted to microbiology laboratories. The objective of our study was to compare chromID CPS Elite (bioMérieux), a chromogenic medium, to conventional primary culture medium for urine specimens.**Methods:** Remnant urine specimens (n=200) submitted to the Barnes Jewish Hospital Microbiology Laboratory (St. Louis, MO) were evaluated. Using a 1 uL calibrated loop, urine was inoculated to blood and MacConkey agars (Hardy) (conventional media) and to the chromID CPS Elite agar (chromID). Cultures were evaluated after 22-24 hours of incubation. The chromID medium was evaluated per the package insert. Organism identification was obtained with VITEK MS v2.0. Time to identification and consumables used were documented for both methods. For accuracy analysis, the conventional media was used as the gold standard for comparison.**Results:** Of the 200 cultures, 61 were no growth, 67 demonstrated clinically insignificant growth, 16 were contaminated, and from 56, clinically significant pathogen(s) were recovered. Of the 56 clinically significant cultures, chromID classified 46 (82.1%) as significant. Overall, the rate of uropathogen agreement between conventional and chromogenic media was 76.8%. In discrepant specimens, organisms that were not recovered on chromID included Group B *Streptococcus*, *Lactobacillus*, and coagulase negative *Staphylococcus.* The time interval between plating and final organism identification of *E. coli* was statistically significant between conventional and chromID ($p<0.0001$). Notably, the number of consumables used was significantly higher with conventional media versus chromID ($p=0.0013$) (Table 1).**Conclusions:** The use of chromID CPS Elite for urine cultures may reduce consumable use. chromID may expedite the identification of *E. coli*, the most commonly recovered uropathogen in clinical specimens.**Table 1. Comparison of Conventional Culture Media to chromID CPS Elite**

	Conventional Medium Mean (SD)	**chromID CPS Elite** Mean (SD)	*p*
Number of consumables used	2.23 (3.694)	1.58 (3.460)	0.0013
Time from plating to final organism identification (h), All positive cultures (n=44)	26.56 (1.283)	25.44 (1.686)	<0.0001

Time from plating to final organism identification (h), *E. coli* (n=18)	27.10 (0.822)	24.37 (1.229)	<0.0001

Ultraviolet Germicidal Irradiation of Influenza-contaminated N95 Filtering Facepiece Respirators

Author Block:

D. Mills, C. Lawrence, **M. Sandoval**, D. A. Harnish, B. K. Heimbuch; Applied Res. Associates, Panama City, FL

Abstract Body:

An influenza pandemic could lead to a shortage of Filtering Facepiece Respirators (FFRs), leaving health care workers unprotected. Past research on FFR decontamination and reuse (FFR-DR) strategies indicate ultraviolet germicidal irradiation (UVGI) is effective at killing influenza on FFRs. This study expands this research by 1) optimizing UVGI dose for influenza kill in the presence of soiling agents, 2) optimizing the dose to reduce exposure time, and 3) evaluating 15 FFR models to understand universal application of the technology.For UVGI dose optimization, triplicate 3M 1870 coupons were contaminated with influenza and either sebum or mucin. Contaminated coupons were exposed to 254-nm UV-C dose ranging from $1 \times 10^3 – 2 \times 10^6$ $\mu J/cm^2$. Influenza virus was extracted and quantified using a median tissue culture infectious dose ($TCID_{50}$) assay. A UVGI device was built for applying the optimized UV dose to an intact FFR in ~1 min. Triplicate samples of 15 FFR models were contaminated as described above on three facemask locations and one strap location per FFR. After UV treatment, coupons were cut from the FFRs, and remaining viable virus extracted and quantified.The optimized dose was determined to be $\sim 1 \times 10^6$ $\mu J/cm^2$. Whole FFR exposure demonstrated high variability in UVGI decontamination between FFR models and surface type, with log reductions ranging from 0.00 – 4.85 $\log_{10}$ $TCID_{50}$. The mean log reduction on the facemask portion of all 15 FFR models was 3.42 ± 1.08 $\log_{10}$ $TCID_{50}$ and 2.48 ± 1.29 $\log_{10}$ $TCID_{50}$ for straps. Only two of the FFR models demonstrated $\geq$ 3-mean log reduction for all contaminated surfaces. FFRs with hydrophilic surfaces correlated with the lowest log reduction values, and vice versa for hydrophobic surfaces.These data suggest that FFR-DR using UVGI is possible, but not universal. Some FFRs are not compatible, presumably due to material incompatibilities. These data are critically important for regulators and hospitals to understand in the event FFR-DR technologies are deployed during a pandemic. Studies are currently underway to evaluate FFR durability and performance following multiple UVGI cycles and to evaluate logistical parameters for implementing UVGI-based FFR-DR technology into health care settings.

Stability Of Hydrogen Peroxide Antimicrobial Activity In Silica Hydrogels: A Pilot Study

Author Block:

H. Mohamed, N. Orbey, N. Goodyear; Univ. of Massachusetts Lowell, Lowell, MA

Abstract Body:

Hydrogen peroxide is an effective, environmentally friendly disinfectant. However, it decays rapidly into water and oxygen, limiting its practical applications. Sol-gel chemistry can be used to microencapsulate H_2O_2 in silica hydrogels, in which the H_2O_2 binds strongly with the silica gel surface. Changing the pH and sodium concentration during hydrogel generation allows fine control of release and decomposition rates through variations in the surface area, pore volume, and pore size. This process will allow H_2O_2 hydrogels to be developed for specific applications through optimization of room temperature stability and decomposition rates. The resultant hydrogels have potential usefulness in wound treatment, hand sanitization, and other disinfection applications.In this study, freshly prepared and 4 month old gels at 0, 10, and 20 wt% were compared for activity against *S. aureus* and *E. coli* using a standard agar well diffusion method. Experimental conditions included: duplicate plates, 0.5 MacFarland density for bacteria (~1.5 x 10^8 CFU/mL), agar depth of 15 mL, 6 mm wells, and 0.04 ±0.01 g of gel. Each gel was tested in 2 separate runs. Average zones of inhibition (ZOI) are shown in the Table.Table. Average zones of inhibition (ZOI) for freshly prepared and 4 month old H_2O_2 hydrogels.

	Hydrogel Weight%	***S. aureus* ZOI (mm) (SD)**		***E. coli* ZOI (mm) (SD)**	
Freshly Prepared Hydrogel	0	6	0.0	6	0.0
	10	51	1.7	44	1.3
	20	54	0.5	45	0.5
4 Month Old Hydrogel	0	6	0.0	6	0.5
	10	34	1.0	28	0.8
	20	39	0.8	34	1.7

Zone sizes are consistently larger for *S. aureus* than *E. coli*, suggesting greater activity, however this must be further tested. The average difference in activity between 10 and 20 wt% is 4% for fresh gel and 16% for 4 month old gel. This suggests a non-linear relationship between gel wt% and activity, however the difference is greater for the older gel, implying that a higher

concentration might be more effective for long-term storage. Antimicrobial activity diminished by an average of 30% over 4 months, but significant activity remained. H_2O_2 can be stabilized in silica hydrogels for at least a 4-month period. Further investigations into ideal concentrations, stability, release rates, and antimicrobial activity are needed.

One to One Counseling is Highly Effective in Increasing Influenza Vaccination among Doctors

Author Block:

Y. Jung, J. Song, M-H. Kwon; Konyang Univ. Hosp., Daejeon, Korea, Republic of

Abstract Body:

Introduction: The influenza vaccination rate among healthcare workers (HCW) remains suboptimal. We tried to increase the vaccine uptake in the 2015-2016 season by non-mandatory measures including one to one counseling. **Methods:** Since 2004, our hospital (a university affiliated, 830-bed acute care center) have given free influenza vaccinations to HCW for three days at a designated location, and, after that period in the clinics. This year (2015-2016), to increase uptake, we used a stepwise approach including text messaging, extending the vaccination period, education and, personal counseling for unvaccinated HCW.**Results:** The number of potential HCW for influenza vaccination was 1454. First, we reminded the unvaccinated HCW of the vaccination by text messaging on the last day of vaccination. By the end of the last day, the uptake rate was 82.2% (1196/1454), lower than in the previous year (85%), so we decided to extend vaccination by three days. One month after starting the vaccination, 89% (1296/1454) of the HCW were vaccinated, but only 78.1% (207/275) of the doctors, the lowest rate among the subgroups. Next, we provided lectures to the doctors three times over two weeks but no one had been vaccinated by one week later. Lastly, we counselled all but one of the unvaccinated doctors (67/68) by telephone or personally, and recommended the influenza vaccine and informed them of the relevant location and time, or made an appointment for vaccination. After that intervention, 63.2% (43/68) of the unvaccinated doctors were vaccinated, thus achieving 91.3% (251/275) compliance, higher than the 58.4% (157/259) in the previous year.**Conclusions:** Influenza vaccination rate is lower among doctors than among other HCW subgroups. One to one counseling is highly effective in increasing influenza vaccination among doctors.

Towards a Novel Method for Detecting Microbial Biofilms on Indwelling Intravascular Catheters in Real Time

Author Block:

R. Donlan, M. A. Mazher, H. Moura, j. barr; CDC, Atlanta, GA

Abstract Body:

Background: Intravascular catheters (IC) colonized with bacterial biofilms are a major source of healthcare-associated infections. Bacteria produce extracellular proteins (EP) during growth and metabolism, and EP profiles for different organisms are unique. Nanoflow liquid chromatography-electrospray ionization-tandem mass spectrometry (nLC-ESI-MS) can detect and identify unique EP from microorganisms. We hypothesized that EP could be developed into biomarkers to detect and identify biofilm microorganisms in IC in real time. **Methods:** Biofilms of *Escherichia coli* were formed on human serum-pretreated silicone coupons in 12-well plates in RPMI 1640 medium at 37^{o}C. After 24 h, coupons were harvested and biofilms were recovered. Biofilms of *Pseudomonas aeruginosa* were developed using the same medium and growth conditions as for *E. coli*. Glass wool was used instead of silicone coupons to increase EP yield. Samples from the spent medium and from the recovered biofilm suspension for both organisms were centrifuged, and the proteins in the supernatants (biofilm EP) were trypsin digested. The resulting peptides were fractionated, ionized, and analyzed using nLC-ESI-MS. Proteins were identified using the MASCOT search engine and validated using Scaffold. **Results:** Flagellin (GI:120312) was the most abundant protein detected from biofilms of 4 different *E. coli* strains, and was selected as a putative biomarker for this organism. *E. coli* biofilm viable counts on silicone surfaces were approximately 10^5 - 10^7CFU/coupon for all strains, demonstrating the ability of this analytical platform to detect biofilm EP in the presence of more highly abundant proteins (e.g. serum albumin), suggesting a wide dynamic range for this method. The most abundant EP in 4 different strains of *P. aeruginosa* was Cpn60 groEL (GI:15599581), demonstrating that *P. aeruginosa* and *E. coli* had unique EP that could be developed into specific biomarkers. **Conclusions:** These results demonstrate the ability of this analytical approach to detect and differentiate biofilm organisms based on their specific protein signatures, and provide preliminary data for the development of a method to detect biomarkers for biofilms on intravascular catheters.

Hlth., Univ. Hosp. of Tours, TOURS, France, [2]Univ. Hosp. of Tours, TOURS, France, [3]IRSA, Lariche, France, [4]Agence de Santé Publique, France, St maurcie, France, [5]Univ. Hosp. of Tours, TOURS, France

Abstract Body:

Background: Hepatitis C virus (HCV) requires a specific continuum of care (CoC) from screening to treatment. However, many patients do not move through the CoC. We assessed the CoC of HCV patients in France in a longitudinal study.**Methods:** A cohort study of subjects undergoing a preventive consultation in one French regional medical centre from 1993 to 2013 was built, providing 12,993 HCV screenings. The HCV CoC was described as followed: Stage 1- HCV screening; Stage 2- HCV RNA infection confirmation; Stage 3- continuing care; Stage 4- antiviral treatment. HCV CoC was first described and Cox multivariate analysis was performed to identify factors favoring CoC, calculating Hazard Ratios (HR and 95%CI).**Results:** In total, 12,993 HCV tests were performed and 478 outpatients were found to be HCV-seropositive. We included 405 seropositive patients, after excluding false positives and patients lost to follow-up. The baseline characteristics were: sex ratio (M/F) 1.4; mean age 38.5 years; intravenous drug use (IDU) in 55%; 28% of precarious situations. Antiviral treatment was initiated for 179 (42.9%) of the 379 (90.9%) patients attending specialist consultations. CoC was associated with screening after 1997 (HR 2.0, 95%CI 1.4-2.9), age >45 years (HR 1.5, 95%CI 1.02-2.3), patient acceptance of care (HR 9.3, 95%CI 5.4-16.10), specialist motivation for treatment (HR 10.9, 95%CI 7.4-16.0), absence of cancer (HR 6.7, 95%CI 1.6- 27.9). Other comorbid conditions, such as depression and IVDU, were not associated with CoC.**Conclusions:** This 20-year overview of CoC of HCV infection in France showed that a substantial proportion of patients have access to antiviral treatment. However, this proportion should be increased, as new direct-acting antiviral drugs are highly effective and well-tolerated.

***Helicobacter pylori* Prevalence in Dental Plaques of Diabetic and Gastritis Patients, as a Possible Source of Re-Infection**

Author Block:

J. A. A. Qasem[1], A. A. Qasem[2], J. Thomas[1]; [1]The Publ. Authority for Applied Ed. and Training, Coll. of Hlth.Sci.,, Al-Ahmadi city, Kuwait, [2]Abu-Fatira Dental Clinic, Ministry of public Hlth.,, Abu-Fatira City, Kuwait

Abstract Body:

Background: *Helicobacter pylori* infection is considered as one of the most prevalent infectious diseases throughout the world. Oral infection with *H. pylori* is usually associated with *H. pylori* infection of the stomach therefore it has been speculated that oral bacteria are responsible for stomach re-infection. The objective of this study is to elucidate the prevalence of *H pylori* infection in dental plaques of type 2 diabetic subjects with and without gastritis. **Methodology:** Supragingival and subgingival samples were collected from 70 patients with chronic periodonitis, 15 of whom were also suffering from gastritis , 26 from diabetic, 9 from both gastritis and diabetic, and 2 from ischemic heart disease, diabetic and gastritis. The samples were analyzed by PCR using two Random sequence nt 4835-5041 primer. DNA extraction was done using the Gentra PureGene DNA isolation Kit **Results:** *H. pylori* was detected in 40% of the patients. The prevalence of *Helicobacter pylori* in dental plaques was 60% in gastritis patients and 31% in patients with diabetes only. Patients with gastritis and diabetes had 56% PCR positivity in gastritis patients with ischemic heart diseases and 100% with diabetes, compared to 24% among the control patients (healthy with no gastritis, diabetes or heart diseases). Interaction of age and infection was not significant but the prevalence of *H. pylori* in dental plaque of both diabetic and gastritis male patients were higher than among female patients. **Conclusion:** The prevalence of *H. pylori* in the dental plaque of gastritis patients was high and the alterations of glucose metabolism in diabetes seems to promote the *Helicobacter pylori* colonization in the dental plaques of the diabetic patients. The oral cavity may be a reservoir for *H pylori* infection, it is therefore suggested that professional plaque removal and oral hygiene procedure be performed, along with the antibiotic treatment of *H. pylori*.

Validation of Quality Indicators to Measure the Appropriateness of Antibiotic Use in a University Hospital

Author Block:

L. Boix Palop[1], C. Nicolas[1], M. Xercavins[2], C. Badia[1], P. Arcenillas[1], L. Gómez[1], E. Calbo[1]; [1]Hosp. Univ.ri Mútua de Terrassa, Terrassa, Spain, [2]Microbiol., Catlab, Terrassa, Spain

Abstract Body:

Background: An important requirement for an effective antibiotic stewardship program is the ability to measure appropriateness of antibiotic prescription (AP). To succesfully design effective and targeted interventions to improve antibiotic prescribing, it is first necessary to better understand the factors that influence appropriate prescribing. The aim of this study was to evaluate the quality of AP in a university hospital using a set of quality indicators (QI) previously described by Van den Bosch et al. **Methods:** A cross-sectional study was conducted (June-November-2015). All adult inpatients receiving systemic antibiotic therapy (SAT) were included in a monthly point-prevalence survey (PPS). Patients on SAT were identified through the Pharmacy Department Database. Patients from ICU, Psychiatry, Paediatrics and Emergency Department were not included. QIs previously described were adapted (Table 1). Three trained Infectious Disease Consultants collected QI checking data from medical records. The 3 evaluators simultaneously collected 10% of the sample in order to evaluate the interobserver concordance. **Results:** 505 patients were on SAT during the study period. 142 were excluded (130 discharge before evaluation or suspension of SAT, 12 antifungal or prophylactic SAT). 363 patients were finally analyzed. An average of 84.2 patients was included per PPS. The results are shown in Table 1. Kappa index for interobserver concordance was 0.67. **Conclusions:** Evaluation of QIs designed to measure the appropriateness of SAT has identified several areas for improvement including culturing, switching to oral therapy, stopping unnecessary SAT and directing therapy to culture results.Table 1

Quality indicators	Numerator description	Denominator description	Results
Empirical systemic antibiotic therapy (EAT) prescribed according to the local guideline	Number of patients (NP) with EAT according to the local guideline	NP with EAT and who had a clinical syndrome described in the local guideline	71.7%
Before starting systemic antibiotic (SAT) therapy 2 sets	NP with 2 blood cultures taken before starting SAT	NP who started with SAT	38%

of blood cultures should be taken			
When starting SAT, specimens for culture from suspected sites of infection should be taken	NP with SAT and in whom cultures from suspected sites of infection were taken	NP with SAT and who had a cultivable site of infection	75.5%
EAT should be changed to pathogen-directed therapy if culture results become available	NP with changing to pathogen-directed therapy done	NP with EAT whose culture became positive with clinical significance	73.5%
Dose adapted to renal function	NP with a compromised renal function with a dosing regimen adjusted to renal function (defined as eGFR <50 mL/min/1.73 m2)	NP with SAT and a compromised renal function	79.7%
SAT should be switched from intravenous to oral antibiotic therapy within 48-72 h on the basis of the clinical condition and when oral treatment is adequate	NP with intravenous antibiotics for 48-72 h, with changing to oral antibiotic therapy on the basis of clinical condition	NP with intravenous antibiotics for 48-72 h, in whom changing to oral antibiotic therapy was indicated	51.6%
No discontinuation of EAT after 5d of treatment without clinical and/or microbiological evidence of infection	NP with EAT ≥ 5d and without clinical and/or microbiological evidence of infection	NP with EAT ≥ 5d	23.2%
Therapeutic drug monitoring	NP with at least 1 serum drug level measurement	NP who received aminoglycosides for >3 d and/or vancomycin for >5 d	33.3%

Development of a Bacterial Consortium of *Lysinibacillus sphaericus* Strains as Biocontrol Agents Against *Aedes aegypti* Larvae

Author Block:

J. Silva, J. Dussán; Univ. de Los Andes, Bogota, Colombia

Abstract Body:

Background: One of the actual problems in public health is the increasing transmission of diseases via mosquito vectors in tropical regions. In this study, we focused on the mosquito *Aedes aegypti* (**Ae**). Biocontrol is a promising solution because it consists of using natural antagonists against target organisms. The bacterium *Lysinibacillus sphaericus* (**Ls**) has been reported to cause mortality in mosquito larvae. Three **Ls** strains were used on this project: the WHO strain 2362 and OT4b.25 and III(3)7 isolated in Colombia, a country with recent reports of dengue, Chykungunya and Zika virus. Previous studies proposed **Ls** as a candidate to control *Culex* and *Anopheles* populations but not for *Aedes*.The objective of this study was to produce a bacterial consortium efficient to control Ae populations in vitro. All bacterial consortia evaluated contained the strain 2362 since it has good toxicity by itself and because it is a reference strain worldwide. **Methods:** Bacterial strains of Ls used during this project were OT4b.25, III(3)7 and 2362. On the other hand, the WHO strain Ae Rockefeller was tested.All larvicidal bioassays were tested according to the parameters stated by the WHO and using four different initial inocula concentrations per assay in order to calculate the LC50 as an efficiency estimator. Bacterial consortia were tested as follows: 2362 + III(3)7, 2362 + OT4b.25, and III(3)7 + OT4b.25 + 2362. We determined statistical differences among lethality counts for the inocula concentrations evaluated on each bioassay with a Kruskal-Wallis test. **Results:** All bioassays showed larval mortality and results were validated by the effectiveness of the positive and negative controls. We found that the consortium of Ls strains 2362 + III(3)7 displayed the most efficient LC50 (8.67e8*) when compared to bioassays: 2362 + OT4b.25 (7.82e9*), and III(3)7 + OT4b.25 + 2362 (9.32e10*) and individual 2362 (1,11e9*) and III(3)7 (1,04e9*). Note: * = means bacterial inoculum units cfu/mL. **Conclusions:** We found that the bacterial consortium of **Ls** strains 2362 + III(3)7 is a good candidate consortium for biocontrol of **Ae** populations *in vitro*. Future *in situ* studies are required to verify the liability of this consortium under both environmental conditions and **Ae** populations.

F1-V Antigen Lead to Elevated Immune Response Against *Yersinia pestis* Together with Chlolera Toxin B Sub-Unit on Mice

Author Block:

J. JEON, O-K. PARK, S-Y. CHOI, G-E. RHIE, J-y. YU; Korea NIH, Osong, Korea, Republic of

Abstract Body:

Yersinia pestis is known as causative agent of plague which is a highly fatal infectious disease to human and certain animals. Despite of the seriousness of infection with *Y. pestis*, an effective plague vaccine is still not available. In this study, we investigated the effect of Cholera toxin B (CTB) subunit on immune response against *Y. pestis* F1-V antigen which has known to potent vaccine candidate for plague and on protection against lethal respiratory challenge with *Y. pestis* strain KIM5. BALB/c mice were immunized with His6-tagged purified F1, V, F1-V, V-F1, and F1+V proteins together with alum or cholera toxin B sub-unit. Immunization with F1-V together with CTB induced elevated immune responses to F1 or V compared to F1, V, F1-V, V-F1, and F1+V together with alum-immunized group. Furthermore, F1-V plus CTB-immunized mice showed a higher survival rate against lethal challenge with *Y. pestis* than F1, V, F1-V, V-F1, and F1+V together with alum-immunized mice. Taken together, these results suggest that CTB could serve as an effective candidate adjuvant for plague vaccination.

Wipe Cleaning Method for Restoring Antibacterial Activities of Soiled Surfaces of an Antibacterial Stainless Steel

Author Block:

H. Kawakami, K. Hirayama, Y. Sato, Y. Kikuchi; Osaka City Univ., Osaka, Japan

Abstract Body:

Background: Introducing antibacterial metals into frequently hand-touched places, such as handrails and doorknobs, has been considered to reduce risks of outbreaks of hospital acquired infections. Antibacterial activities of antibacterial metals will be deteriorated by surface soiling. The object of this study is to study practical wipe cleaning method for restoring antibacterial activities of antibacterial stainless steel surfaces, which were deteriorated by soiling. **Methods:** The sample metal used in this study was an antibacterial stainless steel containing about 3.8 mass% copper. Bovine serum albumin (BSA) and triolein were employed as model protein and oily contaminants, respectively. The contaminants were spread over a test surface of a coupon specimen. The specimen was then subjected to wipe cleaning using a crockmeter. Detergents used for the wipe cleaning were sodium hypochlorite aqueous solutions (NaOCl aq.) and ethyl alcohol aqueous solutions (EtOH). In some cases, surfactant (sodium dodecyl sulfate(SDS)) was added to these detergents. Antibacterial tests of wiped test surfaces were carried out in accordance with ISO 22196, using *Escherichia coli* (NBRC 3972) and *Staphylococcus aureus subsp. aureus* (NBRC 12732). **Results:** NaOCl aq. was effective against the BSA surface contamination, but less effective against the triolein surface contamination. EtOH was, contrary to NaOCl aq, effective against the triolein surface contamination but less effective against the BSA surface contamination. **Conclusion:** The practical wipe cleaning method effective against both protein and oily surface contamination was as follows: firstly wipe the soiled surfaces with wipes loaded with NaOCl aq. containing surfactant and then wipe the surfaces again with wipes loaded with distilled water to remove the surfactant remaining on the surfaces.

Multi-Laboratory Evaluation of the Oecd Quantitative Method for Assessing the Effectiveness of Antimicrobial Products on Hard Surfaces

Author Block:

S. F. Tomasino, R. M. Pines; US EPA, Ft. Meade, MD

Abstract Body:

The US EPA is working with the Organization of Economic Co-operation and Development (OECD) on the development of a standard method for assessing the efficacy of liquid antimicrobial products on hard non-porous surfaces. The method under consideration is based on the OECD Guidance Document on Quantitative Methods for Evaluating the Activity of Microbicides. In the method, 1 cm diameter stainless steel disks (carriers) are inoculated with 10 µL of a suspension of the test microbe and a three-part soil load. After drying, each carrier is placed in a vial and the inoculum is exposed to 50 µL of the antimicrobial agent. Control carriers receive 50 µL of phosphate buffered saline. Following a 5 min contact time, 10 mL of neutralizer is added to the vial, contents vortexed, serially diluted, and viable bacteria are enumerated using filtration and direct plating. The differences between the mean log density (LD) for control and treated carriers are used to calculate a mean log reduction (LR) value. Multi-laboratory studies were conducted on *Staphylococcus aureus, Pseudomonas aeruginosa* and *Mycobacterium terrae* to assess method performance within (repeatability) and between (reproducibility) labs. Sodium hypochlorite solutions and several antimicrobial liquids with a range of efficacy were tested in a blinded and replicated fashion. Repeatability (S_r) and reproducibility (S_R) standard deviations were calculated for the mean control LD and mean treated LR values. Across microbes, the control LDs exhibited S_r from 0.16 to 0.26 and S_R from 0.24 to 0.35. For *S. aureus* tests, the S_r for mean LRs ranged from 0.12 to 0.54 while the S_R ranged from 0.23 to 0.85. For tests involving *P. aeruginosa*, higher S_r (0.19 to 0.84) and S_R (0.28 to 1.2) for mean LRs were observed compared to *S. aureus*. The mean LRs for tests involving *M. terrae* exhibited similar ranges of S_r (0.25 to 0.49) and S_R (0.27 to 1.2) across the treatments. The S_r and S_R for treatments resulting in low LRs (0 to 1.5) or high LRs (4.5 to 6) were smaller with elevated variability occurring with moderately effective treatments. The studies provided the data necessary to further explore the use of the method for regulatory purposes.

The Role of Sodium Percarbonate as an Antimicrobial Ingredient of Laundry Detergents

Author Block:

B. Brands[1], S. Bloomfield[2], **D. P. Bockmühl**[1]; [1]Rhine-Waal-Univ. of Applied Sci., Kleve, Germany, [2]London Sch. of Hygiene and Tropical Med., London, Germany

Abstract Body:

Background: In order to save energy there is a trend towards lower washing temperatures. Especially in countries where it is not common to use chlorine bleach, hygiene problems might be expected due to the lack of temperature as one major antimicrobial impact factor. In general, the decrease in temperature can be compensated for by other washing parameters, such as the use of activated oxygen bleach (AOB), which can be found in solid all-purpose detergents. Although AOB is well known as a biocidal active, it remains unclear to what extent it contributes to the antimicrobial efficacy of the washing process, since other factors such as detergency effects or the mechanical action of the washing machine do also lead to a reduction of microorganisms on the textile. **Methods:** To better understand the impact of the different parameters, we systematically investigated the antimicrobial efficacy of AOB in presence or absence of detergents with regards to time and temperature using quantitative suspension testing according to DIN EN 1276 and DIN EN 1650. **Results:** It turned out that AOB was able to increase the reduction of the chosen test organisms (*Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa, Trichophyton mentagrophytes* and *Candida albicans*) in a time and temperature dependent manner, although the effect strongly depended on the observed organism. While the inactivation of the bacterial strains and *Trichophyton* could be increased by up to three logarithmic steps when using AOB even at temperatures below 40°C, an additional temperature effect was needed for *Candida*. Together with the finding that the addition of detergents did not considerably increase the reduction of microorganisms in suspension, it must be assumed that the removal of bacterial and fungal cells from the textile (driven by either mechanical action or detergency effects) plays an important role in the antimicrobial effect of laundering.**Conclusions:** The results of our study help to understand the role of chemistry (such as AOB and detergents), time, temperature and mechanics for the inactivation of microorganisms in the laundry process and show the necessity for comprehensive investigations when assessing the antimicrobial efficacy of laundering.

Infectious Diseases (Id) Telemedicine: Characteristics of the First 6 Months of an Electronic Id Consultation Service at a Tertiary-care VA Medical Center

Author Block:

M. J. SKALWEIT, **U. STIEFEL**; Cleveland VAMC / Case Western Reserve Univ., Cleveland, OH

Abstract Body:

Background: Electronic medical record systems and other digital technologies have made it possible to deliver quality healthcare in novel ways. Limited data is available regarding provision of ID expertise by these methods. In 2013, we added a physician-led, chart-based, rapid-turnaround, ID electronic consultation (E-consult) service to our pre-existing standard ID inpatient and outpatient consult services. We hypothesized that this service might be useful for particular types of infectious conditions, thus expanding capability in the standard consult arena. **Methods:** A retrospective analysis of patients undergoing ID E-consult for the first six months of our program was conducted. Patient characteristics, medical conditions, location of requesting healthcare providers, reasons for consultation, times to consult completion, and efficacy of consultation (as measured by the need for a further unexpected ID visit, either electronic or physical, within 30 days) were tabulated and expressed as a percentage of the whole, to construct a descriptive profile of this initial cohort of patients. **Results:** 105 ID E-consults were performed. The average age of the subjects was 63; 79% were Caucasian and 95% were male. 48% of consults came from clinics or nursing homes that were physically remote from the main hospital and our ID practice. The most common distinct reason for ID E-consult was management of urinary tract infection (UTI) (20%), followed by interpretation of culture data (14%), vaccine-related questions (13%), management of methicillin-resistant *Staphylococcus aureus* (MRSA) infection (10%) or *Clostridium difficile* infection (9%), concern for syphilis (5%), and travel medicine questions (4%). Average time to consult completion was 1.8 days, and only 6% of subjects required unexpected re-consultation or a physical visit within 30 days. **Conclusion:** We found electronic provision of rapid infectious diseases consultation services to be very efficacious, especially for particular ID syndromes. Such E-consults can successfully be deployed to expand the accessibility of quality ID expertise to patients and primary care providers. These findings could positively impact provision of ID care in busy, resource-poor, or physically remote healthcare settings.

Assessment Of Half-Mask Elastomeric Respirator And Powered Air-Purifying Respirator Reprocessing For An Influenza Pandemic

Author Block:

C. Lawrence, D. Mills, M. Sandoval, D. Harnish, B. Heimbuch; Applied Res. Associates, Inc., Panama City, FL

Abstract Body:

Many health care agencies are considering the use of reusable respiratory protection devices (RPDs) to mitigate an RPD shortage due to an influenza pandemic. US regulators are also considering stockpiling reusable RPDs for a pandemic event, but limited data exists on cleaning and disinfection of these devices. This study focuses on 1) determining if standard protocols provided by the Occupational Safety and Health Administration (OSHA) and manufacturers are capable of disinfecting influenza-contaminated reusable RPDs and 2) assess the durability and performance of these devices after being treated up to 150 times using inert aerosol filtration testing and manikin-based face piece fit procedures. Five half-mask elastomeric respirator (HMER) and three powered air-purifying respirator (PAPR) models were contaminated with influenza and artificial skin oil (sebum) on five unique surfaces. Triplicate RPDs per model were cleaned, or cleaned and decontaminated using standard protocols. Presence of viable influenza was determined via swab sampling and a median tissue culture infectious dose ($TCID_{50}$) assay with Madin-Darby Canine Kidney cells. Filtration efficiency testing and manikin-based fit assessments were performed on HMERs and PAPRs after 75 and 150 cleaning and decontamination cycles. No detectable influenza was found on all models of HMERs and PAPRs regardless of inoculation location or treatment. The mean log reduction was ~5-log $TCID_{50}$ for the HMER/PAPR bodies and on the PAPR hoods, but was lower on some straps (~3-log) due to lower extraction efficiencies. Treated HMERs and PAPRs showed no significant degradation in filtration efficiency or fit performance. These data provide the first evidence that HMERs and PAPRs contaminated with influenza (and sebum) are capable of being disinfected using OSHA or manufacturer-defined cleaning protocols. Cleaning alone was shown to be sufficient for removing/killing influenza. Fit and filtration performance test data indicate the devices would be acceptable for use after 150 cleaning and disinfection treatments. These combined data should provide confidence to hospitals that HMERs and PAPRs can be effectively reprocessed. Time and logistics required for RPD reprocessing may be significant; future work will focus on evaluating automated methods.

Carrying a Buddy to the Gym: Molecular Epidemiological Characterization of *Staphylococcus aureus* in Multiple Gym Facility Types

Author Block:

M. R. Dalman[1], H. Naimi[2], S. Bhatta[1], D. Thapaliya[1], T. C. Smith[1]; [1]Kent State Univ., Kent, OH, [2]Kabul Univ., Kabul, Afghanistan

Abstract Body:

Staphylococcus aureus is a commonly found bacterium of the nose and throat of healthy individuals and can lead to infections and death. Methicillin-resistant *Staphylococcus aureus* (MRSA) invasive infections cause 11,000 yearly deaths with approximately 1 in 3 people asymptomatically colonized with *S. aureus* and ~2% colonized with MRSA. Initially hospital patients were the main risk group for MRSA carriage and infection; though places of close contact such as gym facilities have emerged as risk factors. We investigated environmental contamination of gym facilities with *S. aureus* in order to determine molecular types and antibiotic susceptibility profiles of isolates, which may have the ability to be transmitted to facility patrons. Environmental swabs (n=270) were obtained from several gym facilities across Northeast Ohio including cross-fit type (n=4), traditional iron gyms (n=5), community centers (n=4), and hospital-associated facilities (n=3). Samples were taken from 18 different surfaces per facility and processed within 24 hours using typical bacteriological methods. Five colonies per positive sample were then subjected to antibiotic susceptibility testing and molecular characterization (multilocus sequence, PVL and *mec*A PCR, and *spa* typing). The overall prevalence of *S. aureus* on environmental surfaces in gym facilities was 37.4% (101/270). The most commonly colonized surfaces were the weight ball (8.9%) as well as the treadmill handle (7.9%) and weight plates (7.9%). Interestingly, the bathroom levers and handles were the least colonized in both males and female facilities (1-3%). Of note, traditional iron gyms (44%) and community gyms (39%) had the highest colonization prevalence among sampled surfaces with hospital associated (33%) and crossfit (30%) the least colonized. All samples were resistant to penicillin and several were multidrug resistant, with preliminary results indicating an intermediate vancomycin resistant *S. aureus* isolate present. Additional characterization is ongoing. Our pilot study indicates that a diverse number of surfaces are contaminated by *S. aureus* and that additional studies are needed to better characterize the metagenomic structure of both the surfaces and the patrons that come to these differing facility types.

Pneumococcal Multiple Serotype Carriage Following Vaccination with the 13-Valent Pneumococcal Conjugate Vaccine

Author Block:

C. Valente[1], J. Hinds[2], K. A. Gould[2], H. de Lencastre[3], R. Sá-Leão[1]; [1]ITQB, Oeiras, Portugal, [2]St. George's Univ. of London, London, United Kingdom, [3]The Rockefeller Univ., Oeiras, Portugal

Abstract Body:

Background: *Streptococcus pneumoniae* is a Gram-positive pathogen that frequently colonizes the human nasopharynx, particularly children up to six years old. There are over 90 different capsular types (or serotypes) that are recognized by the immune system. Colonization with multiple serotypes, or co-colonization, is frequent and an important driving force for competition and evolution of the species, either by competition for nutrients or by promoting gene exchange between strains. The study of co-colonization is also important to understand how the pneumococcal population is changing with vaccination. In this study we aimed to determine the impact of the 13-valent pneumococcal conjugate vaccine (PCV13) on multiple serotype carriage.**Methods:** Nasopharyngeal samples from fully vaccinated pneumococcal carriers (4 doses of PCV13, n=141, aged 18-72 months) or from non-vaccinated pneumococcal carriers (0 doses of any PCV, n=140, same age group) were analyzed. Co-colonization was evaluated by DNA hybridization with a molecular serotyping microarray that detects all known serotypes.**Results:** Vaccinated children presented a lower prevalence of co-colonization than the non-vaccinated group (20.6% vs 29.3%, p=0.097), and a significantly lower proportion of PCV13 serotypes (6.4% vs 38.5%, p=0.0001). PCV13 serotypes found among vaccinated children were frequently detected as a minor serotype in co-colonization with a more abundant non-vaccine serotype. Also, vaccinated children were colonized by a significantly higher proportion of commensal non-pneumococcal *Streptococcus spp*. (58.2% vs 42.8%, p=0.012). In vaccinated children there were significantly less non-vaccine type (NVT) co-colonization events than expected based on the distribution of these serotypes in non-vaccinated children.**Conclusions:** The results suggest that vaccinated children have lower pneumococcal co-colonization prevalence due to higher competitive abilities of non-vaccine serotypes expanding after PCV13 use. This might represent an additional benefit of PCV13, as decreased co-colonization rates translate into decreased opportunities for horizontal gene transfer and might have implications for the evolution and virulence of pneumococci.

Optimization of Cluster Analysis Based on Antimicrobial Resistance Profile of Methicillin-resistant *Staphylococcus aureus* (Mrsa) Isolates

Author Block:

H. Mikamo, H. Tani, N. Nishiyama, Y. Koizumi, Y. Yamagishi; Aichi Med. Univ., Aichi, Japan

Abstract Body:

Background: Pulsed-field gel electrophoresis (PFGE) is the gold standard used for the epidemiological analyses of methicillin-resistant *Staphylococcus aureus* (MRSA), but this method has many disadvantages including procedural complexity, the long period of 5 days or more required to obtain results, and the need for special equipment. New techniques such as multi-locus sequence typing, phage open reading frame typing, and repetitive sequence-based PCR are difficult to perform in routine laboratories. Antimicrobial susceptibility testing is routinely performed in hospital laboratories and produces a wide range of results, there have been limited reports of the use of drug susceptibility testing for epidemiological analysis.**Method:** We examined 402 MRSA strains isolated from clinical specimens in our hospital between 2010 and 2011 to evaluate the similarity between cluster analysis of drug susceptibility tests and PFGE.**Results:** The 402 strains tested were classified into 27 PFGE patterns (151 subtypes of patterns). Cluster analyses of drug susceptibility tests with the cut-off distance yielding a similar classification capability showed favorable results - when the MIC method was used, and MIC values were used directly in the method, the level of agreement with PFGE was 74.2% when 15 drugs were tested. the Unweighted Pair Group Method with Arithmetic Mean (UPGMA) method was effective when the cut-off distance was 16. Using the SIR method in which susceptibility (S), intermediate (I), and resistance (R) were coded as 0, 2, and 3, respectively, according to the CLSI criteria, the level of agreement with PFGE was 75.9% when the number of drugs tested was 17, the method used for clustering was the UPGMA, and the cut-off distance was 3.6. In addition, to assess the reproducibility of the results, 10 strains were randomly sampled from the overall test and subjected to cluster analysis. This was repeated 100 times under the same conditions. The results indicated good reproducibility of the results, with the level of agreement with PFGE showing a mean of 82.0%, standard deviation of 12.1%, and mode of 90.0% for the MIC method and a mean of 80.0%, standard deviation of 13.4%, and mode of 90.0% for the SIR method.**Conclusions:** Cluster analysis for drug susceptibility tests would be useful for the epidemiological analysis of MRSA.

Hlth.Agency, Belfast, United Kingdom

Abstract Body:

Infant GBS disease surveillance is essential to assess the impact of current prevention guidelines and guide vaccine development and implementation programmes. To update our estimates of incidence, risk factors, outcome and microbiology, enhanced infant GBS disease surveillance was established across the UK and Ireland during 2014/15.Cases diagnosed from 1st April 2014 to 30th April 2015 were identified through paediatric and microbiology surveillance networks and defined as infants aged <90 days from whom GBS was isolated from a normally sterile site. Isolates were characterised by serotyping, multilocus sequence typing (MLST) and antimicrobial susceptibility testing.GBS were characterised from 399 of 817 confirmed cases, 208 were early onset cases (age <7 days; EOD) (52%) and 191 late onset (age 7-89 days; LOD) (48%). Serotypes Ia, Ib, II, III and V (n=386) comprised 94% of isolates. Serotype III (n=246) and Ia (n=69) were the most prevalent serotypes. The majority of serotype II (94%) and V isolates (78%) were from infants with EOD. Isolates from EOD cases (n=186) were assigned to 29 MLST sequence types (ST) (index of discrimination (D)=0.81) and from LOD (n=160) to 21 STs (D=0.60). ST17 was the most prevalent (n=173, 42%), associated with 67% of EOD and 58% of LOD meningitis cases. Serotype II and V displayed the highest resistance to clindamycin (cli) (33% and 41%) and erythromycin (50% and 63% respectively). Overall 16% of EOD and 20% of LOD isolates were cli resistant but resistance among serotype V isolates from EOD was 26% and 83% in LOD.Differences in serotype, MLST and antimicrobial susceptibilities between EOD and LOD isolates were identified. ST17, serotype Ia and III were common amongst invasive GBS infections indicating protection with a pentavalent vaccine containing these serotypes may potentially provide protection against up to 94% of cases. This surveillance data will contribute towards future clinical guidelines for GBS prevention and to vaccine implementation.

Evidence For Horizontal Transmission Of *streptococcus Mutans* Among Children And Their Family Members By Rep-Pcr

Author Block:

S. S. Momeni, J. Whiddon, S. A. Moser, N. K. Childers; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract Body:

Streptococcus mutans is frequently associated with dental caries. Epidemiological studies of *S. mutans* typically focus on vertical or horizontal transmission, with mother-to-child transmission most commonly considered the primary route of transmission. However, studies evaluating both routes of transmission are limited. In this study, horizontal and vertical transmission of *S. mutans* isolates among index children (IC) and with their household family members (HH) were evaluated by repetitive extragenic palindromic PCR (rep-PCR). *S. mutans* isolates from 119 African American IC (N=7,494) and 414 of their HH (N=5,651) were evaluated by DiversiLab rep-PCR. For each rep-PCR genotype, IC were evaluated as having either no match with any HH or matching with one or more HH. IC with no match were classified as horizontal while IC sharing a genotype with one or more HH were classified as vertical transmission. The mean number of genotypes per IC was 2.69 (range 1-9). Twenty-nine IC (24%) shared no genotype with any HH while 33 IC (28%) shared all genotypes within the household. There were 86 IC (72%) that had at least one genotype not shared with any HH. Since IC can have multiple genotypes, analysis was done for individual genotypes. This resulted in 157 cases among 21 genotypes where the IC did not share the GT with any HH. For these cases, 53 had only 1 isolates (transient), 57 had 2-9 isolates (borderline), and 47 had >10 isolates (established). There were 158 cases among 21 genotypes where an IC and one or more HH shared the genotype. Of these, 87 cases (55%) had genotypes shared with more than one HH. IC most commonly shared a genotype with mother (54%), siblings (46%), and/or cousins (23%). While this study is consistent with mothers as a primary route of transmission for *S. mutans*, it also presents compelling evidence for horizontal transmission among children. This is the largest know study of extra-familial horizontal cases evaluating both horizontal and vertical routes of transmission in the same study. The data is more robust as it considers transient and established genotypes as well as evaluates multiple HH. These findings indicate the importance of considering horizontal, as well as vertical, acquisition of *S. mutans* in prevention strategies for dental caries.

Maldi-Tof Ms for Capsular Typing of *Streptococcus pneumoniae* Isolates

Author Block:

T. C. A. Pinto, N. S. Costa, L. F. S. Castro, R. L. Ribeiro, J. M. Peralta, L. M. Teixeira; UFRJ, Rio de Janeiro, Brazil

Abstract Body:

Streptococcus pneumoniae can be classified in more than 90 capsular types, as determined by Quellung reaction or PCR. Such methods, however, can be expensive, laborious or unable to accurately discriminate among certain serotypes; thus, determination of capsular types, which can predict some virulence and resistance traits, is mainly restricted to research laboratories, being rarely performed in the clinical setting. In the present study, MALDI-TOF MS was evaluated as an alternative tool to characterize 421 pneumococcal isolates belonging to types 6A, 6B, 6C, 9N, 9V or 14. Capsular types were determined by Quellung reaction and/or multiplex PCR. For MALDI-TOF MS analysis, each isolate was submitted to an in-house extraction protocol using formic acid and acetonitrile before applying to the target plate and covering with CHCA matrix. Measurements were performed with a Microflex LT mass spectrometer using the default parameters and generating spectra in the range of 2,000-20,000 *m/z*. Spectra were analyzed with BioNumerics software v7.5. Number of detected peaks (or biomarkers) varied from 22 (in serotype 6A isolates) to 38 (in serotype 6C isolates). Isolates were distributed mainly according to the type in a Neighbor Joining tree and capsular types were discriminated by the presence/absence of 5 selected biomarkers (Graphic 1). The results suggest that MALDI-TOF MS is a promising alternative for typing pneumococcal strains, highlighting its usefulness for rapid and cost-effectiveness routine application in clinical laboratories.

***Streptococcus pneumoniae* of Serogroups 6 and 19 Circulating in Brazil Over a Period of 24 Years**

Author Block:

L. Oliveira[1], L. Castro[1], A. Souza[1], S. Chochua[2], P. Hawkins[2], L. McGee[2], T. Pinto[1], L. Teixeira[1]; [1]Univ.e Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]CDC, Atlanta, GA

Abstract Body:

Streptococcus pneumoniae (*Sp*) is a leading human pathogen that can be characterized into more than 90 capsular types, based on the composition of its polysaccharide capsule. *Sp* strains belonging to certain serotypes, including those of serogroups 6 and 19, can be highlighted by their high prevalence and association with antimicrobial resistance. In this study, 488 *Sp* isolates of serogroups 6 and 19 recovered from patients and healthy carriers in Brazil over a period of 24 years, were subjected to serotyping, multilocus sequencing typing and antimicrobial susceptibility testing to penicillin. Serotype 6B was the predominant serotype (163 strains; 33.4%), followed by serotypes 19F (146 strains; 30.5%, 0.6% being serotype 19Fvar), 19A (61 strains; 12.5%), 6A (58 strains; 11.9%) and 6C (56 strains; 11.5%). Serotypes 6A and 19F were uniformly distributed over the period of time investigated, while serotype 6B has been decreasing and serotypes 6C and 19A have been increasing. Occurrence of penicillin non-susceptible pneumococci (PNSP; MICs of 0.12-4 µg/ml), was higher among serogroup 6 (especially serotype 6B) isolates (81 out of 278 isolates; 29%), and serogroup 19 (46 out of 210 strains; 22%). The highest penicillin MICs were observed for serotype 19A isolates. A total of 45 and 13 different STs were, respectively, detected among serogroup 6 (Simpson's Index of Diversity, SID of 0.952) and serogroup 19 (SID of 0.818) isolates. ST748 was the most common among serogroup 6 isolates, being associated with PNSP and circulating in our country since 1991. ST733 was the most common among serotype 19A isolates, associated with penicillin susceptibility and has been circulating in our setting since 2008. Portugal^{19F}-ST177 was most frequent among serotype 19F isolates, being detected since 1997. Other international clones, including Greece^{6B}-22, Spain^{6B}-2 and Taiwan^{19F}-14, were also identified. Our results demonstrate the genetic diversity among serogroups 6 and 19 circulating in Brazil over a large period of time, revealing the presence of both regional and international clones, some of them highly associated with penicillin non-susceptibility, reinforcing the need for constant surveillance of such serogroups.

Publishing Title:

Distribution of *psp*a and Pilus Type I Genes Among *Streptococcus pneumoniae* Strains Isolated Over a Period of 22 Years in Brazil

Author Block:

A. Souza, N. Costa, S. Pina, T. Pinto, J. Peralta, L. Teixeira; Univ.e Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract Body:

Streptococcus pneumoniae (*Sp*) is a leading cause of vaccine-preventable infections. The polysaccharide capsule is the major virulence factor and the basis for currently licensed vaccines. In Brazil, the 10-valent pneumococcal conjugate vaccine (PCV10) has been available since 2010. In addition, surface proteins such as PspA and pilus type 1 (PI-1) have more recently been proposed as serotype-independent vaccine targets, but data on their prevalence and diversity are still lacking in many areas. In this study, the presence of genes coding for PspA and PI-1 was evaluated among 404 *Sp* strains belonging to 24 serotypes and recovered from different clinical specimens between 1988 and 2012, in Brazil. All isolates had *psp*A genes; 36% and 63% of the strains had, respectively, *psp*A genes of families 1 (mostly clade 1) and 2 (mostly clade 3). Family 3 *psp*A genes (clade 6) were detected in 1% of the strains, all of them being non-typeable, penicillin susceptible pneumococci (PSP) and recovered from asymptomatic nasopharyngeal colonization (NPC). *psp*A genes of family 2 were the most common among isolates belonging to both PCV10 serotypes (65%) and non-PCV10 serotypes (61.3%), as well as they were the most prevalent among isolates from both invasive pneumococcal disease (IPD; 65.5%) and NPC (60.7%). *psp*A genes of family 2 were also highly prevalent among penicillin non-susceptible pneumococci (PNSP; 80%), while family 1 genes were more common among PSP strains (50.5%). A total of 44% of the strains also had PI-1 genes, which were commonly found among PNSP strains (72.5%), isolates belonging to PCV10 serotypes (53.2%), and strains recovered from IPD (70%); but were more rarely detected among PSP (28%) and isolates belonging to non-PCV10 serotypes (6.3%). PI-1 genes were also more common among isolates presenting *psp*A genes of family 2 (92%) when compared to family 1 (8%), while no isolate of family 3 had PI-1 genes. Occurrence of strains harboring PI-1 genes has been increasing along the years, while prevalence of isolates presenting *psp*A genes of family 1 has been decreasing. Our results shows that *psp*A genes of family 2 and PI-1 genes are highly prevalent and have been increasingly detected among *Sp* strains isolated in Brazil since the late 80's, being especially associated with PCV10 serotypes and PNPS.

Emergence of *Streptococcus pneumoniae* Serotype 6c After Pcv10 Implementation on Brazil

Author Block:

J. Caierão[1], **G. Rosa da Cunha**[1], M. P. Mott[1], P. A. d'Azevedo[1], L. McGee[2], C. A. G. Dias[1];
[1]UFCSPA, Porto Alegre, Brazil, [2]CDC, Atlanta, GA

Abstract Body:

Background: Childhood immunization against *Streptococcus pneumoniae* decreased the incidence of pneumococcal diseases around the world; despite of reports, in different regions, of emergence of non-vaccine serotypes, such as 6C. We aimed to analyze frequency of occurrence and molecular epidemiology of serotype 6C before and after PCV10 vaccination in Brazil.**Methods:** *S. pneumoniae* were recovered from invasive and non-invasive sites of patients attended in Porto Alegre, South Brazil during 2007-2015. Identification was performed as described elsewhere (SPELLERBERG & BRANDT, 2011). Isolates were serotyped using multiplex PCR (Dias et al, 2007) and/or Quellung reaction. MLST was performed for molecular analysis (Enright & Spratt,1998).**Results:** From 2007 to 2015, 586 *S. pneumoniae* were serotyped, 202 before and 394 after vaccination; 582 out of 586 had defined site on medical records: 465 pneumococci were recovered from invasive sites, mainly blood, and 117 from other sites. Among the 572 isolates recovered from patients that we had information considering age, 52 were 5 years old or younger, whereas 156 had 65 years or more. Of note, 247 isolates belonged to PCV10 serotypes. Serogroup 6 represented 8.8% (52/586) of all serotypes: 6B (20/586 - 3.4%), 6A (17/586 - 2.9%), and 6C (15/586 - 2.5%). All 6C isolates were recovered after PCV10 implementation and 9 out of 15 came from invasive sites. One isolate of serotype 6C (6.6%) was recovered from vaccine-target population and 40% were related to elderly. MLST results demonstrated a considerable genetic diversity, with six different ST (3390, 2185, 172, 6373, 7288, 9007) and four other representing a new combination of alleles. ST 3930 was the most common ST representing 33.3% of all, being associated with other serotype 6C pneumococci from other region of Brazil before vaccination.**Conclusions:** Serotype 6C has not suffered cross protection of vaccination targeting serotype 6B. Although with a predominant ST, dissemination of serotype 6C does not seem to have a clonal profile, which could suggest distinct genetic origins. Such emergence may be a result of selective pressure exerted by PCV10, but other causes should be considered.

Comparison of Snp-based and Cgmlst-based Typing of *Listeria monocytogenes* Isolates from Seeliger's Historical "Special Listeria Culture Collection"

Author Block:

P. Hayden[1], **C. J. GRIM**[2], A. Pietzka[1], M. Blaschitz[3], A. Indra[3], C. W. Sensen[4], F. Allerberger[1], T. Rattei[5], W. Ruppitsch[1]; [1]Austrian Agency for Hlth.and Food Safety, Vienna, Austria, [2]Food and Drug Admin., Laurel, MD, [3]Austrian Agency for Hlth.and Food Saftey, Vienna, Austria, [4]Graz Univ. of Technology, Graz, Austria, [5]Univ. of Vienna, Vienna, Austria

Abstract Body:

Background: Whole genome sequencing has emerged as the ultimate tool for comparison of bacterial isolates for surveillance and outbreak investigation. In this study we sequenced 12 serotype 4b isolates of Seeliger's historical 'Special Listeria Culture Collection' (SLCC) and compared typing results obtained by mapping of read data against a reference genome followed by single nucleotide polymorphism (SNP) analysis to a de novo assembly of read data followed by a gene-by-gene comparison of a defined core genome (cgMLST).**Material/methods:** Genomic DNA was isolated from SLCC isolates grown overnight and Nextera XT libraries were sequenced on a MiSeq (Illumina). Reads were processed, de-novo assembled with Velvet v.1.1.08 and cgMLST allelic schemes were extracted using SeqSphere+ v2. For SNP based analysis, the CFSAN SNP pipeline was used to produce a SNP matrix by mapping unprocessed reads on the reference genome of strain J1-220 (GenBank CP006047.2). Phylogeny was calculated using RAxML v8.2.2. Visualization was performed on itol.embl.de.**Results:** The Velvet assemblies had a median N50 value of 229,641 bp. Both assemblies and read mappings returned an average coverage of 92x. The SNP-analysis for 12 serotype 4b SLCC isolates resulted in a total of 3,307 single nucleotide variant positions distributed over the reference genome. In the core genome MLST, 205 out of 1,701 genes had more than one sequence type. All isolates could be differentiated by SNP and cgMLST analysis,**Conclusions:** Comparison of 12 serotype 4b isolates by NGS using a standardized cgMLST based typing scheme for Listeria monocytogenes with a SNP analysis pipeline reveals no major differences of these two methods. Thus, although SNP based typing provides higher resolution than cgMLST and might be useful in certain situations, the defined cgMLST scheme has a similar discriminatory power, allows the global exchange of data, and is easier to standardize than mapping followed by SNP calling.

Molecular Comparison of Vancomycin-Resistant *Enterococcus faecium* Bloodstream and Stool Isolates from a Hematology Unit in Salt Lake City, Utah

Author Block:

M. A. GAZDIK, Z. Burr, J. Coombs, B. Lopansri, C. Ford; LDS Hosp., Salt Lake City, UT

Abstract Body:

Background: *Enterococci*, most commonly *E. faecium* and *E. faecalis*, are one of the most frequently isolated organisms in hospital-acquired infections in the US. Patients on hematology/oncology and stem cell transplant units are at high risk of gastrointestinal tract colonization by vancomycin-resistant *E. faecium* (VREfm), a risk factor for development of VREfm bloodstream infection (BSI). The purpose of our study was to identify features of bacterial strains associated with BSI by comparing the molecular characteristics of VREfm from patients with BSI to isolates from colonized patients who never developed infection.**Methods:** DNA was extracted from 38 blood stream isolates and 41 stool isolates followed by whole genome sequencing using NexteraXT library preparation and the MiSeq sequencing platform (Illumina). Read filtering, trimming and de novo assembly of contigs was completed with CLC Genomics Workbench. Assembled contigs were uploaded into the MLST, ResFinder 2.1, and CSI Phylogeny 1.1 pipelines available at the Center for Genomic Epidemiology for molecular characterization. A local BLAST database of Enterococcus virulence genes was generated and searched against assembled contigs in CLC Genomics Workbench.**Results:** Blood isolates were composed of 13 MLST strain types while 12 STs were found in stool colonies, however there was no ST statistically associated with either isolate type. Similarly there was no statistical difference found for any virulence factor or antibiotic resistance gene. In fact isolates showed a high homogeneity of virulence factors, with all isolates containing: *acm*, *ebp*A,B,C, *scm*, *fms*14-17-13, *fms*11-19-16, and *fms*21-20 while none contained *gel*E and only 1 contained *hyl*E.**Conclusions:** Our data indicate that patients on our hematology floor are colonized and infected by similar isolates, indicating that the risk of BSI in colonized patients is more indicative of patient characteristics than traits of the colonizing strain.

Changes in Antimicrobial Resistance and Population Structure of *Streptococcus pneumoniae* Colonizing Children after Four Years of Routine Conjugate Vaccines Use In Brazil

Author Block:

F. P. G. Neves[1], N. T. Cardoso[2], A. R. V. Souza[3], R. E. Snyder[4], M. M. Marlow[4], T. C. A. Pinto[3], S. Chochua[5], P. Hawkins[5], L. McGee[5], L. M. Teixeira[3], L. W. Riley[4]; [1]Univ. of California Berkeley, Berkeley, CA, [2]Univ.e Federal Fluminense, Niterói, Brazil, [3]Univ.e Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [4]Univ. of California, Berkeley, CA, [5]CDC, Atlanta, GA

Abstract Body:

In 2010, the 10-valent pneumococcal conjugate vaccine (PCV10) was progressively implemented regionally and free of charge into the Brazilian childhood immunization schedule, whereas simultaneously the 13-valent vaccine (PCV13) was only offered in private clinics. As part of a study of the response of the pneumococcal population to conjugate vaccines, we report the findings from isolates collected immediately before and after four years of routine use of conjugate vaccines in Niterói, Brazil. We used multilocus sequence typing (MLST) to analyze 257 pneumococcal carriage isolates obtained from children (aged < 6 years) during 11/2009-08/2010 (125 isolates; pre-PCV10/13) and 09-12/2014 (132 isolates; post-PCV10/13). We determined minimum inhibitory concentrations (MIC) to penicillin (PEN), ceftriaxone (CTX) and erythromycin (ERY) with E-test method. MLST revealed 98 different sequence-types (ST), including 37 new ST. Thirty-three ST were only found pre-PCV10/13, 48 only post-PCV10/13 and 17 from both periods. PEN non-susceptible pneumococci (MIC = 0.12-8 µg/mL) made up 24% (30/125) and 37.9% (50/132) of the pre- and post-PCV10/13 isolates, respectively, encompassing 14 and 24 distinct ST in each period. The highest PEN and CTX MIC were observed for the serotype 14-ST156 complex isolates pre-PCV10/13 and for the serotype 19A-ST320 complex isolates post-PCV10/13. Pre-PCV10/13, ERY resistance (MIC = 2 and 4 µg/mL) was restricted to two (1.6%) serotype 6A-ST1190 isolates Post-PCV10/13, 36 (27.3%) isolates of 15 different ST were ERY-resistant (MIC from 1.5 to >256 µg/mL). Changes in ST distribution and increasing resistance to PEN and ERY were evident. Although sources of PEN resistance source remained polyclonal pre- and post-introduction, most resistant isolates belonged to a few clones, namely ST156 pre-PCV10/13 and ST386 post-PCV10/13. The increase in ERY resistance rates was also polyclonal, but largely explained by the emergence of the ST386.

Superantigen Gene Profile Diversity among Non-Pharyngeal Group A *Streptococcal* Isolates

Author Block:

E. Troche Gonzalez[1], **A. Inzunza Montiel**[1], R. Garza Velasco[2], L. M. Perea Mejia[1]; [1]Faculty of Med., UNAM, Mexico, Mexico, [2]Faculty of Chemestry, UNAM, Mexico, Mexico

Abstract Body:

Group A Streptococcus (GAS) is a strict human pathogen; clinical manifestation varies from noninvasive diseases, including tonsillitis and erysipelas, to invasive diseases, such as sepsis, streptococcal toxic shock syndrome (STSS), and necrotizing fasciitis. M-protein and superantigens are important virulence factors in GAS.To determine differences between *emm*-type and superantigens profile in GAS were analyzed 125 isolates from non-pharyngeal source. The *emm*-genotype and distribution of *speA, speB, speC, speG, speH, speI, speJ, speK, speL, speM, ssa, smeZ, prtF,* and *sic* genes to each isolate were determined using PCR and DNA sequencing.Twenty-four different *emm* types were determinate, of them *emm1, emm12, emm6, emm75* and *emm89* account >60% of isolates. *speB, speG* and *smeZ* genes were detected in >90% of all isolates in contast to *speA, speK, speL* and *ssa* genes detected in <25%. Nevertheless some genes were detected in association with certain *emm* types: *sic* (*emm1*); *speA*(*emm1* and *3*); *speC* (*emm2, 4, 11, 43, 59* and *89*); *speM* (*emm1, 12, 75* and *89*), *speL* (*emm75*); *speH* and *speI* (*emm2, 12* and *75*); *speK*(*emm3, 6, 49* and *60*); *ssa* (*emm4* and *22*).A high diversity in superantigen gene profiles both within and between *emm*-genotypes was found in this study indicating that superantigen gene profiling might be useful in tracking the spread of clones in the community and nosocomial outbreaks.

Decrease in Genotypic Penicillin Resistance Due to Serotype Replacement in Isolates from Pediatric Invasive Pneumococcal Diseases after PCV13 Introduction in Japan

Author Block:

S. Iwata, M. Morozumi, M. Takata, K. Ubukata; Keio Univ. Sch. of Med., Tokyo, Japan

Abstract Body:

Background: In Japan, pneumococcal vaccination of children was switched from 7-valent pneumococcal conjugate vaccine (PCV7) to PCV13 in November 2013. We aimed to clarify the capsular types and genotypes based on *pbp* gene alterations in *Streptococcus pneumoniae* (*Spn*) strains that were isolated from pediatric patients with invasive pneumococcal diseases (IPD) around the time of the change from PCV7 to PCV13.**Methods:** We collected *Spn* isolates (n=853) from IPD patients under 16 years of age between 2010 and 2015. We analyzed the capsular type using antisera from Statens Serum Institute (Denmark). Genotypic (g) penicillin resistance was classified into gPSSP, gPISP with one or two abnormal *pbp* genes, and gPRSP with the three abnormal *pbp* genes of *pbp1a*, *pbp2x*, and *pbp2b*, using real-time PCR methods for all *Spn*.**Results:** Introduction of PCV7 has significantly reduced vaccine-type IPD, especially meningitis, within 3 years. Whereas IPD caused by non-PCV7 types such as 19A, 15A, and 24 showed a relative increase, the resulting rate of PCV7 type isolates rapidly decreased from 73.3% in 2010 to 15.2% in 2012. Switching from PCV7 to PCV13 vaccination clearly resulted in a decrease in serotype 19A in 2015. The rate of PCV13 type isolates decreased from 89.0% in 2010 to 28.5% in 2013 and 10.4% in 2015, respectively. Yearly increases in non-PCV13 types were seen in serotypes 12, 22F, and 24. The statistical prevalence of gPRSP decreased from 54.7% in 2010 to 16.0% in 2015. In contrast, gPSSP gradually increased from 8.7% to34.0%.**Conclusions:** In highly populated Japan, epidemiological surveillance of vaccine-induced capsular type replacement of IPD isolates is necessary to continue on a national scale.

***In Silico* Analyses of Antigenicity and Surface Structure Variation of an Emerging Pcv2b Mutant**

Author Block:

Y. Zhan; HUNAN AGRICULTURAL Univ., CHANGSHA, China

Abstract Body:

Background: Infection with PCV2 is a huge burden to swine industry worldwide. Currently there is no specific treatment available for PCV2 infection and PCVADs. Vaccination has proved to be the best way to prevent PCV2 infection in field. Thus, investigation of antigens and capsid structure variations of the virus is critical to improve diagnosis, new vaccine design and our understanding of PCV2 pathogenesis.**Methods:** In this study, 62 PCV2 isolates were identified from seven farms in southern China from 2013 to 2015, and phylogenetic trees were constructed based on whole-genome sequences or the *cap* gene. A novel putative recombination isolate was identified by recombination analysis software. The effects of the PCV2 capsid surface variation on antigenicity and surface structure were displayed by 3D structure simulation.**Results:** PCV2b was the main genotype in circulation throughout these farms, and an emerging mutant (PCV2b-1C), isolated from PCV2-vaccinated farms was the predominant strain prevalent on these farms. In addition, we isolated a new cluster that may represent evolution of the virus through recombination of PCV2b-1A/1B and PCV2b-1C. Finally, we discussed evidence that antigenicity and surface structure variation of the capsid resulted from mutation of the carboxyl terminus loop (Loop CT) of the PCV2b-1C Cap *in silico*.**Conclusions:** Our work characterized the prevalence, genetic variation and phylogenetic characteristics of PCV2 isolates in southern China over the past 3 years. In particular, alterations in antigenicity and surface structure of the capsid due to altered Cap amino acid, were evaluated and discussed. Therefore, ongoing evolution of PCV2b poses a future challenge regarding efficacy of PCV2a-based commercial vaccines.

Molecular Characterization of *Mycobacterium orygis* Isolates from Animals of South Asia

Author Block:

J. Thapa, C Nakajima, Z Rahim, S Paudel, Y Shah, B Maharjan,A Poudel, A Sadula, GE Kaufman, D McCauley, KP Gairhe, Tsubota and Y Suzuki; Hokkaido Univ., Res. Ctr. for Zoonosis Control, Sapparo, Hokkaido, Japan

Abstract Body:

Background: *Mycobacterium orygis* has recently been categorized as a member of *M. tuberculosis* complex (MTC) and has been reported to cause tuberculosis (TB) in a variety of animals and humans. We have isolated this bacterium from different wild animals in Nepal and captured monkeys and dairy cattle in Bangladesh and have performed molecular characterization. **Methods:** MTC isolates from a captive spotted deer, a blue bull and a free ranging greater one-horned rhinoceros in Nepal and 18 isolates from a dairy cattle herd and 2 isolates from captured rhesus monkeys in Bangladesh were included. Most of these animals had TB suspected lung lesions. Spoligotyping, mycobacterial interspersed repetitive units-variable number of tandem repeats (MIRU-VNTR), region of difference analysis and multi locus sequence typing (MLST) of *gyrB, mmpL6*, TbD1, *PPE55* and Rv2042c genes were performed to ascertain species and molecular epidemiology. **Results:** All the isolates had a typical *M. orygis* spoligotype, SIT587. RD analysis and MLST typing of confirmed the isolates to be *M. orygis*. The MIRU-VNTR phylogenetic analysis of these isolates grouped into five clusters. These finding suggests wide distribution and long historical existence of *M. orygis* in the region. Also, most of the other reported isolates of *M. orygis* are from South Asia. Thus, these findings and observation provide evidence for endemic distribution of *M. orygis* in South Asia. **Conclusions:** *M. orygis* isolated from different animals in Nepal and Bangladesh were molecularly characterized. Findings suggested its endemic distribution in South Asia and presents new picture of tuberculosis in South Asia that may be helpful to understand the evolutionary history of MTC.

Molecular Investigation of Circulating *Leptospira* spp. among Water Buffaloes in an Intensive Farming System in the Philippines

Author Block:

M. Villanueva[1], C. Mingala[2], C. Nakajima[1], N. Koizumi[3], Y. Suzuki[1]; [1]Res. Ctr. for Zoonosis Control, Hokkaido Univ., Sapporo, Japan, [2]Philippine Carabao Ctr. Natl. Headquarters and Gene Pool, Science City of Muñoz, Philippines, [3]Natl. Inst. of Infectious Diseases, Tokyo, Japan

Abstract Body:

Background: The water buffalo industry has earned more attention as an alternative source of milk and income for the rural farming communities in the Philippines. However, few serological studies showed the water buffalo as a potential reservoir host of *Leptospira* spp. causing leptospirosis which is also endemic in the country. Therefore, we investigated the circulating *Leptospira* spp. among water buffaloes in the Philippines using molecular techniques primarily in an intensive farm setting.**Methods:** We collected urine samples from field rats (*n*=21) and water buffaloes (*n*=170) from different groups and locations in one intensive-type water buffalo farm in the Philippines. Extracted DNA from urine was subjected to nested PCR amplifying *lipL32* and *flaB* genes as markers for pathogenic leptospires followed by amplification and analysis of *secY* gene for species identification.**Results:** Combined results of *lipL32* and *flaB* nested PCR found 29.4% (50/170) and 38% (8/21) pathogenic leptospires from buffaloes and rats, respectively. Sequence analysis of *secY* nested PCR-positive samples revealed its grouping into *L. borgpetersenii* and *L. kirschneri*. Moreover, clustering of sequences from both animals was found, which may indicate an on-going interspecies transmission. In addition, mixed *Leptospira* sequences were found from several positive animals, suggesting multiple infections. Finally, age and animal grouping was found to be associated with *Leptospira* infection.**Conclusions:** This study highlighted the role of water buffalo and the impact of management in the persistence of leptospirosis in an intensive farm setting in the Philippines. However, further investigation and appropriate control strategies are required to prevent leptospirosis from causing risks to public health and economic losses to the water buffalo farming industry.

Proteomic Analysis and Molecular Characterization of Acanthomoeba Spp. Isolates from Amoebic Keratitis and Meningo-Encephalitis from Northern India

Author Block:

G. Satpathy, H. S. Behera, T. Agarwal, R. Tandon; All India Inst. of Med. Sci., New Delhi, India

Abstract Body:

Background: Ocular infections caused by *Acanthomoeba spp*. are severe, sight threatening and are increasingly reported worldwide. This study aimed to determine genotypes of *Acanthomoeba spp*. isolates from corneal scrapings (n=20) and cerebrospinal fluid (CSF) (n=6) of meningo-encephalitis patients attending a tertiary care hospital and characterize trophozoite and cyst specific proteins from *Acanthomoeba spp.***Methods:** DF3 region (280bp) of 18S RNA gene was PCR amplified and amplicon sequences used for phylogenetic analysis using MEGA-6 programme for genotyping with DNA from axenic culture of 26 *Acanthomoeba spp.* isolates. The trophozoites and cyst proteins from an *Acanthomoeba spp*. eye isolate were purified from axenic culture and analyzed by 2D gel electrophoresis. Two unique, prominent protein spots each from trophozoites and cysts were characterized by MALDI TOF/TOF MS analysis and validated by reverse genomics using real time PCR.**Results:** Phylogenetically, 16 eye and 6 CSF isolates aligned with T4 genotypes of *Acanthomoeba spp*., 2 eye isolates aligned with T10 genotype and 2 were nontypable. Nontypable strains showed <90% sequence similarity with other isolates and reference genotypes from NCBI database. Both trophozoites and cysts showed proteins varying from 1kDa to >200 kDa. In mass spectroscopy, the trophozoite unique proteins were identified as; T1 (acidic) "hypothetical protein ACA1 of *A.castellani* (score: 331 threshold: 64) with mol. Mass: ~36kDa and pI: 4.78 and T2 (basic) "eukaryotic porin protein" (score: 93 threshold: 64), with mol. Mass: ~33 kDa and pI: 9.10 from NCBI *nr* database.The unique cyst proteins (acidic) were identified as chaperonin protein *DanK* (mol. Mass: ~69kDa, pI: 4.78) and chaperonin protein (score: 284, threshold: 49), mol. Mass: ~57kDa, pI: 5.08. In real time PCR, using primers derived from amino acid sequences of proteins, regions encoding trophozoite protein T1&T2 and cyst proteins C1&C2 showed 4-35&1388 fold and 15&12 fold increase in mRNA respectively.**Conclusions:** T4 genotype was dominant genotype in amoebic keratitis. The 2 trophozoite proteins may have a role in pathogenesis/growth, while the cyst protein chaperonins may have role in survival in adverse conditions.

Molecular Characterization of Rotavirus and Astrovirus in Children with Gastroenteritis

Author Block:

G. González-Ochoa[1], G. D. J. Quintero Ochoa[2], P. M. Calleja-García[1], J. A. Rosas-Rodríguez[1], P. Tamez-Guerra[2]; [1]Univ. de Sonora, Navojoa, Mexico, [2]Univ. Autónoma de Nuevo León, San Nicolas de los Garza, Mexico

Abstract Body:

Background: Rotavirus and Astrovirus are viruses associated to diarrhea in children up to five years old. Human Astroviruses are detected in 5-20% of the cases of acute and middle gastroenteritis in children. The common Astroviruses reported worldwide are the classic type (HAstV-1). On the other hand, Rotavirus causes severe gastroenteritis in children with 453,000 children deaths each year. Most of the cases of rotavirus infections are associated to genotypes G1P[8], G2P[8], G4P[8], G2P[4] and G9P[8]. Several studies have shown the Rotavirus genotypes variability between different seasons or geographic areas. In this study, we analyzed 100 fecal samples of children with gastroenteritis testing for human Rotavirus and Astrovirus. **Methods:** The viral RNA was purified from the samples by Trizol® method, followed by the synthesis of cDNA and the amplification of VP4 and VP7 gene of Rotavirus and ORF1b or ORF2 of Astrovirus with specific primers. The PCR products were cloned in the pGEM-T vector and sequenced. **Results:** The results showed that 5% (5/100) samples were positive to Astrovirus and 14% (14/100) to Rotavirus. Twenty percent (1/5) of the Astrovirus strains sequences presented a 98% homology with human astroviruses type 2 (HAstV-2) and 20% (1/5) with HAstV-6. The rotavirus genotypes detected were G12P[8] in 28.6% (4/14) of the analyzed samples and G no typed P[8] in 14.3%(2/14). The phylogenetic analysis of VP7 genotype G12 showed that the sequences reported in this study clustered with rotavirus strains G12 lineage III. **Conclusions:** To the best of our knowledge, this study provides the first report of rotavirus G12 in México. These results together with the detection of HAstV-6, which is an uncommon genotype reported worldwide, indicates that studies of Rotavirus and Astrovirus surveillance in children with gastroenteritis are important for the analysis of the genotype variability.

Molecular Epidemiology of Azole-Resistance in *Aspergillus fumigatus* Obtained from Patients with *Aspergillus* Diseases in Iran over the Last 5 Years

Author Block:

S. Hashemi[1], F. Mohammadi[1], J. Zoll[2], W. Melchers[2], H. van der Lee[3], P. Verweij[2], **S. Seyedmousavi**[4]; [1]Tehran Univ. of Med. Scinces, Tehran, Iran, Islamic Republic of, [2]Radboud Univ. Med. Ctr., Nijmegen, Netherlands, [3]Radboud Univ. Med. center, Nijmegen, Netherlands, [4]Erasmus Univ. Med. Ctr., Nijmegen, Netherlands

Abstract Body:

Background: Azole-resistance in *Aspergillus fumigatus* is a global and evolving public health threat, which translates into treatment failure. Surveillance studies indicate that azole-resistance is increasing, with the emergence of the "TR_{34}/L98H" and the "TR_{46}/Y121F/T289A" mutations in *A. fumigatus* in multiple European countries and in the Middle East, Asia, and Africa and more recently in United States. We investigated the prevalence rate of these mutations in clinical *Aspergillus fumigatus* isolates obtained from patients in Iran over the recent 5 years. **Methods:** One hundred seventy-two clinical *A. fumigatus* isolates were investigated for the antifungal activity of itraconazole, voriconazole and posaconazole using EUCAST broth microdilution method. For all isolates, the *Cyp*51A-gene and its promoter region was amplified and sequenced. **Results:** Of the 172 *A. fumigatus* isolates tested during 2010 to 2014, 6 (3.5%) had high MIC values of itraconazole (>16 mg/L) and voriconazole (≥4 mg/L). The DNA-sequencing of Cyp51A-gene showed the TR_{34}/L98H mutation in *Cyp*51A-gene of six isolates. No isolates harboring the TR_{46}/Y121F/T289A mutation were detected. All of the azole-resistant isolates were different in genotypes by microsatellite typing, from those previously isolates from Iran and from the European TR_{34}/L98H controls. **Conclusions:** In conclusion, there was not significant increase in the prevalence of azole-resistant *A. fumigatus* harboring the TR_{34}/L98H resistance mechanism over the recent 5 years in Iran.

Colony Lift Immunoassay (Cli) as a Successful Technique to Identify Mixed *Helicobacter pylori (H.pylori)* Gastric Infections

Author Block:

D. F. Rojas-Rengifo[1], L. F. Jimenez-Soto[2], B. Mendoza de Molano[3], R. Haas[2], M. P. Delgado[1], J. F. Vera[3], J. Alvarez[3], P. A. Rodriguez-Urrego[3], C. A. Jaramillo Henao[1]; [1]Univ. de los Andes, Bogotá, Colombia, [2]Max von Pettenkofer Inst., München, Germany, [3]Fundación Santa Fe de Bogotá, Bogotá, Colombia

Abstract Body:

Background: *H. pylori* is a gram negative bacteria which efficiently colonizes the human gastric mucosa.There are two types of strains classified by genotype. Type I contains the gene for CagA toxin and type II do not have it. Relative risk to present a gastric pathology increases by CagA positive strains. Colony Lift Immunoassay is a method to analyze and characterize isolated bacterial colonies. We have successfully adapted the assay for the detection of the CagA toxin production by *H. pylori* human isolates[1]. The aim of this study was to determine the prevalence of multiple infections with the *H.pylori* in Colombian patients.**Methods:** Patients older than 18 years presenting digestive symptoms were studied and an upper endoscopy was performed. Biopsies of the gastric antrum and corpus were taken. A culture of antrum and corpus's biopsies was performed and up to 50 colonies from antrum and corpus were isolated and analyzed for CagA expression through a CLI with specific CagA antibodies, as recently published[1]. A paired t-test was used considering a p value <0.05 as significant **Results:** From 97 patients, 24 samples showed a colonization rate with *H. pylori* (24.7%), 4 patients (4/24) presented only type I strains while 20 (20/24) showed mixed infections with *H. pylori* Type I and Type II strains. From these mixed infections, 6 (6/20) patients showed strain specificity tropism for antrum or corpus colonization. There was not statistical significance of tropism for Type I strains (P=0.6) **Conclusions:** We have developed a method for the analysis of several isolated strains from a patient in a fast and reliable way allowing us to evaluate the presence of CagA in up to 100 strains from each patient. The data obtained using the CagA as marker for the type of strains present in the patients show a high prevalence of mixed infections in the population analyzed. Our data opens the possibility of a higher relevance and other implications of mixed infections in gastric pathology and should be considered not only in the evolution of pathological changes in the stomach associated with this bacteria, but as well in their possible relevance in the eradication therapies

Cluster Analysis of *Mycobacterium tuberculosis* Using Whole Genome Sequencing (Wgs): The Irish Mycobacteria Reference Laboratory (Imrl) Experience

Author Block:

E. Roycroft[1], M. M. Fitzgibbon[2], A. Gibertoni Cruz[3], M. O'Meara[4], P. Downes[4], R. F. O'Toole[1], J. Keane[1], T. Walker[3], T. Peto[3], D. Crook[3], T. R. Rogers[1]; [1]Sch. of Med., Trinity Coll., Dublin, Ireland, [2]Irish Mycobacteria Reference Lab., Dublin, Ireland, [3]Modernising Med. Microbiol. Group, Nuffield Dept. of Med., Oxford, United Kingdom, [4]Dept. of Publ. Hlth., Dublin, Ireland

Abstract Body:

Tuberculosis (TB) incidence in Ireland, although low at 7/100,000, remains a challenge to Public Health. Genotyping aims to disrupt transmission chains by flagging potential outbreaks. The IMRL performs 24-locus Mycobacterial-Interspersed-Repetitive-Unit Variable-Number-Tandem-Repeat (MIRU-VNTR) genotyping. However, WGS could be the ultimate genotyping tool as it surveys the entire genome. In this study, Illumina Next-Generation-Sequencing was used to further investigate MIRU-VNTR clusters to discover whether WGS confirms or outrules them as outbreaks. Ten clusters were chosen from the IMRL national collection over the period 2006-14. The largest of these was Cluster 10 from an institutional outbreak (n=25) followed by Cluster 1 (n=23). Cluster 2 contained two sub-clusters (a, n=21 and b, n=20) that differed by a single locus variation (SLV). Seven smaller clusters were also included. Isolates were grown in liquid culture followed by WGS, using published protocols. Fastq files were analysed using a pipeline developed by the Modernising Medical Microbiology Group (Stampy, BWA, Samtools and PhyML form part of a custom pipeline). Phylogenetic trees were visualised using freely available software. The Public Health Department collected linked epidemiological data. Cluster 10 sequences differed by less than 4 single nucleotide variations (SNVs) confirming a single strain outbreak and raising the possibility of a ‘super-spreader’. Cluster 2 was identified as a single strain outbreak (n=41). Cluster 6 isolates differed by at least 60 SNVs, which rules out recent transmission. All six patients in this cluster shared the same country of origin indicating that their isolates are probably from a common ancestor. Our results show that WGS can both rule-in and rule-out outbreaks with greater discrimination than MIRU-VNTR genotyping and can confirm recent transmission events, making it a valuable tool in the fight against TB.

Molecular Evolution of Human Influenza A/H3n2 and A/H1n1 Viruses in MéXico from 2010 to 2015

Author Block:

P. Ramos Cervantes, V. Ibarra, J. Martínez, F. Ledesma-Barrientos, L. Garcia, L. Cervantes-Villar, L. Guerrero, A. Galindo-Fraga, G. Ruiz-Palacios; INCMNSZ, Mexico DF, Mexico

Abstract Body:

Background: The global surveillance of influenza has yielded a substantial amount of sequence and antigenic information covering the virus evolution. From 2010 to date, the Mexico Emerging Infectious Diseases Clinical Research Network (LaRed) implemented a hospital-based program to study the clinical and epidemiologic characteristics of influenza and other respiratory viruses. The aim of this study was to describe the molecular evolution of Influenza AH3 and AH1N1pdm09 from 2010 to 2015. **Methods:** Clinical samples were collected over 5 consecutive seasons, samples from patients with culture-confirmed infection were included, 55 with AH3N2 and 112 with AH1N1pdm09. Segment 4 (HA) gene was amplified and sequenced; phylogenetic analyses of the HA1 region were conducted and 3D protein modeling of cluster representative strains was performed. **Results:** Both types of Influenza circulated in alternate years; for AH3N2, the phylogenetic analyses showed two principal clusters, strains from 2009-2011 belonged to influenza genetic clades 1 and 5, with 9 aminoacid (aa) substitutions in 4 antigenic sites and 1 in a non-antigenic site with respect to APerth16 2009 vaccine strain, 7 of them conserved in all strains. 2012-2015 strains belonged to clade 3, divided in 4 subgroups, showing 10 aa substitutions in 4 antigenic sites and 6 in non-antigenic sites with respect to ATexas50 2012 vaccine strain. AH1N1pdm09 showed 5 clusters, related to influenza season; 2010-2011 cluster belonged to clade 1 and 2, 2012 to clade 5, 2013 to clade 7 and 2014-2015 to clade 6, with 2 subgroups. 2 aa substitution related with enhanced virulence have remained in all the seasons. Since 2013, all Mexican strains possesed K166Q substitution, related with an increment in the number of hospitalized patients. For both AH3N2 and AH1N1pdm09, 3D modeling showed that non-antigenic substitutions are near of receptor binding site. **Conclusions:** Genetically distinct lineages from AH3N2 and AH1N1pdm09 circulate simultaneously. AH3N2 presents a major genetic variation than AH1N1pdm09, with 3 antigenic drift in these 5 seasons. The role of non-antigenic substitution in the antigenic drift and immune response must be studied

Molecular and Clinical Characterization of Human Rhinovirus in Mexico from 2010 to 2014

Author Block:

F. Ledesma B, P. Ramos-Cervantes, J. Ruiz-Quiñones, A. Galindo-Fraga, J. Beigel, G. Ruiz-Palacios; Inst. Natl. de Ciencias Médicas y Nutrición, Mexico DF, Mexico

Abstract Body:

Keywords: Molecular epidemiology, severe respiratory disease, Rhinovirus**Background:** Rhinoviruses (RVs), which are frequently found in the nasopharynx of patients with respiratory disease were identified some years ago and, although they have been widely studied, many aspects of their role in causing respiratory infections remain unclear. Recent studies have related the presence of RV in respiratory disease requiring hospitalization, viral load and severity of disease has been described in few studies.**Objective:** To describe clinical and molecular features of RV infection in the mexican population and determine viral load correlation with severity of disease.**Methods:** Clinical samples from 222 patients with positive infection for hRV/hEV were collected over 5 consecutive seasons (April 2010-2014). VP4 gene was amplified and sequenced and phylogenetic analyses was performed. Viral load was tested by Real Time RT-PCR. We used Fisher's exact test to estimate association between viral load and severity of disease.**Results:** VP4 typing was successful in 78% of samples. hRVA (45.5%) was predominat in all seasons, following by hRVC (19.8%), hRVB (9.9%). hEVD68 (2.8%) was detected only in 2011-2012. hRVA and hRVB strains could be grouped in 4 clusters in the phylogenetic analyses, respectively. hRVC strains shows a great diversity and couldn´t be clustered. Viral load was determined in 119 of a total 222 samples and we found no association between severity of disease and viral load with a p value of 0.8, we also found no association between viral load and ICU patients.**Conclusions:** Viral load did not correlate with severity in hRV infection in the Mexican population. Prevalence of subtypes of hRV was different between consecutive seasons.F. Ledesma-Barrientos fledesmab@outlook.comP. Ramos-Cervantes p_ramos_cervantes@hotmail.comJ.A. Maximum Release of DNA from Difficult-to-Lyse Bacteria for Nucleic Acid Testing Using A Novel Chemical Lysis Reagent

Author Block:

O. M. de Bruin, J. Niles, B. Ray, C. Kelly-Cirino; DNA Genotek Inc., Ottawa, ON, Canada

Abstract Body:

Background: Identification of microorganisms by nucleic acid testing (NAT) is a critical tool for the rapid diagnosis of infectious diseases and identification of bio-threat agents. The sensitivity and clinical utility of any NAT strategy relies on the availability of nucleic acids in a sample. Hardy bacteria such as *Bacillus* spores and *Mycobacterium tuberculosis* (MTB) are notoriously difficult to break open, and as such, the total nucleic acid available for NAT may limit the effectiveness of the assays. The development of a new chemical lysis method called spore•LYSE now enables larger amounts of high quality nucleic acids to be released in a safe manner from difficult-to-lyse microbes. **Methods:** Extraction of DNA by spore•LYSE was compared to bead-beating in phosphate-buffered saline or SDS buffer for release of DNA from *in vitro*-grown microbes, and MTB spiked into sputum. spore•LYSE was evaluated by comparing the amount of DNA released from bacteria to the amount of DNA present inside the bacteria prior to lysis treatment. This was done using acid-hydrolysis/HPLC, and by quantification of extracted DNA using qPCR.**Results:** spore•LYSE was able to release approximately 85% of DNA from *Mycobacterium smegmatis* and greater than 90% of DNA from surrogates of Category A bioterrorism agents, including *Bacillus* spores. Overall, qPCR results support that spore•LYSE releases an equal or greater amount of DNA than bead-beating from both gram positive and negative bacteria. Lysis of *Bacillus thuringiensis* spores with spore•LYSE resulted in qPCR Ct values of 18.3 +/- 0.3 (n=3), whereas C_t values of bead-beating extracts were 19.3 +/- 0.3 (n=3). spore•LYSE was also compared to standard-of-care for DNA extraction from MTB in sputum. When 7 x 10^4 cells of MTB were spiked into sputum, the C_t value of samples extracted with spore•LYSE was 23.7 +/- 2.8 (n=15) compared to 25.3 +/- 2.4 for bead-beating (n=15).**Conclusions:** spore•LYSE employs an easy-to-use liquid reagent that only requires incubation for 5-20 min at 70°C for release of large amounts of DNA from a variety of bacteria, including MTB and *Bacillus* spores. spore•LYSE eliminates the need for bead-beating and simplifies DNA extraction protocols, and can decrease the time and cost associated with diagnosis and identification of low-abundance or difficult-to-lyse bacteria.

Evaluation of the Siemens Tissue Preparation System for Extraction of Microbial Dna from Formalin-Fixed Paraffin-Embedded Tissue

Author Block:

S. P. Buckwalter, L. S. Sloan, B. J. Connelly, J. C. Berry, J. W. Sullivan, II, B. S. Pritt, N. L. Wengenack; Mayo Clinic, Rochester, MN

Abstract Body:

Background: The detection of pathogens by PCR in formalin-fixed paraffin embedded tissue is challenging due to the labor intensive methods required to prepare the tissue for extraction. In this study, we evaluated the performance of the MagNA Pure (Roche) with the Siemen's Tissue Preparation System (TPS). The Siemens platform extracts and purifies nucleic acid using magnetic particle-based isolation, is automated, and requires the use of smaller quantities of tissue than the MagNA Pure system**Methods:** 86 formalin-fixed, paraffin-embedded tissue blocks were sectioned, extracted and tested in parallel on the MagNA Pure and TPS systems; a variety of bacterial and fungal pathogens were tested using previously described real-time PCR assays.**Results:** Of the 86 paraffin blocks tested, 32 (37%) tissues were positive by both extraction systems while 42 (49%) tissues were negative by both methods. 12 (14%) tissues were positive when processed with the TPS, but negative when processed using the MagNA Pure.**Conclusions:** The TPS instrument performed better than the MagNA Pure method for extraction from formalin-fixed, paraffin-embedded tissue. In addition, the TPS is fully automated, faster, limits exposure to hazardous chemicals, and uses 80% (10µm vs 50µm) less tissue than the MagNA Pure system. However, the TPS system did have a higher rate of mechanical issues that led to invalid runs as compared with the MagNA Pure system.

Provincial Implementation of a New Hiv Diagnostic Algorithm

Author Block:

J. Fenton[1], J. Poelzer[1], **C. L. Charlton**[2]; [1]Provincial Lab. for Publ. Hlth., Edmonton, AB, Canada, [2]Univ. of Alberta, Edmonton, AB, Canada

Abstract Body:

Background: Guidelines for HIV diagnosis recommend replacement of Western blot (WB) as final HIV confirmation with Antibody Differentiation (AD) followed by NAT testing. AD was recently Health Canada approved, however an approved HIV NAT test for diagnosis of infection is currently not available in Canada. Here we report the validation of both AD and NAT testing, and outline the provincial roll out program for the new diagnostic algorithm. **Methods:** Only samples repeatedly reactive on the Architect 4th generation HIV Ag/Ab combo assay were used in this evaluation. 102 plasma and 102 matched serum samples were tested by the Abbott *m*2000 RealTime HIV-1 PCR assay, and 105 serum samples were tested by the Bio-Rad Geenius HIV-1/2 Confirmatory Assay (AD) in parallel with WB, according to manufacturer's protocol.**Results:** 70 known HIV-1 positive and 32 negative samples were tested by NAT. Specificity, sensitivity, positive and negative predictive values were calculated compared to true clinical diagnosis (TCD; determined by clinical symptoms, serology and NAT) for plasma (99, 100, 100, 97%) and serum samples (97, 100, 100, 94%) respectively. 42 known HIV-1, 10 known HIV-2 and 53 NEG specimens were tested by AD (92, 100, 100, 93%) and WB (90, 92, 92, 91%) and compared to TCD. AD resolved 94% of all indeterminate (IND) WB samples, and identified HIV earlier in infection than WB. The performance of AD and plasma samples for NAT testing was deemed acceptable for use as a diagnostic tool in our patient population, and a new HIV diagnostic algorithm was developed. A provincial task force recommended a dedicated sample be sent for NAT testing following IND or NEG AD results; active patient follow-up by Public Health teams was therefore required to ensure appropriate specimen collection. An automated system was created to alert physicians and Public Health teams to samples pending for NAT $\geq$10 days. Direct patient contact by Public Health teams ensured required samples were obtained for testing.**Conclusion:** The Bio-Rad Geenius HIV 1/2 assay out performed WB for diagnosis of HIV infection. Implementation of the new HIV algorithm is predicted to decrease the number of IND cases requiring follow-up, and to diagnose HIV earlier in infection. Ultimately, both laboratory and public health collaboration were needed to ensure appropriate specimen collection for acutely infected patients.

A Real-time Quantitative Pcr for Specific Detection of *A. baumannii* in Water and Blood

Author Block:

D. P. Karumathil, **M. Surendran Nair**, K. Venkitanarayanan; Univ. of Connecticut, Storrs, CT

Abstract Body:

Background: Multi-drug resistant (MDR) *Acinetobacter baumannii* is a major nosocomial pathogen causing a wide array of clinical conditions with significant mortality rates. Identification of *A. baumannii* by traditional cultural methods requires at least 48 to 72 h for obtaining results. In addition, biochemical methods for the confirmation of *A. baumannii* from other *Acinetobacter* species are not completely accurate. Thus, there is a need for rapid methods for specific identification of *A. baumannii*.**Methods:** The objective of this study was to develop a real-time polymerase chain reaction (RT-PCR) for specifically detecting *A. baumannii* in water and blood using TaqMan primer/probe set targeting a highly conserved 102-bp DNA sequence in *adeT*, an efflux pump found in *A. baumannii*. For testing the limit of detection, RT-PCR was done directly with 10-fold dilutions of *A. baumannii* suspension in blood or water (10^6 to 10^1 CFU) and various concentrations of genomic DNA. Further, the sensitivity of the RT-PCR was tested after enrichment of *A. baumannii* in tryptic soy broth.**Results and Conclusion:** The results revealed that all *A. baumannii* isolates yielded a 102-bp PCR product, however, none of the tested negative control isolates, including other *Acinetobacter* species produced any amplification. The sensitivity of PCR for detecting *A. baumannii* in blood and water was 3 $\log_{10}$ CFU or 0.1 ng of DNA. However, upon enrichment, the PCR was able to detect 2 $\log_{10}$ and 1 $\log_{10}$ CFU/ml of *A. baumanni* in water after 6 h and 14 h of incubation at 37^{o}C, respectively. The RT-PCR developed in this study could be used for the rapid detection of *A. baumanni* in environmental and clinical samples.

Publishing Title:

The Utility of Rrna Gene Sequencing in Patient Specimens with No Growth in Traditional Culture

Author Block:

K. Lindsey, S. Edappallath, F. Moore; Baystate Hlth., holyoke, MA

Abstract Body:

Background: Broad primer PCR followed by sequencing of rRNA genes can be very valuable in the detection of organisms in patients that have received antimicrobial therapy and may have no growth in traditional culture. Thus there may be no other means of identifying the pathogen. Guidelines for this diagnostic modality are still in the process of being adopted and the impact of this test in clinical decision making is unclear. In this study we summarize data from 52 samples sent to a reference laboratory for 16s gene sequencing. We report on our overall recovery rate and the effects of the results on antibiotic utilization.**Methods: We tested only if the following criteria were met: 1) The test was ordered by an infectious disease specialist 2) the patient received recent antimicrobial therapy 3) there was a minimum of 48 hours of no growth on the traditional aerobic culture and 4) the specimen type was obtained using sterile technique. Specimens were sent to a reference laboratory where DNA was isolated and amplified by conventional PCR using universal primers. Amplified products are sequenced and the organism(s) identified on the basis of sequence data. Results:** Patient ages ranged from 4 months old to 78 years old with the average age of 44. Overall 22 of 52 specimens (43%) were positive for an organism. We recovered 26 different organisms with *Streptococcus* species being the most common (34%), and *Fusobacterium nucleatum* being the second most common (15%), with various other organisms comprising the remainder. Aspirates (n=7) yielded the highest recovery rate at 57%. Fluids (n=23) yielded a 52% recovery and tissues (n=22) 36% recovery. 77% of patients with positive results had their antibiotics changed to a more targeted therapy, while the remaining 23% had no change in therapy. In those with negative results, antibiotic therapy was changed in 37% of patients.**Conclusions:** The relatively high rate of organism recovery in this study is likely due to the restricted ordering criteria. Our results show that 16s RNA gene testing can improve antibiotic stewardship since patients with positive results were more likely to be deescalated from broad spectrum antibiotics to a more targeted therapy. The clinical impact (eg. length of stay, cost of care, mortality)of these results on patient outcome is currently being investigated.

Publishing Title:

Comparison of Ddpcr and Qpcr Assays for Quantifying Nucleic Acid Targets from Arthropod and Ffpe Samples

Author Block:

G. A. Dasch, J. R. Hensley, A. M. Denison, V. N. Loparev; CDC, Atlanta, GA

Abstract Body:

The accurate molecular detection of any infectious disease agent in a sample depends upon the quality and quantity of the target molecules derived from the clinical and environmental source. Formalin-fixed paraffin-embedded (FFPE) samples for pathology are challenging as formalin and embedding lead to degradation and chemical modification of RNA and DNA. Archived ethanol-preserved environmental samples like museum arthropod specimens can also be difficult, especially with hematophagous ectoparasites containing blood. Droplet digital PCR (ddPCR) technologies from BioRad Laboratories QX100 (BR) and RainDance Technologies Rain Droplet (RDT) offer potential for improved agent detection and assessment of sample quality and quantity as the target is partitioned into thousands (BR) or millions (RDT) of individual assays, thus diluting inhibitors and allowing quantitation without a reference standard. We compared TaqMan qPCR assays and derived ddPCR assays with both FFPE and tick samples to assess the enhanced value of ddPCR.Initially, 18 commercial kits (8 RNA, 6 DNA, 4 both) and a conventional phenol-chloroform method were evaluated on 2 non-infected FFPE blocks from human lung, and subsequent extractions were done on 7 additional human lung blocks with the best kits. Sections infected with parvovirus B19, hantavirus, *Mycobacterium tuberculosis*, and influenza A/H3 were analyzed by qPCR and ddPCR. The recovery and quality of DNA and RNA were measured by Qubit fluorometer and Agilent BioAnalyzer, respectively, and compared with housekeeping qPCR and ddPCR assays (RNase P for DNA and beta-2-microglobulin for RNA). Qiagen and Promega kits were used to extract DNA from ticks, and it was assayed for the amount of *Rickettsia*, *Coxiella* and tick DNA by qPCR and derived ddPCR.Nucleic acid yields with different extraction methods varied widely. Quality samples based on BioAnalyzer analysis generally worked well by both qPCR and ddPCR. Although the BR and RDT instruments both performed satisfactorily with some ddPCR assays, direct adaptation of TaqMan assays from qPCR to ddPCR required optimization. The higher throughput of the BR with automated droplet maker made it easier to compare samples but the graphics of the RDT and number of smaller droplets it creates offered some advantages in quantitative analysis, even if it is more expensive per sample.

Comparison of a Molecular Multiplex Panel to Api® Rapid Strips for Bacterial Identification

Author Block:

M. Stonebraker, P. Dawson, D. Hockman, D. Stalons, L. Malone, E. Grigorenko; Diatherix Lab., LLC, Huntsville, AL

Abstract Body:

Background: Conventional microbiological methods are the gold standard for bacterial identification (ID) in clinical laboratories. While accurate, these phenotypic and biochemical tests are laborious and time-consuming. Molecular methods of ID are as sensitive and specific as conventional methods and take hours instead of days for result reporting. Rapid diagnosis is increasingly important for patient therapy where laboratory results can alter treatment. In this study, we compare the performance of Target Enriched Multiplex PCR (*TEM-PCR*™) to gold-standard API® RapID 20E strips (BioMérieux, Marcy-l'Étoile, France) for bacterial ID. **Methods:** Twenty-six well-characterized, blinded isolates were obtained from IHMA, Inc. Isolates were cultured on non-selective media, and 0.5 McFarland standards were prepared. API® RapID 20E strips were inoculated for ID of Enterobacteriaceae. Simultaneously, nucleic acids were extracted using a KingFisher™ Flex instrument (Thermo Fisher Scientific, Waltham, MA) and amplified with TEM-PCR™, utilizing a panel of fourteen gram-negative and gram-positive pathogen targets. Amplified products were hybridized to target probes on microarray plates and detected using a fluorescence imaging reader. Results were reported as "Detected" or "Not Detected".**Results:** Bacterial ID of each isolate was confirmed with IHMA upon completion of TEM-PCR™ and API testing. Results obtained with TEM-PCR™ had 100% correlation with API testing for targets present in the TEM-PCR™ panel. A gene target for *Providencia rettgeri* was not included in the TEM-PCR™ panel, therefore was not detected, yielding an overall correlation of 96% between the two methods.**Conclusions**: Molecular and microbiological techniques are both accurate means for determining bacterial ID, but molecular multiplex methods have added benefits over traditional gold standard testing. TEM-PCR™ is performed directly from the patient specimen and can detect multiple pathogens in a single reaction. Bacterial ID from API® strips takes at least two days, while molecular tests can provide results in less than eight hours, eliminating empirical antibiotic therapy and resulting in faster, more accurate patient treatment.

Highly Sensitive Dual Amplicon-Based Ngs Approach for Bacterial Identification in Primary Clinical Specimens

Author Block:

P. Khil, J-H. Youn, J. Ho, J. P. Dekker, K. M. Frank; NIH Clinical Ctr., Bethesda, MD

Abstract Body:

Next-generation sequencing (NGS) coupled with traditional amplicon-based methods holds promise for diagnostic characterization of pathogens in primary, uncultured, clinical specimens. Here we report the development of a highly sensitive, pan-bacterial diagnostic assay based on nested PCR amplification of the V1-V2 and V3-V4 regions of the 16S rRNA gene followed by sequencing using an Illumina MiSeq. Reads are analyzed with a newly designed modular pipeline that performs data pre-processing, OTU clustering and taxonomic assignment, species abundance estimation, and diagnostic report generation. Three improvements distinguish our assay from previously reported 16S-based approaches for use in clinical diagnostics: (1) nested PCR amplification combined with NGS, (2) semi-quantitative target concentration estimation using barcoded internal controls, and (3) analysis of four 16S hypervariable regions. For OTU load estimation, heptanucleotide barcodes were inserted into cloned *Actinomadura nitritigenes* 16S rDNA and these engineered targets were spiked at different concentrations. Unlike previous single-amplicon methods, our strategy integrates data from two targets allowing improved species-level resolution of certain important human pathogens. Initial analysis of the method including LoD studies using defined DNA mixes and isolate dilutions demonstrated reliable detection of < 100 copies of pathogen in the presence of 1000-fold excess of human cells. Initial clinical evaluation was performed with 24 primary uncultured urine samples representing a mixture of no growth, cultured urinary pathogens, and background commensal flora as reported using routine clinical culture. The method identified 110 organisms corresponding to commensal flora and all 12/12 urinary pathogens reported from culture in this set (100% sensitivity). In addition, we detected *E. faecalis* and *Ureaplasma parvum* that were not reported in culture. Discrepancy analysis was performed using unbiased shotgun sequencing, which detected genomes of both organisms, and repeat culture of specimen identified *E. faecalis*, confirming these results. Blinded validation of the method using 250 specimens is currently in progress under an NIH Clinical Center IRB protocol.

Diagnosis of Culture-Negative Infections Using a Novel Plasma-Based Next-Generation Sequencing Assay

Author Block:

J. Kim[1], L. Shieh[2], **D. K. Hong**[3]; [1]Stanford Univ. Sch. of Med., Palo Alto, CA, [2]Stanford Univ. Sch. of Med., Stanford, CA, [3]Karius, Inc, Menlo Park, CA

Abstract Body:

Background: Many infectious diseases can be difficult to diagnose with conventional culturing methods either due to the need for invasive biopsies for deep infections or the inability of standard cultures to readily isolate viruses, fungi, or fastidious bacteria. Furthermore, single or multiplex PCR assays, while more sensitive, require the physician to target specific organisms. Next-generation sequencing (NGS)-based assays have high sensitivity and have the additional advantage of being completely open-ended, thus allowing for hypothesis-free diagnosis. **Methods:** We developed a minimally invasive NGS-based infectious disease assay that takes advantage of circulating cell-free plasma DNA originating from invasive pathogens. After filtering human sequences, remaining sequences are aligned to a pathogen reference sequence database and relative abundance is assigned. Patients who had negative blood cultures and who had diagnostic biopsies for infectious disease testing had a single blood sample drawn prior to biopsy for NGS analysis. **Results:** We report two patients in whom the etiologic diagnosis for their febrile illness was confirmed with this assay. The first patient had a *Staphylococcus aureus* implantable cardiac defibrillator infection. Initial blood cultures were negative but culture of the explanted device yielded *S. aureus. S. aureus* was identified by NGS from a plasma sample obtained prior to the device being removed. The second patient had extensive cutaneous disease, which on biopsy was thought to be consistent with leprosy. NGS of plasma, however, revealed high levels of Epstein-Barr virus (EBV) which was confirmed by quantitative EBV PCR. The patient was eventually diagnosed with EBV-positive diffuse large B-cell lymphoma (DLBCL) of the elderly. **Conclusions:** We demonstrate the potential utility of a novel plasma-based NGS infectious disease assay. This assay has high sensitivity and can aid in the open-ended diagnosis of culture-negative infections.

Validation Panel for the Implementation of Clia-Compliant Whole Genome Sequencing (WGS) in Public Health Laboratory

Author Block:

V. Kozyreva, C-L. Truong, A. Greninger, V. Chaturvedi; California Dept. of Publ. Hlth., Richmond, CA

Abstract Body:

Background: Public health microbiology (PHL) laboratories use WGS for outbreak investigation, pathogen identification (ID), and antibiotic resistance (ABR) detection. Different platforms, chemistries and analytical tools complicate standardization across the field. We aimed to develop a validation panel of bacterial isolates for multi-laboratory comparisons.**Methods:** WGS validation panel comprised of 34 bacterial samples: 10 *Enterobacteriaceae* samples, 5 gram-positive cocci, 5 gram-negative non-fermenting species, 9 *Mycobacterium tuberculosis*, and 5 miscellaneous bacteria representative of typical workflow in PHL. WGS was done using Nextera XT library prep with 2x300 bp sequencing chemistry on Illumina MiSeq Sequencer with min coverage 30x, min base quality 200. Different operators sequenced bacteria in triplicate within single run, and on three different days. *De novo* assembly was done on CLCbio GW 8.0.2. Genomes were annotated with Prokka v1.1. Accuracy, reproducibility, sensitivity, and specificity was deduced from genotyping based on genome-wide SNP calling, *in silico* multi-locus sequence typing (MLST), 16S rRNA species ID, and ABR genes detection. Accuracy of bioinformatics pipeline was assessed by phylogenetic analysis of raw sequencing reads from previously published outbreaks.**Results:** Genome sizes of validation organisms varied from 1.8 to 4.7kb, with wide range of GC content 32.1-66.1%. Average depth of genome coverage of 78.4x (30.3-216.4x) was achieved. Accuracy of MiSeq platform for individual base calling in bacterial genomes was >99.9%. Accuracy of phylogenetic analysis performed on bioinformatics pipeline was 100%. Both reproducibility and repeatability of genome-wide base calling were >99.9%, while this metrics for selected tests were 100%. Specificity and sensitivity inferred from MLST and genotyping tests were 100%. A customized test report was developed for end users with and without specialized knowledge of WGS.**Conclusions:** We have validated a test panel of bacterial isolates for WGS on MiSeq according to CLIA requirements for laboratory developed test (LDT). The test panel, sequencing analytics and raw sequences are available as valuable tools for future multi-laboratory comparisons of WGS in PHL.

Classification of *Staphylococcus schleiferi* Subspecies Using Whole Genome Comparisons

Author Block:

B. Duim, A. L. Zomer, J. de Laat, J. A. Wagenaar, E. M. Broens; Utrecht Univ., Faculty of veterinary medicine, Utrecht, Netherlands

Abstract Body:

Background: The species *Staphylococcus schleiferi*, includes both a coagulase-negative subspecies (*S. schleiferi* subsp. *schleiferi*) and a coagulase-positive subsp. (*S. schleiferi* subsp. coagulans). Coagulase negative staphylococci are considered less clinical relevant and the species is often not identified in routine diagnostics. Traditional diagnostics using clotting of plasma by extracellular free staphylococcus coagulase has been shown to be variable in *S. schleiferi*. In this study we questioned the phenotypic differentiation of *S. schleiferi* subspecies by identifying the staphylococcal coagulases and subspecies specific characteristics, using whole genome sequencing. **Methods:** The genomes of 12 *S. schleiferi* strains (including 3 Type strains) were obtained from Illumina MiSeq reads. The genomes were annotated using Prokka and the protein orthology was determined using Roary. Phenotypes were determined using slide and tube coagulase tests, Maldi-TOF analysis, and API ID 32 STAPH (bioMérieux, France).**Results:** Maldi-TOF and API tests failed to distinguish coagulase positive strains from coagulase negative strains. Furthermore, coagulase production was not consistently associated with subspecies designation. In the genomes, 9 genes were identified whose presence was putatively associated with coagulase production. These consisted of genes encoding specific variants of Coa coagulase, Von Willebrand factor-binding proteins and variants of the fibrinogen-binding protein Efb. Although in all cases the genomes encoded a coagulase, different variants were present, which may explain the observed phenotypic variable coagulase activity.**Conclusion:** Phenotypic characteristics and the presence of different genes encoding staphylococcal coagulases, questions the reliability of coagulase detection for distinction of *S. schleiferi* subspecies.

Validation of the Modified Abbott Real*time* Assays for Residual Viremia Detection

Author Block:

J. E. McKinnon[1], J. I. Bernardino[2], J. Y. Zhou[1], F. Pulido[3], R. Delgado Vasquez[3], D. Lucic[4], J. R. Arribas[2]; [1]Henry Ford Hosp., Detroit, MI, [2]Hosp. La Paz. IdiPAZ, Madrid, Spain, [3]Hosp. Univ.rio 12 de Octubre, i+12, Madrid, Spain, [4]Abbott Molecular, Des Plaines, IL

Abstract Body:

Background: The study of residual HIV-1 viremia (RV) for clinical trials and cure strategies requires reproducible and practical assays. We modified the Abbott Real*Tim*e HIV-1 (MA) assay to examine RV using low plasma volumes using either an ultracentrifugation (UMA) or tabletop centrifugation (TMA), and tested the feasibility on samples from the KRETA trial, a study of HIV patients with lipodystrophy. **Methods:** HIV stock virus was obtained from the Rush University VQA laboratory. HIV spiked viral controls from 5000 to 0 c/mL were prepared. The UMA assay uses 3 mL of HIV positive plasma added to a 10 mL centrifuge tube with 7mL of tris-buffered saline, then spun at 170,000xg for 30 minutes. Viral pellets were re-suspended in PBS and transferred to the *m*2000sp for testing. The TMA assay uses a new extraction protocol for the *m*2000sp for processing 3mL of plasma and a 2hr- 21,000xg centrifugation step. Plasma samples from the KRETA study were obtained for viremia (VL) testing.**Results:** 129 HIV spiked control samples were used to validate both assays. The MA assays had 100% detection of samples with expected VL >12.5 c/mL. RV detection by UMA and TMA was at 12.5 c/mL (100%/83.3%), 6.25 c/mL (100%/100%), 3.125 c/mL (75%/50%) and 1.56 c/mL (50%/33.3%). A 5 c/mL control was used for testing and validation with >90% detection. UMA and TMA assays viremias correlated well to the expected VL levels, $p<0.000$ & $p=0.026$. At VL 5 c/mL & above, HIV RNA control levels were significantly different from each other, in both assays ($p<= 0.026$). Controls with VL <=5c/mL were not statistically different. For clinical validation, 71 patients from the KRETA study were tested. Viremia was detected in at least one sample in 51 patients (mean 35 c/mL), 20 patients had undetectable samples by MA assays but only 2 had any detectable viremia during the study.**Conclusions:** Ultracentrifuge MA assay is able to detect HIV-1 RNA of ~3 c/mL in 3mL of plasma, allowing for the study of residual viremia. A second simpler TMA assay with new extraction protocol allows for comparable quantification at 6 c/mL as the UMA protocol. These assays provide reproducible methods for HIV RV quantification using clinically attainable plasma volumes.

Evaluation of the Abbott Realtime Cmv Investigational Use Only (IUO) Assay for the Quantification of Cytomegalovirus (CMV) DNA in Plasma

Author Block:

F. Nolte, A. M. Kegl; Med. Univ. of South Carolina, Charleston, SC

Abstract Body:

Background: Quantification of CMV DNA in the blood has become standard of care for surveillance and diagnosis of active CMV infection and for monitoring response to therapy in bone marrow and organ transplant recipients. The Abbott RealTime CMV assay is available in the US as an investigational use only (IUO) assay. **Methods:** We compared the performance characteristics of the above IUO assay with that of a laboratory-developed assay (LDA) using analyte-specific reagents manufactured by Qiagen. Both the IUO and the LDA were run on the Abbott m2000 sp/rt platform. The IOU assay targeted the UL80.5 and UL34 genes and included calibrators which were processed through extraction as patient samples. Calibrators were also standardized to the 1st WHO International Standard. The LDA targeted a region of the MIE gene and calibrators were prepared from quantified CMV AD 169 DNA (Advanced Biotechnologies). Clinical plasma samples, linearity panels and positive controls from Exact Diagnostics, AcroMetrix, and ZeptoMetrix were included in the study. Agreement, accuracy, measurement range and reproducibility of the IOU and LDA were compared.**Results:** Valid results were obtained in both assays for 70 plasma specimens from 54 patients. CMV DNA was detected by both assays in 37, by the IOU alone in 14, by the LDA alone in none of the specimens. CMV was not detected by both assays in 19 specimens ($p=0.0005$). Those detected by the IUO alone had low viral loads ranging from <1.3 to 2.5 log copies (c)/ml. The quantitative results were highly correlated ($p<0.0001$), with $R^2=0.911$. However, the mean difference between the IOU and LDA values was 1.3 log c/ml (95% limits of agreement 0.6 to 2 log). The IUO measured values were on average 0.12 log c/ml lower and 0.12 log c/ml higher than the labelled values for CMV linearity panels obtained from Exact Diagnostics and AcroMetrix, respectively. The IUO inter-run coefficients of variation were 2.8% and 0.7% with low and high external controls, respectively. We confirmed that the IUO reliably quantitated low levels of CMV DNA (≤1.6 log c/ml).**Conclusions:** The results of the IUO and LDA were highly correlated, but the IUO detected and quantified significantly more CMV-positive samples and the results were consistently more than one log greater than the LDA. The IUO appeared to provide a better estimate of the actual CMV viral load than the LDA.

Salvage Microbiology - Detection of Pathogens by Pcr & Electrospray Ionization Mass Spectrometry of Dna Extracts from Archived Formalin-fixed, Paraffin-embedded Tissue Sections in Patients with Suspected Infection

Author Block:

J. J. Farrell[1], R. Sampath[2], R. A. Bonomo[3]; [1]Univ. of Illinois Coll. of Med., Peoria, IL, [2]Ibis BioSci.s, Carlsbad, CA, [3]Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract Body:

Background: Formalin-fixed, paraffin-embedded (FFPE) tissue blocks are typically archived indefinitely. These archived tissue specimens represent a potential resource for recognition of pathogens in patients with suspected infectious diseases but negative cultures. PCR detection of infectious organisms from FFPE tissue is a well described diagnostic technique occasionally employed when microscopic histopathology findings from tissue biopsies suggest a specific underlying infectious pathogen. But when tissue inflammation is only suspicious for infection, without suggesting a specific pathogen, and cultures are negative (or where not requested), conventional PCR is not an option. **Methods:** IRB approval was obtained for examination of archived FFPE tissue sections for potential infectious pathogens by polymerase chain reaction combined with electrospray ionization mass spectrometry (PCR/ESI-MS). A No. 11 blade disposable surgical scalpel (AD Surgical, Sunnyvale, CA) was used to remove tissue samples from FFPE tissue blocks from two patients with suspected infection, but negative cultures. We employed a commercial DNA extraction kit (QIAprep miniprep kit [Qiagen, Inc.]) for DNA extraction of the sample of FFPE tissue. Both DNA extracts were submitted for PCR/ESI-MS (Ibis Biosciences Inc, Carlsbad, CA).**Results:** *Streptococcus intermedius* was detected by PCR/ESI-MS from a FFPE mediastinal lymph node tissue block from a 29 year old man with pulmonary infitrates and metastatic central nervous system lesions. PCR/ESI-MS detected *Ajellomyces capsulatus* (anamorphic name *Histoplasma capsulatum*) from a FFPE block of tissue from an oral ulcer taken from a 34 year old with congenital Hemophilia A, and well controlled HIV-1/AIDS.**Conclusions:** This IRB approved pilot study suggests that PCR/ESI-MS may have utility for identification of infectious pathogen(s) directly from DNA extracts of FFPE tissue blocks when histopathology is suspicious for a non-specific infectious etiology. A prospective study and validation with FFPE tissue from patients with culture confirmed infection is planned.

Clinical Correlates of Adenovirus Detection Using the Focus Diagnostics qPCR Assay

Author Block:

C. Jacquot, A. Plourde, Z. Nagymanyoki, S. Miller; Univ. of California, San Francisco, San Francisco, CA

Abstract Body:

Background: Adenovirus infection is increasingly recognized as a cause of morbidity and mortality in immunosuppressed and transplant patients. It may involve any organ system and can be fatal. Viral detection in blood has been associated with a higher incidence of symptomatic disease. Viral titers may be predictive of disease outcome and could be used to monitor response to antiviral therapy. **Methods:** The Focus Diagnostics Adenovirus Assay is a real-time polymerase chain reaction assay that quantitatively detects adenovirus DNA. Following extraction from plasma, DNA is amplified and detected by fluorescent probe-primers targeting the adenovirus hexon gene. Results from the Focus assay were compared to those from a reference lab (Viracor). Patient chart review was performed to determine laboratory and clinical markers associated with adenovirus blood titers.**Results:** The reportable linear range of the assay was 1x10^3 to 1x10^10 copies/mL (cp/mL); the limit of detection was 812 cp/mL. Serotypes 1, 2, 5, 7a, and 40 were detected at a dilution level of 1x10^3 cp/mL; serotype 3 was detected at a dilution level of 1x10^4 cp/mL. The assay showed no cross-reactivity with other viral and bacterial organisms, and was 100% specific for adenovirus.Assay sensitivity was 94% (50 of 53 samples tested adenovirus positive) and specificity was 98% (62 of 63 samples tested adenovirus negative) as compared to reference lab. Copy numbers for the Focus assay tended to be higher, with an average difference of 1.05 log cp/mL.Chart review of 25 UCSF patients positive for adenovirus infection showed that a number of factors (e.g. immunosuppression, co-infection, age) affected clinical management following virus detection. Changes in viral load over time appeared to correlate with symptoms; however, no consistent correlation was found with other laboratory markers of infection (WBC count) or organ damage (transaminases, serum creatinine).**Conclusions:** The Focus adenovirus qPCR assay showed good analytical sensitivity and specificity. Tested patients had multiple co-morbidities, which may have obscured a correlation between adenovirus viral loads and other laboratory markers of infection or organ damage. Further studies are needed to establish clinical correlation for adenovirus titers and optimal patient management strategies.

Altona Diagnostics Realstar™ Varicella-Zoster Virus Real-Time Quantitative and In-House Qualitative Polymerase Chain Reaction Assays Comparative Analysis

Author Block:

S. Grandjean Lapierre, K. Boissinot, C. Renaud; Ctr. Hosp.ier Univ.ire Sainte-Justine, Montreal, QC, Canada

Abstract Body:

Background: *Varicella Zoster Virus* (VZV) can be responsible for cerebral, cutaneous and congenital infections. Since effective antiviral treatment and prophylaxis are available, rapid and accurate laboratory diagnosis is mandatory. However, no commercial assay has yet been approved by the FDA. The objective of this study was to compare Altona Diagnostics RealStar™ VZV Kit 1.0 commercial real time quantitative polymerase chain reaction (PCR) assay with in house qualitative PCR assay. **Methods:** This study was performed on 145 clinical specimens submitted for routine VZV PCR testing including cerebrospinal fluid (CSF) (43%), cutaneous (43%) and other specimen types (14%) such as serum, ocular and respiratory secretions. Specimens were selected on the basis of their result on the in house assay. To account for this potential selection bias, a variety of positive and negative specimens for each specimen types were included. DNA extraction was performed using Promega extraction kit on a Maxwell instrument. RealStar™ PCR assay was performed according to manufacturer's instructions on the ABI 7500. In house PCR targeting the UL21 gene and producing a 647-bp amplicon for detection by agarose electrophoresis was performed on the ABI 9700.**Results:** Total, positive and negative concordance percentages between both assays were respectively 98.6% (95% CI 94.8-99.9), 98.4% (95% CI 90.7-99.9) and 98.8% (95% CI 92.8-99.9). Kappa statistic value was 0.97 (95% CI 0.93-1.00) indicating excellent agreement beyond chance. One CSF specimen was only positive on RealStar™ PCR with 392 copies/mL at a Ct of 30. One corneal scrapping specimen was only positive on in house PCR. Positive specimens on RealStar™ PCR were so at an average Ct of 23.98 (SD 6.18) and quantitative viral loads varied from $1.85x10^2$ and $6.67x10^7$ copies/mL. Average quantitative viral loads in CSF and cutaneous specimens were respectively $4.4x10^5$ and $1.1x10^7$ copies/mL, a difference found to be statistically significant (p=0,004).**Conclusions:** RealStar™ VZV Kit 1.0 real time quantitative and in house conventional qualitative VZV PCR assays have excellent concordance in CSF, cutaneous and other specimen types. As expected, RealStar™ PCR found quantitative viral loads to be significantly higher in cutaneous than in CSF specimens.

Ultra-Sensitive Detection of *Borrelia S*pecies Using Droplet Digital PCR

Author Block:

A. Bemis; Digital Biology Ctr., Bio-Rad Lab., Pleasanton, CA

Abstract Body:

Lyme disease (LD), or Lyme borreliosis (LB), is a zoonotic, tick borne illness responsible for an estimated 385,000 combined cases in the United States and Europe annually (1,2). Underestimates in the number of confirmed LD cases have been described (3,4), and are partially attributed to the limited specificity and sensitivity of commercially available tests (3,4). Detection of clinically-relevant antibody titers may take several weeks from the time of infection, when utilizing these traditional serologic testing methods (5). Here we describe a novel PCR method, Droplet Digital PCR (ddPCR), to interrogate multiple *Borrelia* species. *Borrelia garinii* gDNA was titrated in a constant human DNA background to yield a dynamic range of more than 5 log, with the limit of detection falling below one DNA molecule per microliter (Fig. 1). *Borrelia garinii, B. afzelii, and B. burgdoferi* were subsequently multiplexed in a single well, in order to demonstrate the efficacy of screening for multiple *Borrelia* strains in parallel. Given these findings, ddPCR may provide additional resolution to traditional serologic testing methods.

Epidemiology, Clinical Characteristics and Outcome of Deep Sternal Wound Infections in a Tertiary Cardiac Surgery Centre in the United Kingdom

Author Block:

A. L. Chue, I. Das, A. Ranasinghe, R. Warner; Univ. Hosp. Birmingham NHS Trust, Birmingham, United Kingdom

Abstract Body:

Background: Deep sternal wound infection is a life threatening complication following median sternotomy. The optimal management remains unclear, with no recent epidemiology from the UK. Over 40,000 cardiac operations are carried out over a 5 year period in the UK, with 3.3% resulting in surgical site infection.**Aim:** To review incidence and epidemiology of deep sternal wound infections.**Method:** A retrospective review of microbiologically confirmed deep sternal wound infections from 1 November 2011 to 1 November 2015 through electronic patient and laboratory records. We defined deep sternal wound infection as infections requiring debridement surgery with microbiologically positive results.**Results:** Forty-eight patients with deep sternal wound infections, a rate of 1.6%, were identified. The following risk factors were common: diabetes (23%), immunosuppression (29%), obesity (35%). Infections mostly first manifested in the early post-operative period with the earliest occurring 16 days after surgery, and the latest 7 years after initial surgery. Two hundred and twenty-six deep samples from 78 patients were received by the Microbiology laboratory, of which 128 from 48 patients were culture positive (57%). Coagulase negative staphylococci were the leading organisms (32%), followed by Gram-negative organisms (26%) and *Staphylococcus aureus* (11%). Forty-six percent of patients (22/48) were found to have polymicrobial infections and only three patients (6%) had a sole fungal aetiology, predominantly a *Candida sp.*. Thirteen patients (27%) were managed with debridement (often multiple, range 1 to 15) alone, 15 patients (31%) were managed with vacuum dressings and 18 patients (38%) were managed with flap reconstructions. The majority of patients received tailored antibiotic regimes according to the aetiological organisms. The antibiotic course ranged from five days to 6 months either through continuous or interrupted courses. Sixty-nine percent (33/48) were cured. In-hospital mortality was low (15%) but associated morbidity with frequent admissions and surgical procedure was high.**Conclusion:** A multidisciplinary approach with meticulous long clinical and microbiological review is important in the management of this infection.

Diversity of Spa Types in *Staphylococcus aureus* Isolates from Three Regions in Kenya

Author Block:

L. Musila[1], V. Oundo[1], D. Matano[1], S. Muriithi[1], W. Sang[2]; [1]USAMRD-K, Village Market, Kenya, [2]KEMRI, Nairobi, Kenya

Abstract Body:

Staphylococcus aureus is a pathogen of global clinical significance with abundant genetic diversity within and between human populations. However there are notable gaps in strain typing data from sub-Saharan Africa. An ongoing surveillance study is being conducted to examine the strain diversity of *S. aureus* from geographically diverse regions in Kenya to provide information on the distribution of methicillin-sensitive and -resistant *S. aureus* (MSSA, MRSA) strains in Kenya. The study is being conducted in 3 hospitals located in the western lake, the western highland and central regions of Kenya. Bacterial isolates were cultured from skin, wound and urine infections. Thirty one *S. aureus* isolates were identified phenotypically by gram stain, catalase, coagulase and API tests. Two MRSA were identified based on the cefoxitin disc screen as per CLSI guidelines. DNA was extracted from overnight cultures of S. aureus and PCR performed using published primers to amplify the highly variable X repeat region of the spa gene. PCR products were purified and sequenced by Sanger sequencing. Spa types were detected using the Ridom SpaServer and compared between MSSA and MRSA isolates in the three geographical regions. From these isolates, 23 different spa types were identified. The predominant spa types were t335 (5), t064 (3), t2029 (2) and t005 (2). 10 isolates had unique spa types (t084, t002, t1886, t223, t10499, t318, t7499, t941, t7258, t037) while 9 isolates had novel unassigned spa types. Isolates of the Spa type t064 and t2029 and 7 unique and distinct spa types were confined to the lake region. The western highlands and central sites both had isolates with spa types t335 and t005, with each site also having their own unique and distinct spa types. The only MRSA strains detected were from the lake region and had spa types t2029 and t002, suggesting emergence from endemic strains. The spa type t037 which is recognized as a globally distributed ST239 strain type was detected in this study and has been reported previously in Kenya. The significant diversity, unique spa types and geographical differences in the distribution of spa types of *S. aureus* in Kenya underscores the need for systematic surveillance to appreciate the genetic geodiversity and identify emergent strain types.

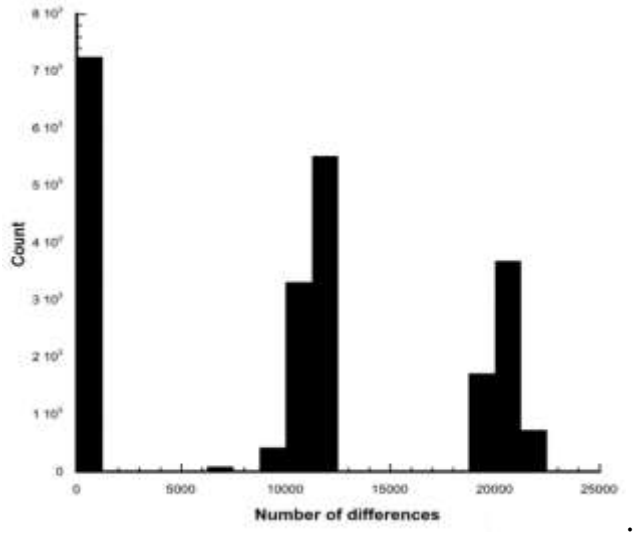
Molecular Analysis of Methicillin Resistant S*taphylococcus aureus* in a Cohort of Cystic Fibrosis Patients

Author Block:

A. Ankrum; Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract Body:

Avoiding chronic lung infection with pathogenic bacteria is critically important to maintaining lung health in Cystic Fibrosis patients. Strict Infection Control measures are implemented in clinical settings in order to prevent patient to patient transmission of these pathogens. We analyzed MRSA isolates from our CF patients to determine strain relatedness in order to validate our infection control practices.From April 2014 to March 2015, 69 MRSA isolates were retained from respiratory cultures on unique CF patients, including 7 pairs of siblings, with 30 isolates representing new acquisition within the past year. Strain relatedness was determined by Whole Genome Sequencing utilizing phylogenetic analysis comparing Single Nucleotide Polymorphism differences between isolates.Three main clusters were identified with Group 1 containing 5 isolates, Group 2 with 36 isolates and Group 3 with 28 isolates (Fig 1) .



.

33 isolates contained a SCCmec IV cassette, while 36 isolates contained SCCmec II. Using a SNP cutoff value of 40 differences, 5 pairs of siblings were the only MRSA isolates that displayed relatedness (Fig 2).

Fig 1. Clusters of MRSA isolates**Fig 2. SNP differences between a sibling pair**We can definitively conclude that none of the non-sibling CF patients with recent acquisition acquired MRSA from other CF patients in this study. These results support our infection control practices by providing evidence that MRSA acquisition is not occurring between CF patients in our clinical setting.

Changes in Gene Expression of *Staphylococcus aureus* in the Presence of Zinc Oxide Nanoparticles

Author Block:

U. Kadiyala, J. VanEpps, N. Kotov; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Annually over 1 million healthcare associated infections are related to implanted medical devices. *Staphylococcus aureus* is one of the most common causative organisms. We have shown that layer-by-layer coatings of zinc oxide nanoparticles (ZnO-NPs) reduce staphylococcal biofilm growth by 3 logs. Furthermore, ZnO-NP mediated growth inhibition is not likely the result of oxidative stress as previously thought. In addition, we have shown that ZnO-NPs crystalized into hexagonal pyramids inhibit β-galactosidase and horseradish peroxidase activity in a biomimetic fashion similar to natural substrate inhibitors. To better understand how this enzyme inhibition function may contribute to the antimicrobial properties, we performed a DNA microarray analysis to determine changes in gene expression for ZnO-NP-exposed *S. aureus*.**Methods:** ZnO-NPs were synthesized into 15-20nm hexagonal pyramids as previously described. *S. aureus* (COL) was grown to mid-log in the presence of sub-lethal but growth inhibitory concentrations of ZnO-NPs. RNA was extracted and transcriptome analysis was performed using Affymetrix Microarray GeneChip®.**Results:** A total of 815 genes were significantly up/down regulated: 333 upregulated and 482 down regulated. Genes related to oxidative stress and redox homeostasis were minimally changed or down regulated. This supports our previous results demonstrating that oxidative stress is not the primary mechanism of action for ZnO-NPs. The genes most highly upregulated by ZnO-NPs relate to uridine monophosphate (UMP) biosynthesis, pyrimidine metabolism, and translation. Genes that were down regulated primarily relate to purine metabolism, amino acid biosynthesis, sugar phosphate transporters, and pathogenesis.**Conclusion**: UMP biosynthesis pathway is highly upregulated in the presence of ZnO-NPs. It is commonly upregulated in anaerobic conditions and is involved in accelerated cell wall synthesis. Notable gene expression changes are currently being confirmed by RT-PCR. Future experiments will be performed on isogenic mutants to better understand the role of the UMP biosynthesis pathway in ZnO-NP mediated growth inhibition. This work sets the foundation to better identify ZnO-NP's mechanism of action against *S. aureus*. Such insight is necessary to optimize coating strategies to prevent medical device infection.

Molecular Typing for Methicillin-resistant *Staphylococcus aureus*: Comparison Between Pcr-Based Open Reading Frame Typing, Multilocus Sequence Typing (Mlst), and *Staphylococcus* Protein A Gene (*spa*) Typing

Author Block:

S. Ogihara[1], R. Saito[2], Y. Kitamura[1], E. Sawabe[1], T. Kozakai[1], M. Shima[1], Y. Nukui[1], M. Hagihara[1], S. Tohda[1]; [1]Tokyo Med. and Dental Univ. Med. Hosp., Tokyo, Japan, [2]Tokyo Med. and Dental Univ., Tokyo, Japan

Abstract Body:

Background: Nosocomial outbreaks of methicillin-resistant *Staphylococcus aureus* (MRSA) infection increase the mortality rate as well as the cost for healthcare. Molecular characterization of MRSA clones is an indispensable prerequisite for investigations into such outbreaks and epidemiological studies. The most widely used techniques for MRSA typing are pulsed-field gel electrophoresis, multilocus sequence typing (MLST) and *Staphylococcus* protein A gene (*spa*) typing. PCR-based open reading frame typing (POT), a multiplex-PCR based typing technique, has been recently developed as a clinical diagnostic tool. In this study, we evaluated the performance of POT for molecular typing of MRSA clinical isolates, and compared it with that of MLST and *spa* typing. **Methods:** A total of 37 non-repetitive MRSA isolates that were suspected to be responsible for a nosocomial outbreak were collected between July 2012 and May 2015 from Tokyo Medical and Dental University hospital of Medicine in Japan. We performed MLST, *spa* typing, and POT, and evaluated their discriminatory power in terms of the Simpson's index. **Results:** The 37 MRSA isolates were classified into 11 types by MLST, 18 types by *spa* typing, and 33 types by POT. The predominant strains identified by MLST, *spa* typing, and POT were ST8 and ST764 (9 strains), t002 (13 strains), and 93-191-127 (3 strains), respectively. The discriminatory power as estimated by Simpson's index was 0.853, 0.875, and 0.992 for MLST, *spa* typing, and POT, respectively. **Conclusion:** Our results show that POT had greater discriminatory power than MLST and *spa* typing. Moreover, while MLST and *spa* typing took more than 2 days to yield results, the turn around time for POT could be shortened to 5 h. POT is easy and rapid to perform, simple to interpret, and is highly discriminatory; we therefore recommend it as a molecular typing tool to monitor nosocomial transmission of MRSA.

***Staphylococcus aureus* Nasal Carriage Rate of Preclinical Nursing Students**

Author Block:

A. Kanayama, I. Kanesaka, H. Takahashi, I. Kobayashi; Toho Univ., Tokyo, Japan

Abstract Body:

Background: Colonization of the nasal cavity with *Staphylococcus aureus* can lead to transmission to others by contaminated fingers. In particular, the high prevalence of MRSA in healthcare settings and its spread within hospitals is a concern. In this study, we report on our 7 year monitoring of *S. aureus* and MRSA nasal cavity carriage rates in preclinical nursing students.**Methods:** During the period 2009 to 2015, nostrils of over 100 preclinical nursing students were sampled each year using sterile swabs and cultured on mannitol salt agar for the presence of *S. aureus*. Colonies with typical *S. aureus* morphology were gram stained. Gram-positive cocci were tested for coagulase agglutination to identify as *S. aureus. S. aureus* isolates were screened for the presence of MRSA using the CLSI cefoxitin disk diffusion method.**Results:** During the period of the study, the overall *S. aureus* nasal cavity colonization rate of nurses was 30.2% (235/779). Colonization rates from 2009 to 2015 were 34%, 37%, 28%, 37%, 28%, 23% and 25%, respectively, showing a *S. aureus* carriage rate in approximately one-third of the nursing students. Of the *S. aureus* carriers, 1 MRSA carrier was detected in 2011 and 2015.**Conclusions:** While the MRSA carriage rate was low of preclinical nursing students, the rate of colonization with *S. aureus* was consistent over the study period which dictates a need to enforce compliance with hand hygiene to prevent transmission within the hospital.

Clinical Outcomes In Vancomycin-Resistant *enterococcus* (Vre)/Methicillin-Resistant *staphylococcus Aureus* (Mrsa) Bloodstream Coinfection Treated With Daptomycin Or Linezolid

Author Block:

N. S. Britt[1], E. M. Potter[2], N. Patel[3], M. E. Steed[4]; [1]Barnes-Jewish Hosp., St. Louis, MO, [2]Dwight D. Eisenhower VA Med. Ctr., Leavenworth, KS, [3]Albany Coll. of Pharmacy and Hlth.Sci., Albany, NY, [4]Univ. of Kansas Sch. of Pharmacy, Kansas City, KS

Abstract Body:

Background: Previous research has demonstrated improved outcomes associated with daptomycin (DAP) treatment for vancomycin-resistant enterococcal bloodstream infection (VRE-BSI) in comparison to linezolid (LZD). However, optimal treatment of bloodstream coinfection with VRE and MRSA is unclear. **Methods:** This was a retrospective cohort study of hospitalized Veterans Affairs (VA) patients (2004-2014) with ≥ 1 blood culture positive for VRE (*E. faecium* or *E.faecalis*) and vancomycin-susceptible MRSA treated with LZD or DAP. Exclusion criteria included: i) treatment < 48 hours; ii) DAP/LZD combination or sequential treatment; iii) concomitant treatment with another active anti-VRE or anti-MRSA agent; and iv) infection caused by a DAP-nonsusceptible or LZD-resistant isolate. The primary outcome was 30-day mortality. Secondary outcomes were hospital mortality, persistent BSI ≥ 7 days (among those with at least one follow-up blood culture), and time to overall microbiologic clearance. A multivariable logistic regression model of factors associated with 30-day mortality was derived using a backward stepwise approach.**Results:** A total of 3,023 patients with VRE-BSI treated with LZD or DAP were identified. Of these, 228 (7.5%) had a concomitant MRSA BSI. Overall mortality was 32.0% (*n*=73/228). Clinical outcomes were compared between DAP and LZD (Table 1). In multivariable regression, factors significantly associated with 30-day mortality were age, *E. faecium*, unknown source, thrombocytopenia, and intensive care unit status.**Conclusions:** DAP was associated with improved time to overall microbiologic clearance and decreased risk of persistent BSI versus LZD in a cohort of VRE/MRSA bloodstream coinfection, with no difference in associated mortality.

Table 1. Comparison of clinical outcomes by treatment for VRE/MRSA bloodstream coinfection

Outcome (*N*=228)	**DAP (*n*=80)**	**LZD (*n*=148)**	***P*-value**
30-day mortality, *n* (%)	24 (30.0)	49 (33.1)	0.631
Hospital mortality, *n* (%)	30 (37.5)	57 (38.5)	0.880
Persistent BSI, *n* (%)	5 (8.2)	20 (19.8)	0.048

Time to overall microbiologic clearance, mean (SD)	2.8 (2.2)	5.4 (10.4)	0.017

Compatibility of Five Sample Collection Devices with the Cobas® Mrsa/Sa Test on the Cobas® 4800 System

Author Block:

S. Cagas, O. Peraud, R. Hein, S. Moseley; Roche Diagnostics Corp., Indianapolis, IN

Abstract Body:

Background: *Staphylococcus aureus* (SA) and methicillin-resistant *Staphylococcus aureus* (MRSA) strains are associated with significant healthcare burdens and cost. Guidelines recommend active screening and isolation and/or decolonization of patients to control the spread of MRSA and SA. The sensitivity of assay and time to result are key factors in successful screening and treatment strategies. Conventional culture-based methods require several days for results to become apparent and do not allow rapid implementation of specific infection control measures. Challenges for testing include turn around time and media collection types. This study was conducted to determine the compatibility of different sample collection media for assessment of contrived samples with a new PCR based molecular test performed on the cobas® 4800 system. **Methods:** Quantified MRSA and SA material was introduced to MSwab (COPAN Italia, Brescia Italy), ESwab (COPAN Italia, Brescia Italy), CultureSwab Plus Amies gel with and without charcoal (BD, Franklin Lakes, New Jersey) and CultureSwab Liquid Stuart (BD, Franklin Lakes, New Jersey), at 5X and 50X limit of detection (LoD) with the cobas® MRSA/SA Test and evaluated in triplicate and mean Ct values calculated.**Results:** The cobas® MRSA/SA Test detected MSwab, ESwab, CultureSwab Plus Amies gel without charcoal collection media at 5x and 50x LoD. Results obtained with ESwab and CultureSwab Plus Amies gel without charcoal were within 1cycle of the approved MSwab media. CultureSwab Liquid Stuart MRSA and SA specimens were detected at 50X LoD, only one of the three 5X LoD replicates for MRSA and SA were detected. CultureSwab Plus Amies gel with charcoal MRSA and SA specimens were detected at 50X LoD, neither MRSA or SA were detected at 5X LoD.**Conclusions:** Preliminary results show compatibility of MSwab, ESwab, CultureSwab Plus Amies gel with and without charcoal and CultureSwab Liquid Stuart collection devices with the cobas® MRSA/SA Test, performed on the fully automated cobas® 4800 system. Further feasibility studies with clinical specimens are necessary to determine full compatibility. PCR technology has potential for media type flexibility and fast turn around time.

Hlth.England, Colindale, United Kingdom, [5]Royal Devon and Exeter Hosp., Exeter, United Kingdom

Abstract Body:

Introduction: Skin and soft tissue infections (SSTI) represent a significant clinical burden in recruits, causing significant morbidity and economic burden. Recently clindamycin has been advocated for use due to concerns regarding PVL *S. aureus*. We sought to determine risk factors for acquisition of organisms associated with SSTI and the relevance of PVL. **Methods:** The anterior nares and throats of consenting recruits were swabbed at weeks 1, 6, 15 and 32 of training. Swabs were cultured to detect *S.aureus* and *S. pyogenes* and isolates were subjected to antimicrobial susceptibility testing, *spa* typing or *emm* typing as appropriate. Demographic data and clinical history of SSTI were collected and linked to microbiological data.**Results:** 1015 male recruits consented (92%) and disease data were collected from 991 recruits (98%). 351 recruits (35%) had an SSTI of which cellultis was the most common. 49% of recruits with a SSTI required admission to the medical centre and 8% to hospital. Carriage of *S.aureus* in week 1 was 41% and showed seasonal variation. Most colonizing *S.aureus* strains were susceptible to standard antibiotics (77%), inducible clindamycin resistance detected in 16% and MRSA in less than 1%. Antimicrobial resistance (AMR) increased during training (16 to 33%, $p<0.001$). The commonest Clonal complexes were 30, 15, 5 and 8. Preliminary work showed PVL and GAS carriage rate to be low (<1%) and no association between carriage of *S.aureus* and smoking status.**Conclusion:** This work aimed to evaluate relationships between carriage and acquisition of SSTI, focussing on risk factors for *S.aureus* that may be amenable to intervention. Of particular note in this study was the low carriage rate of *S.pyogenes.* Incision and drainage was not advised as there was a low rate of purulent infections (<2%). Preliminary analysis shows a rise in AMR during training suggesting the use of clindamycin as first line treatment for SSTI in this military group may need to be re-considered.

Publishing Title:

Prevalence and Molecular Epidemiology of *Staphylococcus aureus* Among Bhutanese Refugees in Nepal and in Northeast Ohio

Author Block:

J. Kadariya[1], D. Thapaliya[1], R. Mahatara[2], S. Bhatta[1], N. Dhakal[3], T. Smith[1]; [1]Kent State Univ., Kent, OH, [2]Intl. Organization for Migration, Jhapa, Nepal, [3]AMDA Hosp., Jhapa, Nepal

Abstract Body:

Every year the United States resettles thousands of refugees from around the world. Although studies have shown that human migration is one of the risk factors for the spread of drug-resistant organisms such as methicillin-resistant *Staphylococcus aureus* (MRSA), there has not been any study conducted regarding the prevalence of MRSA among refugee populations in the U.S. This study aimed to assess the prevalence and molecular characteristics of *S. aureus* among Bhutanese refugees living in Nepal and in Northeast Ohio (NEO). One hundred adult Bhutanese refugees from each location were enrolled between August 2015 and January 2016. The participants were interviewed to collect the demographic information and exposures to potential risk factors for carriage. Nasal and throat swabs were collected from each individual and processed within 24 hours according to the study protocol. All *S. aureus* isolates were typed by *spa* typing and multi-locus sequence typing (MLST). The presence of the Panton-Valentine Leukocidin (PVL) and *mec*A genes were detected via PCR. The Vitek-2 System was used to test the antibiotic susceptibility. Of the 100 participants enrolled in Nepal, the median age was 35 years (mean 36.75; standard deviation, 13.28; range, 57). Twenty-nine percent and 71% of the participants were male and female, respectively. The overall prevalence of *S. aureus* was 45% (45/100). The prevalence of MRSA was 2% (2/100). The overall prevalence of PVL genes among *S. aureus* isolates was 25% (13/52). A total of 31 *spa* types were detected from 52 *S. aureus* isolates. The most common *spa* type was t345(9.6%). One isolate was t008 (USA300), a common community-associated strain. One isolate was found to be t002, a common healthcare-aasociated strain (USA100). Twenty-one isolates (40.4%) were multi-drug resistant. Analyses of data from NEO are ongoing. The findings of this study indicate that Bhutanese refugees living in Nepal had high prevalence of *S. aureus* and high prevalence of multi-drug resistant *S. aureus.*

Environmental Sampling of *Staphylococcus aureus* at a Large Midwest University: A Connection with Health Care Students

Author Block:

M. Taha[1], D. Thapaliya[2], **M. R. Dalman**[2], J. Kadariya[2], T. Smith[2]; [1]Iraqi Ministry of Sci. and Technology, Baghdad, Iraq, [2]Kent State Univ., Kent, OH

Abstract Body:

Staphylococcus aureus is a commonly found bacterium that colonizes a variety of animal species, including humans. Additionally, it is also found on fomites and has the potential to be transferred from person to person via contaminated surfaces. Methicillin-resistant *S. aureus* strains (MRSA) first emerged in hospital settings (HA-MRSA), but are also found in the community (CA-MRSA). With over 11,000 deaths from MRSA and the ability to survive on surfaces for several months, we characterized environmental contamination of both healthcare and non-healthcare associated college student buildings in order to determine molecular type and antibiotic susceptibility profiles of *S. aureus* isolates. Environmental swabs (n=152) were collected from healthcare (n=2) and nonhealthcare- associated buildings (n=2) at a state university. A total of 38 samples were collected per building from high hand-touch areas (door handles, sink handles, etc.) and processed within 24 hours using typical bacteriological methods. Five colonies per positive sample were then subjected to antibiotic susceptibility testing and molecular characterization (multilocus sequence typing, PVL and *mec*A PCR, and *spa* typing). A total of 34 of 152 (22.4%) samples were contaminated with *S. aureus* and 9 (5.9%) were positive for MRSA. Three sites were positive from multidrug resistant (MDR) strains. Within healthcare and non-healthcare facilities, 5/75 (6.75%) and 4/75 (5.26%) were MRSA positive, respectively. The most frequently contaminated surface for MRSA in buildings frequented by healthcare-associated students was the main door, whereas in non-healthcare buildings it was the classroom. All isolates were resistant to penicillin, with methicillin resistant (26.5%) and MDR (8.8%) present. The most common *spa* types found were t1149, t068, t216, t008, and t334. These results point to the ease of *S. aureus* contamination on fomite surfaces and the presence of t008 (a community-associated strain type) in healthcare-associated student buildings, along with MDR *S. aureus* indicates a need for increased awareness of the potential for environmental surfaces, even outside of the hospital setting, to act as reservoirs for *S. aureus*.

Publishing Title:

Predicting Severity or Duration of Infection Based on the Characteristics of *Staphylococcus aureus* Strains Causing Bovine Mastitis

Author Block:

S. Pichette-Jolette[1], G. Millette[1], E. Demontier[1], D. Bran-Barrera[1], M. Cyrenne[1], C. Ster[1], F. Malouin[1], G. Keefe[2], D. Haine[3], J-P. Roy[3]; [1]Univ. de Sherbrooke, Sherbrooke, QC, Canada, [2]Univ. of Prince Edward Island, Charlottetown, PE, Canada, [3]Univ. de Montreal, Saint-Hyacinthe, QC, Canada

Abstract Body:

Background: Bovine mastitis is one of the most frequent infections observed in dairy cattle. *Staphylococcus aureus* is the leading pathogen causing mastitis. The infection is transmitted to healthy cows by the milking instruments and farm workers. The severity of the disease caused by the presence of *S. aureus* can be qualified as subclinical (no visible sign of inflammation) or clinical. Antibiotic treatment often fails and infections can extend for a long period of time. In such cases, more drastic measures must be taken like culling of the infected animals. Here, we compared the genotypes and phenotypes of *S. aureus* isolates collected from subclinical or clinical mastitis cases of varying duration.**Method:** The study includes more than 340 unique quarter isolates from documented mastitis cases and quarter milk samples collected from 64 farms across Canada (Canadian Bovine Mastitis and Milk Quality Research Network (CBMMQRN), Mastitis Pathogen Culture Collection). Variable number of tandem repeats typing was used to assess the persistence of the same *S. aureus* strain in consecutive quarter milk samples and to estimate the duration of infection (up to 500 days in some cases). Strains were compared based on the extent of biofilm production, *spa* typing and presence of virulence genes (*seg*, *tst*, *lukM*).**Results:** The major *spa* types found were t529 (n=167), t267 (n=87), t359 (n=46) and t605 (n=16). The *spa* type significantly influenced the production of biofilm and the severity of infection. The presence of virulence genes was also associated to *spa* types and some virulence genes correlated with the severity of the disease. For example, t605 produced more biofilm and was more likely to lack *lukM* while t529 was most often *seg+* and associated with clinical mastitis. There was no statistical difference between the *spa* type and the duration of the infection.**Conclusion:** Mastitis caused by *S. aureus* is difficult to eliminate from dairy herds. Predicting the severity or duration of infection based on strain characteristics would be extremely useful in herd management practices. We reported here some attributes linked to problematic strains.

Multiresistant Methicillin-resistant *Staphylococcus aureus* St5-Scc*mec IV* and St30-Scc*mec IV* Recovered from Cystic Fibrosis Patients

Author Block:

S. Haim[1], P. Pena Amaya[2], **S. Di Gregorio**[1], S. Fernández[1], A. Teper[2], M. Vázquez[2], S. Lubovich[2], L. Galanternik[2], M. Mollerach[1]; [1]Univ. de Buenos Aires, CABA, Argentina, [2]Hosp de Niños R. Gutiérrez, CABA, Argentina

Abstract Body:

Background: *Staphylococcus aureus* is an early observed pathogen in Cystic Fibrosis (CF) that can chronically infect the lungs of these patients. Methicillin-resistant *S. aureus* (MRSA) colonization in CF patients attending the Hospital de Niños R. Gutiérrez is an increasing problem climbing from 23% in 1995 up to 32% in 2011. However, the information about its epidemiological features is limited. The aim of this study was to analyze the diversity of MRSA isolates recovered from respiratory samples of CF patients. **Methods:** Antimicrobial susceptibility testing (Vitek or disk diffusion method on Mueller Hinton agar + 5% sheep blood) was performed to all *S. aureus* isolates recovered from 41 out of 120 CF patients from June 2012 to May 2013. For each patient, only the first MRSA isolate was included, except when isolates with a different resistance pattern were recovered. *luk*-SF/PV and *mec*A genes were studied by PCR. Strains were genotyped by SCC*mec* typing, PFGE, *spa* typing and MLST. **Results:** 57 isolates from 41 CF patients were included. All were *mec*A positive and 32%, PVL positive. 41/57 (72%) isolates harbored SSC*mec* IV. Among these, 24 (42%) belonged to the main community-acquired MRSA (CA-MRSA) clone complexes described in Argentina: Pulsotype A (PA) ST5-SCC*mec* IVa (16/57) and Pulsotype C (PC) ST30-SCC*mec* IVc (8/57). The antibiotic resistance rates were: gentamicin (63%-57%), erythromycin (44%-43%), clindamycin (44%-14%), ciprofloxacin (25%-57%) and rifampicin (31%-0%), PA and PC respectively. Multiresistance was detected in 11/24 (46%) MRSA strains, 8 corresponding to PA and 3 to PC. For those isolates related to PA, 56% were *spa* type t002 and 44%, t311. Among those with PC, the most frequent *spa* type was t019 (75%). **Conclusions**: The ST5-SCC*mec* IVa-PA and ST30-SCC*mec* IVc-PC clones were the most frequent CA-MRSA clones recovered in this study. Nonetheless, the rate of multiresistance showed by these clones was higher compared to what is reported in non cystic fibrosis patients in our country. These clones could represent an emerging health threat not only for cystic fibrosis patients but also for the general community, as they seem to have originated from CA-MRSA lineages, which are highly transmissible.

Prevalence and Characterization of *Staphylococcus aureus* on Public Recreational Beaches in Northeast Ohio

Author Block:

D. Thapaliya, E. Hellwig, J. Kadariya, M. Dalman, K. Kennedy, M. DiPerna, A. Orihill, D. Grenier, M. Taha, T. Smith; Kent State Univ., Kent, OH

Abstract Body:

Staphylococcus aureus is a major public health concern due to the emergence of virulent and drug-resistant strains such as methicillin-resistant *Staphylococcus aureus* (MRSA), and due to its ever-changing epidemiology. Although MRSA has been isolated from marine water and intertidal beach sand, only few studies have conducted to assess the prevalence of *S. aureus* in freshwater recreational beaches. This study aimed to determine the prevalence and molecular characteristics of *S. aureus* at freshwater recreational beaches in Northeast Ohio. A total of 280 beach sand and water samples were collected from 10 public fresh water beaches in Northeast Ohio, USA between June 24, 2014 and April 30, 2015. Samples were analyzed using established microbiology methods, and resulting *S. aureus* isolates were typed by *spa* typing and multi-locus sequence typing (MLST). PCR was used to detect the presence of the Panton-Valentine Leukocidin (PVL) and *mec*A genes. Antibiotic susceptibility was tested via the Vitek-2 System. The overall prevalence of *S. aureus* in sand and water samples was 22.9% (64/280). The prevalence of MRSA was 7.9% (22/280). The highest prevalence was observed in summer (45.8%; 55/120) compared to fall (4.2%; 5/120), and spring (10%; 4/40). The prevalence of PVL genes among *S. aureus* isolates was 23.4% (15/64). A total of 26 *spa* types were detected from 64 *S. aureus* isolates. Overall, t008 was the most common *spa* type.Two isolates were t002, a common human-associated strain. One isolate was t571 (ST398), a livestock-associated strain. Twenty-eight (43.8%) isolates were multi-drug resistant.The results of this study indicate that beach sand and fresh water of Northeast Ohio was contaminated with *S. aureus* and MRSA. The high prevalence of *S. aureus* in summer months and presence of human –associated strains may indicate the possible role of human beachgoers in *S. aureus* contamination of beach water and sand.

Analysis of Morphologically Similar *Staphylococcus aureus* Colonies to Assess Phenotypic and Genotypic Correlation

Author Block:

M. Totten, T. Ross, A. Voskertchian, A. Milstone, K. Carroll; Johns Hopkins Med. Inst.s, Baltimore, MD

Abstract Body:

Background: When performing surveillance cultures from non-sterile sites for *Staphylococcus aureus* (*S. aureus*), a single bacterial isolate is selected as representative of the cultured strain. Standard practice presumes that morphologically similar colonies constitute the same strain and are thus phenotypically and genetically identical. The objective of this study was to determine how frequently colonies with the same morphology are phenotypically and genetically diverse. **Methods**: As part of a larger study examining parent to infant transmission of *S aureus*, swabs were collected and cultured from multiple body sites. Cultures were inoculated into Tsoy broth with 6.5% NaCl (BD Diagnostics, Inc. Sparks, MD), incubated overnight and subcultured onto 5% sheep blood agar (BD) and SASelect™ chromogenic media (Bio-rad, Hercules, CA). For positive cultures, a set of five separate isolates for each unique colony morphology was characterized using pulsed field gel electrophoresis (PFGE). Additionally, the antimicrobial susceptibility (AST) profile and identification of each isolate was determined using the Phoenix PMIC/ID-105 panel (BD). **Results:** Fourteen neonate and adult participants had positive *S aureus* cultures that yielded 205 isolates (5 isolates tested for each of the 41 observed morphologies). Of the 205 isolates, 204 (99.5%) had the same PFGE pattern as other isolates recovered from the same group of patients. One isolate had a one band difference from the others in its group. AST testing showed that 195 of the 205 isolates tested had the same antibiogram to all 16 antibiotics tested. **Conclusion:** Results from both PFGE and AST support the common assumption that *S aureus* isolates from the same culture with similar morphologies are of the same strain. Thus, saving a single bacterial isolate from a cultured *S. aureus* sample is an appropriate standard practice when archiving isolates for future susceptibility testing and epidemiological studies.

Community-Associated *Staphylococcus aureus* (CA-MRSA) is Associated with Low Level Resistance against Oxacillin, Cefoxitin, and Vancomycin

Author Block:

W-Y. Wang[1], S-M. Tsao[2]; [1]Feng-Yuan Hosp., Taichung, Taiwan, [2]Chung Shan Med. Univ. Hosp., Taichung, Taiwan

Abstract Body:

Background: *Staphylococcus aureus*, including methicillin-susceptible (MSSA) and methicillin-resistant *S. aureus* (MRSA), is a leading pathogen for clinical infections with increasing resistance. *mecA*+ MRSA with oxacillin (OX) and cefoxitin (FOX) susceptibility has been reported elsewhere. We aim at delineating the molecular distribution and prevalence of low level resistance to OX and FOX, and vancomycin (VA) susceptibility pattern among *S. aureus*. **Material/methods:** *S. aureus* were collected from clinical specimens of one medical center in central Taiwan between July, 2011 and June, 2014, and they were identified according to CLSI. MRSA was confirmed with *mecA* existence by PCR. The minimal inhibitory concentrations (MIC) of isolates against OX, FOX, and VA were determined with agar dilution. The staphylococcal cassette chromosome *mec* (SCC*mec*) types were determined by PCR. **Results:** Totally 543 non-duplicate *S. aureus*, including 226 MSSA and 317 MRSA, were collected. Most were cultivated from pus (233, 42.9%), sputum (139, 25.6%), blood (117, 21.5%), and urine (32, 5.9%). Six SCC*mec* types, including I (1, 0.3%), II (36, 11.3%), III (96, 30.3%), IV (95, 30.0%), V (24, 7.6%), and V_T (50, 15.8%), were determined. Also 15 MRSA were not determined by SCC*mec* typing. High sensitivity and specificity were noted for OX (89.6%/99.6%) and FOX (92.4%/99.6%). Mean VA MIC for *S. aureus*, MSSA, and MRSA were 1.24 ± 0.57, 1.16 ± 0.51, and 1.29 ± 0.61 mg/L, respectively ($p = 0.006$). Higher mean VA MIC was seen in SCC*mec* II (1.45 mg/L) and III (1.25 mg/L) than in SCC*mec* IV (0.93 mg/L), V (1.16 mg/L), and V_T (1.03 mg/L) ($p < 0.01$). Mean VA MIC of healthcare-associated MRSA (HA-MRSA, SCC*mec* II and III) was higher than community-associated MRSA (CA-MRSA, SCC*mec* IV, V, and V_T) (1.44 ± 0.60 *vs*. 1.13 ± 0.54 mg/L, $p < 0.001$). Higher mean VA MIC was seen in *S. aureus* and MRSA from blood (1.90/1.91 mg/L) and sputum (1.18/1.26 mg/L) than those from pus (0.99/0.98 mg/L) ($p < 0.001$). Thirty-three MRSA (10.4%) and 24 (7.6%) with OX and FOX susceptibility were found, which most (18 for OX and 9 for FOX) were CA-MRSA. **Conclusions:** Low level resistance againt oxacillin, cefoxitin, and vancomycin are found among CA-MRSA. MRSA harbors increasing vancomycin resistance. Molecular and specimen types can be used as predictors of vancomycin resistance.

Prevalence and Characterization of *Staphylococcus aureus* on Geese Feces Collected from 10 State Parks in Northeast Ohio

Author Block:

D. Grenier, D. Thapiliya, K. Little, V. Mansell, J. Kadariya, M. Dalman, M. Taha, T. Smith; Kent State Univ., Kent, OH

Abstract Body:

Staphylococcus aureus can colonize wide range of hosts including domestic as well as wild animals. Migratory birds colonized with *S. aureus* may spread drug-resistant strains of *S. aureus* such as methicillin-resistant *S. aureus* (MRSA). Although numerous studies have isolated other pathogenic bacteria from wild birds; very limited data are available examining the presence of *S. aureus* among these species. The objective of this study was to determine the prevalence and molecular characteristics of *S. aureus* in geese fecal samples collected from 10 state parks across Northeast Ohio (NEO). A total of 182 fecal samples were collected between April 22, 2015 and April 29, 2015. The samples were processed within 24 hours according to the established microbiology methods. Multi-locus sequence typing (MLST) and *spa* typing were carried out on all isolates. PCR was conducted to detect the presence of the Panton-Valentine Leukocidin (PVL), *mec*A, and *scn* genes. The overall prevalence of *S. aureus* in the fecal samples was 7.1% (13/182). The prevalence of *mec*A gene among the *S. aureus* isolates was 53.8% (7/13), while the prevalence of PVL was 7.7% (1/13). All the isolates harbored the *scn* gene. A total of 8 different *spa* types were observed among 13 isolates. Overall, t008 (USA-300, ST-8), a common community-associated (CA) strain was the most common (46.1%, 6/13) *spa* type. One isolate was t002 (USA-100, ST-5), a common hospital-associated (HA) strain. One livestock-associated (LA) strain (t571, ST-398) was also found. All isolates were resistant to penicillin. Eight isolates (61.5%) were resistant to oxacillin. Nine isolates (69.2%) were multi-drug resistant. The results of this study indicate that the feces of geese collected at various state parks in NEO harbored *S. aureus* and MRSA. The presence of HA, LA, and CA strains of *S. aureus* in freshly voided geese fecal samples suggests that geese in NEO may be subject to bidirectional spread of these pathogens, and may play a role in the transmission of *S. aureus* in the environment.

Retrospective Analysis of Adverse Events (Aes) between Nafcillin Vs. Cefazolin for Complicated Methicillin Susceptible *Staphylcoccus aureus* (Mssa) Infections

Author Block:

L. Chan[1], A. J. Guarascio[2], J. Como[1], N. H. Chan-Tompkins[1]; [1]Allegheny Gen. Hosp., Pittsburgh, PA, [2]Duquesne Univ., Mylan Sch. of Pharmacy, Pittsburgh, PA

Abstract Body:

Background: Nafcillin or cefazolin are frequently prescribed for MSSA infections. Adverse events such as neutropenia, thrombocytopenia, serum creatinine elevation (Scr), and serum transaminase elevation have been reported. Acute kidney injury (AKI), defined as increase in Scr of >0.5 mg/dL or 50% increase from baseline, has previously been described. AKI incidence based on RIFLE (Risk, Injury, Failure, Loss of kidney function, and End-stage kidney disease) criteria has not been studied with nafcillin or cefazolin. Primary objective: To quantify the incidence and time to AKI based on RIFLE criteria for inpatients (pts) who received nafcillin vs. cefazolin therapy. Secondary objectives: To measure the incidence and time to event for neutropenia, thrombocytopenia, elevated transaminases, and *Clostridium difficile* infection (CDI) in this group. **Methods:** IRB approval was obtained for this retrospective cohort study. Inclusion criteria: age ≥ 18 years old, hospitalization from 7/1/2013-6/30/15, and receipt of IV nafcillin or cefazolin for ≥ 72 hours to treat MSSA infection.**Results:** Of 358 pts screened, 96(26.8%) met inclusion criteria: 46(47.9%) nafcillin vs. 50(52.1%) cefazolin. Ten (21.7%) pts developed AEs (all types) with nafcillin vs. no AEs (0%) with cefazolin. Median days of therapy to event was 9 (range, 3-16). Nine (19.6%) nafcillin pts developed AKI. Median baseline Scr was 1.2 mg/dL (range, 0.4-1.9).For patients receiving nafcillin, thrombocytopenia occurred in 1(2.2%)[median time to event = 2 days] and AST elevation occurred in 2(4.3%)[median time = 5 days]. No pts developed neutropenia, CDI, or ALT elevation. The median Naranjo score was 3(range, 0-6).**Conclusions:** AEs were more common with nafcillin vs. cefazolin in the inpatient setting. AKI, the predominant nafcillin-related AE, occurred most commonly in patients with elevated risk and/or subsequent injury leading to renal dysfunction.

Table 1. Incidence and Time to AKI Based on RIFLE Criteria

Adverse Event	Nafcillin (N=46)		Cefazolin (N=50)
	N (%)	Median (range) Time to Event (days)	N(%)
AKI			
Risk	3 (6.5%)	8 (2-13)	0 (0%)
Injury	4 (8.7%)	4.5 (1-14)	0 (0%)

Failure	4 (2.2%)	12	0 (0%)
Loss	1 (2.2%)	4	0 (0%)
ESRD	0 (0%)	--	0 (0%)

Bolaamphiphile Nanocomplex Delivery of Antisense Molecules as a Treatment for *C. difficile*

Author Block:

J. P. Hegarty, J. Krzeminski, A. Sharma, D. B. Stewart; Penn State Univ. Coll. of Med., Hershey, PA

Abstract Body:

Background: Antisense molecules can specifically inhibit the expression of bacterial genes through blocking of RNA translation. As a potential alternative to conventional antibiotics, a critical issue is achieving efficient cellular delivery. We have previously used cell penetrating peptide conjugation to deliver antisense morpholinos into *C. difficile*. Vesicles of bolaamphiphile compounds (e.g. dequalinium) are known to condense and deliver DNA in the form of nanocomplexes into cardiolipin-rich mitochondria. As cardiolipin is also a component of bacterial membranes, we investigated the potential use of dequalinium analogs as nanocarriers of bacterial antisense cargo. **Methods:** Phosphorothioate oligonucleotide sequences were designed *in silico* to target the expression of essential *C. difficile* genes and then quantitatively assessed for their ability to block gene translation using plasmid expression constructs in a cell-free system. Analogs of dequalinium chloride containing polar head groups modified for lower toxicity and with varying alkyl chain lengths were synthesized, HPLC purified, and structures confirmed by NMR spectroscopy. Stable vesicles (~100 nm) of compounds were assembled through probe-sonication in salt-free buffer. The concentrations of cationic delivery vesicles required for nanocomplexation of anionic 12- to 25-mer phosphorothioates were determined using fluorescent dye-exclusion assays. Log phase BHIS cultures of ribotypes 027 and 012 were treated in triplicate with serial doses of nanocomplexes and matched empty vesicles, followed by anaerobic incubation for 24 hours. Cell growth and MIC values were determined by culture absorbance and viable colony plate counts.**Results:** Compared to our previously tested cell penetrating peptides, bolaamphiphile antisense nanocomplexes resulted in a 10-fold decrease in MIC (40 nM). No significant growth inhibition was observed from treatment with matched empty delivery vesicles.**Conclusion:** Bolaamphiphile nanocomplexes show promise as a carrier for antisense molecules into bacteria, with a favorable toxicity profile and with MICs near that of conventional antibiotics. Nanocomplexes may provide a future microbiome-sparing therapy for *C. difficile* infection.

Tobramycin and Bicarbonate Synergize to Kill Planktonic *Pseudomonas aeruginosa*, but Antagonize to Promote Biofilm Survival

Author Block:

K. S. Kaushik, J. Stolhandske, O. Shindell, H. Smyth, V. Gordon; Univ. of Texas at Austin, Austin, TX

Abstract Body:

Rising antibiotic resistance and declining development and approval of new antibiotics motivates approaches to increase the efficacy of existing antibiotics. For the opportunistic human pathogen *Pseudomonas aeruginosa*, we previously observed that alkalis including sodium bicarbonate enhance the bactericidal effect of aminoglycoside antibiotics against antibiotic-resistant mutants. Here, we examine the possibility of using bicarbonate in conjunction with aminoglycosides to enhance the efficacy of antibiotic therapy against *P. aeruginosa* infections.The aminoglycoside tobramycin is standard-of-care for many types of *P. aeruginosa* infections, including acute infections, often caused by planktonic bacteria, and chronic, biofilm infections, such as those found in lungs of cystic fibrosis (CF) patients. Inhaled bicarbonate is being evaluated as a therapy to improve antimicrobial activity of the airway surface liquid and decrease the viscosity of CF mucus. Using checkerboard microdilution assays for planktonic cells and *in vitro* biofilms, we measure the effect of combining tobramycin and bicarbonate against *P. aeruginosa*, for laboratory and clinical CF strains. Bicarbonate synergizes with tobramycin to enhance the killing of planktonic bacteria. In contrast, bicarbonate antagonizes with tobramycin to promote better biofilm growth. This suggests caution when evaluating bicarbonate as a therapy for CF lungs infected with *P. aeruginosa* biofilms.We analyze the above drug interactions using an interpolated dose-response surface. This allows more accurate estimation of therapeutic combinations than do standard isobolograms. Using predictions based on Loewe additivity, we can consolidate information on a wide range of combinations across the dose-response surface into a net effect, enabling rapid initial estimation of the potential benefit or harm of a therapeutic combination.The mechanism(s) underlying antagonism of tobramycin and bicarbonate in biofilm treatment is unknown, but one possibility is binding of tobramycin to the extracellular biofilm matrix. We are currently testing the effect of combining bicarbonate with a chemically modified form of tobramycin (conjugated to polyethylene glycol), which has reduced affinity for matrix polymers and greater efficacy against biofilms.

Antibiofilm Effect of Selenium on Uropathogenic *Escherichia coli*

Author Block:

A. Narayanan, M. Surendran Nair, M. S. Muyyarikkandy, M. A. Amalaradjou, K. Venkitanarayanan; Univ. of Connecticut, Storrs, CT

Abstract Body:

Background: Urinary tract infections (UTI) are the most common hospital-acquired infections in humans, caused primarily by uropathogenic *Escherichia coli* (UPEC). Indwelling urinary catheters for bladder drainage in humans become colonized with UPEC biofilms that are resistant to common antibiotics, resulting in chronic infections. Therefore it is important to control UPEC biofilms on catheters.Se is a natural essential trace mineral which acts as a co-factor for many critical metabolic enzymes in human cells. It plays a significant role in many biological processes in the body, such as immunity and antioxidant defense. This study investigated the efficacy of Se in inhibiting and inactivating UPEC biofilms on urinary catheters.**Materials and methods:** Urinary catheters were inoculated with UPEC (~5 log CFU) and treated with 0%, 0.6% and 0.75% Se at 37°C. In addition, catheters with pre-formed mature UPEC biofilms were treated with a lock solution containing Se (0%, 1.5%, or 2%), and incubated at 37°C. Biofilm-associated UPEC counts on control and Se treated catheters were enumerated on days 0, 1, 3 and 5 of incubation. The study was replicated twice with duplicate samples.**Results:** All Se concentrations were effective in preventing UPEC biofilm formation on catheters compared to controls ($P<0.05$). Biofilm-associated UPEC was below detectable limits (< 1.0 log CFU) on catheters treated with 0.75% Se, while ~5.5 log CFU of UPEC was recovered from control samples after 5 days of incubation. Furthermore, Se as a catheter lock solution ingredient decreased UPEC biofilm populations by > 5 log on catheters.**Conclusion:** Results suggest that Se could be applied as a coating on catheter surface or as an ingredient in catheter lock solution to potentially control UTI in humans.

HT-07 — A Bis-Catechol cefaclor Targeted Sideromycin is a Potent Agent against Both *Acinetobacter baumannii* and *E. coli*

Author Block:

Y-M. Lin[1], P. Miller[2], D. L. Shinabarger[3], **M. J. Miller**[2]; [1]Hsiri Therapeutics, South Bend, IN, [2]Univ. of Notre Dame, Notre Dame, IN, [3]Micromyx, Inc, Kalamazoo, MI

Abstract Body:

Background: Our rationally designed sideromycin HT-07 has previously been shown to be active *in vivo* in a mouse peritoneal sepsis model, with no evidence of bacterial adaptation. HT-07 is targeted using a bis-catechol siderophore as a specific iron chelator, which is recognized by the outer membrane receptors (OMR) of Gram-negative bacteria to enable the cellular uptake of HT-07 through the active transport mechanism initiated by the OMR. **Methods:** Under careful iron deficient conditions, we evaluated the MICs of HT-07 against 40 strains of *Acinetobacter baumannii*, and 40 strains of *E. coli* in the presence or absence of Sulbactam (Su) (*Acinetobacter*) and Su, Tazobactam (Tz), and Clavulanate (Cl) (*E. coli*). MHII Broth and otherwise standard CLSC methods were used in 96 microwell plates.**Results:**Table I. *In vitro* Activity against 40 *Acinetobacter baumannii* strains

Ampicillin (alone) *MIC (μg/mL)*	**HT-07** (alone)	**HT-07+Sulbactam** (1.2 *μg/mL)*	**Ampicillin+ Su** (1.2 *μg/mL)*
MIC < 0.5: 1/40	MIC < 0.5: 21/40	MIC < 0.5: 30/40	MIC< 0.5: 1/40
MIC=16–64: 22/40	MIC =0.5: 2/40	MIC=8: 1/40	MIC=8: 1/40
MIC >64: 17/40	MIC >64: 17/40	MIC>64: 9/40	MIC=2-4:19/40 MIC=4-8: 7/40 MIC>32: 13/40

Table II.*In vitro* Activity against 40 *E. coli* strains

HT-07 (alone) MIC *(μg/mL)*	**HT-07+Su** *(1.2 μg/mL)*	**HT-07+Cl** *(10 μg/mL)*	**HT-07+ Tz** *(10 μg/mL)*
MIC<2: 22/40	MIC<2: 28/40	MIC<2: 35/40	MIC<2: 37/40
MIC>2: 18/40	MIC>2: 12/40	MIC>2: 5/40	MIC>2: 3/40

Meropenem (alone)	**Ampicillin+Su** (2:1)	**Ampicillin+Cl** (2:1)	**Piperacillin+Tz**
MIC<2: 38/40	MIC<2: 4/40	MIC<2: 3/40	MIC<2: 22/40
MIC>2: 2/40	MIC>2: 36/40	MIC>2: 37/40	MIC>2: 18/40

Conclusions: HT-07, when supplemented with Su, Tz, or Cl, was active against the majority of strains of *Acinetobacter baumannii* and had comparable results to meropenem against *E. coli*. Although beta-lactamase inactivation is a major obstacle for beta-lactam containing antibiotics, HT-07 is active against most Gram-negative bacteria with a variety of beta-lactamase enzymes.

The Antibacterial Effects of Silver Polyvinyl Pyrrolidone (Ag-Pvp) against *P aeruginosa* and *S epidermidis*

Author Block:

D. Ashmore, A. A. Chaudhari, S. R. Singh, V. A. Dennis, S. R. Pillai; Alabama State Univ., Montgomery, AL

Abstract Body:

Silver-Polyvinyl Pyrrolidone (Ag-PVP) is not only biocompatible but has been shown to possess antimicrobial activity. Currently, resistance to commonly used antibiotics has increased the need for novel antimicrobials. Ag-PVP has been demonstrated to be a good candidate to inhibit the growth of several Gram-positive and Gram-negative bacteria. In this study, we tested the antimicrobial activity of Ag-PVP against Gram-negative *Pseudomonas aeruginosa* and Gram-positive *Staphylococcus epidermidis. Pseudomonas aeruginosa* is the most frequent Gram-negative pathogen associated with high mortality of patients with ventilator associated pneumonia (VAP) in intensive care units and affects immuno-compromised individuals. *Staphylococcus epidermidis* is a Gram-positive pathogen that causes human disease such as skin and soft tissue infections (SSTI) and invasive disease that lead to bacteremia, sepsis, endocarditis, or pneumonia. Both organisms are known to develop resistance to commonly used antibiotics.The antimicrobial activity of Ag-PVP was examined against Gram-negative *Pseudomonas aeruginosa* and Gram-positive *Staphylococcus epidermidis* using minimum inhibition concentration (MIC), minimum bactericidal concentration (MBC) and time-kill studies. Our preliminary data revealed some antimicrobial activity of Ag-PVP against other various strains. We determined that the MIC for *P. aeruginosa* was 125 µg/mL and that the MBC was 250 µg/mL. The MIC for S. epidermidis was determined to be >500 µg/mL. The Time Kill study for *P. aeruginosa* showed cell death at concentrations of 500 µg/mL and 250 µg/mL by 8hrs. Future studies will focus upon the possible mechanism of action and by testing a pool of genes essential for viability using quantitative real-time polymerase chain reaction and sequencing after exposure to Ag-PVP at sub-MIC levels. Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) will also be used to evaluate cellular change in both *P. aeruginosa* and *S. epidermidis*.

Peptide-Conjugated Phosphorodiamidate Morpholino Oligomers (PPMOS) for Burkholderia Cepacia Complex Retain Activity in Sputum and During Aerosolization

Author Block:

J. J. Howard[1], K. Marshall-Batty[2], F. C. Afolabi[1], M. Wong[3], B. L. Geller[4], D. E. Greenberg[1]; [1]UT Southwestern Med. Ctr., Dallas, TX, [2]Frederick Natl. Lab. for Cancer Res., Frederick, MD, [3]Sarepta Therapeutics, Cambridge, MA, [4]Oregon State Univ., Corvallis, OR

Abstract Body:

Burkholderia cepacia complex (Bcc) cause significant morbidity and mortality in patients with chronic granulomatous disease (CGD) and cystic fibrosis (CF). Bcc are frequently antibiotic-resistant, making treatment difficult. We have been using antisense molecules (PPMOs) to inhibit pathogens in a sequence-specific manner. We have shown efficacy *in vitro* and *in vivo* when targeting the essential gene *acpP* encoding an acyl carrier protein. Studies were performed to assess the efficacy of PPMOs in the sputum environment as well as determine the activity of PPMOs when delivered via aerosol.*B. cenocepacia* K56-2 was grown in artificial CF sputum. AcpP PPMO (20 μM, 5570 g/mol) added to culture at 0, 2, 8, and 12 hours resulted in time-dependent killing with a ~3-log decrease in colony-forming units (cfu) at 24 hours (p=0.00004 ANOVA). A scrambled sequence control (Scr PPMO) had no effect on growth. Aerosol delivery of PPMOs was tested in a CGD mouse model. Groups of mice were infected intranasally (IN) with $6x10^5$ cfu of *B. multivorans* (SH-2) and then treated with either AcpP (300 μg or 30 μg; ~1-10 mg/kg) or Scr PPMO (300 μg) via an Aeroneb® Lab nebulizer 6 hours post-infection. All mice were euthanized at 24 hours and lung burden was quantified. Compared to the SCR PPMO group, the AcpP PPMO resulted in a 34% and 93% reduction in cfu/gram of lung (30 μg vs 300 μg, respectively, $p<0.005$) Mice infected IN with K56-2 received aerosolized AcpP PPMO (300 μg) conjugated to the fluorophore Cy3. Fluorescent microscopy was used to analyze the degree of co-localization of PPMO with K56-2. At 24 hours post-infection, 60% of PPMO had co-localized with K56-2 (Mander's coefficient of 0.608; Imaris® 7).The AcpP PPMO demonstrates *in vitro* activity in settings likely to be encountered in the lungs of patients. In addition, we demonstrate for the first time that PPMOs targeted against bacterial pathogens can be successfully delivered via the aerosol route. PPMOs represent a novel approach for the development of antibacterials in multidrug-resistant pathogens such as the Bcc.

Antimicrobial Activity of Halogenated Biaryl Compound against Gram-Positive Pathogens

Author Block:

K. N. Shah[1], P. N. Shah[1], H. Gao[2], O. Ogun[1], M. Yabe-Gill[3], L. Kurti[2], C. Cannon[1]; [1]Texas A & M Hlth.Sci. Ctr., College Station, TX, [2]Rice Univ., Houston, TX, [3]UT Southwestern Med. Ctr., Dallas, TX

Abstract Body:

Fatal infections caused by multi-drug resistant Gram-positive pathogens are increasing at an alarming rate, yet the antimicrobial pipeline is rapidly shrinking. Resistance against several standard-of-care antimicrobials including vancomycin has been reported. MC21-A (C58), a natural brominated biaryl, is a strong candidate for development as a clinically relevant antimicrobial due to its ability to eradicate methicillin-resistant *Staphylococcus aureus* (MRSA). However, its progress has been mired by cumbersome biosynthesis and purification. We have developed a unique scheme that allows large-scale synthesis of C58 and its analogues. From a library of 33 synthesized compounds, two non-toxic candidates, C58 and C59, exhibit superior antimicrobial activity over standard-of-care antibiotics against bacteria growing in planktonic, stationary, and biofilm modes. These compounds inhibit and eradicate 90% of 37 test MRSA strains (MIC_{90}, MBC_{90}) at lower concentrations compared with vancomycin and linezolid. Similar results were obtained with *S. epidermidis* and *Streptococcus pneumoniae.* An MRSA strain grown to stationary phase exhibits dose dependent eradication at a higher rate with C59 treatment compared with vancomycin. Similarly, C58 treatment (16 μg/mL) results in complete eradication of established MRSA biofilms after 6 hours. Incubation of MRSA strain USA300 with sub-MIC concentrations of vancomycin, but not C59, results in development of spontaneous resistance. Additionally, these biaryls are non-toxic to on- and off-target mammalian cells at concentrations that exert antimicrobial activity; the lethal dose at median cell viability (LD_{50}) is at least five fold higher than the MBC_{90}. Finally, we have verified that the biaryl mechanism of action involves membrane permeabilization. Our results demonstrate the potential of biaryls as non-toxic, next-generation antimicrobials that can be structurally optimized to yield superior, pathogen-specific efficacy over current antimicrobials.

Comparative Evaluation of Oritavancin, Dalbavancin, and Tedizolid *In Vitro* Antimicrobial Activity Against Clinical Isolates of *Staphylococcus aureus* at a Tertiary Care Hospital

Author Block:

F. Foolad, C. Young, D. Newton, A. Smith, T. S. Patel; Univ. of Michigan Hlth.System, Ann Arbor, MI

Abstract Body:

Background: *Staphylococcus aureus* continues to be a problematic pathogen causing high rates of morbidity and mortality. New antimicrobial agents, oritavancin, dalbavancin, and tedizolid, have been added to the arsenal of agents used to treat infections caused by *S. aureus*. However, there are minimal data comparing the in vitro activities of these new antimicrobials for clinical isolates from a variety of sources using a custom TREK Sensititre panel.**Methods:** All cultures from patient infections with isolated *S. aureus* from February 2015 to November 2015 were identified at the University of Michigan Health System. Organisms were identified by MALDI-TOF mass spectrometry using the Bruker Microflex instrument (Bruker Daltonik, Bremen, Germany). Minimum inhibitory concentrations (MICs) for all antimicrobials were determined using broth microdilution methods (TREK Diagnostic Systems, Cleveland, Ohio). The percentage of isolates within the susceptible range was determined using Clinical and Laboratory Standards Institute (CLSI) and US Food and Drug Administration (FDA) breakpoint criteria.**Results**: A total of 2,579 *S. aureus* isolates from clinical specimens were included. Similar MIC_{50} and MIC_{90} were determined for methicillin-sensitive *S. aureus* (MSSA) and methicillin-resistant *S. aureus* (MRSA, table). Using published interpretive criteria, 98.8%, 100%, and 99.8% of all *S. aureus* isolates were considered susceptible to oritavancin, dalbavancin, and tedizolid, respectively as compared to 100% and 99.7% susceptible to vancomycin and daptomycin.**Conclusions**: Oritavancin, dalbavancin, and tedizolid demonstrated good in vitro activity against *S. aureus* isolated from a variety of clinical infections with no major differences observed between MRSA and MSSA.

	Range (µg/ml)	**MIC_{50} (µg/ml)**	**MIC_{90} (µg/ml)**
MSSA (n= 1550)			
Oritavancin	≤0.004 - >0.5	0.03	0.06
Dalbavancin	≤0.06 - >0.25	≤0.06	≤0.06

Publishing Title:

Effectiveness of Oritavancin to Treat Acute Bacterial Skin and Skin Structure Infections in a Physician Owned Infusion Center

Author Block:

P. J. Anastasio[1], P. Wolthoff[2], **W. Fan**[3]; [1]Emerald Coast Infusion Ctr., Fort Walton Beach, FL, [2]Med. Data Analytics, Parsippany, NJ, [3]The Med.s Company, Parsippany, NJ

Abstract Body:

Background: Acute bacterial skin and skin structure infections (ABSSSI) can be treated in the outpatient setting, but most IV antibiotics require multiple days of treatment. Single-dose oritavancin has been demonstrated to be non-inferior to 7-10 days of vancomycin in two randomized controlled trials, but little is known about its effectiveness in the real world. The objective of this analysis was to assess the effectiveness of oritavancin in the real world. **Methods:** A retrospective, chart-review was conducted at the Emerald Coast Infusion Center of consecutive patients who received at least one dose of oritavancin for treatment of ABSSSI from August 6, 2014 to June 30, 2015. Patients were matched by age, gender, insurance status, type of ABSSSI, diabetes, BMI and fever to standard of care (SOC) patients who received either vancomycin, daptomycin, dalbavancin or other antibiotics. Clinical response was assessed between 5 to 30 days post treatment. Success was defined as either cured or improved at follow-up visit. Clinical and resource utilization data were extracted from patient records. **Results:** Fifty-nine (59) oritavancin patients and 59 SoC patients were matched. The average age was 64.6 years, with 57.6% female. 57.6% cellulitis, 23.7% abscess and 18.6 % wound infection. Eighteen patients had confirmed MRSA. 41 oritavancin patients and 31 standard of care patients could be assessed for clinical cure. Oritavancin had a 90% success rate (cured or improved) compared to 77% in SOC, with 73% vs. 48% considered cured, respectively. Similar success rates can be seen in clinically-relevant subgroups such as elderly, female, diabetes, and infection type. The average antibiotic treatment length was 7.2 days for SOC vs. 1 day for oritavancin. No oritavancin patients visited the ED following index treatment compared to 2 (3%) in the SOC group, and no oritavancin patients were admitted to a hospital following index treatment, compared to 3 (5%) in the SOC group. **Conclusions:** Data from this analysis of ABSSSI treatment in an outpatient infusion center indicate that oritavancin is effective in real world use. Cure rates were higher than the standard of care, while use of follow-up resources was lower.

***In Vitro* Activity of Oritavancin against Gram-positive Pathogens Isolated in Canadian Hospitals from 2011 to 2015**

Author Block:

J. Karlowsky[1], H. Adam[1], M. Baxter[2], K. Nichol[1], B. Weshnoweski[1], R. Vashisht[2], D. Hoban[1], G. G. ZHANEL[2], CARA; [1]Diagnostic Services Manitoba, Winnipeg, MB, Canada, [2]Univ. of Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: Oritavancin (ORI) is a semisynthetic lipoglycopeptide that was approved by the US FDA in 2014 for the single dose (1200 mg) intravenous treatment of adult patients with acute bacterial skin and skin structure infections caused by susceptible isolates of designated gram-positive bacteria, including methicillin-susceptible and methicillin-resistant *Staphylococcus aureus* (MSSA and MRSA). This surveillance study assessed the susceptibility of recent clinical isolates to ORI and comparators.**Methods:** From January 2011 to October 2015, 12-15 sentinel Canadian hospital laboratories were requested to submit consecutive bacterial pathogens, 1 per patient, from blood (*n* = 100), respiratory (*n* = 100), urine (*n* = 25), and wound (*n* = 25) infections each year to the CANWARD Surveillance Program (Winnipeg, MB, Canada). Antimicrobial susceptibilities were determined for 4,480 gram-positive isolates using the CLSI broth microdilution standard method (M07-A10, 2015). MICs for ORI were determined using validated frozen broth microdilution panels provided by The Medicines Company (St. Laurent, PQ, Canada). MICs were interpreted using CLSI M100-S25 (2015) breakpoints against indicated species, where available; ORI MICs were interpreted using US FDA breakpoints.**Results:** MIC and % susceptibility data for selected organisms and antimicrobial agents are presented in the Table.

	MIC_{90} (µg/mL)/% Susceptible

Oritavancin Activity Against *Enterococcus faecalis In vitro* and in a Murine Thigh Infection Model

Author Block:

M. Sabet[1], Z. Tarazi[1], D. Lalonde Seguin[2], F. F. Arhin[2], G. Moeck[2], D. C. Griffith[1]; [1]The Med.s Company, San Diego, CA, [2]The Med.s Company, St-Laurent, QC, Canada

Abstract Body:

Background: Oritavancin (ORI) is a lipoglycopeptide that has in vitro activity against enterococci. We evaluated the pharmacodynamics of a single dose of ORI against *Enterococcus faecalis* (EF) isolates in a neutropenic murine thigh infection (TI) model and in vitro time-kill (TK) assays.**Methods:** 3 vancomycin-susceptible EF isolates were tested: ATCC 29212, 23241 and 33186. MIC determinations followed CLSI M7-A10 guidelines while MBC and TK assays followed M26-A guidelines. TK assays were conducted at both standard and high inoculum density (~10^6 and ~10^8 colony forming units (CFU)/ml, respectively) using ORI at concentrations approximating its mean free peak (*f*C_{max}, 16 µg/mL) in plasma based on a single 1200 mg dose. TI was established in neutropenic mice (n = 2/group) with an inoculum of 10^6 CFU in each thigh. ORI and vancomycin (VAN) were dosed 40 mg/kg once (IV) and 120 mg/kg BID (SQ), respectively, which produce *f*AUCs equivalent to human exposures. Efficacy was evaluated by determining mean log CFU/thigh changes from baseline after 24 h treatment.**Results:** ORI MICs ranged from 0.015 - 0.03 µg/mL against the 3 EF isolates and ORI MBC/MIC ratios ranged from 4 - >16. In TK assays, ORI was bactericidal (>= 3 log kill by 24h) against all isolates at both inoculum densities. Results in the TI model are shown in the table below.

Strain	**Compound**	**Total Daily Dose (mg/kg)**	**MIC (µg/mL)**	**Change in Log CFU/thigh at 24h**
*E. faecalis A*TCC 29212	ORI	40	0.016	-1.24
	VAN	240	2	-0.51

E. faecalis ATCC 23241	ORI	40	0.016	-1.50
	VAN	240	4	-1.24
E. faecalis ATCC 33186	ORI	40	0.03	-0.76
	VAN	240	1	-0.86

Conclusion: ORI was bactericidal at fC_{max} concentrations in TK assays. In the TI model, ORI activity was similar to VAN and both drugs produced bacterial killing at human equivalent exposures. Further studies are warranted.

Publishing Title:

Assessment of Antibacterial Activity (AA) of Oritavancin (ORI), Dalbavancin (DAL) andVancomycin (VAN) against Non-Dividing (ND) Methicillin-Resistant *Staphylococcus aureus* (MRSA) Using Fluorescence Microscopy (FM)

Author Block:

A. Belley, D. Lalonde-Seguin, F. Arhin, G. Moeck; The Med.s Company, St-Laurent, QC, Canada

Abstract Body:

Background: Antibacterial agents that kill ND bacteria may be of utility in treating persistent infections. ORI and DAL are bactericidal lipoglycopeptides approved for acute bacterial skin and skin structure infections. Using FM, we assessed the AA of ORI, DAL and VAN against MRSA isolates maintained in a ND state in vitro.**Methods:** Stationary-phase cultures of MRSA ATCC 43300 and ATCC 700698 were resuspended in 5 mM HEPES pH 7.2 containing 0.1% dextrose and 0.002% polysorbate-80 (Buffer) at 10^7 CFU/ml and exposed to 4 µg/ml of ORI or 16 µg/ml of either DAL or VAN for 24h at 37ºC. Bacterial viability (BV) was assessed by serial dilution plating and by FM using the Live/Dead *Bac*light reagent containing the green fluorophore SYTO 9 (live cells appear green) and the red fluorophore propidium iodide (dead cells appear red).**Results:** Control (unexposed) cultures of MRSA ATCC 43300 in a ND state remained viable in Buffer over 24h with the majority of bacteria observed appearing green by FM (Figure, FM panel). ND ATCC 43300 exposed to 4 µg/ml ORI for 2h and 24h mostly appeared red by FM, consistent with concomitant decreases in BV of 3.2 ± 1.1-log and 4.8 ± 0.0-log CFU/ml, respectively. In contrast, the majority of bacteria exposed to 16 µg/ml of either DAL or VAN for 24h appeared green by FM, consistent with observed minor decreases in BV of 0.5 ± 0.6-log and 0.4 ± 0.4-log CFU/ml, respectively. Similar trends in FM and BV were observed for MRSA ATCC 700698 in a ND state exposed to each agent (data not shown). **Conclusion:** The AA of ORI against ND MRSA, as confirmed by FM and BV assessment, may prove to be of benefit against persistent infections.

Evaluation of the Development of Resistance in a Novel Class of Antimicrobial Agents

Author Block:

J. REMY, A. Marra, E. Duffy; Melinta Therapeutics, Inc., New Haven, CT

Abstract Body:

Background: The pyrrolocytosines have been designed and optimized for broad-spectrum activity, focusing on isolates resistant to commercial antibiotics. As novel protein synthesis inhibitors interacting principally with ribosomal RNA in the large subunit, they are not expected to exhibit a high frequency of resistance. The spontaneous development of resistance for this novel class was evaluated. **Methods:** Pyrrolocytosine exemplars were evaluated for spontaneous resistance. In this study, *Escherichia coli* W3110 was studied as it allowed for sequencing of any resistant mutants. *E. coli* W3110 was inoculated onto plates containing compounds at 2X, 4X, and 8X MIC. After 48 hrs the resistance frequency (RF) for each compound was determined. Colonies were chosen for further evaluation. Mutant MICs for the pyrrolocytosines and commercial agents were determined by broth microdilution from plates containing the pyrrolocytosine selecting compound at day 1 and following 10 days of drug-free passaging. Cross-resistance (XR) to an antibiotic was defined as being >4X the parent MIC. Growth curves were performed on representative mutants to determine fitness cost compared to the parent. DNA was isolated from nine mutants selected on plates containing RX-P873, and whole genome sequencing was performed.**Results:** RFs depended on the drug concentration and the inoculum (~10^{-5} to ~10^{-10}). Fewer than half of the pyrrolocytosines generated mutants with elevated MICs to the selecting agent. XR was observed for the aminoglycosides tested and some beta-lactams, to differing extents. A fitness cost was observed for most of the mutants, with log phase growth rates of up to 180 minutes. For RX-P873, whole-genome sequencing revealed there was no single mutation common to all mutants and no mutations were identified in the ribosomal target.**Conclusions:** Although the RFs were higher than expected for this novel class, there are three main findings: mutants with elevated MICs to the selecting agent were uncommon; most mutants demonstrated a profound fitness cost and target-based resistance was not observed. These support the continued investigation of the pyrrolocytosines against multidrug- and extremely-drug resistant pathogens.

A Risk Assessment Framework for Antimicrobial Resistance Development Associated with the Use of Microbicides in Home and Personal Care Products

Author Block:

A. Amezquita, M. Parker, L. Knapp, D. Tang; Unilever, Sharnbrook, United Kingdom

Abstract Body:

Background: Responsible evaluation and development of new microbicidal systems need to consider the risk of microbial resistance developing during their use, particularly where clinically-relevant cross-resistance might emerge. There are currently no risk assessment frameworks available for this purpose, resulting in lack of consistency of data interpretation from susceptibility studies and ultimately on decisions on safety. We have therefore developed a risk assessment framework and validated it with six different case studies.**Methods:** The framework consists of three tiers of increasing experimental data demands. The starting point (Tier 0) is an evidence-weighted model for assessment of candidate microbicides considering realistic exposure (consumer use) conditions; this progresses to Tier 1, which is an *in vitro* exposure test on a broad range of bacteria in various physiological states (planktonic, biofilm, and desiccated cells); and, Tier 2, which consists of mechanism of resistance studies for favoured systems. The end-point of the framework is the probability of resistance development (i.e. microbicide resistance and cross-resistance to clinically-relevant antimicrobials) following use of home and personal care (HPC) products containing microbicides. Validation was conducted with the following products (microbicides in brackets): hand soap bar (thymol, terpineol, silver), liquid hand wash (thymol, terpineol, triclosan), mouthwash (zinc sulphate, sodium benzoate), eye make-up remover (chlorhexidine), general purpose cleaner (benzalkonium chloride), and hand dish wash liquid (sodium salicylate).**Results:** Enough evidence was available for the hand soap bar to conclude on negligible risk of resistance development at Tier 0. The other formulations were taken through to Tier 1, resulting in no significant changes in microbicide susceptibility and no development of clinical resistance to any of the antibiotics tested (using EUCAST breakpoints). As Tier 0 and Tier 1 provided sufficient data/information to conclude on safety, Tier 2 data were not needed for these risk assessments.**Conclusions:** The risk assessment framework is evidence and realism-based. It provides a systematic approach to assure HPC products are safe by design.

Publishing Title:

Treatment of Acute Bacterial Skin and Skin Structure Infection (ABSSSI) with Single Dose Dalbavancin in the Intravenous Drug User (IVDU) Population

Author Block:

P. L. Gonzalez, U. Rappo, K. Akinapelli, S. Puttagunta; Allergan, PLC, Jersey City, NJ

Abstract Body:

Background: Medical care for patients with a history of IVDU is complicated by medical, social and economic issues that affect adherence to treatment. We describe the demographics and outcomes for patients with and without a history of IVDU in a phase 3 clinical trial evaluating the efficacy of a single 1500 mg dose of dalbavancin vs a 2-dose regimen for treatment of ABSSSI. **Methods:** In a double-blind, single dummy Phase 3 trial, adult patients with ABSSSI were randomized to dalbavancin 1500 mg as a single IV infusion over 30 minutes *or* 1000 mg IV on Day 1 and 500 mg IV on Day 8. The primary endpoint was ≥20% reduction in erythema 48-72 hours after start of treatment. Clinical success assessed on Days 14 and 28 was based on a composite of clinical measures. P values were obtained using Fisher's exact test for categorical variables and the Wilcoxon rank sum test for continuous variables.**Results: Table 1 Baseline Characteristics**

Characteristic	**IVDU (n=212)**	**Without IVDU (n=486)**	**p-value**
Age, y, mean	44.9	49.6	<0.0001
Male (%)	67.0	54.5	0.003
Hispanic or Latino (%)	41.0	4.9	<0.001
BMI, kg/m^2, median	25.1	28.2	<0.0001
Major abscess (%) Traumatic wound/surgical site infection (%) Cellulitis (%)	42.9 40.1 17.0	18.1 21.2 60.7	<0.001
SIRS (%)	28.3	50.0	<0.0001
Bandemia ≥ 10% (%)	4.9	26.7	<0.0001

Table 2 Clinical Outcomes

Timing	Outcome (Population)	IVDU		Without IVDU	
		Dalbavancin Single-Dose n/N (%)	**Dalbavancin 2-dose n/N (%)**	**Dalbavancin Single-Dose n/N (%)**	**Dalbavancin 2-dose n/N (%)**
48-72 hours	Treatment response (ITT)	94/105 (89.5)	92/107 (86.0)	190/244 (77.9)	202/242 (83.5)
	95% CI	3.5 (-5.6, 12.7)		-5.6 (-12.7, 1.4)	
Day 14	Clinical success (CE)	78/87 (89.7)	78/85 (91.8)	189/215 (87.9)	192/217 (88.5)
	95% CI	-2.1 (-11.5, 7.1)		-0.6 (-6.8, 5.6)	
Day 28	Clinical success (CE)	80/85 (94.1)	72/75 (96.0)	170/186 (91.4)	175/192 (91.1)
	95% CI	-1.9 (9.7, 6.0)		1.3 (-5.7, 6.1)	

Adverse events were similar between the IVDU and non-IVDU, and between the single and 2-dose regimens.**Conclusion:** Patients with a history of IVDU had similar success rates for treatment of ABSSSI at all time-points as those without IVDU, with either regimen. A single, convenient 30-minute IV infusion and lack of a need for indwelling IV access may optimize adherence without increasing the potential for abuse in the IVDU.

Publishing Title:

Control of *Staphylococcus aureus* and *Staphylococcus epidermidis* Skin Strains Virulence by Substance P and Cutaneous Defense Peptides

Author Block:

A. R. Ndiaye, L. MiJouin, M. G. J. Feuilloley; Lab. of Microbiol., Signals and Microenvironment, Evreux, France

Abstract Body:

Background: Skin is the largest human neuroendocrine organ and hosts the second most numerous microbial population, but little is known about the bacteria/skin interactions. In 2013, Mijouin *et al*. demonstrated that Substance P (SP) increases *Bacillus cereus* virulence, an occasional member of the cutaneous microflora. Hence, s SP can likely have the same effect on other members of the cutaneous microflora such as *Staphylococcus aureus (SA) and Staphylococcus epidermidis (SE).***Methods:** The effect of SP and two antimicrobial peptides were tested on bacterial cytotoxicity, its biofilm activity. Virulence factors were identified via 2D gel. The bacteria virulence was also observed on Reconstitued Epidermidis genome via a qRT-PCR of 64 genes.**Results:** SP promotes *SA* and *SE* virulence and enhances their adhesion of on keratinocytes. However, whereas *SE* reacts to SP by an increase in biofilm formation activity, *S. aureus* shows a raise in Staphylococcal Enterotoxin C2 (SEC2) production. The ribosomal elongation factor Ef-Tu was identified as the SP binding site in *S. aureus* and *S. epidermidis.* Tested at non-antibacterial concentrations, human B-defensin 2 (HBD2) and the cathelicidin LL37 alter the biofilm formation activity and cytotoxicity of *SE* and *SA*. *SA* and *SE* treated with SP showed some effects on the 64 genes selected for qRT-PCR.**Conclusion:** *Staphylococci* are the principal human skin commensal bacteria but they have also high infectious potential. As SP strongly increases during inflammation, stress or depression, this could mediate an increase in Staphylococci virulence. This process should explain the link between some skin inflammatory syndromes involving the skin microbiote but where dysbiosis are rarely observed, such as atopic dermatitis, and the mental status of individuals.

Exploring *Escherichia coli* Clinical Isolate Collateral Sensitivity Networks

Author Block:

N. L. Podnecky[1], E. G. A. Fredheim[1], J. M. Kloos[1], A. L. G. Utnes[1], R. Primicerio[1], Ø. Samuelsen[2], P. J. Johnsen[1]; [1]UiT – The Arctic Univ. of Norway, Tromsø, Norway, [2]Univ. Hosp. of North Norway, Tromsø, Norway

Abstract Body:

Background: Recent studies on collateral sensitivity (CS) suggest the use of suppressive drug pairs and drug cycling may reduce antimicrobial resistance (AMR) development and ensure future treatment options. CS patterns and the underlying mechanism(s) have been investigated in a few laboratory and clinical strains. The purpose of our study is to further map CS networks across diverse clinical isolates and determine if and to what extent genetic diversity and resistance mechanism contribute to CS. In this study we focus on *Escherichia coli* and antimicrobials commonly used for urinary tract infections.**Methods:** AMR mutants were selected for resistance to single antimicrobials (ciprofloxacin, CIP; mecillinam, MEC; nitrofurantoin, NIT; and trimethoprim, TMP) in 10 genetically diverse pan-susceptible *E. coli* strains from the ECO-SENS collection of clinical urinary tract infection isolates to achieve clinically significant resistance. Minimal inhibitory concentration (MIC) testing for 16 antimicrobials was determined by gradient strip diffusion assays. The overarching collateral effects were modeled and assessed by multivariate statistical approaches.**Results:** MIC analysis of 40 AMR mutants revealed frequent and diverse collateral effects both within and across drug classes. A principal component analysis of the log MIC values showed CIP and MEC mutants display clear patterns of cross-resistance and CS, respectively, in most of the strains. CS and cross-resistance in TMP and NIT mutants were overall less pronounced. In our study, the selection drug had a greater impact on CS networks than strain background.**Conclusions:** From these experiments we can begin to understand cross-resistance and CS networks in a broader context within *E. coli*. MEC is the preferred treatment as it increases susceptibilities to many clinically relevant antimicrobials, while TMP would maintain pre-existing susceptibilities. Conversely, CIP resistance will greatly limit downstream treatment options. Broader knowledge of CS networks will provide important insight for future treatment recommendations.

Evaluation of Extended- Versus Traditional-infusion Cefepime in Gram-negative Pneumonia and Bacteremia

Author Block:

M. Guido[1], S. Liao[1], **A. Miller**[2]; [1]Univ. of Cincinnati Med. Ctr., Cincinnati, OH, [2]Univ. of Kansas Hosp., Kansas City, KS

Abstract Body:

Based on the challenges of treating multi-drug resistant Gram-negative infections, several Monte-Carlo simulations have demonstrated higher probability of target attainment when administering cefepime by extended (4 hour) infusion (EI) compared to traditional (30 minute) infusion (TI). Studies showing conflicting results question whether EI cefepime is necessary for all indications. This study was designed to evaluate the clinical response with EI cefepime compared to TI and identify unique population that would benefit from EI cefepime.This single center, retrospective study evaluated subjects receiving at least 48 hours of cefepime for treatment of pneumonia or bacteremia. Subjects with a positive blood or respiratory culture for a Gram-negative pathogen were included. Subjects were excluded if they received cefepime at a dose not appropriate for renal function. The primary outcome was clinical response, defined for each included indication, which was evaluated at the point of antibiotic de-escalation or end of therapy.A total of 110 subjects met criteria for inclusion during the study period. Baseline characteristics were similar except for an older population in TI group (65.7 vs 57.3 years, p=0.01). Approximately 49% of subjects were treated for *Enterbacteriaceae* infection and 51% were treated for infection caused by *Pseudomonas* (PSA) or *Acinetobacter spp*. Overall, there was no difference in clinical response between the EI and TI group (78% vs 81.7%, p=0.811). No difference was found between EI and TI cefepime based on treatment indication or isolated pathogen. A multi-variable logistic regression analysis showed no significant increase in odds ratio to predict clinical improvement for independent variables including age, presence of critical illness, pneumonia, and SOFA score. Isolate MIC greater than or equal to 8 mg/L, while not statistically significant, had the most suggestive effect on clinical outcome (OR 0.592, CI=0.192-1.921).Implementation of EI cefepime did not improve clinical outcome when compared to traditional infusion. The effect of extended infusion for pathogens with an MIC of greater than or equal to 8 mg/L is a trend that should be further explored, as it is possible that EI cefepime may have the greatest impact on clinical outcome in this population.

Publishing Title:

Evaluation of Patients with Complicated Intra-abdominal Infections (cIAI) and Concomitant Bacteremia (CB) from IGNITE1: A Phase 3 Study to Evaluate the Efficacy and Safety of Eravacycline (ERV) versus Ertapenem (ETP) in Complicated Intra-Abdominal Infections (cIAI)

Author Block:

M. Michaud[1], **H. Hoffman-Roberts**[1], A. Marsh[1], P. Horn[1], J. Solomkin[2]; [1]Tetraphase Pharmaceuticals, Watertown, MA, [2]Univ. of Cincinnati, Cincinnati, OH

Abstract Body:

BACKGROUND: Empiric treatment of cIAI represents a clinical challenge because of the polymicrobial etiology and the emergence of antibiotic resistance. There is no consensus on the best way to treat patients with cIAI and CB. We report results in a subgroup of patients in IGNITE1 with cIAI and CB.**METHODS:** In this randomized, double-blind, non-inferiority phase 3 trial, patients with documented cIAI were randomized (1:1) to either ERV (1.0 mg/kg IV q12h) or ETP (1g IV daily) for up to 14 days. Clinical outcome at the test of cure (TOC) visit, approximately 28 days after randomization, was the primary efficacy endpoint in the microbiological intent-to-treat (micro-ITT) population (≥ 1 pathogen consistent with cIAI in baseline cultures).**RESULTS:** 541 patients were randomized and 446 were included in the micro-ITT population. The study met criteria for non-inferiority (Δ=-0.8, 95% CI=-7.1 to 5.5). 40 patients had positive blood cultures of which 5 cultures on post-hoc analysis were determined to be contaminants. Among the 35 remaining patients, (ERV 18, ETP 17), there were 44 baseline pathogens identified in the blood. The most common pathogens isolated were *Streptococcus* sp. 12 (27.3%), *E. coli* 10 (22.7%), and *Bacteroides* sp. 8 (18.2%). 24/35 (68.6%) patients had at least one organism present in the blood duplicated in the IAI culture. Patients with CB received an average 1.2 days longer duration of antibiotic therapy.

	Combined (ERV + ETP)		**Eravacycline**		**Ertapenem**	
	CB (n=35)	**No CB (n=411)**	**CB (n=18)**	**No CB (n=202)**	**CB (n=17)**	**No CB (n=209)**
Average duration of therapy (days)	8.3	7.1	8.0	7.2	8.5	7.0
Diagnosis Complicated appendicitis	8 (22.9%)	124 (30.2%)	4 (22.3%)	61 (30.2%)	4 (23.5%)	63 (30.1%)

Other cIAI	27 (77.1%)	287 (69.8%)	14 (77.7%)	141 (69.8%)	13 (76.5%)	146 (69.9%)
Clinical Response Cure	29 (82.9%)	360 (87.6%)	17 (94.4%)	174 (86.1%)	12 (70.6%)	186 (89.0%)
Failure	1 (2.8%)	29 (7.1%)	0 (0.0%)	19 (9.4%)	1 (5.9%)	10 (4.8%)
Indeterminant	5 (14.3%)	22 (5.3%)	1 (5.6%)	9 (4.5%)	4 (23.5%)	13 (6.2%)

CONCLUSIONS: These data suggest that the presence of CB in cIAI does not increase treatment failure or require prolonged antimicrobial therapy duration. Treatment outcomes among patients with cIAI and CB were similar with ERV compared to those without CB. High success rates in this study suggest ERV may be a treatment option for patients with cIAI and CB.

Piperacillin-Tazobactam versus Carbapenem for the Treatment of Blood Stream Infections Caused by Extended-spectrum Beta-Lactamase Producing *Enterobacteriaceae*

Author Block:

N. N. MUKHTAR, L. A. AKKIELAH, M. M. AYAS, L. N. ALBALAWI, M. M. SHOUKRI, S. I. ALTHAWADI, A. A. ALRAJHI, A. S. OMRANI; King Faisal Specialist Hosp. & Res. Ctr., Riyadh, Saudi Arabia

Abstract Body:

Background: The role of piperacillin-tazobactam (PTZ) in the treatment of blood stream infections (BSI) caused by extended-spectrum beta-lactamase producing *Enterobacteriacea*e (ESBL-PE) remains unconfirmed. We investigated clinical outcomes in patients with ESBL-PE BSI who received empiric therapy with PTZ or a carbapenem (CAR). **Methods:** In a retrospective, cohort, single-center study, we included adult patients who received empiric PTZ or CAR therapy within 48 hours of isolation of an ESBL-PE from a blood culture. The primary endpoint was 30-day mortality. Chi square, t-test, Kaplan-Meier and Cox Regression were used for the analysis.**Results:** The study included 93 patients (43% males), mean age 53.8 years (SD 19.9). The most frequent source of BSI was the urinary tract (45.2%). All BSI were caused by *E. coli* (66.7%) or *K. pneumoniae* (33.3%). Patients received CAR (48.4%) or PTZ (51.6%). Baseline characteristic were similar except underlying diagnosis of cancer (PTZ 54.2% *vs.* CAR 26.7%; *P* 0.007) and the presence of central venous lines (PTZ 25.0% *vs.* CAR 46.7%; *P* 0.029). 30-day mortality was not significantly different between the two groups (PTZ 6.3% *vs.* CAR 13.3%; *P* 0.225 (log rank test). In adjusted analysis, cancer and Charlson co-morbidity index were associated with 30-day mortality, but not CAR therapy (HR 0.27, 95% confidence interval 0.06 to1.17, *P* 0.08) (Table).**Conclusion:** PTZ is not associated with increased mortality in patients with ESBL-PE BSI. Further evaluation in randomized clinical trials is required to confirm these findings.

Clinical Outcomes with Ceftazidime-Avibactam in Patients with Carbapenem-Resistant *Enterobacteriaceae* (Cre) Infections

Author Block:

M. King, J. Gallagher; Temple Univ., Philadelphia, PA

Abstract Body:

Background: Ceftazidime-avibactam is a cephalosporin-beta-lactamase inhibitor combination that is active against *Enterobacteriaceae* and *Pseudomonas aeruginosa* that is resistant to other agents, including carbapenems and late-generation cephalosporins. This purpose of this study is to describe the outcomes of patients receiving ceftazidime-avibactam for CRE infections.**Methods**: A retrospective chart review was completed from March 2014 through December 2015 at Temple University Hospital for adult patients who received ceftazidime-avibactam for a CRE infection, defined as having an MIC>4 to imipenem and meropenem. Patients were included if they received ceftazidime-avibactam for at least 24 hours. Primary outcomes were 30-day and in-hospital mortality. Microbiologic and clinical outcomes were also evaluated. Microbiological success required a negative culture at the end of therapy. Clinical success was judged by improved symptoms and defervesence.**Results:**

Characteristic	**Results (N=9)**
Male gender (n,%))	6 (67%)
Age (median, range)	70 (26-82)
Charlson Comorbidity Index (median, range)	4 (2-11)
Pitt Bacteremia Score (median, range)	4 (0-7)
ICU (n,%)	7 (78%)
Organ transplant (n,%)	6 (67%)
Organism (n, %)) *Klebsiella pneumoniae* *Enterobacter aerogenes*	 8 1
Primary Infection (n,%) Pneumonia Bacteremia Urinary tract Intra-abdominal	 5 1 2 1

30-day mortality (n,%)	2 (22%)
Microbiologic Cure (n,%)	5 (55%)
Clinical Success (n,%)	5 (55%)

Conclusion: In our series, 5/9 (55%) of patients had both clinical and microbiological success, and 7/9 (78%) were alive 30-days after therapy. Ceftazidime-avibactam is a potential option for patients with multi-drug resistant organisms causing *Enterobacteriaceae* infections, including those in intensive care.

Colistin Nephrotoxicity: Not as High as We Fear! -A Study from South India

Author Block:

A. Ghafur, V. Lakshmi, v. P; apollo speciality Hosp.,, Chennai, India

Abstract Body:

Background: Colistin is extensively used in tertiary care hospitals in countries with high prevalence of carbapenem resistant Gram-negative bacteria(CRGNB). Though nephrotoxicity is a well know side effect, there is limited published data from India, a country with very high CRGNB rate and high colistin utilization. Aim of our study was to analyse nephrotoxicity data in patients who received colistin for the treatment of CR GNB bacteremic infections**Methods:** We conducted a retrospective observational study of patients with CRGNB blood stream infections treated with colistin,in our oncology and bone marrow transplant centre. RIFLE score was used to detect nephrotoxicity while on colistin therapy. Concomitant administration of other nephrotoxic agents was looked into. **Results:** Over a 3-year study period (2011-14), we could identify 91 patients satisfying study criteria. Out of 91 cases of CRGNB bacteremia treated with colistin,10 had pre-existing renal failure and so excluded. Mean colistin dose in the study group was 8.6± 1.02 million units/day. Of the 81 patients included in the study,9(11.11%) developed renal impairment during colistin therapy ,as per RIFLE criteria (3 risk, 6 failure). Of these, 2 received concomitant diuretics, 3 Liposomal amphotericin B, 2 aminoglycosides, 4 inotropes, and 7 out of 9 received 2 nephrotoxic agents in addition to colistin. **Conclusions:** Colistin nephrotoxicity rate in our study was low and most patients who developed renal impairment received other concomitant nephrotoxic agents.

Publishing Title:

Analysis of Diabetes Patients with Complicated Intra-abdominal Infection or Complicated Urinary Tract Infection in Phase 3 Trials of Ceftolozane/Tazobactam

Author Block:

M. W. Popejoy, B. Miller, J. A. Huntington, E. Hershberger, J. Long; Merck and Co., Inc., Kenilworth, NJ

Abstract Body:

Diabetes mellitus (DM) increases susceptibility to bacterial infections and is often associated with poor outcome. Ceftolozane/tazobactam (C/T) is an IV antibacterial with activity against Gram-negative pathogens approved for treatment of complicated intra-abdominal infection (cIAI), in combination with metronidazole (MTZ), and complicated urinary tract infection (cUTI). Patient (pt) characteristics and outcomes were evaluated post hoc in DM (65 cIAI; 133 cUTI) and non-DM pts (741 cIAI; 667 cUTI) in phase 3 trials of C/T. cIAI pts received C/T (1.5 g q8h) + MTZ (500 mg q8h) or meropenem (1 g q8h); cUTI pts received C/T (1.5 g q8h) or levofloxacin (750 mg qd). DM pts were older, had higher body mass index, and had a higher incidence of renal impairment than non-DM pts. In cIAI, a higher percentage of DM pts had APACHE II scores ≥10. Biliary and colonic infections were more common in DM pts; appendiceal infections were more common in non-DM pts (**Table**). In cUTI, pyelonephritis rates were similar in DM and non-DM pts. Bacteriology across all groups was similar; *E coli* was the most common pathogen. In general, DM pts had lower cure rates than non-DM pts; but, cure rates were similar between treatments in both indications (**Table**). Compared with non-DM pts, DM pts had a higher rate of adverse events (AEs; 49.0% vs 37.3%) and serious AEs (10.6% vs 4.6%). However, rates of treatment-related AEs were similar between DM and non-DM pts (8.2% vs 10.1%), suggesting comorbidities were responsible for differences in AE rates. AE rates were similar between treatments in both indications. This analysis showed that C/T was effective in treating cIAI and cUTI in DM pts despite a higher incidence of complicating factors.

Table. Patient Characteristics and Clinical Outcomes in DM and Non-DM Patients with cIAI and cUTI

Patient Characteristics	cIAI[1] (N=806)		cUTI[2] (N=800)	
	DM n=65	Non-DM n=741	DM n=133	Non-DM n=667
Mean age, years (SD)	61.7 (12.6)	49.6 (17.6)	59.1 (14.4)	46.5 (20.2)
Mean BMI, kg/m^2 (SD)	29.3 (6.6)	26.7 (5.2)	29.2 (5.4)	25.2 (5.5)
Mild to moderate renal impairment,[3] n (%)	32 (49.2)	211 (28.5)	63 (47.4)	211 (31.6)
APACHE II score ≥10, n (%)	22 (33.8)	126 (17.0)	–	–
Pyelonephritis, n (%)	–	–	106 (79.7)	550 (82.5)
Infection site, n (%)				
Biliary (cholecystitis)	21 (32.3)	121 (16.3)	–	–
Colon	14 (21.5)	104 (14.0)	–	–
Appendix	14 (21.5)	370 (49.9)	–	–
Clinical/composite[4] cure at TOC visit, m/n (%)				
C/T + MTZ	23/32 (71.9)	300/357 (84.0)	–	–
MEM	26/33 (78.8)	338/384 (88.0)	–	–
C/T	–	–	43/67 (64.2)	263/331 (79.5)
LVX	–	–	40/66 (60.6)	235/336 (69.9)

APACHE II, Acute Physiology and Chronic Health Evaluation II; BMI, body mass index; cIAI, complicated intra-abdominal infection; C/T, ceftolozane/tazobactam; cUTI, complicated urinary tract infection; DM, diabetes mellitus; LVX, levofloxacin; m, number of clinical cures in each category; MEM, meropenem; MTZ, metronidazole; N, number of patients in each group; n, number of patients in each category; "–", not applicable; TOC, test of cure.

[1]In the microbiological intent-to-treat population (all randomized patients with at least 1 baseline intra-abdominal pathogen regardless of susceptibility to study drug).

Publishing Title:

Efficacy of Fosfomycin for the Treatment of Cystitis in Abdominal Transplant Recipients

Author Block:

A. Loethen, M. Jorgenson, J. Fose, S. Emanuele, J. Smith; Univ. of Wisconsin Hosp., Madison, WI

Abstract Body:

Purpose: Increased use of antimicrobial prophylaxis following abdominal solid organ transplant (aSOT) has led to a rise the emergence of multidrug resistant organisms (MDRs) in this population. Fosfomycin (FOS) has broad-spectrum activity and is FDA approved for the treatment of uncomplicated urinary tract infections (UTIs) in women. Literature supports in vitro efficacy against MDR pathogens including vancomycin resistant enterococci (VRE). However, there is limited data supporting the clinical efficacy of FOS in aSOT. The aim of this study is to investigate the efficacy of FOS for the treatment of cystitis in the aSOT population.**Methods:** Retrospective chart review of all adult aSOT recipients treated with FOS from 1/1/2007-1/1/2013.**Results:** A total of 76 courses of FOS were identified in 64 patients, with all treatment courses documented as targeted therapy. Of the total courses, 66% were in woman. Patients with a history of renal transplant alone or in combination accounted for 74% of courses. Approximately 40% of courses were initiated in patients who had urinary foreign body placement, of which 20% were ureteral stents. The overall rate of treatment success was 85.5%. Enterococcus was isolated in 59% of courses, 72.2% of these were VRE. In 22% of courses FOS was used for the treatment of gram-negative organisms. Concomitant systemic antibiotics for other indications were present in 36.8% of treatment courses. These antibiotics were not targeted therapy for the urinary pathogens however, synergy with FOS could be possible. In the 11 treatment courses that failed, 90% were targeted against enterococcus, of which 82% were VRE. Six of these failures were then successfully retreated with nonsystemic therapy (FOS or nitrofurantoin). A subgroup analysis was conducted comparing single dose therapy (n=36) against multidose therapy (n=40) in a matched cohort of courses. There was no difference in the success rate of single dose therapy versus multidose therapy (80.6% vs 90%, p=0.24). However, concomitant systemic antimicrobial therapy was more common in the multidose group (70% vs 47.2%, p 0.04), possibly suggesting selection bias toward multidose for more subjectively ill individuals.**Conclusion:** FOS appears to be efficacious for the treatment of cystis in aSOT recipients and in this study single dose was non-inferior to multidose therapy.

Faropenem and Fosfomycin Combination Treatment for Complicated Urinary Tract Infections Due to Extended-Spectrum Beta-Lactamase Producing Enterobacteriaceae

Author Block:

A. Sakurai, K. Furukawa; St. Luke's Intl. Hosp., Tokyo, Japan

Abstract Body:

Background: There are few oral agents that are active against Extended-spectrum beta-lactamase producing Enterobacteriaceae (ESBL-E). Fosfomycin (FOM) has been used for lower urinary tract infections (UTIs), but increasing resistance is a problem. Faropenem (FRPM) is a penem-class oral beta-lactam agent and active against ESBL-E. We evaluated the susceptibility of urinary isolates positive for ESBL-E to FRPM and FOM, and the clinical efficacy of the combination treatment with FRPM and FOM for complicated UTIs due to ESBL-E. **Methods:** 1. We examined the susceptibility to FRPM and FOM of all urinary isolates positive for ESBL-E using K-B disc method from Nov 2012 to Feb 2015 at St. Luke's Intl Hosp (530beds acute care hosp in Tokyo).2. We also retrospectively investigated all the pts who were diagnosed as complicated UTIs due to ESBL-E, and were treated with combination of FRPM 1200mg/day and FOM 3.0g/day for minimum 7 days. Clinical success was defined as resolution of symptoms at 2 weeks after starting the treatment and 4 weeks after the completion of therapy.**Results:** 1**.** In total 220 ESBL-E isolated from urine cultures, the percentage and the susceptibility were; *E.coli* (89%): FRPM97.3%, FOM89.4%, *Klebsiella pneumoniae* (5.9%): FRPM69%, FOM23%, *K.oxytoca* (3.6%): FRPM88%, FOM13%, and *P. mirabilis* (3.6%): FRPM75%, FOM13%. 2. Total 37 pts (aged 71.3 ± 14.1, range 34-95; 23 women) with complicated UTIs due to ESBL-E were treated with FRPM and FOM. 3. Ten of the 37 pts were treated with only the combination without IV agents. Nine pts (90%) were successfully treated with the combination therapy. In only one pt the therapy was stopped because of diarrhea. 4. Twenty-seven pts were initially treated with Meropenem (88.8%) or PIPC/TAZ (11.1%) for median 14 days (7-34) and as a sequential therapy the pts received FRPM and FOM for median 14 days (6-75). 26 pts (96%) were successfully treated with no clinical recurrence for 4 weeks after the therapy. Side effect was diarrhea in 7 pts (18.9%).**Conclusion:** Combination of FRPM and FOM could be a good oral treatment of choice for complicated UTIs due to ESBL-E as a sequential therapy after IV carbapenem or as an initial outpatient therapy in mild infection.

Publishing Title:

Multicenter Evaluation of Clinical Outcomes Among Cefepime-treated Patients with Gram-negative Bloodstream Infections (Gnbsi) According to S, Sdd, or R Category

Author Block:

N. J. Rhodes[1], S. N. Rao[2], S. K. Wang[1], J. Liu[1], B. J. Lee[3], B. G. Chiu[4], J. Gener[1], E. Hang[1], K. Singh[5], M. H. Scheetz[1]; [1]Midwestern Univ., Downers Grove, IL, [2]Actavis, PLC, Gurnee, IL, [3]UC Irvine Hlth., Orange, CA, [4]Swedish Covenent, Chicago, IL, [5]Rush Univ. Med. Ctr., Chicago, IL

Abstract Body:

Background: Increased rates of clinical failure at cefepime (FEP) MICs within the susceptible range have been seen. Current Enterobacteriaceae (EB) breakpoints are S:≤2mg/L, SDD:4-8mg/L, R:≥16mg/L, yet few studies have reported mortality rates according to SDD and organism type.**Methods:** We conducted a retrospective, multicenter, cohort study of FEP-treated patients with GNBSI. Clinical variables: demographics, comorbidities, modified APACHE II (A2) score, ICU status, and concurrent neutropenia. Microbiologic variables: pathogen genera, MIC category, and EB status. Susceptibility testing: Vitek2 and E-test. Day 0 was considered the first culture-positive day of GNBSI. Primary outcome: all-cause, in-hospital, mortality stratified by MIC category. Secondary outcomes: A2-adjusted in-hospital mortality probability stratified by MIC category and organism subgroup (i.e., EB v. non-EB).**Results:** A total of 209 patients were included. The majority were male (56.9%) with a mean age of 57.2 years. The majority of patients (65.6%) received FEP as their first GNBSI therapy. A total of 45 patients (21.5%) were in the ICU on day 0. All cause in-hospital mortality occurred in 31 (14.8%) patients with death occurring in 15 (9.7%) S, 11 (33.3%) SDD, and 5 (23.8%) R (P=0.001) infections. A2 [mean (SD)] scores on day 0 were higher among those who died v. those who survived [16.4 (5.0) v. 14.2 (4.6); P=0.02]. Logistic regression of the MIC category, adjusted for A2, revealed that the probability of death within the cohort was significantly higher (P=0.002) at SDD v. S MICs [9.2% (S), 30.7% (SDD), 22.7% (R)]. Adjusted probabilities of death were higher (P=0.03) for SDD v. S MICs in non-EB [8.8%(S), 35.1%(SDD), 29.6%(R)] and numerically higher (P=0.06) in EB [9.0%(S), 26.6%(SDD), 16.7%(R)].**Conclusions:** Among FEP-treated GNBSI, SDD MICs carry an excess risk of mortality which was more similar to R MICs.

Hosp., Seoul, Korea, Republic of

Abstract Body:

Backgrounds: Colistimethate sodium (Colistin) has been used as one of the last options for carbapenem-resistant *Acinetobacter baumannii* (CRAB) bacteremia. However, the efficacy of colistin has not been fully investigated yet.**Methods:** All patients aged ≥18 years with a CRAB-positive blood culture were enrolled retrospectively at five teaching hospitals in South Korea. Risk factors for 14-day mortality were evaluated by a multivariate analysis.**Results:** A total of 332 patients with CRAB bacteremia were identified. After excluding 11 patients who transferred out, 14-day mortality was 53.0% (170/321). Of them, excluding 125 (37.7%) patients who died before the result of blood culture was reported, 196 patients enrolled in the analysis (45 died vs. 151 survived). All isolates from enrolled patients were susceptible to colistin. Patients receiving colistin monotherapy had highest 14-day mortality (12/37, 32.4%)(Table). Interestingly, 18 (20.7%) of patients with CRAB bacteremia survived, even they did not receive appropriate antibiotics. SOFA score > 8 (adjusted odds ratio [aOR] 4.73, 95% confidence interval [CI] 2.19 - 10.21, P < 0.001) and colistin monotherapy (aOR 2.53, 95% CI 1.02 - 6.29, P = 0.045) were independently associated with 14-day mortality.**Conclusions:** Our data suggest the intravenous colistin therapy may not alter the outcome of patients with CRAB bacteremia. Colistin monotherapy should be avoided for CRAB bacteremia treatment.**Table. Comparison of clinical characteristics between carbapenem-resistant *Acinetobacter baumannii* (CRAB) bacteremic patients with and without 14-day mortality.**

Carbapenem-resistant *Enterobacteriaceae* (Cre) Bloodstream Infection (Bsi) Treatment Strategies and Corresponding Outcomes

Author Block:

N. N. Pettit, Z. Han, J. Pisano, A. Charnot-katsikas; Univ. of Chicago Med., Chicago, IL

Abstract Body:

Background: Infections caused by CRE are difficult to treat and associated with poor outcomes. Combination therapy including a carbapenem (CBP) is generally recommended for severe CRE infections. We sought to identify preferred regimens for CRE BSI from an outcomes perspective. **Methods:** All patients with a blood culture growing a CRE isolate (*E. coli* or *K. pneumoniae*) between 3/1/2010 - 6/30/2014 were included, only counting the first isolate per patient per admission. Patients were assessed for antibiotics received for at least 48 hours within 72 hours of the culture date (or within 7 days of colistin or tigecycline). Treatment outcomes evaluated included: all-cause inpatient mortality (ACM), total length of stay (LOS), LOS following culture result, and time to documented blood culture clearance (TTDBCC). **Results:** A total of 29 isolates were included. *K. pneumoniae* was the most common organism (n=28). The CBP MIC was >=16 for 20 isolates. Among 26 patients who received antibiotic therapy, ACM was 38% (n=11), LOS 43.9 days, LOS following culture result 26.6 days, and TTDBCC 3.5 days. The treatment regimens and associated outcomes are shown in Table 1, differences in outcomes were non-statistically significant. Available antibiotic susceptibilities (VITEK-2® or e-test) are as follows: GENT (n=29, 76%); TIG (n=24, 71%), TIGEUCAST (n=24, 21%), COL (n=27, 70%); AMIK (n=28, 71%); TOBRA (n=29; 3%). **Conclusions:** While the sample size precludes definitive conclusions, we have identified that treatment outcomes may not be affected by the number of additional agents and may not be improved when a CBP is part of a combination regimen for CRE BSI. The lack of added benefit of a CBP may be related to high CBP MIC >=16 as most isolates had in this data-set.

TABLE 1: Outcomes based on antimicrobial regimen

Regimen	Specific Agents	ACM (%)	LOS (days, mean)	TTDBCC (days, mean)	LOS following culture result (days, mean)	Total Duration antibiotics (days, mean)
CBP Given (n=11)	CBP + GENT (n=3) CBP + COL (n=4) CBP + TIG + COL (n=1) CBP + COL + GENT (n=2) CBP + TIG + COL + AMIK (n=1)	54	34.2	4.4	20.4	23.7
No CBP Given (n=15)	TIG + COL (n=3) TIG + COL + GENT (n=2) TIG + GENT (n=3) TIG + COL + AMIK (n=1) COL + GENT (n=1) GENT + CIPR (n=1) AMIK alone (n=1) COL alone (n=3)	33	44.9	3.5	23.4	22.8
CBP + 1 Antibiotic (n=7)	CBP + GENT (n=3) CBP + COL (n=4)	43	26.1	2.3	17.3	26.7
CBP + 2 -3 Antibiotics (n=4)	CBP + TIG + COL (n=1) CBP + COL + GENT (n=2) CBP + TIG + COL + AMIK (n=1)	75	48.2	9.5*	26	35

CBP: meropenem or imipenem; TIG: tigecycline, COL: colistin; GENT: gentamicin; AMIK: amikacin; CIPR: ciprofloxacin.
* TTBCC only evaluable in 3 of 4 patients, 1 patient expired prior to documentation of blood culture clearance
Note: All differences in outcomes between groups were non-statistically significant (using Fisher's exact for categorical variables, Mann-Whitney U for continuous variables)

Clinical Outcomes of Patients with Infections Due to Carbapenem-Resistant Enterobacteriaceae (CRE) Treated with Ceftazidime-Avibactam (C/A)

Author Block:

B. A. Potoski[1], R. K. Shields[1], B. Hao[1], G. Haidar[1], Y. Doi[1], C. J. Clancy[2], M. H. Nguyen[1]; [1]Univ. of Pittsburgh, Pittsburgh, PA, [2]VAMC, Pittsburgh, PA

Abstract Body:

Background: C/A is a new agent with *in vitro* activity against Enterobacteriaceae, including extended-spectrum β lactamases (ESBL) and *K. pneumoniae* carbapenemase (KPC) producers. Real-world experience with C/A against CRE infections is limited.**Methods:** We performed a retrospective review of patients (pts) with CRE infection treated with C/A from April to Nov 2015. Pts with CRE colonization were excluded. C/A susceptibility testing was performed by broth microdilution. Presence of KPC and other ESBLs were detected by PCR.**Results:** 32 pts with 33 episodes of CRE infection were identified. Mean age was 59 years. Solid organ and stem cell transplant recipients were 28% and 6%, respectively. Median SAPS II and SOFA scores were 39 (range 12-72) and 7 (range 0-18), respectively. Infection types were pneumonia (11, 4 were ventilator-associated), bacteremia (9), complicated urinary tract or pyelonephritis (4), intra-abdominal infection (2), wound infection (2), and 1 each of subdural empyema and meningitis, mediastinitis, osteomyelitis, septic arthritis, and disseminated infection. 32 CRE isolates from unique pts were available for β-lactamase testing: KPC and ESBL- (23 *K. pneumoniae*, 1 *E. cloacae*, 1 *K. oxytoca*), and ESBL- producing (3 *K. pneumoniae*, 3 *E. coli* and 1 *E. cloacae).* Among non-KPC producers, all were CTX-M group 1; 3 SHV, and 1 TEM variants. All were susceptible to C/A *in vitro* with median MIC of 1 µg/mL (range 0.25 to 4). Median duration of C/A therapy was 11 days (range 7-72). C/A was used as part of combination therapy in 47% (mostly aminoglycosides). Therapeutic success at 14 days (clinical improvement and survival) was achieved in 69%. Both 14- and 30-day mortality was 29%. Among 22 survivors at 30 days, 9% had relapse at the same site, and 1 pt had relapsing CRE infection at a different site. One pt had 2 bacteremia relapses at 34 and 129 days from the initial episode; the KPC isolates remained susceptible to C/A.**Conclusions: Outcomes of pts with CRE infections treated with C/A were promising, and emergence of resistance was not observed. The absence of resistant isolates is encouraging particularly when empiric coverage against CRE is warranted. C/A tolerance assays and whole genome sequencing of isolates may provide insight into treatment failures.**

Utility of Combination Antimicrobial Therapy for Bloodstream Infections Due to *Enterobacteriaceae* and Non-Fermenting Gram-Negative Bacilli

Author Block:

C. Troficanto[1], J. Kohn[2], J. A. Justo[3], P. B. Bookstaver[3], H. Albrecht[4], M. N. Al-Hasan[4]; [1]Palmetto Hlth.Baptist, Columbia, SC, [2]Palmetto Hlth.Richland, Columbia, SC, [3]SC Coll. of Pharmacy, Univ. of South Carolina, Columbia, SC, [4]Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract Body:

Background: The role of empiric combination antimicrobial therapy for gram-negative bloodstream infections (GN BSI) remains uncertain. This study examines potential benefit of combination therapy on adequacy of empiric antimicrobial regimen in GN BSI patients.**Methods:** Hospitalized adults with GN BSI from January 2010 to June 2015 at Palmetto Health Hospitals in Columbia, SC, USA were identified. The effect of adding a combination agent on antimicrobial susceptibility rates within the study cohort was estimated using matched pair mean differences. The background regimen was a third-generation cephalosporin (3GC), i.e. ceftriaxone for *Enterobacteriaceae*, ceftazidime for non-fermenting gram-negative bacilli (NFGNs).**Results:** Among *Enterobacteriaceae*, 996/1063 (94%) isolates were susceptible to 3GC with marginal change in susceptibilities by adding either ciprofloxacin or gentamicin (mean difference +2.4% [95% CI: 1.5, 3.4] and +3.0% [95% CI: 2.0, 4.0], respectively). In a subset of patients with *Enterobacteriaceae* BSI and prior beta-lactam use, 168/200 (84%) isolates were susceptible to 3GC with mean improvement in susceptibilities of +4.0% (95% CI: 1.3, 6.8) and +7.6% (95% CI: 3.9, 11.3) after adding ciprofloxacin and gentamicin, respectively. Regarding NFGNs, 83/105 (79%) bloodstream isolates were susceptible to 3GC overall and 29/39 (74%) in patients with prior beta-lactam exposure. Adding ciprofloxacin or gentamicin contributed to mean difference in susceptibilities of +15.2% (95% CI: 8.3, 22.2) and +17.1 % (95% CI: 9.8, 24.5), respectively, overall and +23.1% (95% CI: 9.2, 36.9) for both combinations in patients with prior beta-lactam use.**Conclusions:** Empiric combination antimicrobial therapy has limited utility in *Enterobacteriaceae* BSI. However, combination regimens provided significant additional antimicrobial coverage to 3GC for NFGNs. Identification of patients with NFGN BSI using clinical risk factors or rapid diagnostics may aid the decision to utilize empiric combination therapy.

Medical vs. Interventional Treatment of Intra-Abdominal Abscess in Patients with Crohn's Disease

Author Block:

E. Graham, S. Cinti, K. Rao; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Few studies exist to guide the treatment approach to intra-abdominal abscesses in Crohn's disease, which can include antimicrobials alone or in conjunction with percutaneous drainage or surgery. The aims of this study are to compare outcomes among medical and interventional approaches and to evaluate the impact of infectious disease (ID) consultant involvement in management.**Methods:** Medical records were reviewed for patients admitted to the University of Michigan healthcare system from January 2010 to September 2014 with a diagnosis of Crohn's disease and radiographically confirmed intra-abdominal abscess. Treatment groups were defined as medical (antimicrobials alone without aspiration or drainage) and interventional (antimicrobials plus percutaneous drainage or surgery). Treatment failure was defined as abscess recurrence or non-resolution within six months. ID consultant involvement was also recorded and compared between treatment success and treatment failure groups. The X^2 test was used to test for statistical significance.**Results**: Of the 33 patients included, 13 were in the medical treatment group and 20 were in the interventional treatment group (**Table**). Abscess recurrence/non-resolution occurred in 31% of patients in the medical group and 25% of patients in the interventional group ($P = .7$). ID consultants were involved in managing 33% of patients with abscess resolution and 33% of patients with abscess recurrence/non-resolution. There was no difference in outcome between patients with and without ID consults ($P > .99$).**Conclusions:** In this study, there was no significant difference in outcome between medical and interventional therapy for intra-abdominal abscess in Crohn's disease. ID consultant involvement did not affect treatment outcome.**Outcome of medical vs interventional treatment for intra-abdominal abscess**

Variable	Abscess recurrence or non-resolution, n (%)	Abscess resolution, n (%)	*P*
Medical	4 (31%)	9 (69%)	.7
Interventional Percutaneous Surgical	5 (25%) 3 (23%) 2 (29%)	15 (75%) 10 (77%) 5 (71%)

Targeting Myd88/Arf6 Pathway As A Novel Treatment For Multidrug-Resistant *acinetobacter* infection

Author Block:

L. Lin[1], T. Gebremariam[1], A. Mueller[2], D. Li[2], **A. S. Ibrahim**[1]; [1]Los Angeles BioMed. Res. Inst. at Harbor-UCLA Med. Ctr., Torrance, CA, [2]Navigen Pharmaceuticals, Salt Lake City, UT

Abstract Body:

Background: Multi-drug resistant (MDR) organisms due to Gram negative bacilli (GNB), including those related to *Acinetobacter baumannii* (*AB*) have become endemic in healthcare systems throughout the world. Thus, novel methods to treat these infections are needed. Septicemia triggered by lipopolysaccharide (LPS) is a common manifestation of GNB infections. LPS triggers an inflammatory immune response via the MyD88/NF-κB cascade. However, LPS also induces vascular leak which leads to tissue edema resulting in organ failure and death. Vascular leak is caused by the GTPase Arf6 which falls in the MyD88/Arf6 pathway and functions independently from the MyD88/NF-κB cascade. We hypothesize that the pharmacological inhibition of Arf6 will be a novel treatment for *AB* infection.**Methods:** We used immunoprecipitation (IP) and trans-well permeability assays to study the role of small molecules on inhibiting GTPase Arf6 formation in human umbilical vein endothelial cells (HUVECs) infected with *AB*. Immunofluorescence was used to evaluate the effect of Arf6 inhibitors on VE-Cadherin expression in HUVECs infected with *AB*. Inhibitors were evaluated for their protective effect in neutropenic mice (cyclophosphamide [200 mg/kg] and cortisone acetate [500 mg/kg] on day -2, +3, relative to infection) with *AB* pneumonia. Treatment with 30 mg/kg inhibitors started 2 h post infection and continued through day +7.**Results:** *AB* infection resulted in activation of Arf6 (Arf6·GTP by IP assay) and the inhibitors significantly reduced this activation. The inhibitors reduced trans-membrane HUVECs leakage caused by *AB* by ~85% ($P<0.05$). Further, *AB* disrupted cell-to-cell junction of HUVECs via reduction of surface expression of VE-Cadherin and the inhibitors reversed this effect. Finally, two inhibitors (NAV2729, and NAV4424) significantly improved survival of mice (n=20 per arm) when compared to placebo (21 day survival of 5% for placebo, 85% for NAV2729, and 50% for NAV4424, $P<0.05$) with surviving mice appearing healthy.**Conclusions:** Inhibition of GTPase Arf6 formation reduces vascular leak and enhances survival of mice infected with lethal *AB*. Continued investigations of Arf6 inhibitors as a novel treatment of MDR-GNB is warranted.

Arf6 Inhibitors for Treatment of Acute Lung Injury

Author Block:

A. L. Mueller[1], K. Ostanin[1], C. Dunn[1], Z. Tong[1], D. Li[2]; [1]Navigen, Inc., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: Acute lung injury (ALI) and the more severe acute respiratory distress syndrome (ARDS) result from a common pathogenic process: pulmonary injury or infection triggers an overwhelming inflammatory response ("cytokine storm") that results in increased endothelial and epithelial permeability and efflux of inflammatory cells, protein, and water from the vascular system into the alveolar space. The laboratory of Dr. Dean Li and Navigen scientists have discovered a critical role of the GTPase ARF6 in control of vascular barrier integrity in the face of cytokine storm. Navigen has discovered a first-in-class chemical series of direct small molecule ARF6 inhibitors that show robust efficacy in a mouse model of LPS-induced ALI.**Methods:** LPS was instilled into the trachea of anesthetized mice. ARF6 inhibitor was injected IP at 30 or 60 mg/kg at 0 (T=0) or 3 h (T=3) after LPS. BAL fluid was collected 24 h after LPS; cell count and protein were measured. **Results:** LPS-induced marked increases in BALF cell count that were inhibited significantly by NAV2729 (49% at 30 mg/kg T=0; 61% at 60 mg/kg T=0; 26% at 30 mg/kg T=3; 64% at 60 mg/kg T=3) and NAV4424 (57% at 30 mg/kg T=0; 95% at 60 mg/kg T=0; 55% at 30 mg/kg T=3; 91% at 60 mg/kg T=3). Cytospin analysis confirmed that >90% of the cells in BALF after LPS-induced injury were neutrophils, and that treatment with ARF6 inhibitor reduced neutrophil infiltration. LPS-induced increases in BALF protein were inhibited significantly only at 60 mg/kg of either compound (NAV2729: 61% at 60 mg/kg T=0, 60% at 60 mg/kg T=3; NAV4424: 46% at 60 mg/kg T=0, 55% at 60 mg/kg T=3). Importantly, efficacy is observed when treatment with ARF6 inhibitor is delayed by 3 h after LPS.**Conclusions:** The small GTPase ARF6 plays a critical role in vascular leak elicited by a variety of inflammatory mediators. Small molecule inhibitors of ARF6 provide significant protection in an LPS-induced ALI model in mice. These inhibitors have potential as first-in-class therapeutics for treatment of ALI/ARDS.

Complex Defined Bacteriotherapy Inhibits Acute Colitis in Mice

Author Block:

T. Fofanova[1], F. Ihekweazu[1], D. Nagy-Szakal[2], K. Hulten[1], A. Opekun[3], J. Petrosino[1], D. Graham[1], R. Kellermayer[1]; [1]Baylor Coll. of Med., Houston, TX, [2]Columbia Univ., New York, NY, [3]BCM, Houston, TX

Abstract Body:

Inflammatory bowel disease (IBD) is thought to develop secondary to an uncontrolled immune response against the gut microbiome in the intestinal mucosa. Therefore, dysbiosis may be an important element in disease development, and restoration of normal microbiota structure via fecal microbiota transplantation (FMT) may be therapeutic for IBD. The fecal microbiome is a complex and dynamic community, which complicates dissection of the therapeutic contributions of FMT. Therefore, the identification of stable, defined bacterial communities that carry the therapeutic effects of FMT could result in a more consistent bacteriotherapy for IBD. Such a treatment has been developed for *C. difficile* colitis, where a 10 species preparation has been efficacious in treating disease. Observing that many of the species in this community belong to the *Bacteroides* genus, we compared the anti-colitic effects of a triple-*Bacteroides* (tri*Bac*) bacteriotherapy against FMT in a murine model of acute colitis. Experimental colitis was induced in 8-12 week old C57BL/6 mice using 3% dextran sulfate sodium for 5 days. Mice were simultaneously treated by oral gavage for 9 days with the tri*Bac* combination, individual *Bacteroides* strains, FMT using stool from healthy donor mice (FMT group), or autologous FMT (control group). Survival was significantly lower in the control group than in the FMT and tri*Bac* groups (40%, 73%, and 100% respectively). Importantly, mice receiving tri*Bac* therapy lost significantly less body weight than both the control and FMT groups (3.5%, 17.4%, 9.1% respectively). Histopathologic and gene expression analyses are pending. Microbiome analysis (16s rDNA profiling) of stool and mucosal samples is near completion. All 3 strains, individually and in combination, resulted in significantly increased survival and decreased weight loss compared to controls. However, treatment with *B. ovatus* alone resulted in the least loss of body weight. Our tri*Bac* approach was significantly more effective than FMT in reducing weight loss during acute colitis in mice. We are currently validating our results in an alternative model of murine colitis and are co-culturing these strains with human, colon-derived enteroid monolayers to investigate their effects on the barrier integrity, cytokine profile, and gene expression of the human intestinal epithelium.

Recombinant Human Trefoil Factor 2: Expression and Impact on Protection of Neonatal Rats against *Escherichia coli* K1 Systemic Infection

Author Block:

A. J. McCarthy[1], D. Negus[1], F. Dalgakiran[1], N. Crespo Tapia[2], I. Lopes Periera[1], K. Malec[1], G. M. H. Birchenough[3], P. W. Taylor[1]; [1]Univ. Coll. London, London, United Kingdom, [2]London Sch. of Hygiene & Tropical Med., London, United Kingdom, [3]Univ. of Gothenburg, Gothenburg, Sweden

Abstract Body:

Background: The newborn infant is highly susceptible to systemic bacterial infection during the first four weeks of life, and morbidity and mortality associated with neonatal bacterial meningitis and associated sepsis remains high. A major causative agent is *Escherichia coli* K1. During neonatal development, the gastrointestinal (GI) defences mature and thereby prevent translocation of colonizing bacteria from the GI tract to the blood and subsequent systemic infection. Trefoil factor 2 (TFF2) is proposed to have a key role in the stabilization of mucin structure and maintenance of mucosal health. Notably, *Tff2* expression is dysregulated in two-day-old (P2) but not nine-day-old (P9) rat pups colonised with the major neonatal pathogen *Escherichia coli* K1. **Objective:** To construct an *E. coli* SHuffle strain for the production of recombinant human TFF2 (r-hTFF2), in order to examine the capacity of r-hTFF2 to provide protection for P2 rat pups against systemic infection by *E. coli* K1 A192PP. **Methods:** We amplified and cloned a human *Tff2* transcript into vector pET26b. The pET26b.h*Tff2* vector was transferred into *E. coli* SHuffle, an expression strain able to express correctly folded, disulphide bonded proteins. The production of recombinant proteins by *E. coli* SHuffle + pET26b.h*Tff2* under various growth conditions was quantified using IMAC columns. Rat pups were fed r-hTFF2 or vehicle control at P2 (and every 12 h) and challenged by the oral route with *E. coli* K1 A192PP at P3; the health of the animals was monitored up to P10. **Results:** We confirmed the expression of r-hTFF2 by SDS-PAGE (12kDAa protein) and Western Blotting (anti-human TFF2), optimised expression within the *E. coli* SHuffle strain, and assessed functional activity of r-hTFF2 with *in vitro* assays. Survival of rat pups fed r-hTFF2 was ~30%, whereas survival of pups fed vehicle alone was 10%. **Conclusions:** We have generated and validated *E. coli* Shuffle expressing bioactive r-hTFF2; oral administration of the protein to neonatal rats susceptible to *E. coli* K1 infection protects against lethal systemic disease.

Control of Korean Sacbrood Virus Using Dsrna in Apis Cerana

Author Block:

M-S. Yoo, H-J. Seo, H-N. Jung, J-S. Lee, W. Bae, H-S. Lee, Y. Cho; Animal and Plant Quarantine Agency, Anyangsi, Gyeonggido, Korea, Republic of

Abstract Body:

Background: Sacbrood virus (SBV), a causative pathogen of larval death in honeybees, is one of the most devastating diseases in bee industry throughout the world. Since 2010, the Korean Sacbrood virus (KSBV) caused great losses in Korean honeybee (*Apis cerana*) colonies. However, there is no treatment for honeybee viruses including SBV. RNA interference (RNAi) is a gene-silencing technology by which small double-stranded RNAs are used to target the degradation of RNA with complementary sequence.**Methods:** In this study, we report on prevention of SBV infection by feeding with double-stranded RNA both in vitro and in vivo. SBV sequences corresponding to a segment of structural protein VP1 gene for dsVP1 and a segment of the structural polyprotein open reading frame for dsSBV1 were used for cloning. Small scale of dsRNA synthesis was carried out according to the protocol of the mMESSAGE mMACHINE T7 kit and large scale of dsRNA was synthesized by Genelution Inc. It was treated with food.**Results:** The mortality and viral load were observed every day. Experiments were carried out to examine whether ingestion of dsRNAs of SBV sequences would protect bees from SBV infection. The survivability of larvae was increased upto 40% in vitro test. The viral load of laevae and bee colonies were significantly decreased to a level similar to pre-infection in vivo test. The result indicated that two SBV-derived dsRNAs (dsSBV1 and dsVP1) protected bee larvae from subsequent SBV infection.**Conclusions:** dsRNA of SBV will be used as an efficient and feasible way of controlling other bee viral diseases as well as SBV.

Effects of Nspef on *In-Vitro* Viability of HPV-16 Infected Cervical Carcinoma Cell Line Caski

Author Block:

H. A. Ryan, S. J. Beebe; Old Dominion Univ., Norfolk, VA

Abstract Body:

Background: Human papillomavirus 16 (HPV-16) is a double-stranded DNA virus known to associate highly with human cervical cancer. Nanosecond pulsed electric fields (nsPEF) are ultra-short pulses with high electric field intensity (kV/cm) and high power (MW), but low energy density (mJ/cc). Recent studies suggest that nsPEFs can ablate tumors, alter gene expression and interfere with protein synthesis, but studies relating nsPEF and viral gene expression and the efficacy of nsPEF as an anti-viral biotechnology are few or unknown. This study examined the in-vitro anti-proliferative effect of nsPEF in human epithelial cervical carcinoma cell line CaSki infected with HPV-16.**Methods:** Adherent CaSki cells were detached from culture and treated with nsPEF in a 0.1 cm gapped electrode cuvette at different electric field strengths (0, 20, 40, 50 and 60 kV/cm) and pulse numbers (0, 1, 5, 10, 50 and 100 pulses). 1 × 10^5 cells from each sample were transferred into a 96-well plate and incubated for 4-6 and/or 24 hours, after which time cell viability was determined using a colorimetric cell proliferation assay (MTS) at an absorbance wavelength of 490 nm. Samples were tested in triplicate, and each set of experiments was replicated at least three times. Viability is reported using median values as percent of untreated cells. Statistical significance was evaluated by Student's t-test ($p<0.05$).**Results:** The MTS assay showed that nsPEF induced a distinct electric field strength- and pulse number-dependent reduction of cell proliferation. The EC50 under the various electric field and pulsing conditions occurred within the first 6 hours after treatment for: nsPEF of 50 kV/cm (50 and 100 pulses) and 60 kV/cm (10 pulses). The conditions 50 kV/cm and 10 pulses at 24 hours post-treatment achieved the most significant decrease in cell viability. NsPEF induced cell death was not shown to be statistically significant after 4 and 24 hours for nsPEF intensities of 20, 40 for 1, 5, and 10 pulses, and 60 kV/cm for 1 and 5 pulses.**Conclusions:** NsPEF inhibits cell proliferation in human papillomavirus-infected tumor cell line CaSki. Anti-proliferative effects of nsPEF may contribute to reducing cancer metastasis, and possibly play a direct antiviral role in clearing virus-associated metastatic cells.

Development of Orally-Delivered Therapeutics to Protect the Gut Microbiome from Antibiotic-Mediated Damage

Author Block:

S. Connelly[1], C. Freguia[1], T. Parsley[2], N. Hasan[3], P. Subramanian[3], M. Kaleko[1]; [1]Synthetic Biologics, Inc., Rockville, MD, [2]SynPhaGen, LLC., Rockville, MD, [3]CosmosID, Inc., Rockville, MD

Abstract Body:

Beta-lactam antibiotics (abx) are excreted in bile and can damage the colonic microflora leading to serious adventitious infections. SYN-004 is an orally-delivered beta-lactamase intended to degrade certain intravenous (IV) abx in the gut to protect the microbiome. A Phase 2b clinical study is in progress to assess SYN-004-mediated prevention of *C. difficile* infection (CDI) and abx-associated diarrhea (AAD). SYN-004 degrades penicillins and cephalosporins, but not carbapenems. We identified SYN-006, a potent carbapenemase, to expand this prophylactic approach to all beta-lactam abx classes.SYN-006, a metallo-beta-lactamase derived from *B. cereus*, was produced in *E. coli* with yields of ~600 mg/L at 95% purity. Using a bacterial growth assay as a readout for abx degradation, SYN-006 displayed a broad degradation profile that included carbapenems, penicillins, and cephalosporins, and was resistant to beta-lactamase inhibitors. SYN-006 retained biological activity for at least 6 hrs in human chyme. The inactivation of the carbapenem, meropenem (30 mg/kg, IV), in the GI tract was evaluated in fistulated dogs (n=6) using SYN-006 formulated in PBS, pH 7.5 (1 mg/kg). While SYN-006 jejunal levels were variable, most likely due to its sensitivity to low pH, at SYN-006 concentrations of $\geq$ 0.5 U/ml, meropenem was undetectable. SYN-006 did not affect serum meropenem levels, verifying it functioned solely in the GI tract. SYN-006 is currently being formulated into enteric-coated pellets that release at pHs >5.5. To evaluate the effect of carbapenems on the gut microbiome, a piglet model was developed. Animals (20 kg; n=5) were treated with ertapenem (30 mg/kg, QD, IV) for 7 days. Analysis of microbiome data from fecal DNA whole genome shotgun sequencing demonstrated that ertapenem caused dysbiosis, including loss of species diversity and changes in species abundance (Likelihood Ratio Test, $p=7.0 \times 10^{-16}$). Pig efficacy studies using the enteric-coated SYN-006 are being planned.These data demonstrate that SYN-006 displays manufacturability and sufficient potency to continue to be developed into an oral therapeutic. SYN-006 has the potential to protect the microbiome from all classes of beta-lactam abx and to provide prophylaxis for CDI and AAD.

Lipid Nanoparticles for Reviving Antibiotics: Efficacy of a Gel of Daptomycin in a Methicillin-Resistant *Staphylococcus aureus* Rabbit Osteomyelitis Model

Author Block:

C. Jacqueline, A. Reghal, K. Asehnoune, G. Potel, J. Caillon; ATLANGRAM, Nantes, France

Abstract Body:

Background: Daptomycin (DAP) is a bactericidal antibiotic with activity against Gram-positive organisms, including methicillin-resistant *Staphylococcus aureus* (MRSA) isolates, but its administration is exclusively by IV route. Lipid Nano-Capsules (LNCs) are known to vehicle medicines and could offer new therapeutic options. The efficacy of LNC-daptomycin (LNC-DAP) formulated in a gel was compared with that of other antistaphylococcal drugs in a MRSA osteomyelitis rabbit model. **Methods:** Femoral trepanation of rabbits was performed, followed by injection of 10^8 CFU *S. aureus* suspension into the knee cavity. A surgical debridement of the infected tissues was performed 3 days later and animals were randomly assigned to: no treatment (controls), LNC-DAP [one application of 50 mg (Low Dose) or 200 mg (High Dose)], linezolid (LZO, simulating a human-equivalent dose of 10 mg/kg/12h), or vancomycin (VAN, constant IV infusion to reach a 20xMIC serum steady-state concentration), or daptomycin (DAP, simulating a human-equivalent dose of 6 mg/kg). Surviving bacteria were counted in bone marrow (BM) and bone (BO) at day 3 and at the end of 4-days treatment (day 7). **Results**: The nanotechnology manufacturing process of daptomycin was demonstrated with an entrapment efficiency of 100%. The minimum inhibitory and bactericidal concentrations of the free antibiotic DAP and the LNC-encapsulated DAP (LNC-DAP) against the MRSA strain were equivalent (0.5 mg/L). One topic dose of the gel formulation of LNC-DAP versus four days of IV standard antibiotics (LZO, DAP, VAN) showed significant decrease of the bacterial burdens in both BO and BM compartments as compared to IV antibiotic regimens.

Treatment (no. of animals)	Mean ± SD $\log_{10}$ CFU/g of tissue (day 7 – day 3)	
	BM	BO
Controls (6)	0.19 ± 0.68	0.10 ± 0.87
VAN (11)	-0.65 ± 1.76	-0.61 ± 0.72
LZO (8)	-2.68 ± 1.91[a]	-2.27 ± 1.52[a]
DAP (10)	-0.56 ± 0.72	-0.67 ± 1.12
LNC-DAP LD (12)	-4.90 ± 1.48[b]	-5.27 ± 0.85[b]
LNC-DAP HD (6)	-5.76 ± 0.45[b]	-5.60 ± 0.31[b]

[a] *P*<0.05 vs controls, VAN, and DAP; [b] P <0.001 vs controls, VAN, LZO, and DAP. LD, Low Dose; HD, High Dose

Conclusions: In this model, a gel of lipid nano-encapsulated daptomycin (LNC-DAP) showed significant *in vivo* activity after ONE topic application in comparison with 4 days of IV anti-staphylococcal drugs. The use of LNCs for local delivery of antibiotics is a promising approach to revive old antibiotics or to develop new antibacterial agents.

Publishing Title:

Double β-Lactam Combination Is Synergistic Against Daptomycin-Resistant *Enterococcus faecium* harboring YycFG Substitutions and an Intact LiaFSR System

Author Block:

T. T. Tran, C. A. Arias; Univ Texas Med Schl, Houston, TX

Abstract Body:

Background: Previous studies have shown that the daptomycin (DAP) and β-lactam combination is synergistic against DAP-resistant (R) isolates that harbor mutations in the *liaFSR* encoding a three-component regulatory system that control cell envelop homeostasis. However, a subset of DAP-R *E. faecium* isolates lack LiaFSR substitutions and the DAP-β-lactam combination seems to be ineffective against these organisms. A high proportion of these *E. faecium* harbor mutation in the *yycFG* system (and accessory proteins), an essential two-component system predicted to regulate cell wall synthesis. In this work, we aim to determine the activity of double β-lactams, alone and in combination with DAP, against a DAP-R *E. faecium* strain (R446) harboring 8 mutations, including one in YycG. **Methods:** MICs of ampicillin (AMP), ceftaroline (CPT), ceftriaxone (CRO) and DAP against R446 were determined by Etest. Time-kill assays were performed with initial bacteria inoculum of 10^7 CFU/ml in Mueller-Hinton broth supplemented with calcium (50 mg/L). Antibiotics (AMP 64 μg/ml, CPT 10 μg/ml, CRO 10 μg/ml, and DAP 13 μg/ml) were used independently and in combination (AMP + CPT, AMP + CRO, AMP + CPT + DAP, and AMP + CRO + DAP) for time-kill studies. Bacteria were enumerated at 0, 6, and 24 h.**Results:** *E. faecium* R446 was resistant to all antibiotics tested (MICs of 128 μg/ml, > 32 μg/ml, ≥ 256 μg/ml, and 16 μg/ml for AMP, CPT, CRO and DAP, respectively). None of the antibiotic tested were effective in killing *E. faecium* R446 alone. AMP + CPT and AMP + CPT + DAP decreased bacterial loads by 3.01 ± 0.951 and 3.38 ± 0.09 $\log_{10}$ CFU at 24 h, respectively. AMP + CRO modestly decreased bacterial load by 0.88 ± 1.057 $\log_{10}$ CFU/ml. The addition of DAP to the CRO + AMP combination effectively decreased bacterial loads by 3.56 $\log_{10}$ CFU/ml.**Conclusions:** Double β-lactam AMP + CPT without DAP was bactericidal against DAP-R *E. faecium* R446. The addition of AMP + CRO restored the bactericidal activity of DAP. These results suggest the utility of double β-lactam against DAP-R *E. faecium* which may not respond to the combination of DAP and AMP.

Tsuji[2]; [1]Huashan Hosp., Fudan Univ., Shanghai, China, [2]Sch. of Pharmacy and Pharmaceutical Sci., Univ. at Buffalo, Buffalo, NY, [3]Weill Cornell Med., New York, NY, [4]Publ. Hlth.Res. Inst., Newark, NJ, [5]Monash Univ., Parkville, Australia

Abstract Body:

Background: FOS and COL are often of the few remaining agents that remain susceptible to KPC-Kp. However, FOS and COL resistance develops rapidly in monotherapy requiring the need for combinations. We therefore evaluated the *in vitro* pharmacodynamics of FOS and COL alone and in combination against KPC-Kp.**Methods:** Static time-kill studies (~10^6 CFU/mL inoculum) over 48 h were conducted using two KPC-2 expressing KPC-Kp clinical isolates. One isolate was COL-susceptible (COL^S, MIC_{COL} 0.25 mg/L & MIC_{FOS} 32 mg/L) while the second isolate was COL-resistant (COL^R, MIC_{Col} 64 mg/L & MIC_{FOS} >128 mg/L). Three concentrations of COL (0.25, 1 & 4 mg/L) and seven concentrations of FOS (8, 16, 32, 64, 128, 256 & 512 mg/L) based on free plasma concentrations were studied alone and in combination. Synergy was defined as a ≥2-log_{10} CFU/mL between the combination and the most active single agent.**Results:** FOS & COL alone produced extensive initial killing (~2 to 5 log10 CFU/ml) against the COL^S strain followed by regrowth. Synergy was evident at 4 h with all combinations resulting in complete eradication, except for combinations with a low FOS concentrations of 8 mg/L, which regrew by 24 h. The combination time-kill data was modeled as FOS concentration versus 48 h log ratio area and fit excellently to a Hill function (R^2>0.999). In combination experiments, in the presence of COL of 0.25, 1 & 4 mg/L, FOS EC_{50} values were 9.90, 8.75 & 9.94 mg/L, whereas E_{max} values were -5.05, -5.06 & -5.05, respectively. Against the COL^R strain, synergy was evident in only one combination (COL 4 mg/L + FOS 512 mg/L at 48 h); combination time-kill data were fit linearly with slopes of -0.0036 ,-0.0035 & -0.0085 for FOS in the presence of COL 0.25, 1 & 4 mg/L, respectively.**Conclusions:** All FOS and COL combinations showed synergistic killing and complete eradication of COLS KPC-Kp; against COLR KPC-Kp, this was evident only at high FOS and COL concentrations. These data highlight the potential utility of FOS and COL combinations against COLS KPC-Kp in the clinic.

Synergistic Activity of Isavuconazole (Isa) and Micafungin (Mfg): Dosage Optimization in Treatment of Experimental Invasive Pulmonary Aspergillosis (Ipa)

Author Block:

R. Petraitiene[1], V. Petraitis[1], B. W. Maung[1], N. Shaikh[1], N. K. Sekhon[1], W. W. Hope[2], T. J. Walsh[1]; [1]Weill Cornell Med. of Cornell Univ, New York, NY, [2]Univ. of Liverpool, Liverpool, United Kingdom

Abstract Body:

Background: Despite the advances in antifungal therapy with single agents, mortality associated with IPA remains high. We hypothesize that simultaneous inhibition of biosynthesis of fungal cell membrane and cell wall by an antifungal triazole and echinocandin combination may result in synergistic interaction *in vivo* with more rapid elimination of organisms and prevention of organism-mediated pulmonary injury. We therefore studied ISA and MFG in combination therapy of experimental IPA in persistently neutropenic rabbits. **Methods:** Treatment (up to 12 days) started 24 h after endotracheal inoculation of $1x10^8$ *A. fumigatus* conidia. Treatment groups consisted of rabbits receiving orally active moiety of ISA (BAL4815, ISA) at 20 (ISA20), 40 (ISA40), and 60 (ISA60) mg/kg/day, MFG at 2 mg/kg/day IV (MFG2), combinations of (ISA20+MFG2), (ISA40+MFG2), (ISA60+MFG2), and untreated controls (UC). Blood samples for serum galactomannan (GM) antigen and (1,3)-β-D-glucan (BG) levels were obtained QOD.**Results:** GM index (GMI) increased on day 1 postinoculation in all groups. While GMI continued to increase in ISA20, ISA40, and MFG2 treated rabbits, GMI was lower in ISA20+MFG2 ($p \leq 0.05$) and ISA40+MFG2 ($p \leq 0.01$) treated in comparison to monotherapies. There also were lower serum BG levels and prolonged survival in ISA20+MFG2 ($p \leq 0.05$) and ISA40+MFG2 ($p \leq 0.01$) vs. monotherapies. These results correlated with a significantly lower organism-mediated pulmonary injury (measured by lung weights and pulmonary infarct scores) in ISA20+MFG2 ($p \leq 0.05$), ISA40+MFG2 treated ($p \leq 0.01$) animals in comparison to ISA20, ISA40, and MFG2 treated alone. Residual fungal burden (CFU/g) in ISA20, ISA40, ISA60, ISA20+MFG2, ISA40+MFG2, and ISA60+MFG2 treated rabbits also was reduced vs that of MFG2 treated or UC ($p < 0.01$).**Conclusion:** Rabbits treated with ISA20+MFG2 and ISA40+MFG2 demonstrated synergistic interaction resulting in significantly lower serum GMI, serum BG levels, and mortality in comparison of that of monotherapy. Synergistic interaction of combinations of ISA20+MFG2 and ISA40+MFG2 prevented organism-mediated pulmonary injury, resulting in significantly lower lung weights and pulmonary infarct scores.

Efficacy of Telavancin (Tlv) and Daptomycin (Dap) in an Experimental Endocarditis (Ie) Model Due to Dap-resistant Methicillin-resistant *Staphylococcus aureus* (Mrsa)

Author Block:

W. Abdelhady, A. Bayer, R. Gonzales, L. Li, **Y. Q. Xiong**; LABiomed at Harbor-UCLA Med. Ctr., Torrance, CA

Abstract Body:

Background: TLV is a semi-synthetic bactericidal lipoglycopeptide active against many pathogenic Gram-Positive bacteria, including MRSA. The bactericidal activity is produced by a dual mechanism of action: inhibition of bacterial cell wall synthesis; and disruption of bacterial membranes by depolarization. The drug was FDA-approved in 2009 for complicated skin and skin structure infections, and in 2013 for hospital-acquired and ventilator-associated pneumonia caused by *S. aureus*. The current studies compared the efficacy of TLV and DAP in an experimental IE model using DAP-resistant (DAP-R) MRSA strains.**Methods:** A well-characterized catheter-induced rabbit model of aortic IE was used to compare efficacy of TLV against two clinically-derived DAP-R MRSA strains from patients who failed DAP therapy ($B_{2.0}$ and SA684). The MICs of TLV and DAP were 0.12 μg/ml and 4.0 μg/ml for the both strains, respectively. At 24 hr post-induction of IE, animals were randomized to receive: i) no therapy; ii) TLV 30 mg/kg iv bid which simulates PK/PD of the recommended clinical dose (10 mg/kg iv once daily); or iii) DAP 12 or 18 mg/kg iv once daily which mimics human PK of DAP regimens at standard (6 mg/kg iv once daily) or high (10 mg/kg iv once daily) doses. Treatments were administered 3 days. Control and antibiotic-treated animals were sacrificed at 24 hr post-infection or 24 hr after the last antibiotic dose, respectively. At sacrifice, cardiac vegetations, kidney and spleen were quantitatively cultured. The mean $\log_{10}$ CFU/g of tissue (±SD) was calculated and statistical analyzed via Student t test.**Results:** Only TLV significantly reduced MRSA densities in all three target tissues in the IE model compared to those in the untreated controls and DAP-treated groups (P<0.000001). Importantly, TLV-treated rabbits had 71-100% culture-negative target tissues, while DAP did not sterilize any target tissues. In addition, there was no mortality observed in the TLV and DAP high dose groups as compared to 29% mortality observed in the standard DAP treatment group (12 mg/kg).**Conclusions:** TLV has potent *in vivo* efficacy against DAP-R MRSA isolates in this rigorous IE model, and should be evaluated further in endovascular infections in humans.

In-Vitro* Characterization of Amikacin and Polymyxin B Therapy in Combination with Meropenem for Carbapenem-resistant *Enterobacter cloacae

Author Block:

W. C. Rutter, D. S. Burgess; Univ. of Kentucky, Lexington, KY

Abstract Body:

Background: Carbapenem-resistant (CR) *Enterobacter cloacae* (EC) typically contain multiple resistance mechanisms for many alternative agents. Polymyxin B (PB) remains reliably effective against these organisms, but resistance develops rapidly with monotherapy, indicating that combination therapy is needed. It is unclear which combination regimen is most effective.**Methods:** Four CR EC isolates were chosen based on meropenem (MEM) MIC. Inocula of 10^6 CFU/mL were exposed to amikacin (AMK) 8 and 16 µg/mL, PB 0.25 and 1 µg/mL, and MEM 4 and 16 µg/mL alone and in combination of AMK or PB with MEM. Samples were obtained at 0, 1, 2, 4, 8, 24, and 48 hours, plated via an automated spiral plater, and subsequently read by colony counting software.**Results:** AMK and PB monotherapy was characterized by initial bactericidal activity and rapid regrowth at 24h in all strains. MEM 4 was not bactericidal at any point and all strains regrew. MEM 16 was bactericidal for isolate 19 at 4h and 24h regrowth was limited to isolates 10 and 17. The combination of MEM 16 and PB 0.25 was bactericidal at 2h for all isolates with no regrowth after 48h of incubation. MEM 4 and PB 0.25 or 1 were rapidly bactericidal but significant regrowth occurred after 24h in isolates 10 and 17. MEM/AMK combinations were less rapidly bactericidal compared to the MEM/PB combinations; however, MEM/AMK maintained bacterial levels below the lower limits of detection after 24h in all isolates.**Conclusions:** Combination therapy with MEM and AMK at lower concentrations were able to prevent regrowth of resistant subpopulations at 48h in AMK susceptible CR EC strains. In contrast, the lower concentration MEM/PB combinations were unable to prevent regrowth at 48h in 50% of strains despite achieving bactericidal activity quicker. AMK based combinations may be a valid treatment option in CR EC isolates.

Properties of selected organisms

Isolate	Resistance mechanism	MEM MIC (µg/mL)	PB MIC (µg/mL)	AMK MIC (µg/mL)

Evaluation of Synergistic Activities & Efficacy of Combination Drug Therapy for Antibiotic-Resistant Inhalation Anthrax in a Murine Model

Author Block:

H. S. HEINE[1], S. Shadomy[2], A. Boyer[2], L. Chuvala[1], R. Riggins[1], J. Myrick[1], J. Craig[1], G. Drusano[1], M. Candela[2], J. Barr[2], K. Hendricks[2], W. Bower[2], H. Walke[2]; [1]Univ. of Florida, Orlando, FL, [2]CDC, Atlanta, GA

Abstract Body:

Background: Efficacy was tested using the murine model of inhalational anthrax to evaluate the therapeutic benefit and synergistic activity of various antimicrobial (AM) agent combinations for the treatment of inhalation anthrax resulting from a *Bacillus anthracis* (BA) strain resistant to the first-line AM treatment agent ciprofloxacin (C).**Methods:** Aerosolized spores from a C-resistant derivative of the Ames strain of BA were delivered to 10 groups of 46 female BALB/c mice. At 36h postexposure (PE), intraperitoneal therapy was initiated with combinations of two AM plus C. AMs combined with C included: linezolid (L), rifampin (R), meropenem (M), doxycycline (D), clindamycin (Cl) and penicillin (P). Controls received saline or C alone. Ten mice per group were treated for 14 days and observed until day 28 PE. The remainder were serially euthanized by threes at 6-12h intervals; from these, heparinized blood was collected, and lungs and spleens were removed, weighed, homogenized, and plated to determine bacterial load. 3x MIC AM-containing plates were also included to determine emergence of resistance. Plasma lethal factor (LF) levels were determined by MALDI-TOF mass spectrometry.**Results:** All AM combinations tested were significantly different from the saline control ($p < 0.0004$), and also from the C control, M/L ($p=0.004$), M/Cl ($p=0.005$), M/R ($p=0.012$), M/D ($p=0.032$), P/L ($p=0.026$), P/D ($p=0.012$), R/L ($p=0.001$), and R/Cl ($p=0.032$). There were no significant differences in survival between any of the AM combination groups. By 66h PE, plasma LF fell to low levels or below the limit of detection (LOD) for all AM combination groups with AM combinations containing L showing greatest reductions. No additional AM resistance was detected.**Conclusions:** Multi-drug therapy including a protein synthesis inhibitor can overcome a single first-line AM-resistant infection and also decrease circulating toxin levels. The data suggest that combinations with L had the greatest inhibitory effect on LF, and that combinations including L, Cl, or D, in addition to M or P, reduced LF to below LOD by 36h after initiation of therapy, validating their key role in treatment recommendations.

Maltodextrin Enhances the Effectiveness of Electrochemical Saffold Generated H_2o_2 Against Biofilms

Author Block:

S. T. Sultana, D. R. Call, H. Beyenal; Washington State Univ., PULLMAN, WA

Abstract Body:

Electrochemical scaffolds (e-scaffolds) reduce oxygen to low but constant concentrations of H_2O_2 that damage existing biofilms without damaging host tissue. Nevertheless, decomposition of H_2O_2 combined with retarded diffusion into mature and thicker biofilms can limit the efficacy of this potential clinical tool. Exposure to a hyperosmotic agent has the potential to mitigate this limitation by improving H_2O_2 diffusion into biofilms and by activating H_2O_2 membrane transportation channels in bacterial cells. Consequently, we hypothesized that e-scaffolds would be more effective against *Acinetobacter baumannii, Pseudomonas aeruginosa* and *Staphylococcus aureus* biofilms in the presence of maltodextrin, a hyperosmotic agent. Carbon fabric E-scaffolds were overlaid onto existing biofilms in medium containing different concentrations of maltodextrin. The e-scaffold alone decreased viable cell density of *A. baumannii, P. aeruginosa* and *S. aureus* biofilms by log (3.92 ± 0.15) (n=3, $P<0.001$), log (4.80 ± 0.22) (n=3, $P<0.001$) and log (2.31 ± 0.12) (n=3, $P<0.001$), respectively. Compared to treatment with e-scaffold alone, combining 10 mM maltodextrin with e-scaffold treatment achieved a further reduction in viable cells from *A. baumannii* biofilms log (4.35 ± 0.16) (n=3, $P<0.001$) and *P. aeruginosa* biofilms by log (1.0 ± 0.38) (n=3, $P<0.001$). A further reduction in *S. aureus* biofilm cell density by log (2.40 ± 0.17) (n=3, $P<0.001$) was observed in presence of 30 mM maltodextrin. Thus, compared to untreated biofilms, a combination of e-scaffold and maltodextrin achieved an overall reduction of log (8.20 ± 0.05) (n=3, $P<0.001$), log (5.7 ± 0.38) (n=3, $P<0.001$) and log (4.67 ± 0.12) (n=3, $P<0.001$) in *A. baumannii*, *P. aeruginosa* and *S. aureus* biofilms, respectively. The study demonstrates a simple means to enhance the effectiveness of e-scaffold treatment of biofilm infections in wounds.

***In Vitro* Antibacterial Effects and Time-kill Assessment of Amoxicillin Combined with Nalidixic Acid Against Bacteria of Clinical Importance**

Author Block:

O. O. Olajuyigbe[1], R. M. Coopoosamy[2]; [1]Bsbcock Univ., Ilisan Remo, Ogun State, Nigeria, [2]Mangosuthu Univ. of Technology, Durban, South Africa

Abstract Body:

Background: Sequel to the emergence of multidrug-resistant bacteria and lack of funds for development of novel anti-infective agents in third world countries, combining the existing antibiotics may be an alternative to combat the menace of bacteria. This study evaluates the *in vitro* effects of combining amoxicillin with nalidixic acid against bacterial isolates by agar diffusion, checkerboard and time-kill assays.**Methods:** Inhibition zones and MICs of antibiotics and their combinations were determined by agar diffusion and macrobroth dilution assays while checkerboard assay determined types of interactions between them.**Results:** Zones of inhibition ranged between 19.00 and 37.00 ± 0.00 mm for amoxicillin, 6.00 - 29.0 ± 0.58 mm for nalidixic acid and 21.0 - 39.33 ± 0.58 mm for the combined antibiotics at their highest concentrations. The MICs for amoxicillin alone ranged between 0.06 and 125.0 µg/ml. Those of nalidixic acid alone ranged between 1.953 and 62.5 µg/ml. The fractional inhibitory concentrations (FICs) of amoxicillin were between 0.0078 and 16.3, nalidixic acid alone between 0.0157 and 0.502 and those of the combinations ranged between 0.0703 and 16.316. Except for antagonistic interaction with FICIs ranging between 4.031 and 16.316 against *Pr. vulgaris* CSIR 0030 and *M. luteus* and indifference interaction with FICI equal to 0.517 against *Pr. vulgaris* ATCC 6830, the combination of these antibiotics resulted in synergistic interactions with FICIs ranging between 0.0468 and 0.345 against the *A. calcaoceuticus anitratus* CSIR, *B. cereus* ATCC 10702, *S. faecalis* ATCC 29212, *S. aureus* ATCC 6538, *S. aureus* OK_{2a}, *S. flexneri* KZN and *E. coli* ATCC 8739. The time kill assay showed that both ½ x MIC and MIC of the combined antibiotics eliminated the bacterial isolates from the cultures within 24 h. The post antibiotic effects after 48 h showed that all the broth cultures were sterile.**Conclusions:** Synergistic interactions between amoxicillin and nalidixic acid, rather than individual antibiotic usage, could result to improved therapy of bacterial infections in clinical settings.

Syn-004, an Oral β-Lactamase to Prevent *Clostridium difficile*, Degrades Ceftriaxone Excreted in the Human Intestine in Phase 2a Trials

Author Block:

J. F. Kokai-Kun[1], T. Roberts[1], E. Sicard[2], M. Rufiange[2], R. Fedorak[3], C. Carter[3], O. Coughlin[1], H. Whalen[1], K. Gottlieb[1], J. Sliman[1]; [1]Synthetic Biologics, Inc., Rockville, MD, [2]Algorithme Pharma, Laval, QC, Canada, [3]Univ. of Alberta/Alberta Hlth.Service, Edmonton, AB, Canada

Abstract Body:

SYN-004 is a novel, orally-administered recombinant β-lactamase given during treatment with IV β-lactam antibiotics (ABX) for prevention of the adverse effects of the ABX in the intestine. SYN-004 is released in the small intestine when the pH > 5.5 to degrade β-lactam ABX excreted into the intestine via the bile. This is expected to protect the gut microbiome from disruption by residual ABX, preventing opportunistic infections like *C. difficile*. For SYN-004 to be effective, it must be capable of degrading β-lactam ABX in the intestine, without affecting systemic ABX concentrations. Phase 1 clinical trials of oral SYN-004 have demonstrated a good tolerability with no systemic absorption in healthy volunteers. Two phase 2a studies have now been conducted in subjects with ileostomies to allow sampling of intestinal chyme which provides a unique *in vivo* approach to support the mechanism of action of SYN-004. In the first study, subjects were administered 1 g of IV ceftriaxone alone or in combination with two dose strengths of oral SYN-004. Serial plasma and intestinal chyme samples were then analyzed for their concentrations of ceftriaxone and SYN-004. In the second study, ceftriaxone plus SYN-004 was administered in the presence or absence of a proton pump inhibitor to determine the effect of pH change on SYN-004 function. These studies demonstrate that, 1) SYN-004 is well tolerated when given with IV ceftriaxone, 2) SYN-004 effectively catabolizes excreted ceftriaxone in the small intestine reducing the concentration to below detection when both substances are present, 3) the plasma concentration of ceftriaxone is unchanged upon oral SYN-004 administration, 4) SYN-004 is not detected in the plasma and 5) the use of proton pump inhibitors does not reduce SYN-004 efficacy. These two studies provide evidence of SYN-004's ability to degrade certain β-lactam ABX in the human intestine and support progression into a currently enrolling phase 2b clinical trial to examine its capacity to prevent *C. difficile*-associated disease and antibiotic-associated diarrhea in patients being treated with IV ceftriaxone for lower respiratory tract infection.

***In Vitro* Antimicrobial Activity of Surma,Kajal, Antibiotics Alone and Synergistic Combination of Cefazolin Sodium andOfloxacin against Opportunistic Biofilm Formers on Contact Lens**

Author Block:

J. Zaheer, Z. Zahid, **N. H. Ali**; Dow Univ. of Hlth.Sci., Karachi, Pakistan

Abstract Body:

Background: In contact lens wearer rate of bacterial keratitis due to biofilm forming species of opportunistic *Pseudomonas*, *Serratia* and *Staphylococcus* has increased. In many cases antibiotic therapy fails if single antibiotic prescribed. This study relates biofilm formers present on hand may adhere to lens during its handling, routine cleansing of lens with its solution partially removes bacterial load, results in formation of biofilm on lens. These microbes then gets attached to surface that interacts with contaminated lens. Besides antimicrobial susceptibility profile of eye cosmetics Kajal, Surma and antibiotic evaluated. Combination of Cefazolin Sodium and Ofloxacin tested for its synergistic activity for isolated bacteria. So that new regime of antibiotics be developed. **Methods:** Biofilm forming species (30 each) of *P.aeruginosa*, *S.marcescans* and *S.aureus* isolated from hands. Assessment of Biofilm formation is done by Crystal violet binding assay. Sterile lens immersed for 3hrs in nutrient broth culture (turbidity 0.5 McFarland) of individual species, washed with lens solution stored overnight in case of (SILCO multi-acting disinfectant) sterile lens solution, incubated in broth for 24 hrs. Bacteria recovered identified by micro broth dilution and checkerboard titration, MIC and FICI evaluated.**Results:** Bacterial species in which lens immersed were re-isolated from solution. MIC for organisms isolated from Surma and Kajal 16 – 125 µg/ml. MIC Alone cefazolin and ofloxain 125-500, 64-500 µg/ml. Fractional Inhibitory Index (FICI) of combination is 0.03- 0.4 for 80%. No antagonism observed. Synergy is defined as FICI $\leq$ 0.5. MIC Cefoxitin 250-500µg/ml, Ceftadizime 125-500 µg/ml, Vancomycin 31.25-500 µg/ml, Erythromycin 31.25-500 µg/ml.**Conclusion:** Presence of identified microbes in lens solution reflects cornea of eye wearing contact lens may get infected with microbes present on it. After antibiotic therapy vision loss, a complication of keratitis frequently reported. Antibiotic prescribed for treatment of keratitis has high MIC value against bacteria studied. Kajal and Surma, synergistic combination of cefazolin and ofloxacin are potential candidates to develop antibiotics that can combat against biofilm formers and drug resistant bacteria.

Depletion of Neutrophils Attenuates *Paracoccidioides brasiliensis* Induced Pulmonary Fibrosis in Mice Might Be Meditated by Decreasing of TGF-β1, TNF-α, Il-17, MMP-8 and TIMP-2

Author Block:

J. Puerta[1], P. Pino[1], J. Arango[1], A. Gonzalez[2]; [1]CIB-UdeA-UPB, medellin, Colombia, [2]Univ. de Antioquia, medellin, Colombia

Abstract Body:

Introduction: Chronic stages of paracoccidioidomycosis are characterized by granulomatous lesions, which promote the development of pulmonary fibrosis with loss of respiratory function in 50% of the patients. Recently, we demonstrated that depletion of neutrophils is associated with a better control of infection and a decrease of both the inflammatory response and the fibrotic process; however the mechanism, in which neutrophils participate, is not completely understood. In the present study, we evaluated some of the mechanisms that could be involved in the development of fibrosis in *P. brasiliensis* infected and neutrophils-depleted mice during the chronic stages of infection.**Methodology:** Isogenic BALB/c male mice were inoculated i.n. with $1.5x10^6$ *P. brasiliensis* yeasts. Groups of mice were untreated or treated with a monoclonal antibody (mAb) specific to neutrophils or an isotype control. The treatment was administered at week 4 post-infection (PI) followed by additional doses every 48h for two weeks. The animals were sacrificed at week 12 PI in order to determine levels of cytokines and collagen, expression of TGF, matrix metalloproteinases (MMP) and tissue inhibitor metalloproteinases (TIMP), besides histopathological aspects.**Results:** We observed that depletion of neutrophils during the chronic stages of *P. brasiliensis* infection was associated with a significant decrease of TGFb1 expression, TNF and IL17 levels, the latter being linked to additional results suggesting that neutrophil was one of the most important sources of IL17 in this fungal infection. Furthermore, recovery of lung architecture was also associated with reduced levels of collagen and decreased expression of MMP8 and TIMP2.**Conclusions:** Depletion of neutrophils might attenuate lung fibrosis and inflammation through down-regulating TGFb1, TNF, IL17, MMP8 and TIMP2. These data suggest that neutrophil could be considered as a therapeutic target in pulmonary fibrosis induced by *P. brasiliensis*.Study supported by Colciencias (project No.183-2010).

Monoclonal Antibodies Targeting *staphylococcus Aureus* Capsular Polysaccharides Elicit Protection In A Murine Bacteremia Model

Author Block:

B. Liu, S. Park, X. Li, C. Thompson, J. C. Lee; Brigham and Women's Hosp. and Harvard Med. Sch., Boston, MA

Abstract Body:

The capsular polysaccharide (CP) produced by *Staphylococcus aureus* is a virulence factor that allows the organism to evade uptake and killing by host neutrophils. Passive immunotherapy using CP antibodies could be a novel therapeutic approach to prevent and/or treat invasive antibiotic-resistant *S. aureus* infections. We showed previously that polyclonal antibodies to the serotype 5 (CP5) and type 8 (CP8) capsular polysaccharides are opsonic and protect mice against experimental bacteremia provoked by highly encapsulated staphylococci. In this study, we generated monoclonal antibodies (mAbs) against *S. aureus* CP5 or CP8. Backbone specific mAbs reacted with native and O-deacetylated CPs, whereas O-acetyl specific mAbs reacted only with native CPs. Reference strains of *S. aureus* and a selection of clinical isolates reacted by colony immunoblot with the CP5 and CP8 mAbs in a serotype-specific manner. The mAbs mediated CP type-specific opsonophagocytic killing of *S. aureus* strains, but the CP5 O-acetyl specific mAb was not opsonic for a *S. aureus* mutant that expresses O-deacetylated CP5. Mice passively immunized with mAbs specific for CP5 were protected against infection in a mouse model of *S. aureus* bacteremia. CP8 mAbs were protective against *S. aureus* Reynolds (CP8)-induced bacteremia, but not against bacteremia provoked by clinical isolates that readily released CP8 into culture supernatants. mAbs to *S. aureus* CPs, in combination with mAbs targeting other virulence factors, may be a promising therapeutic candidate for prophylaxis against or therapeutic treatment of staphylococcal infections.

An Ebpa Antibody-Based Therapeutic Against A Broad Range Of Enterococcal Catheter Associated Urinary Tract Infections

Author Block:

A. L. Flores-Mireles, M. G. Caparon, S. J. Hultgren; Washington Univ. Sch. of Med., St. Louis, MO

Abstract Body:

Urinary catheterization is a very common intervention in hospitalized patients, estimating that 20%-50% of the hospitalized patients are catheterized. The duration of a catheter increases the risk of developing a catheter-associated urinary tract infection (CAUTI) 3%-10% per day and can lead to serious complications such as bloodstream infections and death. *Enterococcus faecalis* is a leading cause of CAUTI and it is becoming increasingly resistant to multiple antibiotics, including last line of defense antibiotics such as the vancomycin, leaving few or no treatment options. Biofilm formation on the catheter is critical for CAUTI pathogenesis as it enables *E. faecalis* persistence in the bladder and dissemination to the kidneys. **In this study, we identified and targeted a critical step in biofilm formation to develop a therapy that prevents and resolves enterococcal CAUTI.** We found that host fibrinogen (Fg) is released and deposited on catheters following their introduction into the bladders of mice and/or humans. *E. faecalis* expresses a Fg-binding adhesin, EbpA, that tips the endocarditis and biofilm-associated (Ebp) pilus, which is critical for the formation of catheter-associated biofilms in a CAUTI murine model. The Fg-binding activity resides in the N-terminal domain of EbpA ($EbpA^{NTD}$) to promote catheter colonization and biofilm formation. We found that *E. faecalis* requires Fg for catheter colonization in humans and that vaccination with the EbpA and $EbpA^{NTD}$, but not its C-terminal domain or other Ebp subunits, inhibited biofilm formation *in vivo* and significantly protected against CAUTI in a murine model. Moreover, passive transfer of $EbpA^{NTD}$ antibodies prevented CAUTI and reduced bacterial titers of an existing *E. faecalis* infection. This therapy was also tested against a broad range of clinical strains, which included *E. faecalis, E. faecium*, VRE, and urinary tract, blood, and gut isolates. We found that the bacterial titers were reduced when mice were treated with anti-$EbpA^{NTD}$ antibodies. This suggests that this approach could be use against infections caused by abroad range of enterococcal and may provide a new strategy for the prevention of CAUTI and for other enterococcal infections where Fg is present such as infective endocarditis, bacteremia, and intra-abdominal and surgical-site infections.

Efficacy of Therapeutic Monoclonal Antibodies against Multi-Drug Resistant *Escherichia coli* St131

Author Block:

V. Szijarto, L. Guachalla, K. Hartl, Z. Visram, E. Nagy, **G. Nagy**; Arsanis BioSci.s, Vienna, Austria

Abstract Body:

Background: The globally spread multi-drug resistant *E. coli* clone ST131-O25b:H4 is responsible for a significant proportion of resistant extra-intestinal infections. By definition, isolates of this clone express the O25b antigen, whose unique structure was resolved recently. We aimed to develop humanized monoclonal mAbs against the O25b antigen that may provide an alternative adjunct or stand-alone therapeutic option against this *E. coli* lineage. **Methods**: Murine mAbs against the O25b carbohydrate epitopes were generated by standard hybridoma technique following repeated immunizations with live bacteria. Selected murine mAbs were subjected to humanization. Specificity and binding characteristics were assessed by immunoblots and biolayer interferometry using purified antigens. Surface staining of *E. coli* was measured by flow cytometry. Protective efficacy of passive immunization with the mAbs was investigated in murine and rat models of bacteremia and endotoxemia. Mode of action for protection was assessed in serum and whole blood bactericidal tests as well as in an endotoxin neutralization assay. Experiments were performed with bacteria grown in standard culture medium as well as in heat-inactivated pooled human serum in order to mimic *in vivo*-like conditions. **Results:** Specific humanized mAbs with high affinity to the O25b antigen were discovered. These antibodies showed strong binding to ST131-O25b strains irrespective of the capsular type. Upon binding to the bacterial surface, mAbs triggered a complement mediated bactericidal activity in the presence of human serum. An additional opsonophagocytotic activity was confirmed in the whole blood assay. Prophylactic immunization with the mAbs elicited significant protection against lethal systemic infection in mice and rats. Surprisingly, the mAbs efficiently neutralized endotoxic activity of purified O25b LPS or bacterial lysates. Protection in a murine endotoxemia model was also confirmed. **Conclusions:** Humanized mAbs against the *E. coli* O25b antigen exhibited protection in various animal models via different modes of action. Prophylactic passive immunization of colonized individuals or adjunct therapy of infected patients by mAbs may replace/complement antibiotic therapy against this drug resistant clone.

Publishing Title:

Enhanced Activity of Medi3902 with Adjunctive Antibiotic Treatment Against Resistant *P. aeruginosa* is Driven by Anti-Psl Activity

Author Block:

J. Quetz, A. Keller, C. K. Stover, A. DiGiandomenico; MedImmune, Gaithersburg, MD

Abstract Body:

Background: *P. aeruginosa* is a leading cause of morbidity and mortality in hospital infections. Because of its ability to develop resistance to antibiotics, there is a need for novel strategies to combat these infections. Recently described anti-Pseudomonal monoclonal antibodies (Mabs) that target the exopolysaccharide (EPS) Psl, the type 3 secretion (T3S) protein PcrV, and a bispecific construct that targets both Psl and PcrV (clinical candidate, MEDI3902), have shown promising preclinical activity. MEDI3902 mediates enhanced activity against resistant *P. aeruginosa* when combined with tobramycin (TOB). We sought to define the underlying mechanism(s) behind this enhanced activity with TOB. **Methods:** Anti-Psl/Anti-PcrV mAbs and TOB were evaluated in an acute pneumonia (AP) model. The role of Psl EPS in mediating antibiotic resistance and in potentiating anti-Psl mAb activity was evaluated with a Psl-inducible strain. We also determined the effect of sub-inhibitory concentrations (sub-MICs) of TOB and other standard of care (SOC) antibiotics on: membrane-associated Psl accessibility (flow cytometry), *pslA* expression (qPCR), and opsonophagocytic killing (OPK) activity. **Results:** In the AP model, TOB administration with anti-Psl (p=0.0014), but not anti-PcrV (p=0.31), resulted in a significant increase in survival when compared to animals treated with MAbs or TOB alone. In addition, Psl overexpression with a Psl-inducible strain correlated with enhanced resistance to TOB and greater anti-Psl Mab mediated OPK activity. Furthermore, exposure of *P. aeruginosa* to sub-MICs of TOB increased *psl* transcript levels 3-fold, enhanced binding of anti-Psl mAbs (41.3% *vs.* 27.9%; p=0.006), and increased anti-Psl OPK activity (61% *vs.* 42%; p=0.014) compared to non-TOB-treated controls. Similar results were observed with other SOC antibiotics. **Conclusion:** Our results suggest that the enhanced activity of MEDI3902 administered in combination with TOB against TOB-resistant *P. aeruginosa* is driven by the anti-Psl arm of the bispecific molecule. In addition, we provide evidence that sub-MICs of antibiotics enhance *in vitro* Psl expression and anti-Psl mAb mediated activity. Taken together these data demonstrate the potential of targeting Psl to mitigate clinical *P. aeruginosa* infections where chemotherapeutic pressure is a reality.

Monoclonal Antibodies Targeting the Conserved Lps O-Antigen of *Klebsiella pneumoniae* St258 Elicit Protection

Author Block:

V. Szijarto, L. Guachalla, K. Hartl, Z. Visram, E. Nagy, **G. Nagy**; Arsanis BioSci.s, Vienna, Austria

Abstract Body:

Background: ST258 is an epidemic carbapenem resistant *K. pneumoniae* clone. Within ST258 two different clades are distinguished that express at least 2 different capsular types. In contrast, we showed recently, that the LPS O-antigen (D-galactan III) is conserved within the lineage. Binding, function, and protective capacity of mAbs against this carbohydrate antigen were investigated in the present study.**Methods**: Selected D-galactan-III specific murine mAbs generated by hybridoma technology were humanized by CDR grafting. Surface staining of representative strains from both ST258 clades was measured by flow cytometry. Complement mediated killing was investigated with or without specific mAbs in a serum bactericidal assay. Neutralization of endotoxin was assessed in a cell based TLR4 reporter assay. Protective efficacy of passive immunization with the mAbs was tested in murine and rabbit models of systemic infection.**Results:** Humanized mAbs with high specificity and affinity to D-galactan-III antigen were discovered. Antibodies showed strong binding to both clades of ST258 strains irrespective of the capsular polysaccharide expressed. Surprisingly, most ST258 isolates showed high susceptibility to normal human serum in vitro, and rapid lysis in mouse blood in vivo. Still, in extensively depleted serum samples that allowed bacterial survival, antibody dependent complement mediated killing could have been shown. Furthermore, mAbs elicited in vitro endotoxin neutralization activity of purified LPS or bacterial lysates. The efficacy of neutralization exceeded that of polymixin B by several magnitudes. Importantly, high level of protection in a murine model of endotoxemia model was observed. Protection in the rabbit model of bacteremia, i.e. in a host naturally susceptible to endotoxin was confirmed.**Conclusions:** Monoclonal antibodies to D-galactan-III elicit significant protection against *K. pneumoniae* ST258 isolates in animal models of systemic infection. Given the low survival of ST258 in serum the protection observed is considered to originate mainly from the excellent endotoxin neutralizing potency exhibited by these mAbs. Passive immunization with bactericidal and endotoxin-neutralizing mAbs may complement antimicrobial therapy by last resort antibiotics and reduce disease severity and mortality.

The *candida* Hyr1p And Anti-Hyr1p Antibodies Protect Against Multidrug-Resistant *acinetobacter* infections

Author Block:

L. Lin, T. Gebremariam, G. Luo, S. Soliman, M. Yeaman, J. Edwards, Jr., **A. S. Ibrahim**; Los Angeles BioMed. Res. Inst. at Habor-UCLA Med. Ctr., Torrance, CA

Abstract Body:

Background: Infections due to multi-drug resistant (MDR) Gram-negative bacilli (GNB) such as *Acinetobacter baumannii* (*AB*) are now endemic in healthcare. New methods to prevent or treat these infections are needed. We used computational molecular modeling and bioinformatics to discover antigen candidates for immunotherapy targeting distinct pathogens. *Candida* cell surface Hyr1p shares 3D and sequence homology with the putative hemagglutinin/hemolysin and siderophore-interacting proteins of *AB* and other GNB, respectively. We hypothesized that active and passive immunization targeting Hyr1p can protect against *AB* and other GNB.**Methods:** Cross reactivities of rabbit anti-Hyr1p IgG with MDR *AB*, carbapenemase producing *Klebsiella pneumoniae* (*KP*), or *Pseudomonas aeruginosa* (*PA*) were studied by flow cytometry and Western blotting. Recombinant Hyr1p (30 μg; 0.1% alum) was used to vaccinate diabetic CD1 mice on D0, boosted on D21 prior to infecting them i.v. with a lethal dose of MDR *AB* on D35. Further, cyclophosphamide + cortisone acetate-treated mice were infected via inhalation with MDR *AB* and treated 24 h post infection with antiHyr1p IgG (30 μg) or isotype control IgG. Terminal morbidity served as a primary endpoint. The ability of Hyr1p IgG to kill MDR *Ab, KPC,* or *PA* was also studied *in vitro*. **Results:** AntiHyr1p IgG specifically bound *AB,* but not *PA,* and identified an *AB* siderophore-interacting protein as a major cross reacting antigen. The Hyr1p vaccine protected mice from hematogenously disseminated *AB* (60% survival in the vaccinated mice at D20 post infection vs. 0% for controls, P=0.005 by Log Rank test). Further, immunosuppressed mice with *AB* pneumonia were extensively protected by antiHyr1p IgG (90% survival at D20 post infection vs. 0% for isotype control IgG, P=0.002). Finally, Hyr1p IgG exposure killed *AB,* and *KPC,* but not *PA.* The killing effect was reversed by administration of iron.**Conclusions:** AntiHyr1p IgG cross-reacts to siderophore-binding protein and protects mice from *AB* infection, potentially by a cidal mechanism. These results affirm our convergent immunity strategy to target cross-kingdom antigens for innovative anti-infectives. Further development of immunotherapies exploiting *Candida* Hyr1p homology in MDR *AB* and other GNB is warranted.

Interleukin-10 Encapsulated Within Poly (Lactic Acid)-B-Poly (Ethylene Glycol) Nanoparticles Is Functional By Down-Regulating Cytokines And Inducing Suppressor Of Cytokine Signaling 1 And 3 In Mouse Macrophages Exposed To Chlamydia Trachomatis

Author Block:

S. A. Duncan, S. Dixit, R. Sahu, E. Nyairo, S. R. Singh, V. A. Dennis; Alabama State Univ., Montgomery, AL

Abstract Body:

Inflammation which is induced by the presence of cytokines and chemokines is an integral part of *Chlamydia trachomatis* (CT) infection. Nevertheless, it can be regulated using effective anti-inflammatory molecules. We recently reported that the anti-inflammatory cytokine, IL-10 can effectively regulate CT inflammation by inhibiting its associated-induced inflammatory mediators in mouse J774 macrophages. A major problem with IL-10 however, is its short biological half-life thus requiring frequent applications at high dosages for biomedical applications. Our goal in this study was to encapsulate IL-10 within the biodegradable polymer, PLA-PEG (Poly (lactic acid)-b-Poly (ethylene glycol) nanoparticles in an attempt to prolong its half-life. IL-10 was encapsulated in PLA-PEG by the double emulsion method, followed by physiochemical characterizations and functional studies. Results from Ultra Violet (UV) visible and Fourier Transform-Infrared Spectroscopy (FT-IR) revealed the successful encapsulation of IL-10 within PLA-PEG. Encapsulated IL-10 had an average size of ~ 100 to 200 nm, with an encapsulation efficiency > 90 %. Temperature stability of encapsulated IL-10 was up to 89C as shown by differential scanning calorimetry analysis. The anti-inflammatory effect of encapsulated IL-10 was tested using various concentrations (1-1000 ng/mL) over a 24-72 hour time-point in mouse J774 macrophages exposed to the recombinant major outer membrane protein of CT. Cytokine specific ELISAs showed that encapsulated IL-10 reduced the levels of both IL-6 and IL-12 in macrophages in a time- and concentration-dependent fashion, correlating with its stability and slow release capacity. By Taqman qRT-PCR, we demonstrate that encapsulated IL-10 induced higher levels of SOCS3 as compared to SOCS1, independent of the encapsulated IL-10 concentration, suggesting their probable role in the encapsulated IL-10 molecular mechanism of inhibition. Conclusively, our data shows successful encapsulation of IL-10 and that PLA PEG can prolong the half-life of IL-10. Moreover, encapsulated IL-10 is functional by down-regulating cytokines and inducing SOCS1 and 3 in macrophages exposed to CT at low dosages.

Oral Immunization with Non-Toxic *C. difficile* Strains Expressing Chimeric Fragments of TCDA and TCDB Elicit Protective Immunity against *C. difficile* Infection in Both Mice and Hamsters

Author Block:

Y. Wang[1], L. Bouillaut[2], X. Ju[3], Y. Wang[1], A. L. Sonenshein[2], X. Sun[1]; [1]Morsani Sch. of Med., Univ. of South Florida, Tampa, FL, [2]Tufts Univ. Sch. of Med., Boston, MA, [3]Tufts Univ. Cummings Sch. of Vet. Med., Grafton, MA

Abstract Body:

The symptoms of *Clostridium difficile* infection (CDI) are attributed largely to two *C. difficile* toxins, TcdA and TcdB. Significant efforts have been devoted to developing vaccines trargeting both toxins through parenteral immunization routes. However, accumulating evidence shows that anti-TcdA IgG, but not IgA, dramatically enhances TcdA-mediated cytotoxicity *in vitro* and disease *in vivo*, raising safety concerns with parenteral immunization. In addition, *C. difficile* is an enteric pathogen, and mucosal/oral immunization would be particularly useful to protect the host against CDI considering that the gut is the main site of disease onset and progression. Moreover, vaccines directed only against toxins do not target the cells and spores that transmit the disease. Previously, we constructed a chimeric vaccine candidate mTcd138, comprised of the glucosyltransferase and cysteine proteinase domains of TcdB and the receptor binding domain of TcdA. Purified mTcd138 induced protective immunity against *C.difficile* challenge in mice and hamsters. In the current study, we exressed mTcd138 in a non-toxigenic *C.difficile* strain with the goal of developing an oral vaccine that targets both *C.difficile* toxins and colonization/adhesion factors. mTcd138 expression in the non-toxigenic *C.difficile* strain was verified by Western-blot analysis. Oral immunization with spores of the non-toxigenic strain expressing mTcd138 provided mice with full protection against the clinically relevant *C.difficile* strain UK1 (ribotype 027). The protective strength and efficacy of the mTcd138-expressing non-toxigenic *C.difficile* strain were further tested in the acute hamster model of CDI. Oral immunization with spores of the mTcd138-expressing non-toxigenic strain also provided hamsters significant protection against infection with 10^4 spores of UK1, a dose100-fold higher than the lethal dose of UK1 in hamsters. In conclusion, the genetically modified, non-toxigenic *C.difficile* strain expressing mTcd138 represents a novel mucosal vaccine candidate against CDI.

Bone Marrow-Derived Mesenchymal Stem Cells Transplantation Exacerbates the Chronic Inflammatory Response and Pulmonary Fibrosis in Mice Infected with *Paracoccidioides brasiliensis*

Author Block:

J. Arango[1], J. D. Puerta-Arias[1], P. A. Pino[1], D. Arboleda[2], A. Gonzalez[2]; [1]CIB-UdeA-UPB, Medellin, Colombia, [2]Univ. de Antioquia, Medellin, Colombia

Abstract Body:

Introduction: Paracoccidioidomycosis (PCM) is an endemic and systemic mycosis caused by *Paracoccidioides* spp. PCM is characterized as a chronic progressive disease, which leads to pulmonary fibrosis (PF) in 50% of the patients. Currently, the treatment of PF, developed during PCM, uses immunosuppressive drugs; however, they have not been completely successful. Recently, the usage of bone marrow-derived mesenchymal stem cells (BMSCs) transplantation, as alternative therapy for PF induced by chemicals, has demonstrated to be beneficial. In the present study, we used BMSCs in an experimental model of PF induced by the fungus *P. brasiliensis* in order to determine their immunoregulatory and regenerative capabilities.**Methodology:** BMSCs were isolated from femur of BALB/c mice using Cell Depletion Kit and cultured in a low glucose medium. BALB/c male mice were inoculated i.n. with $1.5x10^6$ *P. brasiliensis* yeasts. BMSCs ($1x10^6$ cells) were administered i.v. eight weeks after infection in a single dose and animals were sacrificed four weeks later in order to determine: cellularity, fungal burden and histopathological aspects.**Results:** BMSCs-treated mice showed a significant increase of: i) fungal burden in the lungs and spleen, and ii) M2 macrophages, eosinophils and Th1 lymphocytes in comparison with control animals. M1 Macrophages, neutrophils, T-reg cells, Th17 and Th9 lymphocytes were decreased in number in those animals. Furthermore, histopathological analysis of the lungs from BMSCs-treated mice showed an increase in the number and size of granulomas as well as in the deposition of collagen fibers.**Conclusion:** Contrary to previous reports on chemical-induced pulmonary fibrosis, our results showed a deleterious effect of the BMSCs therapy on the *P. brasiliensis* infected animals. We hypothesize that in our animal model, BMSCs induced an immunosuppressive effect on the immune response and do not participate in the reparation of the tissue damaged during PCM.Study supported by Colciencias (project No. 358-2011).

***Candida albicans* and *Acinetobacter baumannii* Interactions in a Mixed Species Biofilm**

Author Block:

S. Alshehri, H. Shah, J. Edwards, A. Ibrahim, **P. Uppuluri**; LA BioMed. Res. Inst., Torrance, CA

Abstract Body:

Background: *Candida albicans* (CA) and *Acinetobacter baumannii* (AB) share common niches in healthcare settings, and can co-develop biofilms on vascular and urinary catheters, and patient wounds. Owing to the drug resistant nature of biofilms, novel methods to combat co-habiting organisms are needed. We have investigated the nature of interaction between CA and AB in a biofilm setting. Our bioinformatics studies have predicted significant homology between CA hyphal surface protein Hyr1p and a siderophore-interacting protein of AB. We have tested the efficacy of anti-Hyr1p antibodies to disrupt the stubborn mixed species biofilm and make the biofilms more susceptible to antimicrobials. **Methods:** Biofilms of CA and AB were grown individually or together *in vitro* for 24 h. Interaction between the two organisms was monitored microscopically and viability of both populations was quantified by cfu. Conditioned medium of each organism was obtained after stationary growth phase and its impact on single as well as mixed spp. biofilm formation was studied. The ability of anti-Hyr1 antibodies to inhibit biofilms, as well as disrupt a mature mixed spp. biofilm was investigated *in vitro*. **Results:** In a co-culture**,** AB did not inhibit CA germination. However once filaments developed, the bacterium interacted only with, and killed > 60% of the hyphae overnight which lead to predomination of the bacterium in the mixed spp. biofilm. Interestingly, the conditioned medium of AB biofilms promoted CA filamentation and biofilm formation in conditions non-permissive for hyphenation and biofilm growth (at 30^{o}C). In contrast, conditioned medium from CA yeast, but not filaments, inhibited growth of AB. Anti-Hyr1 antibodies were lethal to AB cells but not to CA in the mixed spp. biofilm. However, in the presence of antibodies, the otherwise drug resistant CA demonstrated significant susceptibility to the antifungal drug fluconazole. **Conclusions:** Our results depict a tug-of-war that exists between two species of organisms in an intimate setting such as a biofilm, indicating that the predominance of one over the other is highly dependent on the environmental conditions that they co-inhabit. Investigations targeting the CA Hyr1p as novel therapeutics for drug resistant AB and CA biofilms is currently being tested by us *in vivo*.

Abstract Body:

Background: Active IFD defer bone marrow transplantation (BMT). **Objective:** analyze the impact of granulocyte transfusions in patients undergoing allogeneic BMT with active IFD diagnosed immediately prior to the procedure. **Methods:** Adult ABO compatible donors received G-CSF 10 µg/kg , SQ, 12-18h before continuous flow leukapheresis in a COBE Spectra 7.0 LRS. We processed 7.5L with Htc 5%-7%, <65 ml/min and a 1:13 blood:ACD ratio and continuous infusion of 500 mL of hydroxyethyl starch 6% (Halexlstar) as an RBC-sedimenting agent. The leukapheresis products were irradiated with 40 Gy and divided in 3 bags with <1x109 granulocytes/kg, kept at 4°C and leukapheresis products were infunsed daily to keep neutrophils over 1000 cells/mm3 . **Results:** Between 2009- 2015, 5 children with proven active IFD were transplanted using antifungals and granulocyte transfusions to prevent neutropenia. 1) 5-yo girl with immunodeficiency and invasive pulmonary aspergillosis (IPA). She had a related BMT 2) 18-yo male with refractory AML developed disseminated fusariosis . He had double unrelated cord blood (UCB) transplant; 3) 8-yo male with AML in 2nd remission with *Fusarium* osteomyelits and skin infection, undergoing UCB 4) 10-yo male with relapsed AML, with IPA who had UCB and haploidentical graft 5) 11-yo female with AML in remission, with IPA , undergoing related BMT. Only one patient died due to bacterial sepsis. **Conclusion:** The use of granulocyte transfusions associated to conventional antifungals may allow the patient to proceed to BMT despite the fungal infection. No patient had worsening of the fungal infection

Human Monoclonal Antibodies That Neutralize Vaccine and Wild Type Poliovirus Strains

Author Block:

R. PULIGEDDA, S. DESSAIN; Lankenau Inst. for Med. Res., Wynnewood, PA

Abstract Body:

Background: Eradication of poliomyelitis requires elimination of reservoirs of immunodeficiency-related vaccine-derived poliovirus (iVDPV), chronically excreted by individuals with immune dysfunction and reintroduced into general population. MAbs specific for poliovirus may contribute to clearance of iVDPV in chronic carriers by neutralizing the virus directly and reducing the outgrowth of PV strains resistant to anti viral drugs. Human mAbs, specifically cross-neutralizing mAbs are ideal for anti-PV therapeutics. Here, we describe a panel of cross neutralizing human mAbs with potent neutralizing activity against Sabin and wild type strains.**Methods:** We isolated mAbs from OPV-vaccinated, IPV-boosted subjects using a novel cell fusion method and measured the neutralization against Sabin and wild type PV strains. We generated escape mutant PV strains using selected cross-neutralizing mAbs (1E4, 12F8) and mono-neutralizing mAbs, mapped the mutated amino acids to virion structure. We compared these mAbs to neutralize each other's escape mutant strains and strains resistant to a previously described mAb, A12, that reduces viral excretion in animal studies. We tested 1E4 and 12F8 to neutralize a panel of patient-derived, type 1 PVs including WT strains, iVDPVs and aVDPV, also strains resistant to anti-PV small molecule drug V-073.**Results:** We identified a panel of mAbs with potent neutralization activities against PV wild type and Sabin strains. Escape mutant studies showed that mono-specific mAbs 7E2 and 8F9 interact with residues in antigenic site 1, whereas cross-specific mAbs, 1E4 and 12F8 bind to residues in the canyon domain, which interacts with the PV cellular receptor, CD155. Cross specific mAbs, 12F8 and 1E4 neutralized A12 escape mutant PV strains. They also neutralized a panel of patient-derived type 1 PVs including WT strains, iVDPVs and aVDPV. The virus mutants resistant to the anti-poliovirus drug V-073 were also neutralized by the human mAbs.**Conclusions:** The isolated cross-neutralizing human mAbs may be used as a PV therapeutic for immunodeficient subjects. These mAbs were able to neutralize A12 escape mutant strains, suggesting that they could be given along with A12 to reduce the outgrowth of mAb-resistant PV strains. The cross specific mAbs 12F8 and 1E4 may be suitable to clear iVDPVs in chronically infected individuals, particularly in combination with V-073.

Mechanisms of Neutralization of *Clostridium difficile* Toxins by the Antitoxin Antibodies Actoxumab and Bezlotoxumab

Author Block:

L. D. Hernandez[1], H. K. Kroh[2], M. Beaumont[3], P. R. Sheth[1], X. Yang[1], E. DiNunzio[1], S. A. Rutherford[2], M. D. Ohi[2], N. J. Murgolo[1], L. Xiao[1], F. Racine[1], E. Hsieh[1], G. Ermakov[3], D. B. Lacy[2], **A. G. Therien**[1]; [1]Merck & Co., Inc., Kenilworth, NJ, [2]Vanderbilt Sch. of Med., Nashville, TN, [3]Merck & Co., Inc., Palo Alto, CA

Abstract Body:

Clostridium difficile is a spore forming anaerobic bacterium that infects the intestinal tract. The organism expresses two exotoxins, TcdA and TcdB, that target the epithelial cells of the gut and cause damage and inflammation leading to symptoms ranging in severity from mild diarrhea to colonic rupture and death. The toxins are thought to bind to specific cell-surface receptors in part via C-terminal domains known as combined repetitive oligopeptides (CROP). The neutralizing antitoxin antibodies actoxumab and bezlotoxumab, specific for TcdA and TcdB respectively, are protective in animal models of CDI when administered in combination. Furthermore bezlotoxumab was recently shown to reduce the rate of recurrent CDI in phase 3 clinical trials. In this study, we characterize the binding of actoxumab and bezlotoxumab to their respective toxins and propose mechanisms of neutralization for the two antibodies. The epitopes of each antibody were identified using a combination of Western blotting, surface plasmon resonance, hydrogen-deuterium exchange - mass spectrometry, and negative stain electron microscopy. The nature of the immune complexes formed between the antibodies and toxins was investigated using size exclusion chromatography coupled with multi-angle laser light scattering. Overall, our data show that actoxumab and bezlotoxumab bind to two homologous but distinct epitopes within the CROP domains of TcdA and TcdB, respectively. Binding of actoxumab to TcdA causes formation of large immune complexes whose sizes increase at higher antibody:toxin ratios, whereas binding of bezlotoxumab to TcdB does not. Despite these differences, the mechanisms of toxin neutralization are similar; each antibody prevents binding of their respective toxin to host cells, thereby blocking the intoxication cascade at its first step. These mechanisms of neutralization are presumed to underlie the efficacy of the antibodies in pre-clinical models of CDI and of bezlotoxumab alone in prevention of recurrent CDI in patients.

Utilizing the Antimicrobial and Immunomodulatory Properties of Platelets to Combat Infectious Arthritis *In Vitro*

Author Block:

J. Gilbertie, T. Schaer; Univ. of Pennsylvania, Kennett Square, PA

Abstract Body:

Bacterial colonization of synovial structures can cause infections that are difficult to treat and is a significant clinical problem in both veterinary and human medicine. It has recently been shown that antimicrobial recalcitrance in human synovial fluid could be due to bacterial clumping or the formation of biofloats. These biofloats have similar gene expression to bacteria within biofilms and are equally difficult to treat exhibiting profound resistance to antimicrobials *in vitro.* Data from our lab has shown that bacteria form biofloats within equine synovial fluid as well. Recent reports show that platelet-rich plasma (PRP) has bacteriostatic effects. Platelets are powerful immunomodulators and key players in innate immunity. Upon activation, they release bioactive factors that can be directly bactericidal. We hypothesized that the bioactive factors derived from the platelet-rich plasma will decrease bacterial load in synovial fluid and increase immune cell function *in vitro*. PRP was isolated from 16 healthy horses; platelet-poor plasma (PPP) was also isolated as a negative control. The PRP and PPP underwent five consecutive freeze-thaw cycles to lyse the platelets. Equine synovial fluid was inoculated with two clinical isolates from musculoskeletal infections, *Staphylococcus aureus* and *Escherichia coli*. Two hours after inoculation the synovial fluid was treated with PPP lysate (PPP-L), PRP plasma lysate (PRP-L), vancomycin or left untreated. PRP-L resulted in a 5 log reduction in bacterial load while PPP-L resulted in an 2 log reduction compared to the untreated control. Vancomycin has negligible effect on bacterial load; however, when PRP-L and vancomycin were used together no bacterial growth was observed. Neutrophil functionality was assessed by measuring respiratory burst and phagocytosis. Neutrophils stimulated with PRP-L had significantly higher levels of respiratory burst and phagocytosis compared to those stimulated with PPP-L or the untreated control. Taken together PRP-L was both antimicrobial and immunomodulatory. This biologic is easily accessible and could have a significant impact on cases of infectious arthritis when used in combination with current antimicrobials such as Vancomycin.

Progress Toward a Multivalent, Monoclonal Antibody Cocktail to Prevent *Acinetobacter baumannii* Infections

Author Block:

S. Singh, J. Luka, A. Jacobs, I. Soojhawon, Y. Alamneh, M. G. Thompson, R. Abu-Taleb, S. Noble, S. D. Tyner, **D. V. Zurawski**; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

The lack of new antibiotics currently being pursued against Gram-negative, ESKAPE pathogens is a concern given the increase of infections and antibiotic resistance. While some monotherapy treatments are in the pipeline, small molecules are susceptible to rapid resistance; and therefore, alternative approaches should be considered. One such approach could be monoclonal antibodies (mAb) as serum was used with success before the "Golden Age" of antibiotics. A key to successful mAb development is choosing the appropriate antigen(s). Targets have to be required for virulence at the various stages of infection. To this end, we have identified proteins on the surface of *Acinetobacter baumannii* required for pathogenicity. Once we found an appropriate model strain (AB5075) and developed tools to manipulate the genome, we hypothesized that the Type Six Secretion System (T6SS), and in particular, the Hcp needle, was a virulence factor that could be exploited for therapy. First, we identified a transposon mutant *hcp*::Tn*5* from our mutant library that was avirulent in a murine pulmonary model when compared to wild-type infected mice. Then, we cloned, overexpressed, and purified a 6XHis-tagged Hcp protein that was injected into mice to generate mAb. The mAb 13F7 was selected because of its high affinity for Hcp. We confirmed that 13F7 could recognize native Hcp on the surface of *A. baumannii* using ELISA and immunofluorescence. Then, we confirmed that antibody did not recognize Hcp in the *hcp*::Tn5 background. Subsequently, 13F7 was evaluated in two murine models of *A. baumannii* infection where 13F7 was prophylactically delivered up to 100 µg (5 mg/kg) via intraperitoneal injection. In the pulmonary infection model, 13F7 provided >60% protection from infection in a dose-dependent manner when compared to a mock-treated control. In a wound infection model, wound area and inflammation were significantly reduced in animals that received 13F7 as compared to a mock-treated control ($P \leq 0.01$). Since protection was not 100%, we have identified additional surface targets and this strategy will be applied. Our goal is to combine all of these antibodies into a cocktail that could be a prophylactic treatment to prevent *A. baumannii* infection or treat infected patients in combination with antibiotics.

Active Hexose Correlated Compound Oral Feeding Enhances Immune Function and *Chlamydia trachomatis* Clearance in a Stress Mouse Model

Author Block:

T. Belay, K. Brown; Bluefield State Coll., Bluefield, WV

Abstract Body:

Background: *Chlamydia trachomatis* genital infection is a serious public-health problem that disproportionately affects populations of low socio-economic status. Stress is a risk factor to infection that has a significant impact in public health and is generally greater in populations of lower socioeconomic status. We have shown that cold-induced stress results in suppression of the immune response and increased intensity of chlamydia genital infection in a mouse model. Here we evaluated the potential therapeutic value of active hexose correlated compound (AHCC) against chlamydia genital infection in cold water-induced stressed mice. AHCC is a extract of a mushroom commonly used as a dietary supplement known to boost the immune system.**Methods:** Mice were infected intravaginally with *Chlamydia trachomatis* after a 24-day cold water-stress series. Oral administration of AHCC to stressed or non-stressed mice was carried out seven days before and during the course of infection along with cervicovaginal swabbing. Splenic T cells from both animal groups were co-cultured with mouse monocyte J774.2 cell line or cultured by addition of supernatants of AHCC-treated J774.2 cell line for 24 hours. Cytokine production by peritoneal and splenic T cells isolated from mice was measured by ELISA.**Results:** Stressed mice suffered loss of weight before feeding, however, improvement in body weight gain was shown in AHCC-fed mice. A significant reduction in the shedding of *Chlamydia trachomatis* from the genital tract of AHCC-fed mice on day 18 after infection was observed. Increased levels of tumor necrosis factor-alpha (TNF-α), interleukin 6 (IL-6) in peritoneal cells of stressed mice receiving AHCC compared to control mice receiving. Decreased production of interferon gamma (IFN-γ) and interleukin 2 (IL-2) in the AHCC group was observed.**Conclusions:** Results obtained in this study show that AHCC improves the function of immune cells as indicated by the restoration of levels of cytokines production that were suppressed under cold induced-stress conditions. This is the first report showing that oral administration of AHCC enhances the function of the immune system, which could result in increased resistance of the host to chlamydia genital infection.

(ICCBS), Univ. of Karachi, karachi, Pakistan, [5]IIDRL, Dept. of Microbiol., Univ. of Karachi. 4Dadabhoy Inst. of Higher Ed., karachi, Pakistan

Abstract Body:

Objective: The main purpose of study is to check different extracts of dried seeds of *B. orellana* for their anti-inflammatory activity.**Background:**Inflammatory diseases are important cause of mortality and morbidity. The concept of strengthening the host immune system to combat diseases is not new, plants has been used for immunomodulation since ages. *Bixa orellana* belongs to family Bixaceae, popular in treatment of various diseases. Therefore, extracts of seeds of *B. orelana* were choosen to check their anti-inflammatory potential.**Methods***Bixa* seeds were extracted with methanol (M), petroleum ether (PE) and acetone (Ace) for 48 hours. The solvents were evaporated to give respective residues, Bixa P-1, P-2, M-1, M-2, Ace 1 and Acc-.2.The immunomodulatory activity of the extracts were evaluated on whole human blood phagocytes, isolated neutrophils and J774.2 macrophages cell lines for ROS (reactive oxygen species) production using luminol- and lucigenin-based chemiluminescence tests.**Results:**Bixa P-1, P-2, M-1, M-2 exhibited active inhibition of ROS production on whole blood phagocytes IC 50 values (10.6±0.21 to 14.7±0.5 µg/ml), whereas, Bixa P-1, P-2, Ace-1, Ace-2 showed moderately active inhibition with IC 50 values (24.6±0.11 to 34.7±0.23 µg/ml) compared with control Ibuprufen (11.2 ± 0.1µg/ml). All extracts performed remarkable inhibition on intracellular and extracellular production of neutrophils ROS with an IC50 values ((2.5±0.32 to < 1) compared with controls Ibuprufen (2.5±<1) and Diphenylene iodonium (0.56±0.04). Similarly profound inhibition on the intracellular and extracellular macrophage ROS production (1.60±0.561 to <1) was observed.**Conclusion**Extracts of seeds of *B.orellana* showed significant inhibition of ROS production. Studies are carried out for exploration of active component and evaluation for its molecular mechanism of action in order to use them as anti-inflammatory agent in future.

***In Vitro* Activity of WCK 5999 against *Acinetobacter baumannii* and *Pseudomonas aeruginosa* Isolates from a Worldwide Surveillance Program (2015)**

Author Block:

M. D. Huband, D. J. Farrell, R. K. Flamm, R. N. Jones, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: WCK 5999 is a novel carbapenem/β-lactamase inhibitor combination comprising meropenem (MEM) and WCK 4234, a broader-spectrum β-lactamase inhibitor with enhanced activity against Class D carbapenemases. The *in vitro* activity of MEM-WCK 4234 using both fixed 4 (F4) and fixed 8 (F8) µg/mL of WCK 4234 was evaluated against *A. baumannii* (ACB) and *P.* aeruginosa (PSA) isolates (n=490) collected during 2015 from the SENTRY worldwide surveillance program and also included PSA resistant isolate subgroups.**Methods:** MIC values for MEM-WCK 4234 (F4 and F8) and comparator compounds were determined using reference broth microdilution methodology. Breakpoint interpretative criteria followed CLSI guidelines.**Results:** MEM-WCK 4234 (F4 and F8) was active against ACB isolates (MIC_{50}/MIC_{90} values of 2/16 and 1/8 µg/mL, respectively; Table). The addition of WCK 4234 to MEM significantly increased the % of ACB isolates with MEM-WCK 4234 MICs ≤4 µg/mL (based on 2g TID MEM dose) from 35.8% (MEM alone) to 78.8% (F4) and 87.6 (F8). Against PSA, the % of isolates with MEM-WCK 4234 MICs ≤4 µg/mL increased from 73.7% (MEM alone) to 83.6% (F4) and 84.1% (F8). MEM-WCK 4234 MIC_{50} values (F4 and F8) against PSA were also two-fold lower than MEM. MEM-WCK 4234 (F4 and F8) combinations demonstrated enhanced activity against resistant PSA subgroups including ceftazidime (CAZ) non-S (43.9-47.4% S), MDR (33.3-36.8% S), and XDR (21.4-23.8% S) isolates whereas comparator agent S ranged 0.0-21.1%.**Conclusions:** WCK 5999 was very active against ACB isolates and demonstrated enhanced activity over MEM alone against PSA, most notably against CAZ NS, MDR, and XDR PSA isolates. These data support the continued development of this promising antibacterial combination.

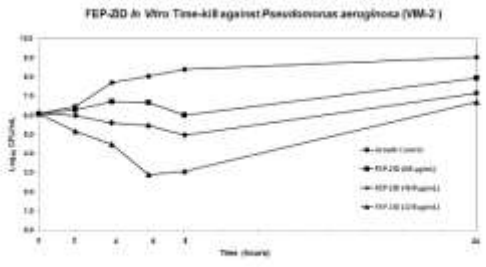
Wck 5222 (Cefepime-Zidebactam) *In Vitro* Time-kill Studies Against *Pseudomonas aeruginosa* (Psa) and *Acinetobacter baumannii* (Acb) Isolates with Defined β-Lactamases

Author Block:

M. D. Huband, M. Castanheira, R. N. Jones, P. R. Rhomberg, A. A. Watters, H. S. Sader; JMI Lab., North Liberty, IA

Abstract Body:

Background: Zidebactam (ZID) is a new bicyclo-acyl hydrazide with a dual mechanism of action including selective binding to Gram-negative PBP2 and β-lactamase inhibition for Class A and C but not of Class B. We evaluated the activity of cefepime (FEP) and ZID alone and combined against 3 ACB and 7 PSA isolates expressing Class A (KPC), B (IMP or VIM), C (AmpC) or D (OXA) β-lactamases by MIC and time-kill studies.**Methods**: Broth microdilution MIC values for FEP, ZID and FEP-ZID (1:1 ratio and ZID at fixed 4, 8 and 16 µg/mL) were determined according to CLSI guidelines. Isolates were selected for time-kill based on β-lactamase content and MIC values. Time-kill testing employed sub-inhibitory concentrations of FEP and ZID as well as MIC multiples. Time-kill studies were sampled for colony counts at T_0, T_2, T_4, T_6, T_8 and T_{24}.**Results**: Time-kill studies showed that ≤32 µg/mL of FEP or ≤16 µg/mL of ZID tested alone were not bactericidal against PSA (VIM-2). However, FEP-ZID combinations (32/8 [Figure] and 8-32/16 µg/mL) were bactericidal against VIM-2 producing PSA by T_8. Other FEP-ZID combinations were bactericidal against PSA producing IMP-13 (32/8 and 8-32/16 µg/mL) and AmpC (8-32/8 µg/mL) by T_8 and T_{24}, respectively. Two $\log_{10}$ CFU/mL colony count reductions were observed for FEP-ZID combinations against OXA-23 (16-32/8 µg/mL) and OXA-24 (32/8 µg/mL) producing ACB by T_8.**Conclusion**: FEP-ZID combinations showed potent activity in time-kill studies against PSA and ACB isolates expressing clinically relevant β-lactamases including AmpC, IMP, KPC, OXA, and VIM enzymes for which limited treatment options may be available. These results support further clinical development studies



with FEP-ZID (WCK 5222).

Antimicrobial Activity of WCK 5222 (Cefepime-Zidebactam) Tested against Clinical Isolates of *Pseudomonas aeruginosa* and *Acinetobacter* spp. Collected Worldwide (2015)

Author Block:

H. S. Sader, D. J. Farrell, R. K. Flamm, R. N. Jones; JMI Lab., Inc., North Liberty, IA

Abstract Body:

Background: WCK 5222 consists of cefepime (FEP) combined with zidebactam (ZID), a bicyclo-acyl hydrazide with a dual mechanism of action involving selective and high binding affinity to Gram-negative PBP2 and β-lactamase inhibition.**Methods:** 353 *P. aeruginosa* (PSA) and 137 *Acinetobacter* spp. (ASP) isolates were collected from 68 medical centers (21 countries) in 2015 by the SENTRY Antimicrobial Surveillance Program and susceptibility (S) tested by a reference broth microdilution method against FEP-ZID (1:1 and 2:1 ratios) and comparator agents.**Results:** FEP-ZID was very active against PSA with $MIC_{50/90}$ of 1/4 μg/mL and 99.7% of isolates inhibited at ≤8 μg/mL (1:1 ratio; Table). FEP-ZID (1:1 ratio) MIC values were generally 2-fold lower than those for FEP ($MIC_{50/90}$, 2/16 μg/mL) and ZID alone ($MIC_{50/90}$, 2/8 μg/mL). Colistin (COL; $MIC_{50/90}$ of ≤0.5/1 μg/mL; 100.0% S) and amikacin (AMK; $MIC_{50/90}$, 4/16 μg/mL; 92.4% S) were also active against PSA. FEP-ZID exhibited consistent activity against PSA from all continents (99.0-100.0% inhibited at ≤8 μg/mL) and retained potent activity against ceftazidime (CAZ)-non-S and meropenem (MEM)-non-S PSA (98.2-98.9% inhibited at ≤8 μg/mL). FEP-ZID 1:1 and 2:1 ratios ($MIC_{50/90}$, 16/32 μg/mL for both) were 4-fold more active than FEP against ASP. The most active compounds tested against ASP were COL ($MIC_{50/90}$, ≤0.5/1 μg/mL; 94.9% S) and AMK ($MIC_{50/90}$, 16/>32 μg/mL; 50.4% S).**Conclusion:** FEP-ZID (WCK 5222) demonstrated potent in vitro activity against this worldwide collection of PSA, including isolates resistant to CAZ and/or MEM, and moderate activity against ASP. These in vitro results support further development of WCK 5222 for treatment of systemic PSA and ASP infections.

WCK 5107 (Zidebactam, Zid): Structure Activity Relationship (Sar) of Novel Bicyclo Acyl Hydrazide (Bch) Pharmacophore Active against Gram-Negatives Including P*seudomonas* (Pa)

Author Block:

P. K. Deshpande, S. B. Bhavsar, S. N. Joshi, S. S. Pawar, R. P. Kale, A. Mishra, S. B. Jadhav, L. S. Pavase, S. V. Gupta, R. D. Yeole, V. P. Rane, V. K. Ahirrao, S. S. Bhagwat, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: β-lactam-β-lactamase inhibitor (BL-BLI) combinations lack coverage of all 4 classes of β-lactamases. Here, we report the first pan Gram-negative BL enhancer (ZID) with high specificity and affinity for PBP2 and overcomes resistance in combination with cefepime.**Methods:** Extensive modifications of diazabicyclo octane (DBO) core were made to obtain novel series of BCHs with intrinsic antibacterial activity. BCH NCEs were prepared by coupling acid hydrazide side chains with DBO core followed by hydrogenolysis, sulfation, and de-protection. ZID MICs (as a measure of PBP2 affinity) were determined as per CLSI guidelines for MDR enterics (ENT) and PA strains. In *Acinetobacter* (AB) expressing Class D β-lactamases, microscopy was performed to confirm minimum spheroplasting concentration (MSC) required for spheroplastation, to judge PBP2 binding efficiency.**Results:** BCH pharmacophore with amine substitutions on hydrazide moiety with C_1-C_4 carbon distance rendered activity against ENT and PA (MIC 0.25-8 and 8->32 µg/mL respectively). Further, amine function and its position from the point of attachment and in particular two carbon distance between amine function and BCH core provided both PA and AB activity (PA MIC 2-8 µg/mL, AB MSC 0.25-1 µg/mL). Terminal amine function and hydrazide moiety determined superior activity over classical DBO, while 'R' stereochemistry in the terminal heterocycles led to improved activity.**Conclusion:** SAR and preclinical studies led to clinical candidate WCK 5107 with potent PBP2 binding activity against MDR ENT, PA and AB strains.

Publishing Title:

***In Vitro* Susceptibility of a Collection of Carbapenem-resistant *Enterobacteriaceae* and *Pseudomonas aeruginosa* to Ceftazidime/Avibactam and Ceftolozane/Tazobactam**

Author Block:

A. Clowes, M. Lam, C. Hamula, **T. Dingle**; Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract Body:

Background: The frequency of isolation of pan-resistant Gram-negative organisms has been steadily increasing. Ceftazidime/avibactam (C/A) and ceftolozane/tazobactam (C/T) are two new cephalosporin β-lactamase inhibitor combination antibiotics targeting Gram-negative organisms. Notably, C/A and C/T have been shown to retain activity against some carbapenem-resistant *Enterobacteriaceae* and *P. aeruginosa*, respectively. The goal of this study was to test the susceptibility of a collection of carbapenem-resistant *Enterobacteriaceae* and *P. aeruginosa* isolates collected in New York City against C/A and C/T. **Methods:** All clinical isolates were collected in the Mount Sinai Clinical Microbiology Laboratory. The collection consisted of 57 *Enterobacteriaceae*, resistant to all β-lactams including ertapenem and imipenem, and 20 *Pseudomonas aeruginosa* isolates resistant to ceftazidime, cefepime, imipenem and meropenem. The *Enterobacteriaceae* isolates were tested against C/A and the *P. aeruginosa* isolates were tested against both C/A and C/T. All isolates were tested by standard E-test procedures and susceptibility interpretations were recorded per the breakpoints found in the package insert for each drug.**Results:** Of the 57 multi-drug resistant *Enterobacteriaceae* isolates, 55 (96.5%) were susceptible *in vitro* to C/A. The two resistant isolates, an *Escherichia coli* and *Klebsiella pneumoniae*, were pan-resistant to all drugs tested other than tigecycline. Of the multi-drug resistant *P. aeruginosa* isolates tested, 8/18 (44.4%) were susceptible to C/A and 13/20 (65%) were susceptible to C/T. Of note, both C/A susceptible-C/T resistant and C/A-resistant-C/T susceptible *P. aeruginosa* isolates were observed.**Conclusion:** Whereas C/A showed good activity against the carbapenem-resistant *Enterobacteriaceae*, decreased susceptibility was observed for the *P. aeruginosa* isolates. When comparing the activity of each drug against the *P. aeruginosa* isolates, C/T showed improved activity over C/A. Determination of the genotypic mechanism of resistance for this collection of carbapenem-resistant isolates is currently underway and will provide further associations between resistance mechanism and susceptibility patterns of C/A and C/T.

Abstract Body:

Background: Antibiotic options for treatment of CF exacerbations due to MDR PA are limited. C/T is a novel cephalosporin/β-lactamase inhibitor with potent activity against MDR PA. C/T use in children has not been described.**Methods:** A 14 year old CF girl with history of cefepime allergy was infected with 2 strains of MDR PA that was susceptible to C/T (MIC: 0.05 and 1 ug/mL). She underwent C/T desensitization until 1.5 gm q8h (30 mg/kg/day of C component).C/T concentration and PK modeling was performed using HPLC. PK samples were collected after the 4th dose. PK parameters were modeled using one-compartment first-order input and elimination, by nonlinear least-squares techniques. PK parameters were also used to simulate a variety of C/T dosing regimens against various MICs.**Results:** PK estimates are shown in Table 1. The percentage of dosing interval in which free drug concentrations remain above the MIC (%*f*T>MIC) for each simulated doses against tested MIC range are shown in Table 2. All regimens exceeded the target *f*T>MIC of 40% against the tested MICs. There was rapid clinical improvement over the following 5 days. After a 14-day treatment course her respiratory status returned to baseline.**Conclusions:** C/T may be considered to treat CF patients infected with MDR PA with MIC of up to 8 µg/ml when given at doses of 1.5 g q8h over 1h or higher. Further studies assessing the PK of C/T in CF patients are warranted.**Table 1.** Modeled PK parameters of C/T at steady state based on total plasma concentrations

A Novel Kynureninase Inhibitor Reduces Quorum Sensing and Virulence Factor Expression in *Pseudomonas aeruginosa*

Author Block:

S. H. Kasper[1], R. P. Bonocora[2], J. T. Wade[2], R. A. Musah[3], **N. C. Cady**[1]; [1]SUNY Polytechnic Inst., Albany, NY, [2]New York State Dept. of Hlth., Albany, NY, [3]Univ. at Albany, SUNY, Albany, NY

Abstract Body:

Pseudomonas aeruginosa is an opportunistic pathogen that utilizes multiple quorum sensing (QS) systems to regulate virulence factor expression. In a high-throughput, phenotypic screen, we have previously identified a small molecule that does not affect bacterial viability, but is capable of interfering with *P. aeruginosa* biofilm formation as well as QS in a *las*-based reporter. This inhibitor, *S*-phenyl-L-cysteine sulfoxide, lacks structural similarity to any of the known *P. aeruginosa* autoinducers. Therefore, we sought a deeper understanding of the mechanism of action and the effects of this compound. In this work we performed a global transcriptomic analysis of *P. aeruginosa* in response to *S*-phenyl-L-cysteine sulfoxide using RNA-seq. This analysis revealed that the inhibitor down-regulates expression of several QS-regulated virulence operons. Of the genes that were differentially regulated, many are interrelated through the metabolic pathways that yield precursors of pyochelin, tricarboxylic acid cycle intermediates, phenazines, and the *Pseudomonas* quinolone signal (PQS). Upon examination of these pathways, we identified structural similarity between the inhibitor and kynurenine, a precursor of anthranilate, which is necessary for PQS production and critical for *P. aeruginosa* virulence. Biochemical analysis revealed that *S*-phenyl-L-cysteine sulfoxide is a competitive inhibitor of kynureninase, the enzyme responsible for the conversion of kynurenine to anthranilate. By adding exogenous anthranilate, the QS-inhibitory effect of *S*-phenyl-L-cysteine sulfoxide could be reversed in reporter assays. Finally, it was shown that *S*-phenyl-L-cysteine sulfoxide significantly reduces PQS production in vivo. Several studies have previously shown that mutant strains deficient in the kynurenine pathway are associated with reduced QS and virulence factor expression; however, this is the first study to demonstrate a small molecule that inhibits *P. aeruginosa* kynureninase, and associated QS and virulence systems, suggesting a potential anti-virulence strategy.

Assessing Target Engagement *In Vitro* and *In Vivo* of Mvfr Inhibitors in *Pseudomonas aeruginosa* (Pa)

Author Block:

A. RUBIO[1], M. Antolini[2], E. Benetta[2], V. Costantini[2], A. Felici[2], S. Fontana[2], L. Rahme[3], J. Teague[4], P. Thommes[4], P. Turnpenny[5], P. Warn[4], T. Parr[1], M. Pucci[1], R. Zahler[1]; [1]Spero Therapeutics, Cambridge, MA, [2]Aptuit, Verona, Italy, [3]Massachusetts Gen. Hosp., Boston, MA, [4]Evotec, Manchester, United Kingdom, [5]Evotec, Abingdon, United Kingdom

Abstract Body:

Objective: Pa is a common opportunistic human pathogen and has developed resistance to many classes of the available antibiotics. MvfR is a global transcriptional regulator responsible for expression of many virulence factors, including 4-hydroxy-2-heptylquinoline (HHQ), 3,4-dihydroxy-2-heptoquinoline (PQS) and pyocyanin (PYO). PQS, HHQ and PYO are produced both *in vitro* and *in vivo* and provide a surrogate measurement to the MvfR IC_{50}. Here we describe the *in vitro* properties of a novel MvfR inhibitor, SPR00305, and measure target engagement *in vivo* using both neutropenic and immunocompetent acute models of Pa infection. **Methods:** IC_{50} values against biomarkers on the MvfR pathway were determined in the Pa strain PA14. PYO IC_{50} was measured in a deep 96 well colorimetric assay format adapted from the method described in Essar *et al* J Bacteriol 172: 884. HHQ and PQS IC_{50} were measured using the isotope-dilution method followed by LC-MS/MS analysis. Target engagement was measured *in vivo* as HHQ and PQS levels quantified from murine thigh tissues (both immunocompetent and neutropenic) infected with PA14. **Results:** SPR00305 was found to be a potent *in vitro* inhibitor of the MvfR pathway with IC_{50} values of 93 nM against PYO, 115 nM against HHQ and 109 nM against PQS in PA14. *In vivo* the analytical methods quantified HHQ and PQS from the immunocompetent acute thigh infection model with a sensitivity of 5 ng/mL as the LLQ. After oral administration, 200 mg/kg SPR00305 was found to decrease HHQ by 40% and PQS by 50% compared to vehicle. The analytical methods quantified HHQ from the neutropenic acute thigh infection model with a sensitivity of 1 pg/mL as the LLQ. SPR00305 administered orally (up to 200 mg/kg tid) induced a slight decrease in HHQ levels compared to vehicle in the neutropenic acute thigh infection model. **Conclusion:** SPR00305 represents a novel, potent MvfR inhibitor *in vitro* that also displays target engagement *in vivo*.

Abstract Body:

P. aeruginosa is a highly virulent multidrug-resistant pathogen that causes significant morbidity and mortality in a variety of patients, particularly in those with Cystic Fibrosis (CF). We utilize antisense oligomers, specifically PPMOs, for sequence-specific, species-specific silencing of target genes. We have previously demonstrated *in vitro* and *in vivo* success in targeting essential genes in other Gram-negative pathogens, and here attempt to use PPMOs to inhibit *P. aeruginosa*.PPMOs were designed to complement known or putative essential genes in *P. aeruginosa* PAO1. When co-incubated with colistin (Polymyxin B) or Polymyxin B Nonapeptide (PMBN) at sub-inhibitory concentrations (2 μg/ml), a number of PPMOs were found to be inhibitory in a panel of *P. aeruginosa* strains with IC_{50} concentrations of 1-4 μM (in Mueller-Hinton media) for the essential genes *acpP* (acyl carrier protein), *rpsJ* (30S ribosomal protein S10) and *lpxC* (UDP-(3-*O*-acyl)-N-acetylglucosamine deacetylase). Growth inhibition was enhanced when PPMOs were screened in minimal media (MOPS). Lead PPMOs against these targets prevented *P. aeruginosa* biofilm formation. Importantly, PPMOs were capable of penetrating pre-formed biofilms, reducing biofilm thickness from 20-40 μM to <10 μM as assessed by confocal microscopy of GFP-expressing PAO1. Furthermore, examination of combinations of PPMOs and clinically relevant antibiotics (such as tobramycin) revealed that they could act synergistically to reduce the growth of *Pseudomonas*.These are the first studies demonstrating that PPMOs are effective against the *P. aeruginosa* essential gene targets *acpP*, *rpsJ* and *lpxC* and can be used synergistically with conventional antibiotics. Efficacy of PPMOs is enhanced by the presence of sub-inhibitory amounts of PMBN and may serve as a future co-delivery adjuvant.

Inhibition Of Biofilm And Quorum-Sensing Pathways In *pseudomonas Aeruginosa* by Peptide-Conjugated Phosphorodiamidate Morpholino Oligomers (Ppmos)

Author Block:

C. R. Sturge[1], J. Howard[1], H. Justice[1], M. Wong[2], B. L. Geller[3], D. E. Greenberg[1]; [1]UT Southwestern Med. Ctr., Dallas, TX, [2]Sarepta Therapeutics, Cambridge, MA, [3]Oregon State Univ., Corvallis, OR

Abstract Body:

Given the global crisis of increasing antibiotic resistance, the development of novel antibiotics is of the utmost importance. We utilize antisense oligomers, specifically PPMOs, for sequence-specific, species-specific silencing of target genes. We have previously demonstrated *in vitro* and *in vivo* success in targeting essential genes in various Gram-negative pathogens. Here we focus on targeting virulence mechanisms, specifically biofilm production pathways in the major human pathogen *Pseudomonas aeruginosa*.*Pseudomonas* biofilms were grown utilizing a minimum biofilm eradication concentration (MBEC™) assay. Biofilm production was measured utilizing crystal violet staining with measurements at OD570. *P. aeruginosa* PAO1 was used to screen for the prevention of biofilm utilizing 25 PPMOs targeting various genes involved in biofilm or quorum-sensing. Polymyxin B nonapeptide (PMBN) at sub-inhibitory concentrations was used to enhance entry of PPMOs into *Pseudomonas*. Six potential lead PPMOs were identified and further screened for activity against multidrug-resistant clinical strains from patients with cystic fibrosis (CF). 3 PPMOs targeting the genes *algZ* (alginate biosynthesis), *algU* (sigma factor) and *lasR* (transcriptional regulator) displayed a greater than 50% reduction in biofilm formation at 18 hours (compared to no treatment controls) in 80% of the strains tested. In the strains that were tested, PPMO concentrations needed to reduce biofilm to this degree ranged from 8 μM to at or below 0.5 μM. Confocal microscopy of GFP-PAO1 displayed markedly reduced biofilm formation with these 3 PPMOs compared to no PPMO or a scrambled-sequence control PPMO. Lead PPMOs did not cause cytotoxicity in cell culture.The use of PPMOs to target non-essential genes has the theoretical advantages of circumventing classic pressures that can select for drug resistance. These are the first studies demonstrating that PPMOs are effective against virulence mechanisms (biofilm formation) in the major human pathogen *P. aeruginosa*.

A Novel Combination of Tobramycin with a Potentiator for the Treatment of Chronic *Pseudomonas aeruginosa* Infections

Author Block:

M. Koeva[1], A. D. Gutu[2], F. M. Ausubel[2], **D. Joseph-McCarthy**[1]; [1]EnBiotix, Inc., Cambridge, MA, [2]Massachusetts Gen. Hosp., Boston, MA

Abstract Body:

Background: EBX-001, a combination of tobramycin with a bacterial metabolite as a potentiator, is being developed for the treatment of chronic *P. aeruginosa* infections in Cystic Fibrosis patients. The combination utilizes an anti-persisters strategy and is aimed at reducing recurrent infections.**Methods:** *P. aeruginosa* cultures in the planktonic stationary phase (PSP) were used to select for bacterial persisters, bacteria in a quasi-dormant state. In these PSP experiments, a range of tobramycin concentrations was tested with a range of metabolite concentrations to determine the potentiation effect of the metabolite under a variety of conditions. MICs were also determined for a variety of CF clinical isolates to select a diverse set of strains for inclusion in the study.**Results:** Enhanced killing of up to 6 orders of magnitude of *P. aeruginosa* persisters for a range of strains was observed (see example in the figure below).**Conclusions:** A combination of tobramycin with a potentiator remains an attractive therapeutic option for eliminating recurrent *P. aeruginosa* infections through the eradication of bacterial persisters.

Alginate Oligomer Oligog Cf-5/20 Treatment of *Pseudomonas aeruginosa* Grown in Artificial Sputum Medium

Author Block:

L. C. Powell[1], M. F. Pritchard[1], A. A. Jack[1], E. Onsøyen[2], P. D. Rye[2], K. E. Hill[1], D. W. Thomas[1]; [1]Cardiff Univ., Cardiff, United Kingdom, [2]AlgiPharma AS, Sandvika, Norway

Abstract Body:

Background: Traditional *in vitro* antimicrobial testing of cystic fibrosis (CF) isolates has been shown to relate poorly to *in vivo* test conditions. An artificial sputum medium (AS) model has been developed to mimic the restricted nutritional environment of sputum, and more closely resemble growth conditions of mucoid *Pseudomonas aeruginosa* in the CF lung. The antimicrobial effects of the low molecular weight alginate oligomer, OligoG CF-5/20, (previously shown to disrupt pseudomonal biofilms and potentiate antibiotics) was tested in this low nutrient medium. **Methods:** Susceptibility of the CF clinical isolate *P. aeruginosa* NH57388**A** to OligoG (2-6%) ± the commonly-inhaled antibiotic colistin (0.05-0.2 µg/ml) was compared in Mueller-Hinton (MH) and AS media using growth curves (36 h; n=3), with antibiofilm effects visualized using LIVE/DEAD® confocal laser scanning microscopy (CLSM) and quantified using COMSTAT software analysis (n=6) and scanning electron microscopy. Acyl-homoserine lactones (AHLs) were extracted from planktonic cells grown in AS ±OligoG (24 h) and quantified using high performance mass spectrometry (n=3). **Results:** Growth curves demonstrated a synergistic decrease in bacterial growth when treated with OligoG and colistin in MH. OligoG maintained its effectiveness in AS, colistin alone however, was less capable of hindering bacterial growth. CLSM using MH, demonstrated cellular aggregation and decreased bacterial viability when OligoG was tested in conjunction with colistin, reflecting an enhanced combined antimicrobial effect ($P<0.05$). Growth was significantly lower in AS compared to MH, with a 4-fold decrease in the minimum inhibitory concentrations (MICs) for colistin (0.4 Vs 0.1 mg/ml in MH). Distinct bacterial micro-colonies formed in AS, which were considerably smaller when treated with OligoG ($P<0.05$). The effect of OligoG on pseudomonal quorum sensing was confirmed by dose-dependent decreases in C4-AHL production ($P<0.05$). **Conclusions:** The pronounced differences observed in the two media, reflect the role of environmental conditions on the effectiveness of antimicrobial therapies. The ability of OligoG to exhibit its anti-bacterial and anti-biofilm properties under these nutrient conditions was evident.

Oligog Cf-5/20 Reduces *Pseudomonas aeruginosa* Biofilm Formation and Virulence via Quorum Sensing Inhibition

Author Block:

A. Jack[1], S. Khan[1], H. Sadh[1], E. Onsøyen[2], P. Rye[2], D. Thomas[1], **K. E. Hill**[1]; [1]Cardiff Univ., Cardiff, United Kingdom, [2]Algipharma AS, Sandvika, Norway

Abstract Body:

Background: *Pseudomonas aeruginosa* is a nosocomial, opportunistic pathogen, able to infect almost all areas of the human body. Virulence in *P. aeruginosa* is regulated by the quorum sensing (QS) Las and Rhl pathways. OligoG CF-5/20 is an alginate previously shown to reduce biofilm formation, as well as QS regulated motility and swarming in *P. aeruginosa.* OligoG could therefore directly affect QS signalling in *P. aeruginosa***Methods:** Cell-free supernatants of OligoG (0.2-10%)-treated *P. aeruginosa* PAO1 virulence factor (pyocyanin, rhamnolipids, elastase, protease) production was monitored using spectrophotometric assays (Mueller Hinton broth, MH; 24 h). A *Chromobacterium violaceum* CV026 bio-sensor assay determined expression of acyl homoserine lactones (AHLs), C4-AHL and C12-AHL (controlled by Las and Rhl respectively) in PAO1 ± OligoG (0.2-10%) with AHL extracts from PAO1 grown in MH (12, 18, 24, 30 h) and Artificial Sputum (AS) medium (30, 48 h) quantified using liquid chromatography mass spectrometry (LC/MS). SYBR-Green Real-time RT-PCR (qPCR) was used to characterise the effect of OligoG on expression of QS genes *lasI, lasR, rhlI, rhlR, pvdQ, pqsE* and *pilE*. Dry weight was used to normalise differences in culture biomass.**Results:** Virulence factor assays showed decreasing production of pyocyanin and rhamnolipid (at 0.2 and 10% OligoG; $P<0.05$) and of elastase and protease at 10% ($P<0.05$). Significant reductions at 2 and 10% were also seen in AHL production of both C12-AHL and C4-AHL. LC/MS showed decreasing production of C12-AHL and C4-AHL over time, (with a 3-fold greater overall yield of C4 than C12), and with the greatest concentrations seen at the earliest time point (12 h). In contrast, *P. aeruginosa* grown in nutrient limited AS medium showed extremely low concentrations of both AHLs which decreased over time for C12-AHL (being greatest at 10% OligoG 30 h) with surprisingly similar levels of C4-AHL seen for both time points. A significant decrease in gene expression was seen for *lasI/R* at 0.2, 2 and 10%, while a decrease was also seen for *rhlR* at 2 and 10% and *rhlI* at 10% ($p<0.05$).**Conclusions:** Expression of Las and Rhl QS pathways were altered in a time-dependent manner following OligoG treatment, offering insight into the molecular mechanism by which OligoG induces its antibiofilm effect.

Publishing Title:

Sasp: A Novel Antibacterial Targeting *Pseudomonas aeruginosa* Demonstrating a Rapid Mode of Action and Low Propensity for Resistance Development

Author Block:

A. L. Castillo, S. Cullen, A. S. Nepal, J. Cass, A. Wilkinson, **H. Fairhead**; Phico Therapeutics, Cambridge, United Kingdom

Abstract Body:

Background: For novel antibacterials to be successful it is critical that they demonstrate a low propensity for the development of resistance. SASPject is a unique antibacterial technology utilising engineered gene delivery vehicles to inject the gene encoding SASP, a protein found in bacterial spores, into target pathogens. The unique mode of action of SASP, which binds to DNA in a non-sequence specific manner to prevent DNA replication and gene transcription, coupled with rapid bactericidal activity, suggests SASP has a low propensity to induce resistance compared to other antibiotics. Here the potential for resistance of *Pseudomonas aeruginosa* (*Pa*) to develop in response to SASPject PT3.8 was measured under both a 24 h exposure regime and in a 52-day passaging study.**Methods:** Passaging studies: *Pa* 3503 and 2923 cultures at ~10^6 cfu/ml in Luria Bertani broth supplemented with magnesium, calcium, and glucose (LB+) were passaged daily after 24 h growth at 37 °C in the presence of *Pa* SASPject at 1 x 10^7, 5 x 10^6, 2.5 x 10^6 and 1.25 x 10^6 SASPject PT3.8 Units (U)/ml. A control without added PT3.8 was passaged in parallel. Susceptibility of the cultures to PT3.8 was assessed daily by 3 h kill assays. 24 h exposure regime: 4 *Pa* strains were assayed by time-kill curve over 24 h, and remaining bacterial survivors isolated and tested for sensitivity in a 3 h kill.**Results:** During long-term exposure studies, using 3 sub-inhibitory concentrations of PT3.8, no decrease in sensitivity was observed during 21 and 52 days of passaging *Pa* strains 2923 and 3503, respectively. During 24 hour exposure to bactericidal concentrations of PT3.8, bacterial kill was rapid with numbers declining to within the limit of detection within 1 hour for all strains tested. Survivors isolated after 24 hours of exposure to PT3.8 remained highly sensitive to PT3.8.**Conclusions:** The unique mode of action of SASP means that mutations in bacterial DNA cannot lead to resistance as SASP inactivates bacterial DNA in a sequence-independent manner. This is supported by the data presented here, where resistance did not develop in the *Pa* strains tested in either a 24 h kill assay or within 52 days of passaging with PT3.8. In conclusion the SASPject technology platform displays a low propensity for resistance development in the treatment of *Pa*.

Characterization of the Interaction with, and Disruption of Mucoid *Pseudomonas aeruginosa* Biofilms by the Alginate Oligosaccharide Oligog Cf-5/20

Author Block:

L. C. Powell[1], M. F. Pritchard[1], E. L. Ferguson[1], K. A. Powell[1], H. Sadh[1], E. Onsøyen[2], P. D. Rye[2], K. E. Hill[1], D. W. Thomas[1]; [1]Cardiff Univ., Cardiff, United Kingdom, [2]AlgiPharma AS, Sandvika, Norway

Abstract Body:

Background: Biofilm-associated infections are a major cause of morbidity in chronic respiratory diseases such as cystic fibrosis (CF); resisting antibiotic/antimicrobial therapy and host immune responses. A novel alginate oligosaccharide, OligoG CF-5/20, potentiates antibiotic activity against multi-drug resistant bacteria. In this study, the effects of OligoG on the establishment and disruption of pseudomonal mucoid biofilms was characterized and quantified.**Methods:** A mucoid *Pseudomonas aeruginosa* (NH57388A) CF isolate was used to determine the effect of OligoG (0.5, 2, 6%) on biofilm formation (24 h) and on disruption following OligoG treatment of pre-established biofilms (24 h), grown *in vitro* in Mueller Hinton broth (MHB) at 37ºC. OligoG was conjugated to the fluorophore Texas Red (TxRd®) cadaverine to determine the diffusion of OligoG through the biofilm extracellular polysaccharide (EPS) matrix. Confocal laser scanning microscopy (CLSM) with LIVE/DEAD®, Sypro Ruby Biofilm Matrix® and SYTO 9® stains was used for biofilm imaging and COMSTAT image analysis software used to quantify the physical properties of the biofilm. Supernatant removed from the biofilms was stained with crystal violet and the OD_{595} was measured to quantify displaced planktonic cells.**Results:** OligoG treatment impaired formation of *P. aeruginosa* biofilms in a dose-dependent manner, resulting in a significant reduction in bacterial biomass and mean biofilm thickness ($p<0.05$), with increased EPS matrix porosity. Planktonic cells from the biofilm supernatant were significantly increased at 0.2 and 0.5% OligoG (but not at 2 and 6%) compared to the control ($p<0.05$). Established biofilms were also disrupted following 24 h OligoG treatment, leading to biofilm height reduction ($p<0.05$) and disruption of the EPS matrix. TxRd®-labelled OligoG penetrated through the entire biofilm depth; TxRd® alone showed no evidence of biofilm disruption.**Conclusions:** The ability of OligoG to inhibit biofilm formation and diffuse into and disrupt established biofilm structures highlights the potential for this novel therapy to be used as a treatment of biofilm-associated infections in CF, and other biofilm-mediated diseases.

Publishing Title:

Polymyxin (Pm) Resistance in *Pseudomonas aeruginosa* (Pa): Metabolomic Changes Underpin Lipid A Modifications

Author Block:

M-L. Han, Y. Zhu, S-E. Cheah, M. D. Johnson, H. H. Yu, H-H. Shen, D. J. Creek, T. Velkov, J. Li; Monash Univ., Melbourne, Australia

Abstract Body:

Background: Modification of lipid A with positively charged 4-amino-4-deoxy-L-arabinose (L-Ara4N) is a major mechanism of PM resistance in PA[1]. However, the metabolomic changes due to lipid A modifications have not been well characterized in PM-resistant PA.**Methods:** Structural analysis of lipid A was performed with ESI-MS in the negative ion mode with PM-susceptible PAK (PMB MIC 1 mg/L) and -resistant PAK*pmrB6* (MIC 16 mg/L)[2]. The influence of PM treatment on lipid A modifications was investigated with both strains (initial inoculum at ~10^6 CFU/mL) in the presence of 1×MIC PMB. The metabolomes of PAK and PAK*pmrB6* were studied using LC-MS with samples collected at mid-logarithmic phase (OD_{600nm} 0.5) without PMB treatment. Global metabolic changes in both strains were examined with multivariate and univariate analyses. The synthesis pathway of L-Ara4N involved in the lipid A modification was analyzed.**Results:** Structural analysis of lipid A from the wild-type PAK strain and the *pmrB* mutant (PAK*pmrB6*) showed penta- and hexa-acylated lipid A species, differing in the absence or presence of 3-hydroxydecanoate acyl chain. The structures of lipid A from PAK*pmrB6* without PMB treatment revealed modifications with one or two L-Ara4N, but not with the PAK strain. In the presence of 1×MIC PMB, L-Ara4N modified lipid A was detected in PAK at 24 h; however, in PAK*pmrB6*, the proportion of the modified lipid A did not changed over 24 h. Interestingly, the relative abundance of penta-acylated lipid A (i.e. removal of 3-hydroxydecanoate) in both strains substantially increased in response to PMB treatment at 24 h. The global metabolomics revealed 30% decrease of total glycerophospholipids in PAK*pmrB6*, compared to PAK. Remarkably, metabolic pathway analysis on the synthesis of L-Ara4N showed the intracellular level of UDP-glucuronate in PAK*pmrB6* increased ~400 folds compared to PAK, while UDP-L-Ara4N, UDP-L-Ara4FN and undecaprenyl phosphate-L-Ara4N were only detected in PAK*pmrB6*.**Conclusions:** For the first time, our study revealed significant metabolomic changes in the synthesis pathway of L-Ara4N in a PM-resistant PA strain. Importantly, besides addition of L-Ara4N, lipid A deacylation and reduction of membrane glycerophospholipids also contribute to PM resistance in PA.

Phenotypic and Genomic Evaluation of Isogenic Mutants of *Pseudomonas aeruginosa* (Pa) Hypersusceptible to Multiple Classes of Antibiotics

Author Block:

L. B. Harrison[1], R. C. Fowler[2], N. D. Hanson[1]; [1]Creighton Univ., Omaha, NE, [2]Univ of NE Med Ctr, Omaha, NE

Abstract Body:

Background: : PA colonized in the lungs of cystic fibrosis patients are exposed to a myriad of antibiotics. Hypersusceptibility of PA to multiple antibiotic drug classes has been reported but the genetic mechanisms responsible for this phenotype remain unclear. The purpose of this study was to use phenotypic, molecular and genomic data to characterize chromosomal modifications leading to a hypersusceptible phenotype in isogenic mutants of PA. **Methods:** Mutants were generated from the clinical isolate PA34 by exposure to subinhibitory concentrations of doripenem or meropenem. MICs were determined by agar dilution. Two carbapenem-resistant mutants (PA34-822D and PA34-812M) hypersusceptible to non-carbapenem antibiotics were evaluated. Gene expression was evaluated by RT-qPCR and OprD production was evaluated by SDS-PAGE and Coomassie Blue. Strains were sequenced on the Illumina MiSeq and SNPs verified by IGV visualization. Lipid polysaccharide (LPS) profiles were evaluated by SDS-PAGE and visualized with ethidium bromide. **Results:** : MICs for imipenem, meropenem and doripenem in PA34 were 1, 0.12 and 0.25 µg/mL while both mutants had MICs of 8, 1 and 2 µg/mL, respectively. Both mutants were hypersusceptible to aminoglycosides, fluoroquinolones and non-carbapenem β-lactams. Compared to PA34 no change in expression was observed in ampC or the mex-opr efflux pump systems. Outer membrane protein analysis showed decreased OprD production. Genomic analysis revealed 4 SNPs in PA34-812M and 5 SNPs in PA34-822D compared to PA34. SNP induced amino acid substitutions in both mutants included E108D in AlgU and G77C in LptG. SNP induced truncations of OprD at loop 7 in PA-34812M and loop 8 in PA34-822D were observed. Preliminary LPS gel evaluation indicated modified rough LPS profiles in PA34-812M and PA34-822D compared to PA34.**Conclusions:** These data show that upon emergence of carbapenem resistance mutations can occur which lead to a hypersusceptible phenotype. Evaluation of these hypersusceptible isogenic mutants identified only two candidate genes for this phenotype, *algU* and *lptG*. Modificaitons in the LPS profiles observed in the mutants suggests that the amino acid substitutions found in LptG interfere with LPS transport and may contribute to the hypersusceptible phenotype observed.

Streinu-Cercel[1]; [1]Carol Davila Univ. of Med. and Pharm; Natl. Inst. Infect Dis Matei Balș, Bucharest, Romania, [2]Ș. Nicolau Inst Virol;Univ. Buc, Bucharest, Romania, [3]Ș Nicolau Inst Virol, Bucharest, Romania, [4]Univ. Buc, Bucharest, Romania

Abstract Body:

Background: *P. aeruginosa*, a Gram-negative opportunistic pathogen, has become a serious threat especially for immunocompromised patients, associating high biofilm burden. **Methods:** We have tested the impact of binary dilution of commercial phages on biofilm inhibition in 44 clinically relevant strains of *P. aeruginosa* collected from patients admitted in a Romanian national reference center following the protocol presented in Neguț et al., GERMS 2014.**Results:** All patients were Caucasian, 56.8% (25/44) were males, 15.9% (7/44) had diabetes mellitus and 59.1% (29/44) were evaluated as Carmeli 3. *P. aeruginosa* was isolated mostly from urinary infections (17/44) and skin infections (15/44). Antibiotic susceptibility was 51.4% for piperacillin < 52.5% piperacillin-tazobactam and ceftazidime < 56.8% imipenem < 100% colistin. Susceptibility to phages was 68.9% for PYO and 66.7% for INTESTI, with 35.6% for both PHAGYO and PHAGESTI.We performed the PYO and INTESTI assays for 31 and 32 strains, respectively. Most strains formed strong biofilm, 80.6% (25/31) in the first experiment and 78.1% (25/32) in the second one.In both experiments, all phage dilutions significantly decreased optical density (OD) of the culture (p=0.001) even if for the highest concentration of phages, complete biofilm inhibition occurred in 6/31 strains in the PYO assay, and 12/32 in the INTESTI assay, respectively. (Table 1)**Conclusion:** In our experiment a higher susceptibility occurred for phages compared with antibiotics, in clinically significant strains. Biofilm development significantly decreased when adding phages. All these data suggest that bacteriophages should be further investigated as options for hard to treat infections.Table 1. Effect of phages on biofilm

	OD culture	OD 1/64 phage dilution	OD 1/2 phage dilution
INTESTI	0.241	0.163	0.130
PYO	0.225	0.156	0.129
p-value INTESTI	NA	**0.000***	**0.000***

p-value PYO	NA	**0.001***	**0.000***

Validation of a Porcine Wound Model for *Acinetobacter baumannii* Infection

Author Block:

C. C. Black, Y. Alamneh, R. K. Kim, C. L. Jones, M. G. Thompson, L. Biggeman, R. Patel, C. L. Honnold, X. Feng, C. Paranavitana, S. D. Tyner, **D. V. Zurawski**; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

Patients exposed to combat injury often require weeks of hospitalization increasing the risk of wound and surgical-site soft tissue infections (SSTI). Highlighting this, during the recent wars in Iraq and Afghanistan infection rates were 25% in casualties and approached 50% in patients admitted to an ICU. In particular, these infections are mediated in large part by multidrug-resistant (MDR) ESKAPE pathogens. Of these, *A. baumannii* is still relatively understudied, but novel antibacterials are needed because even colistin-resistant strains are now emerging. While many have developed murine models to evaluate antibacterials, a large animal model is lacking. To facilitate understanding *A. baumannii* pathogenesis and drug discovery, we present a porcine full thickness, excisional wound model of *A. baumannii* infection using a clinically-relevant MDR-*A. baumannii* isolate, AB5075, that proliferates to 10^8 CFU/g in tissue, forms biofilm, and can then be effectively treated with an antibiotic. The model requires cyclophosphamide-induced neutropenia to establish a SSTI that persists beyond seven days. Multiple 12 mm diameter wounds are created in the skin overlying the cervical and thoracic dorsum. Wound beds are inoculated with 5.0×10^4 AB5075 and covered with a dressing. The positive control, polymyxin B, is applied topically and endpoints are assessed using multiple quantitative and qualitative techniques to include gross pathology, weight gain, CFU burden, histopathology, peptide nucleic acid fluorescence in situ hybridization (PNA-FISH), and scanning electron microscopic (SEM) assessment of biofilm. Polymyxin B treatment resulted in a 3 $\log_{10}$ reduction of CFU/g tissue on Day 2 of treatment. By Day 6, there were on average 3.79×10^8 CFU/g AB5075 in wound tissue in untreated wounds, but no bacteria could be detected in treated samples. These measures provide a clear therapeutic window where novel antimicrobial therapies can be assessed. This model will be used to evaluate systemic and topical compounds for the ability to reduce pathogen load and clear biofilms. The combination of our porcine model with our murine wound model allows for a robust, multi-faceted *in vivo*, pre-clinical assessment of novel antibacterials for SSTI prior to testing in clinical trials.

Development and Validation of a Novel Ovine Model of Catheter Associated Urinary Tract Infections Caused by Uropathogenic *E. coli* (Upec)

Author Block:

P. J. Plummer, O. Sahin, K. Mullin, M. Beal, M. Ackermann, N. L. Barbieri, G. Li, Q. Zhang, C. Logue, and L. Nolan; Iowa State Univ., Ames, IA

Abstract Body:

Catheter associated urinary tract infections (CAUTI) are important and common cause of nosocomial infections in modern health care. While CAUTIs are typically polymicrobial in nature, uropathogenic *Escherichia coli* are commonly involved and can lead to significant clinical disease. Despite the clinical significance of CAUTIs, there are few clinically relevant animal models of the disease that can be used to study the host-pathogen interactions associated with this process. The goal of this study was to develop and validate an ovine (sheep) model of CAUTI that could be used to further our understanding of the host-pathogen interaction during infection with UPEC. For this study, eight mature female cross-bred sheep were divided into three groups, which included an uninoculated control group having two sheep , and two treatment groups each having three animals that were inoculated with UPEC. Prior to the start of the study all sheep had indwelling 14Fr x 9 inch radiopaque silicone Foley catheter with a 10 cc balloon placed through the external os of the urethra into the urinary bladder. The external end of the catheter was stabilized using a Bard Medical StatLock® Foley Device that was glued to the inner thigh of the ewe. On day zero of the study the two treatment groups were inoculated with one of two UPEC strains, UPEC CFT073 or *E. coli* ec958. CBC, serum chemistry, coagulation profiles and urinalysis were performed daily throughout the two-week study. Indwelling silicone Foley catheters were successfully maintained for the 16-day study in 7 of the eight sheep (one was removed at day 10 due to occlusion by a bacterial biofilm). Both strains of UPEC demonstrated immediate and long-term colonization of the bladder with urinalysis counts averaging between 10^5-10^8 CFU/ml from day 1 through day 14. At necropsy one treatment animal had severe pyelonephritis. All inoculated animals were culture positive in the ureters as were the majority in the renal pelvis, whereas neither of the control sheep developed any signs of infection nor yielded culture positive specimen.. This data indicates that the ovine indwelling urinary catheter model could replicate human CAUTI with high-level consistent colonization of the bladder with UPEC and subsequent development of clinical disease.

A Novel Foreign Body Osteomyelitis Model That Allows for Quantitative Cultures of the Infection Site Over Multiple Time-points

Author Block:

C. L. Brinkman, S. Schmidt-Malan, R. Patel; Mayo Clinic, Rochester, MN

Abstract Body:

In previous studies, we have utilized a rat model of foreign body osteomyelitis that involves implantation of a stainless steel wire into the intramedullary cavity of the rat tibia. One disadvantage to this model is that samples for culture are only collected at sacrifice, at which time bone and wire may be removed and quantitatively cultured. We sought to develop a model that would allow us to remove samples for culture at multiple time-points from the same animal.A novel rat foreign body osteomyelitis was established in six male Wistar rats using three stainless steel wires per animal. Three 1 mm holes were drilled into the left tibia using a bone drill. Stainless steel wires, 5 mm in length, were placed into the holes, perpendicular to the tibia, and dental gypsum was placed on the bone to secure the wires into place. Wires were seeded with either methicillin-resistant *Staphylococcus aureus* or *Staphylococcus epidermidis* by incubating wires in a 1.0 McFarland culture at 37°C, shaking at 140 rpm, for 2 hours prior to implantation. Infection was established for 28 days, after which wires were removed from the animals at one week intervals and quantitatively cultured to determine bacterial quantities.Wires from animals infected with *S. aureus* had a bacterial quantity of 4.81 $\log_{10}$ CFU/cm^2 at implantation and had an average bacterial quantity of 3.56, 3.60 and 5.51 $\log_{10}$ CFU/cm^2 at 5, 6 and 7 weeks post-infection, respectively. Wires removed from animals infected with *S. epidermidis* had an initial bacterial quantity of 4.61 $\log_{10}$ CFU/cm^2 and had an average bacterial quantity of 2.08, 2.17 and 2.62 $\log_{10}$ CFU/cm^2 at 5, 6 and 7 weeks post-infection, respectively. There was no contamination of either the wire or infection site over the course of the study.We have established a novel model using wires seeded with either *S. aureus* or *S. epidermidis*. This model will be used in the future to determine the kinetics of response to therapy and emergence of antimicrobial resistance during treatment of foreign body infection. Being able to sample bacteria at multiple time points from the same animal decreases the number of animals needed for an experiment and provides the ability to monitor foreign body infections in the same animal over time.

Multispectral Opto-Acoustic Tomography and Segmental 360-Degree Bioluminescent Imaging Both Show Potential for the Dynamic Study of Staphylococcal Infections

Author Block:

P. Panizzi; Auburn Univ., Auburn, AL

Abstract Body:

Background: Bio-luminescence imaging (BLI) of light-producing pathogens has made it possible to track infections non-invasively in mice. However, there exist inherent biases in tracking these infections as they spread. One of the primary issues is the consistent positioning of animal in the imager in relation to the detector. There are also cases where the signal from a deep tissue or bone infection has difficultly being seen, due to the light absorption and scattering properties of blood, fat, and muscle. Here, we use two techniques to overcome these issues and monitor *in vivo* propagation of a pathogen in mouse models over time. **Methods:** First, we used our newly developed semi-automated full 360-degree imager called the **M**ouse **I**maging **Spinner** (MiSpinner), which allows for the actuated rotation of the animal during the imaging process to reduce any positioning biases. Secondly, we used multispectral optoaccoustic tomography (MSOT) to image bacteria via their photo-acoustic signal generated after systemic administration of the near-infrared bacterial surface probe called XenoLight RediJect. This would allow for the detection of deep tissue signals. **Results:** In the images collected by the MiSpinner prototype housed in the IVIS Lumina XRMS system, we were able to appreciate liver signal in 1 of 5 mice on day 5 following bolus injection of *Staphylococcus aureus* Xen29 (1e5 CFUs). Using the MSOT imager and XenoLight RediJect agent, we could detect 2 of the 5 animals imaged had splenic and liver abscesses present on day 5 following Xen29 injection. A representative transverse plane image of a mouse is shown below with the green regions denoting the abscesses. **Conclusions**: Taken together, these results suggest new avenues available for the *in vivo* study Staphylococcal infections.

An *In Vitro* Urinary Catheterisation Model That Approximates Clinical Conditions for Evaluation of Innovations to Prevent Catheter Associated Urinary Tract Infections

Author Block:

R. Y. R. Chua[1], K. Lim[2], S. S. J. Leong[2], P. A. Tambyah[1], B. Ho[1]; [1]Natl. Univ. of Singapore, Singapore, Singapore, [2]Singapore Inst. of Technology, Singapore, Singapore

Abstract Body:

Catheter associated urinary tract infections (CAUTI), which account for about 25% of nosocomial infections globally, result in increased morbidity and healthcare cost. Biofilm colonized catheters also present opportunistic sources of increasingly antibiotics resistant bacteria. Since the practice of the closed drainage system, innovations to combat CAUTI have not produced significant improvement in clinical outcomes. The lack of a robust laboratory platform to test new CAUTI preventive strategies could be a key reason. We described an *in vitro* catheterization model (IVCM) in which a continuous supply of "urine medium" flows into a 250 mL polypropylene bottle (the "bladder") that is drained by a urinary catheter connected to a drainage container (the "drainage bag"). The set-up was carried out for 3 days to assess the anti-bacteria and anti-biofilm properties of catheters. On day 3, viable bacteria were detected from biofilm in a normal 100% silicone catheter (~10^4 CFU/cm^2, intraluminal), and "bacteriuria" reached a steady concentration of ~10^8 CFU/mL. In contrast, an anti-microbial peptide (AMP) CP116A coated catheter showed negligible biofilm colonization and no detectable "bacteriuria". The protection against biofilm and planktonic bacteria/"bacteriuria" offered by this novel AMP-based engineered catheter could be attributed to the rapid bactericidal effect of CP116A released from the catheter surface. Our IVCM has demonstrated to be a cost-effective preclinical approach to evaluate new strategies for the prevention of CAUTI.

***Podoviridae* Bacteriophage (Phage) Infection Efficiency of *Staphylococcus aureus* Isolated from Prosthetic Joint Infection (Pji)**

Author Block:

D. J. Ferullo[1], R. Patel[2], J. Radding[1]; [1]EnBiotix, Inc., Cambridge, MA, [2]Mayo Clinic, Rochester, MN

Abstract Body:

Background: *Staphylococcus aureus* causes 20-40% of prosthetic hip and knee arthroplasty infections, often leading to multiple surgeries, replacement of the prosthesis, long term antibiotic therapy, and potentially, to arthrodesis or amputation of the limb. Debridement, antibiotics and implant retention (DAIR) is an effective approach in carefully selected patients with acute PJI. However, DAIR is not appropriate for chronic PJI. Novel approaches to target *S. aureus* associated with PJI are needed. EnBiotix is engineering phage to deliver biofilm-dispersing enzymes to *S. aureus* for use in combination with antibiotic therapy.**Methods:** The plaque-forming efficiency of 3 highly related virulent *Podoviridae* phages was determined using dilution agar overlay assays with *S. aureus* isolates, including 14 non-implant-associated isolates from multiple sources, and 27 isolates from PJIs (Mayo Clinic). Lytic efficiency was scored visually on a scale of 4 (total clearing) to 0 (no plaques) based on Kutter, Meth Mol Biol 2009:501:141-9. Phage genome sequences were obtained from NCBI and compared using Geneious v.6.1.4.**Results:** Two of the phages (GRCS and P68), but not 44AHJD, exhibited increased plaque-forming efficiency with *S. aureus* isolates from PJI compared to non-implant-associated isolates ($p<0.05$). Phage genome analysis revealed protein sequence divergence in a single ORF associated with a minor tail protein.

Phage	PJI isolates[1] % infected	Non-implant-associated isolates[1] % infected	p-value
GRCS	74%	14%	<0.001
P68	48%	7%	0.004
44AHJD	22%	21%	0.477

[1]Clearing at 10^4 dilution (from 10^9 pfu/ml)**Conclusions:** Two of three *Podoviridae* phages showed better plaque-forming efficiency with isolates from PJI compared to non-implant-associated isolates. Phage infectivity of *S. aureus* may depend upon expression, and cognate recognition by the minor tail phage protein, of determinants related to clinical source and/or the microenvironment of the isolates. The recognition of clinical isolates of *S. aureus* specifically

from PJI provides a starting point for engineering phage to deliver transgenes to *S. aureus* to disperse biofilms in implant-associated infections.

Isolation & Identification of Lytic Phages against Drug Resistant Pathogens: Finding Cure in Holy Rivers of Kathmandu, Nepal

Author Block:

R. NEPAL, R. Malla; Tribhuvan Univ., Kathmandu, Nepal

Abstract Body:

Antimicrobial resistance is a global problem & emergence of superbugs have threatened advances of modern medicine pushing us closer to post antibiotic era. Once easily treatable infections are now killing & alternatives to antibiotics are being explored. Among all alternatives, phage therapy - though used longest in clinics - is largely ignored by western world. Bacteriophages or phages are viruses that infect bacteria but leave animal & plant cells unscathed. As MDR becomes a threat, interest in phage therapy is revitalized & now even US-NIAID lists 'phage' as research priority to address antibiotic crisis. Here, we explore availability of phages against MDR bacteria in real world & assess their efficacy in-vivo followed by morphological identification.40 different drug resistant human pathogens representing 12 genera were collected from hospital after biochemical identification & antibiotic susceptibility test. Water sample from 5 holy rivers was screened for presence of phages by double layer agar assay. Phages were purified by successively sub-culturing single plaque thrice & standard spot assay was employed to determine multiple host range. Most potent phages were amplified & confirmed by TEM.34 lytic phages - 16 *E. coli*, 13 *Salmonella*, 2 *Shigella*, 2 *Klebsiella*, 1 *Citrobacter* - were isolated. Except 2 *Klebsiella* phages all 32 phages showed multiple host range (lysed >1 strains). All *Salmonella* phages showed interspecific (*S. typhi* & *S. paratyphi*) lytic ability. Bacteriophage induced mutants were only observed in *Klebsiella* phages. All except *Klebsiella* phage completely lysed bacterial host in their log & stationary phase of growth cycle & were Caudovirales (tailed virus) implying that multiple host range is a function of tail or tail fibers.Our findings show 'phages against MDR bacteria' that could be used therapeutically exists in real world & they are not extremely host specific as professed in scientific world. They've evolved to achieve broader host range & even possess interspecific lytic capability. Absolute absence of multiple host range in tailless phages but not in tailed led us to new hypothesis that phage evolution might have occurred from tailless to tailed. Conclusively - Phage Therapy is not a 'myth' but an alternative when antibiotics fail.

Bacteriophages to Fight Respiratory Tract Infections - Pneumophage Project

Author Block:

H. Blois[1], N. Pallaoro[2], G. L'Hostis[1], E. Morello[2], A. Guillon[2], R. Respaud[2], L. Vecellio[3], N. Heuzé-Vourc'h[2], **J. Gabard**[1]; [1]Pherecydes-Pharma, Romainville, France, [2]Université François Rabelais, Tours, France, [3]Diffusion Technique Française, Saint-Etienne, France

Abstract Body:

Background: Hospital-acquired pneumonia is the second most frequent HAI infection and the first in terms of morbidity, mortality and cost (A. Torres, 2010). *P. aeruginosa* (*Pa*) is one of the predominant pathogens responsible for pneumonia acquired in hospital, and 30% of *Pa* strains are antibiotic multidrug resistant (MDR) (S.T. Micek, 2015). **Methods:** This project aims at developing a new strategy, based on bacteriophages (phages), to fight Pa pneumonia.**Results:** First, phages were isolated from sewage water and selected against a wide variety of *Pa* strains coming from several International collections and MDR patient isolates. They were characterized by transmission electronic microscopy and genome sequencing. Burst size ranges from 30 to 500 PFU/bacterium. The phage drug (PP1231) is a cocktail of 9 phages, including myoviridae, podoviridae and siphoviridae. When tested *in vitro* on 641 *Pa* strains, PP1231 provides 94 % efficacy. PP1231 was then tested in an animal model of *Pa* acute lung injury, using a bioluminescent strain (PAK-Lux). Animals were infected with 10^7 CFU/animal of PAK-Lux and treated, two hours post-infection, once intranasally with various concentrations of PP1231 (10^6 or 10^8 PFU/animal) or amikacin , used as a positive control. Lung infection was followed up over time, for up to 6 days, by bioluminescence imaging and *Pa* counted by microbiological assay in the lungs after animal sacrifice. All untreated infected animals died within 24h post-infection whereas, at a multiplicity of infection of 10, 100% of the animals treated with a single intranasal administration of PP1231 survived at day 2 and 60% at day 6. PP1231 cleared the lung from *Pa*, but secondary intestinal of ENT infections, probably due to ingestion, were detected in some animals and associated to death.**Conclusions:** Overall, local delivery of PP1231 is highly efficient at eradicating *Pa* in the lungs but may be unable to control secondary infections when locally administered only. The efficacy of PP1231 phage cocktail on *Pa* in this model suggests its potential use for treating pneumonia in humans.

Genomic and Phenotypic Analysis of *Bacillus* Bacteriophage Endolysins

Author Block:

L. Harb[1], K. Eldridge[1], L. Rizkalla[2], R. Duong[2], **L. M. Temple**[1], A. Johnson[2], D. Nelson[3];
[1]James Madison Univ., Harrisonburg, VA, [2]Virginia Commonwealth Univ., Richmond, VA,
[3]Univ. of Maryland, College Park, MD

Abstract Body:

As antibiotic-resistant bacteria become more prevalent in clinical settings and the environment, the need for solutions to remedy this issue becomes of greater importance. Utilizing bacteriophages to control bacterial populations is a viable alternative to antibiotics and has been shown to be more effective at treating bacterial infections than antibiotics. Bacteriophage endolysins play a key role in host cell lysis and have their own potential therapeutic capabilities. In this study, we explored the efficacy and host range of different *Bacillus* phage endolysins. We annotated and identified putative endolysins from a collection of *Bacillus* phages and chose nine phages that represent different classes of endolysins by bioinformatics analysis. We synthesized these genes with His-tags, cloned them into inducible expression plasmids, and transformed them into *E. coli*. Cells were grown at 37°C to OD_{600} 0.40 and induced with 0.2% arabinose overnight. After induction, cells were mechanically lysed and the endolysins purified with nickel column chromatography using 500 mM imidazole. Whereas crude lysates of three phages (Waukesha92, Stitch, and Angel) only showed lytic activity by spot assay on one of eight different *Bacillus* strains tested, the purified endolysins fared much better, suggesting the crude lysates did not contain sufficient endolysin concentrations to observe lysis from without. Five of the nine purified endolysins demonstrated lytic activity on multiple strains of *Bacillus* including *B. simplex* RWR2, *B. thuringiensis* Kurstaki, and *B. cereus* 4342, a *B. anthracis* transition state strain. Our findings demonstrate that these bacteriophage endolysins are capable of lysing different strains of *Bacillus* independently. Future work will involve further characterization of the endolysins and exploring their full host range potential.

Detection of Endotoxin Using LAL Test in Injectable Drugs Commonly Used for Parental Administration: A Blind Study from Karachi, Pakistan

Author Block:

S. G. NADEEM[1], M. Jan[1], S. T. HAKIM[2]; [1]MYCOLOGY RESEARCH & REFERENCE LABORATORY, JINNAH Univ. FOR WOMEN, KARACHI, Pakistan, [2]VIROLOGY & TISSUE CULTURE LABORATORY, JINNAH Univ. FOR WOMEN, KARACHI, Pakistan

Abstract Body:

Background: Toxins of the gram negative bacteria are considered a real threat, especially endotoxins (lipopolysacchrides) liberated on the death and cell lysis of gram negative bacteria particularly. An attractive hypothesis about endotoxic shock could be linked with administration of parenteral antibiotic drugs, lethal dose of endotoxin in the body, or massive bacterial killing that release endotoxin and patient deterioration. **Methodology: A** blind study was conducted for the detection and quantification of endotoxin in injectable drugs commonly used for parental administration and are easily available in the local markets in Karachi, Pakistan. A total of 100 pharmaceutical drugs were provided for the said research in injectable form. Each injectable drug samples was manufactured by a different pharmaceutical company and a total of 100 samples; 20 injectable drug samples each from each selected locality were obtained from the different localities, to quantify the amount of endotoxin by using Limulus Amoebocyte Lysate (LAL) endpoint chromogenic method. **Results:** Upon analysis, a total of 48% parental drugs were found endotoxin positive with above permissible limits; while 52 % were found negative that is below the permissible limits. The sensitivity and specificity of this kit ranges from 98.6% to 96.6%. On the basis of statistical analysis, this study showed that there is a significant linear correlation between absorbance and concentration of endotoxin found in intravenous drugs. The calculated Pearson coefficient of correlation value was 0.998 and found significant at < 0.100, that showed a positive correlation between absorbance and concentration of endotoxin. By testing several samples of intravenous drugs available in the local markets of metropolis, it was speculated that manufacturing of these products need to follow appropriate Good manufacturing practices (GMP), improve drugs quality delivery, reporting systems and establishment of quality-control testing of intravenous drugs. Large scale studies are recommended and needed for understanding the magnitude of this important problem and to reduce the impact of this infectivity of the parental drugs.

The Impact of Rapid Identification of Influenza via Polymerase Chain Reaction (PCR) on Antimicrobial Management in Hospitalized Patients

Author Block:

S. Kuhn, K. Beadle, V. Creswell; Wesley Med. Ctr., Wichita, KS

Abstract Body:

Background: Early antiviral treatment of influenza has shown to decrease the duration of symptoms and may decrease the risk of complications. Antigen-based rapid diagnostic tests commonly result in false negatives. PCR has proven to be the most sensitive and accurate, as reflected in the current CDC recommendations. Recently, WMC implemented the use of the Biofire FilmArray®, which has the ability to test for 17 respiratory viruses (RV) via PCR. Rapid identification, along with pharmacist intervention, can lead to early appropriate antiviral use and may decrease the use of unnecessary antibiotics.**Methods:** This retrospective, quality improvement project aimed to describe the impact of PCR identification of RV on antimicrobial management in adult patients admitted for possible influenza and/or pneumonia during December 2014-March 2015. Data collection included antimicrobials initiated, discontinued or modified based on PCR results and changes in antimicrobial management based on a positive influenza result (PIR).**Results:** Of the 153 patients included, 73% had influenza A, 16% influenza B, and 11% were influenza negative. Median time between admission and PCR results was 13h11m. Twenty five percent of patients had an antiviral started empirically, and 71% had an antiviral started following PCR identification. Four percent never received an antiviral. Median time between influenza detection and start of antivirals was 1h30m. Following identification of influenza, 21% of patients had all antibiotics discontinued. Antibiotics were narrowed following PIR in 8% of patients. Median duration between PIR and antibiotic discontinuation was 4h7m. 71% of patients had antibiotics continued following a PIR. Of those, 22% of patients had antibiotics continued for an unrelated infection and 58% had antibiotics continued due to concern of a secondary pneumonia. Estimated cost savings due to discontinuation of inappropriate antimicrobials was $5200.**Conclusions:** Rapid identification of influenza via PCR combined with pharmacist intervention can reduce the inappropriate use of antimicrobials in patients with suspected respiratory infections. Further studies are needed to determine the clinical impact of these stewardship efforts on patient outcomes.

Survey of Antimicrobial Prescribing Practices and Interpretation of Rapid Blood Culture Identification Results

Author Block:

L. Donner, W. S. Campbell, E. Lyden, P. D. Fey, T. C. Van Schooneveld; Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract Body:

Background: Microbiology reporting can be difficult to understand and new rapid pathogen identification technology has made it more challenging. Nebraska Medicine recently implemented the Biofire FilmArray Blood Culture Identification Panel (BCID) with stewardship-based education on test result interpretation. Provider BCID result interpretation and prescribing decisions were assessed via survey.**Methods:** An email survey was distributed to 382 physicians. Questions addressed physician characteristics, antibiotic prescribing practices, and interpretation of BCID results. Seven questions required respondents to interpret BCID results and make clinical decisions. Tallied correct responses resulted in a knowledge score. Descriptive statistics summarized survey responses. General linear models evaluated the effect of role and specialty on the mean knowledge score and correct responses to specific scenarios. Kappa statistics were used to evaluate the agreement between use of antimicrobial stewardship resources and correct responses to knowledge-based questions.**Results:** The response rate was 40.8% with a distribution of specialties of 57% internal medicine, 20% family medicine, and 25% other. Role included 41% residents, 5% fellows, and 53% faculty. Of those surveyed, 89.4% reported reviewing antimicrobial susceptibility results with 81.6% adjusting therapy based on this review while only 60% reported adjusting therapy based on BCID results. Correct response rates for interpretation questions ranged from 52 - 86%. Common errors included misinterpretation of *Enterobacteriaceae* and *Staphylococcus* genus results. After adjusting for role, the mean total knowledge score did not differ among specialties (p=0.13). After adjusting for specialty, the score did not differ among role (p=0.47). There was low agreement between correctly answering the knowledge questions and having reviewed antimicrobial resources on the BCID (all Kappa statistics <0.2).**Conclusions:** Misinterpretation of BCID results is relatively common and may result in ineffective treatment or missing the opportunity to narrow therapy. Improved reporting practices of BCID results with clinical decision support tools providing interpretation guidance available at the point of care may improve the clinical impact of this technology.

Outcomes of Antimicrobial Stewardship Intervention (Asi) in Bloodstream Infections (Bsi) with & without a Rapid Pcr Based Blood Culture Identification Panel (Bcid)

Author Block:

S. H. MacVane, F. S. Nolte; Med. Univ. of South Carolina, Charleston, SC

Abstract Body:

Background: Studies have demonstrated the combination of ASI & rapid organism identification (ID) improves outcomes in BSI, but have not controlled for the contribution of the ASI element. We conducted a retrospective study comparing antimicrobial use & outcomes among patients with BSI that underwent either: conventional organism ID (controls, 8/1/10-10/31/10), conventional organism ID with ASI (ASA, 8/1/12-10/31/12), or BCID with ASI (ASB, 8/1/14-10/31/14). **Methods:** Hospitalized adult patients with positive blood cultures (BC) of organisms on BCID (19 bacteria, 5 Candida spp., & mecA, vanA/B, & KPC antimicrobial resistance genes) were studied. The primary outcome was time to effective therapy (TTET) & antimicrobial utilization in the first 96 h. Clinical endpoints included length of stay (LOS), mortality, readmission, & hospital cost. Patients with organisms not included on BCID, or those with blood culture contaminants were excluded. **Results:** There were 783 patients with positive BC, 364 met inclusion criteria (115 control, 104 ASA, 145 ASB) representing 404 BC pathogens (41.6% gram-positive, 50.5% gram-negative, 7.9% Candida spp.). BCs were polymicrobial in 9.3% of patients. Groups did not differ in Charlson comorbidity index or Pitt bacteremia score. Antimicrobial resistance was minimal & did not differ across the study periods (2 VRE, 5 ESBL, 0 KPC). Time from BC collection to organism ID was shorter in ASB (17.2 h; $P<0.001$) compared with control (57.4 h) or ASA (53.9 h). ASB had shorter TTET (4.9 h; $P<0.001$) than control (15.0 h) or ASA (13.0). ASA (56.7%) & ASB (52.4%) had significantly higher rates of antimicrobial de-escalation than control (33.9%), with time to 1st antimicrobial de-escalation occurring sooner in ASB (48.1 h; $P=0.034$) than ASA (60.5 h) or control (63.0 h). No difference occurred between control, ASA, or ASB in mortality (11.3%, 11.5%, 13.8%), 30-d readmission (25.5%, 26.1%, 18.4%), ICU LOS (7, 5, 5 d), post-culture LOS (8.4, 7.8, 8.2 d), or costs ($27,564, $21,222, $23,840). **Conclusions:** In patients with BSI, an ASI program was associated with improved antimicrobial utilization during the initial 96 h. Addition of BCID to ASI shortened time to effective therapy & further improved antimicrobial use compared to ASI alone, even in a setting of low rates of antimicrobial resistance.

Strategizing Procalcitonin Assessment with Antibiotic Stewardship: Partering Microbiology

Author Block:

J. Kuzyck, K. Kasarda, T. Walsh, J. Thomas; Allegheny Gen. Hosp., Pittsburgh, PA

Abstract Body:

Background: Recently, rapid serum procalcitonin (PCT) assessment has emerged as a complimentary tool for focusing on the infectious etiology, virus versus bacteria, highlighting the importance of antibiotic stewardship. Here, we wanted to maximize the benefit of rapid TAT within the Microbiology Laboratory partnering with a new Antibiotic Stewardship Program charged with tailoring antibiotic use in LRI and sepsis. **Methods:** Although a consortium of six hospitals with approximately 2,000 beds, this pilot study focused on Allegheny General Hospital (AGH) and it's off-site consortium core Microbiology Laboratory. Lower Respiratory Infections ,LRI, and sepsis, were target hospital diseases compared with ER testing using the Biomereux (BMX) Mini Vidas, results provided to the ordering MD, the ER and Antibiotic Stewardship 24/7, starting in March 2015. Interpretation of PCT serum results was provided by BMX: LRI had three and sepsis two reporting categories, one each for "increased likelihood for bacterial etiology; antibiotics encouraged". A web based algorithm was provided by Antibiotic Ste**Results:**Average number of samples per week was 139 +/- 24, with Saturday/Sunday 19 +/- 6. ER provided essentially 15-40% of samples per week. Heaviest load was Tuesday-Thursday during daytime shift; evening shift assayed 1-2 times. ER specimens were treated "stat" with 2 hour TAT; all others were "batched" with 6 hour TAT window, with 91% compliance for all assays. For sepsis, an average of 34.7% PCT samples were above 0.5ng/ml and for LRI 42.3% above 0.25 ng/ml indicative of bacterial etiology and potential benefit of antibiotic intervention. The need for heightened education also focused on the approximate 20% unintended disease assessment, primarily UTI's. Repeat samples at 6-24 hours were minimal. **Conclusions:** We found incorporating PCT in Microbiology a logical partnering to the Antibiotic Stewardship Program, heightening the present armamentarium provided by Microbiology and antibiotic testing, featuring its central and controllable data management available 24/7.

DailyAntimicrobial Stewardship Review of Positive Culture Results and Impact onAppropriateness of Antimicrobial Therapy - a Randomized Controlled Trial

Author Block:

B. Langford, A. Chan, M. Downing, J. Seah, J. Johnstone; St. Joseph's Hlth.Ctr., Toronto, ON, Canada

Abstract Body:

Antimicrobial stewardship (AS) interventions can minimize unnecessary exposure to antimicrobial therapy (AT) and limit the emergence of resistant pathogens. The optimal approach to identifying and communicating AS recommendations is unknown. Our site is a 400-bed community teaching hospital in Toronto, Canada. We examined whether a positive culture review system improved the appropriateness of AT for hospitalized adult patients.AS pharmacists reviewed all positive culture reports daily during weekdays from May 2015 to January 2016. For each patient, the electronic health record was reviewed to assess the appropriateness of AT and identify any specific recommendations for improvement. Each recommendation was written on a standardized form and then randomized (using a concealed random number table) to either the intervention group (send recommendation to clinical pharmacist caring for the patient) or control group (withhold recommendation). The primary endpoint was improvement in appropriateness of AT (as specified on the recommendation note) within 24 hours of the recommendation. Differences in proportions were analyzed using the chi-square test.From 170 recommendations randomized, 167 from 165 patients were evaluable. Seventy three (73) were randomized to intervention and 94 to control. Recommendations based on positive urine cultures were most common (51%), followed by positive blood cultures (25%). The most common recommendation was to streamline therapy (59%), followed by optimize duration (17%). The primary outcome of improvement in appropriateness of AT was achieved in 35 patients (48%) in the intervention group and 37 patients (39%) in the control group (p=0.27). A subgroup analysis found a marginally significant difference in improved therapy when only examining recommendations that suggested streamlining (65% vs. 45%, p=0.053).In conclusion, a daily positive culture review system did not significantly improve the appropriateness of AT in our patient population. However, recommendations focusing on streamlining therapy may be more useful. Further research is required to determine the optimal method of communicating AS recommendations.

Implementing Satellite Blood Culture in the Emergency Department Significantly Decreases Time to Incubation

Author Block:

G. Johnson; Lakeridge Hlth., Oshawa, ON, Canada

Abstract Body:

Background: Lakeridge Health is a 450 bed hospital servicing a community of over 600,000 people. The Emergency Department (ED) collects ~50% of blood cultures. When cultures were loaded 24/7 into the BD BACTEC™ FX Blood Culture System in the Core Laboratory, an average delay of 2.48 hours was noted from collection to loading. To reduce time to pathogen identification and improve outcomes for patients with sepsis; guidelines recommend cultures should be incubated within 2 hours from draw.* The implementation of a satellite BACTEC™ FX and EpiCenter™ Data Management System in the ED provided an opportunity to reduce time to detection and reporting results. **Methods:** Pre- and post-install time to incubate (TTI) data was collected from LIS and BACTEC plots (n=76, 29 positives) and LIS and EpiCenter - Specimen Registration (n=120, 51 positives), respectively. Data was extracted and analyzed for improvement in TTI. **Results:** Following implementation, an 82% decrease in TTI for all ED blood cultures over all shifts was observed: 2.48 hours from collection to incubation pre-install versus 0.45 hours post install. An 84% reduction for positive cultures was realized: 2.67 hours from collection to incubation pre-install versus 0.43 hours post install. The largest improvement was noted during the night shift: from 2.57 hours to 0.45 hours. EpiCenter monitored instrument status, capacity, contamination, positivity rates and blood volume. **Conclusions:** This study demonstrates that placement of a blood culture incubator close to the site of collection can dramatically reduce TTI allowing for alignment with best practices and improved patient care. In a recent survey**: 1. 1.Over 50% of Canadian physicians indicated they weekly encounter a patient with suspected sepsis. 2. Blood culture with subsequent identification/susceptibility was rated as the two most important lab tests for detection, antibiotic optimization and improved patient outcomes.3. Delays in TTI are inherent in many institutions.

Publishing Title:

Daptomycin Dosing Optimization in Obese Patients: Experiences in a Large Community Teaching Hospital

Author Block:

S. Kuhn, V. Creswell; Wesley Med. Ctr., Wichita, KS

Abstract Body:

Background: Conventional daptomycin dosing has been based on actual body weight to achieve an effective area under the curve (AUC) to minimum inhibitory concentration ratio. Studies suggest obese patients will have an increased maximum concentration and AUC versus normal weight individuals. In recent years, alternative dosing regimens of daptomycin have been conducted including dosing based on ideal and adjusted body weight. These studies have shown no difference in clinical outcomes in patients dosed on ideal body weight or adjusted weight versus actual body weight. In 2014, Wesley Medical Center changed their standard dosing of daptomycin based upon this literature.**Methods:** This retrospective, observational quality improvement study described the safety and efficacy of dosing daptomycin based on ideal or adjusted body weight in obese patients. Patients were included if they received daptomycin between June-October 2014 and were obese (actual body weight ≥130% of ideal body weight.) Data collected included indication, patient characteristics, dosing, cultures, complications during therapy, and outcome measures.**Results:** Of the nine patients included, 67% were started on daptomycin to facilitate transition to outpatient care. Thirty-three percent were placed on daptomycin following an allergic reaction to vancomycin. *Staphylococcus aureus* was the most common pathogen isolated (50%). Most patients (89%) received a dose of 6 mg/kg. Seventy-eight percent of patients were dosed based on adjusted weight, with 22% dosed on ideal body weight. Sixty-six percent of patients had complete resolution of symptoms. Eleven percent discontinued daptomycin due to adverse reactions. Two patients (22%) completed their course, but were re-admitted for similar joint infections.**Conclusions:** Daptomycin dosed per adjusted body weight is safe and effective in most patients when implemented in a community hospital. Further studies should be conducted in patients with bone and joint infections prior to implementation of an adjusted body weight dosing strategy of daptomycin for this indication.

Publishing Title:

Necessity of Carbapenem Use When Prescribed Per Infectious Diseases Specialists

Author Block:

K. J. Goodlet[1], S. M. Cardwell[2], M. D. Nailor[3]; [1]Hartford Hosp., Hartford, CT, [2]Flagstaff Med. Ctr., Flagstaff, AZ, [3]Univ. of Connecticut, Storrs, CT

Abstract Body:

Background: Combating antibiotic resistance requires stewardship programs aimed at reducing the overuse of broad-spectrum antibiotics. A common methodology employed to restrict the use of these agents is to require infectious diseases (ID) approval. The objective of this study is to assess the frequency at which ID appropriately identify patients requiring carbapenem therapy as opposed to other agents, specifically cefepime (FEP), and evaluate patient risk factors for multi-drug resistant organisms (MDRO) used by ID to justify carbapenems empirically. **Methods:** This study is a retrospective, descriptive chart review of patients ages 18 to 88 prescribed a carbapenem between January 1, 2014 and June 30, 2014, inclusive, by an ID physician. Patients with cystic fibrosis, definitive therapy, or protocol-concordant therapy were excluded. Necessary carbapenem use was defined as the presence of an organism susceptible to the prescribed carbapenem and resistant to FEP, the agent of choice at the study facility for MDRO.**Results:** 235 charts were reviewed, of which 84 were included. The most common infection source was intra-abdominal (38%) or respiratory (35%). In the past 90 days, 52% of patients had a prior hospitalization and 58% received prior antibiotic therapy. 19% of patients were immunosuppressed, 19% were admitted from a long-term care facility, and 20% had MDRO isolated in the past year. At the time of carbapenem prescribing, 49% of patients were in the intensive care unit, with 29% intubated and 24% on at least one vasopressor. Mean carbapenem therapy was 5.0 ± 4.0 days, with 44% prescribed as initial therapy and 56% as escalation of current therapy. Cultures were drawn for 94% of patients, of which 61% were positive. The most commonly isolated organism was *Escherichia coli* (44%). Carbapenem use was necessary for only 7% of patients. De-escalation occurred in 54% of culture-positive patients, with mean time to de-escalation of 0.73 ± 1.4 days.**Conclusions:** Carbapenem therapy by ID was generally in severely ill patients with risk factors for drug resistance. However, the factors selected by ID to utilize carbapenems were poor indicators for resistance to the hospital's first line agent, FEP. Hospital-specific risk factors may more appropriately identify patients requiring carbapenem therapy.

Publishing Title:

Use of Intravenous versus Oral Antibiotics in the Emergency Department/Observation Unit (ED/OU) for the Treatment of Acute Bacterial Skin and Skin Structure Infections (ABSSSIS)

Author Block:

K. C. Claeys, E. J. Zasowski, A. M. Lagnf, S. L. Davis, M. J. Rybak; Wayne State Univ., Detroit, MI

Abstract Body:

Background: Perceived need for intravenous (IV) antibiotics (abx) to treat ABSSSIs has been shown to be a common reason for inpatient admission. In a recent prospective study this was the only cited reason for nearly half of patients. As with the decision to admit patients, administration of IV abx is largely subjective. This current study aimed to describe prescribing patterns in patients treated in the ED/OU setting without inpatient admission.**Methods:** Retrospective, single-centered, observational cohort of consecutive adult patients with primary diagnosis of ABSSSI treated in the ED/OU between April 2012 - 2015. Type of ABSSSI, baseline clinical characteristics and patient severity, and past medical conditions were collected and analyzed. Patient outcomes included abx received, 96-hour ED re-visit, and 30-day ABSSSI-related admission.**Results:** A total of 347 patients were included in the final analysis: 223 received IV abx, 124 received PO abx. Patients receiving IV abx were older [median age 42 (IQR 31 - 52) vs. 34 (IQR 25 - 49) years, $p = 0.019$], and had a higher median Charlson Comorbidity Score (CCS) [1 (IQR 0 - 2) versus 0 (IQR 0 - 1), $p = 0.011$]. Presence of at least one systemic inflammatory response syndrome (SIRS) criterion was significantly associated with the receipt of IV abx. Patients with primary ABSSSI sites of the head/neck or hand were more likely to receive IV abx (27.8% vs. 15.3%, $p = 0.004$). Among patients with CCS of zero and no SIRS criteria 41.7% received IV abx. With the exception of IV drug use (8.5% IV vs. 2.4% PO, $p = 0.025$), there were no significant differences based on individual comorbid conditions. MRSA coverage was more common in patients with PO abx (99.2% PO vs. 80.3% IV, $p < 0.001$), regardless of type of ABSSSI (i.e. cellulitis vs. abscess). A similar number of patients in both groups experienced 96-hour ED revisit (8.0% IV vs. 7.7% PO), and 30-day infection-related admission (1.6% vs. 2.3%).**Conclusions:** There is a large degree of heterogeneity in clinical presentation associated with the receipt of IV abx in the ED/OU, however at least one SIRS criterion, higher CCS, and infections of the head/neck or hand were more likely to receive IV abx. A significant portion of patients with no SIRS criteria and a CCS of zero received IV abx and were potential candidates for PO.

Publishing Title:

Challenges in Antimicrobial Stewardship: Oritavancin for Acute Bacterial Skin and Skin Structure Infections (Absssis)

Author Block:

N. H. Chan-Tompkins[1], T. L. Trienski[1], D. N. Bremmer[2], T. L. Walsh[1]; [1]Allegheny Gen. Hosp., Allegheny Hlth.Network, Pittsburgh, PA, [2]Western Pennsylvania Hosp., Allegheny Hlth.Network, Pittsburgh, PA

Abstract Body:

Background: Oritavancin is FDA-approved for treatment of ABSSSIs as a one-time intravenous (IV) dose. Although the wholesale acquisition cost is $2,900.00, reimbursement of the average sale price plus 6% is possible for select patients (pts) in the outpatient setting. In August 2015, an Antimicrobial Stewardship Program (ASP) ABSSSI initiative was implemented on pts admitted to the hospital. If IV antibiotic therapy was warranted for the treatment duration, the ASP assessed the feasibility of discharging the pt and administering oritavancin in the outpatient setting one day post-discharge. The objective was to describe the insurance benefit coverage of oritavancin in pts with an ABSSSI. **Methods:** Pts identified for potential treatment with oritavancin were assessed based on submission of the physician request form to the oritavancin support program and review of the summary of benefits form. IRB exemption was obtained for this quality improvement project. **Results:** The ASP assessed 38 pts for potential oritavancin use between 8/1/15-12/31/15. Three (7.9%) pts without insurance and income were eligible for oritavancin via the pt assistance program. The remaining 35(92.1%) were assessed for insurance benefit coverage where all submissions were processed with the available generic C-code or J-code. Oritavancin was not covered in 4/35(11.4%) pts. Oritavancin was covered in 17/35(48.6%) pts. Prior authorization or additional processing was required in the remaining 14/35(40%) pts. Overall, 14 pts had deductibles listed for their insurance. Median annual deductible in 14 pts was $350 (range, $147-4000). Twelve pts had co-insurance requirements: 6/12(50%) had 20%; 6/12(50%) had 10%. **Conclusion:** Although oritavancin was found to be covered by most insurers, use often required prior authorization or additional processing. The presence of co-insurance presented a challenge with determination of a pt's true out-of-pocket cost. As of January 2016, oritavancin now has a permanent J-code, which warrants further assessment of insurance benefit coverage. Despite the challenges with insurance coverage of oritavancin, it continues to be a viable tool for our ASP ABSSSI initiative.

Publishing Title:

Incidence of and Risk Factors for Acyclovir-associated Nephrotoxicity

Author Block:

K. E. Barber, K. R. Stover, J. L. Wagner; Univ. of Mississippi Sch. of Pharmacy, Jackson, MS

Abstract Body:

Background: As obesity rates increase, it is unclear which acyclovir (ACY) dosing weight should be utilized for central nervous system and skin/soft tissue infections to optimize efficacy and limit toxicity. We evaluated the incidence of and risk factors for ACY-associated nephrotoxicity. **Methods:** This retrospective case-control included adult patients who received IV ACY for ≥ 72 hours in 2014. Excluded: receipt of renal replacement therapy (RRT) or vasoactive medications at start of ACY therapy. Incidence of nephrotoxicity defined by RIFLE criteria. Data collected: ACY medication use information, renal function, concomitant nephrotoxins, and clinical data. Risk factors were determined utilizing multivariate logistic regression analyses.**Results:** 62 patients included: 17 (27%) developed nephrotoxicity (cases). Groups were similar, but more cases were admitted to the ICU (53% vs 20%, p=0.025) and remained in ICU longer (12 days vs 3 days, p=0.008). Median daily ACY dose (1725 mg vs 2175 mg, p=0.559) and duration of therapy (10 days vs 5 days, p=0.129) were similar. No differences were found in mg/kg dose regardless of dosing weight used. Case patients classified as Risk (41.2%), Injury (23.5%), Failure (35.3%); 3 patients needed RRT. Nephrotoxicity led to more frequent ACY dose adjustments (47.1% vs 2.2%, p<0.001). 82% received at least 1 concomitant nephrotoxic agent; vancomycin was most frequently co-administered (50%). Case patients were more likely to receive vancomycin (71% vs. 42%, p=0.046), but total concomitant nephrotoxic agents was similar (p=0.712). No differences in fluid hydration (82% vs 76%, p=0.739). Patient characteristics related to ACY-associated nephrotoxicity are in Table 1.

Table 1. Patient characteristics associated with nephrotoxicity.	N (% Total Population)	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
ICU admission	18 (29)	4.5 (1.36 – 14.94)	3.3 (0.90 – 12.27)
Concomitant vancomycin administration	31 (50)	3.3 (0.99 – 10.90)	2.1 (0.55 – 7.82)

Conclusion: Concomitant vancomcyin and ICU admission influenced ACY-associated nephrotoxicity in bivariate but not multivariate analyses. Further studies are warranted to determine optimal ACY dosing weight and additional concomitant risk factors.

Publishing Title:

Impact of 2010 Cephalosporin CLSI Breakpoint Revisions for *Enterobacteriaceae* on Susceptibility and Antibiotic Utilization

Author Block:

S. S. Doyen, A. D. Junkins, A. M. Wilde; Norton Hlth.care, Louisville, KY

Abstract Body:

Background: In January 2015, Norton Healthcare adopted the 2010 Clinical and Laboratory Standards Institute (CLSI) breakpoints for 1st-3rd generation cephalosporins for Enterobacteriaceae but continued to detect and report ESBL and AmpC production. The purpose of this study is to assess the impact of the breakpoint implementation and describe the prevalence, treatments, and outcomes of third generation cephalosporin (TGC) susceptible, ESBL or AmpC positive Enterobacteriaceae. **Methods**: This was a retrospective, observational study performed at Norton Healthcare, a multihospital system in Louisville, Kentucky. Ceftriaxone susceptibilities were reviewed for inpatient and outpatient antibiograms and antibiotic utilization was collected as days of therapy (DOT) per 1,000 patient days pre- (2014) and post-implementation (2015) of breakpoints. Enzyme-producing, TGC-susceptible Enterobacteriaceae were reviewed for source, definitive therapy, and 30 day mortality. **Results**: Ceftriaxone susceptibility for Enterobacteriaceae minimally decreased post-implementation for inpatient [90% (6221/6936) to 89% (6912/7784), p=0.0856] and outpatient [96% (7652/7959) to 94% (9058/9643), p=0.0001] antibiograms. Carbapenem utilization decreased from 34.2 DOT/1000 patient days, 95% CI [33.5, 34.9] in 2014 to 32.6, 95% CI [31.9, 33.2] in 2015. There were 168 cases of enzyme-positive, TGC-susceptible isolates and 65% were from outpatients (109/168). The most common sources were urine (89%), wound (9%) and blood (2%). Definitive therapy most commonly used for enzyme-positive, TGC-susceptible isolates was nitrofurantoin (22%) and fluoroquinolones (22%). Patients with enzyme-positive, TGC-susceptible isolates that received a TGC as definitive therapy had a thirty day mortality rate of 0% (0/18) and 14% (1/7) for urine and non-urine sources, respectively. **Conclusion**: The implementation of the 2010 CLSI breakpoints had a small effect on ceftriaxone susceptibilities without increasing broad spectrum antibiotic use. TGC-susceptible, enzyme-positive organisms were isolated primarily in outpatient urine cultures. The detection and reporting of ESBL and AmpC enzymes may not be needed for patient care, especially from urine cultures. More data on treatment with TGC in non-urine sourced infections is needed.

Publishing Title:

Comparative Rates of Acute Kidney Injury in Patients on Vancomycin Combined with Either Piperacillin/Tazobactam or Cefepime

Author Block:

B. Navalkele, J. Pogue, S. Karino, B. Nishan, M. Salim, J. Koons, W. Perry, T. Hussain, S. Solanki, A. Pervaiz, N. Tashtoush, H. Shaikh, S. Koppula, K. Kaye; Wayne State Univ., Detroit, MI

Abstract Body:

Background: Recent evidence suggests that receipt of concomitant piperacillin/tazobactam increases the risk of vancomycin-associated nephrotoxicity. Well-controlled, adequately powered studies comparing rates of acute kidney injury (AKI) in patients receiving vancomycin+piperacillin/tazobactam (VPT) compared to similar patients receiving vancomycin+cefepime (VC) are lacking. This study compared the incidence of AKI among patients receiving combination therapy with VPT to a matched cohort of patients receiving VC.**Methods:** A retrospective matched outcomes study was performed including patients cared for at Detroit Medical Center from 2011 to 2013. Patients were eligible if they a) received combination therapy with either VC or VPT; b) had antibiotics initiated within 24 hours of one another; and c) had combination therapy continued for ≥ 48 hours. Patients were excluded if their baseline serum creatinine was >1.2mg/dl or they were receiving renal replacement therapy at the initiation of combination therapy. Patients receiving VC were matched to patients receiving VPT in a 1:1 ratio based on severity of illness, ICU status at onset of combination therapy, duration of combination therapy, daily dose of vancomycin and number of concomitant nephrotoxins. The primary outcome was the incidence of RIFLE criteria-defined AKI. Multivariate modelling was performed using cox proportional hazards.**Results:** 558 patients were included (279 received VC, 279 VPT). The mean age was 55.9±16.6 years. There were more females in VC group (p=0.03) and more patients who were white in the VPT group (p=0.0005). AKI was significantly higher in the VPT than the VC group (81/279 (29%) vs. 31/279 (11%), HR=4.0, 95% CI=2.6-6.2). In multivariate analysis, therapy with VPT was an independent predictor for AKI (HR=3.7, 95% CI=2.3-6.0). Patients receiving VPT had greater median length of stay (LOS) compared to patients receiving VC (8 vs 6 days, p=0.01). Among patients who developed AKI, the median onset was more rapid in the VPT compared to the VC group (3 vs 5days, p=<0.0001).**Conclusions:** The VPT combination was associated with an increase in AKI risk, a more rapid onset of AKI, and a greater LOS compared to the VC combination.

Publishing Title:

Impact of Area Under the Curve-targeted Dosing (Auc-Td) on Vancomycin (Van)-Associated Nephrotoxicity (Vn)

Author Block:

N. Finch[1], K. Murray[1], E. Zasowski[2], R. Mynatt[1], J. Zhao[1], R. Yost[1], J. Pogue[1], M. Rybak[1]; [1]Detroit Med. Ctr., Detroit, MI, [2]Wayne State Univ., Detroit, MI

Abstract Body:

Background: Despite widespread VAN use, the optimal dosing strategy remains poorly defined. Guidelines recommend targeting trough (Tr) concentrations of 15-20 mg/L in complicated infections to maximize the likelihood of achieving an AUC_{24h}/ MIC ratio of ≥400 when the VAN MIC ≤1 mg/L. However, Tr of 15-20 mg/L have been associated with increased VN, and evidence suggests AUC_{24h} exposures can be met with lower Tr values. In 2015, the DMC converted from VAN Tr monitoring to AUC-TD for invasive infections. The primary objective of this study was to investigate VN rates with AUC-TD versus dosing for Tr concentrations of 15-20 mg/L. **Methods:** Retrospective quasi-experimental study from 9/2014 - 4/2015. Inclusion: ≥18 yr; ≥1 VAN Tr obtained in pre-intervention group or ≥2 VAN levels for AUC_{24h} determination in the post-intervention group; received VAN ≥72 h. Exclusion: baseline SCr ≥2 mg/dL or pre-existing need for renal replacement therapy, concomitant piperacillin-tazobactam, or the use of VAN for an indication excluded from AUC-TD. Primary outcome: nephrotoxicity as defined in VAN Guidelines, RIFLE, and AKIN criteria.**Results**: Outcomes were evaluated for 632 patients; 333 in the pre- and 299 in the post-intervention group. Baseline characteristics were similar. VAN Tr were higher in the pre-intervention group. VN rates were numerically higher with Tr-directed dosing compared to AUC-TD, though this did not reach statistical significance (Table).

	Tr Directed	AUC-TD	P
Age, yr	61 (49-74)	61 (50-72)	0.735
Baseline CrCl, ml/min	76 (53-112)	81 (53-109)	0.962
APACHE II	12 (8-18)	12 (9-19)	0.161
VN per Guideline Definition	30 (9.0%)	16 (5.4%)	0.077
RIFLE Class 2 or 3	39 (11.7%)	26 (8.7%)	0.213
AKIN Stage 2 or 3	33 (9.9%)	23 (7.7%)	0.327
Initial Tr, mg/L	14.6 (10.4-19.6)	12.6 (9.6-16.6)	0.001

Initial $AUC_{24h,}$ mg*h/L	n/a	492 (399-571)	

Data displayed as median (IQR) or *n* (%).**Conclusions**: This is the first comparison of VN with AUC-TD vs Tr-directed dosing. The AUC-TD approach was associated with a numerically lower rate of VN. Further study will determine whether this difference is statistically significant.

Publishing Title:

Antibiotics for *Clostridium difficile* Infection: Impact of Drug Selection on Treatment Outcomes

Author Block:

S. L. Revolinski[1], J. N. Wainaina[2], M. Graham[2], L. S. Munoz-Price[1]; [1]Froedtert and the Med. Coll. of Wisconsin, Milwaukee, WI, [2]Med. Coll. of Wisconsin, Milwaukee, WI

Abstract Body:

Background: National guidelines from the IDSA stratify treatment (tx) for *Clostridium difficile* infection (CDI) by severity, with recommendations to treat severe CDI with vancomycin (VAN) and mild to moderate CDI with metronidazole (MTN). Recent literature has suggested VAN may be the drug of choice for CDI of any severity. The purpose of this study is to evaluate tx outcomes in patients (pts) with CDI treated with either VAN or MTN.**Methods:** A retrospective review conducted from 10/1/14 - 5/31/15 evaluated inpts initially treated with VAN or MTN for CDI, defined as diarrhea (≥3 liquid stools in 24 hours) and a positive *C. difficile* NAAT. Pts were excluded if tx began prior to admission, or received initial combination therapy or drug other than VAN or MTN. Outcomes (as binary variables) included: therapy escalation (TE) after 72 hours of initial treatment, lack of clinical cure (CC) defined as diarrhea at end of overall therapy (EOT), and CDI recurrence within 28 or 56 days. The effect of tx (modeled as a binary variable [VAN or MTN]), Charlson Comorbidity Index, age, sex, BMI, and CDI severity were using SAS.**Results:** In the final analysis, 77 patients received VAN and 166 MTN. TE evaluated using logistic regression. Regression analyses were performed occurred in 2.6% and 19.9% of pts receiving VAN and MTN, respectively (p=0.0001). The need for TE was associated with choice of drug (OR = 0.11 for pts treated with VAN compared to MTN; 95% CI: 0.03-0.47; p<0.0001). Age over 60 was also associated with TE, and drug choice remained significant after adjusting for age. Lack of CC at EOT occurred in 11.7% and 4.2% of pts treated with VAN and MTN, respectively (p=0.0478). Achieving CC was associated with choice of drug (OR=0.33 for treatment with VAN compared to MTN; 95% CI: 0.12-0.93; p<0.0001). No other factors were found to be significant. Recurrence at 28 or 56 days occurred in 9.1% of those treated with VAN and 13.9% with MTN (p=0.4021). CDI recurrence was not associated with choice of drug.**Conclusion:** Our data suggest that CDI tx with VAN may be associated with decreased need for therapy escalation. CC at EOT and recurrence may be skewed as these were evaluated at the end of overall therapy and TE could have impacted these results.

Systematic Review: Is Trimethoprim-Sulfamethoxazole (TMP-SMX) a Valid Alternative in the Management of Infections in Children in the Era of Community-Acquired Methicillin Resistant *Staphylococcus aureus*? : A Comprehensive Systematic Review

Author Block:

M. T. Rosanova, Cuellar Pompa Leticia MD. Fundación Canaria de Investigación Sanitaria (FUNCANIS), Tenerife, Spain., G. Perez, N. Sberna, P. Serrano Aguilar, G. Berberian, R. lede; Hosp. Garrahan, Buenos Aires, Argentina

Abstract Body:

Background: To evaluate the use of TMP-SMX compared with other options available for the treatment of children with CA-MRSA infections. **Methods:** Data sources: The following data base were searched: Medline and PreMedline (OivdSP interface); Excerpta Medica Database (EMBASE) (Elsevier interface); Cumulative Index to the Nursing and Allied Health Literature (CINAHL) (EbscoHost interface); Sciences Citation Index Expanded (SCI-EXPANDED) (Web of Science interface); Cochrane Library (Wiley interface); Scopus (Elsevier interface) and DARE, HTA (CRD interface). The search strategy was the one developed by SIGN to identify randomized clinical trials and systematic reviews. Also, we conducted a hand review of all reference lists of included studies. Nor language or data limits were added. The last search was done on October 1, 2015. Main key words were Trimethoprim or Trimethoprim-Sulfamethoxazole combination and *Staphylococcus aureus*. Study Selection: Only randomized controlled trials (RCT) comparing TMP-SMX vs any other antibiotic as the first-line treatment in CA-MRSA infections in children were included. Articles were reviewed by two reviewers and in case of discrepancy the final decision was made by the study coordinator. Data Extraction: Only 27 out of 364 papers identified were RCTs and only 4 fulfilled the eligibility criteria (Jadad score $\geq$3). Data synthesis: Evidence found only referred to use of TMP-SMX in soft-tissue infections **Conclusions:** Available evidence is not conclusive to promote or refuse TMP-SMX as first line treatment in CA-MRSA infections in children. Additional well-designed studies are required to further elucidate this issue.

Implications of Reappraisal of Fluoroquinolone Minimum Inhibitory Concentration Susceptibility Breakpoints in Gram-negative Bloodstream Isolates

Author Block:

M. M. Brigmon[1], J. A. Justo[2], P. B. Bookstaver[2], J. Kohn[3], C. Troficanto[3], H. Albrecht[1], M. N. Al-Hasan[1]; [1]Univ. of South Carolina Sch. of Med./Palmetto Hlth., Columbia, SC, [2]South Carolina Coll. of Pharmacy/Palmetto Hlth., Columbia, SC, [3]Palmetto Hlth., Columbia, SC

Abstract Body:

Background: The National Antimicrobial Susceptibility Testing Committee for the United States (USCAST) has recently proposed changing ciprofloxacin minimum inhibitory concentration (MIC) susceptibility breakpoints for gram-negative bacilli from ≤ 1 μg/mL as per current Clinical and Laboratory Standards Institute (CLSI) and Food and Drug Administration (FDA) criteria to ≤0.25 for *Enterobacteriaceae* and ≤0.5 for non-fermenters. This study examines the impact of these proposed changes on ciprofloxacin susceptibility of gram-negative bloodstream isolates (GN-BSI). **Methods:** Matched pairs mean difference (MD) with 95% confidence intervals (CI) was calculated to examine change in ciprofloxacin susceptibility after reappraisal among GN-BSI at Palmetto Health Hospitals in Columbia, SC from 2010-2014. **Results:** Ciprofloxacin MIC distributions of 1055 GN-BSI are in Table as number (%). An overall downshift in *E. coli* ciprofloxacin susceptibility will occur after reappraisal (MD -5.5, 95% CI -7.5, -3.5) with more notable decline among residents of skilled nursing facilities (MD -9.3, 95% CI -15.6, -3.0) and patients with recent fluoroquinolone exposure (MD -14.3, 95% CI -26.5, -2.1). Reappraisal will have most impact on *P. aeruginosa* (MD -7.8, 95% CI -14.5, -1.1) and least on *Enterobacter* species (MD -3.0, 95% CI -7.2, 1.2). **Conclusion:** Reappraisal of current CLSI/FDA fluoroquinolone susceptibility breakpoints will significantly impact GN-BSI, particularly non-fermenters and in the presence of risk factors for fluoroquinolone resistance.

Table. Distribution of ciprofloxacin minimum inhibitory concentration in gram-negative bloodstream isolates

Bacteria	≤ 0.25	0.5	1	≥ 2
Enterobacteriaceae (n=967)	753 (78)	23 (2)	27 (3)	164 (17)
Escherichia coli (n=543)	386 (71)	16 (3)	14 (3)	127 (23)
Klebsiella species (n=205)	176 (86)	2 (1)	9 (4)	18 (9)
Proteus mirabilis (n=72)	60 (83)	2 (3)	1 (1)	9 (13)
Enterobacter species (n=67)	63 (94)	2 (3)	0 (0)	2 (3)
Non-fermenters (n=88)	62 (70)	9 (10)	7 (8)	10 (11)

Colistin-Associated Renal Dysfunction: A Retrospective Analysis of 282 Patients

Author Block:

J. Jacob[1], K. Haynes[2], **J. C. Gallagher**[3]; [1]Univ. of Pennsylvania, Philadelphia, PA, [2]Hlth.Core, Inc, Wilmington, DE, [3]Temple Univ., Philadelphia, PA

Abstract Body:

Background: Colistin use has increased considerably in recent years. Studies examining colistin associated nephrotoxicity have yielded variable incidence rates and risk factors. The objective of this study was to assess the incidence and risk factors associated with the development of colistin associated nephrotoxicity among a large cohort of patients.**Methods:** A retrospective cohort study was performed among patients who received at least 24h of colistin intravenously during a ten-year period at a tertiary care academic medical center. Exclusion criteria included use of renal replacement therapy (RRT) at the start of therapy. The primary outcome was renal dysfunction, defined by RIFLE criteria, or the initiation of RRT. A multivariate analysis was performed to evaluate the influence of risk factors on the development of nephrotoxicity during colistin therapy.**Results:** 409 hospitalizations with colistin administration were identified, with 282 subjects eligible for study analysis. 78% of patients resided in the ICU. Results are in Table 1.

Table 1.				
	Renal Dysfunction (n=142)	No Renal Dysfunction (n=140)	Univariate OR (95% CI)	Multivariate OR (95% CI)
Age, mean, yrs	56	50	1.02 (1.01-1.03)	1.02 (1.01-1.03)
Dose, mg/kg/day	3.83	3.65	1.12 (0.93-1.36)	1.16 (0.95-1.41)
Concurrent Nephrotoxin	115	97	1.89 (1.09-3.29)	1.82 (1.04-3.21)
Duration of Therapy, days	10.2	8.9	1.03 (0.99-1.06)	
Charlson Comorbidity Index, mean	2.1	2.1	1.01 (0.90-1.11)	

Acute Physiology and Chronic Health Evaluation II (APACHE II)	19.7	18.5	1.02 (0.99-1.05)	

Conclusions: In the largest studied cohort to date using RIFLE criteria, half of patients who received colistin experienced renal dysfunction. There was no evidence of a relationship between dose and renal dysfunction. Providers should be especially cautious when using colistin in patients who are older or receiving concomitant nephrotoxins.

Tolerance of Ceftriaxone Administrated Subcutaneously - A French Prospective Multicenter Observational Study

Author Block:

C. Roubaud Baudron[1], E. Forestier[2], T. Fraisse[3], G. Gavazzi[4], L. Pagani[5], M. Paccalin[6]; [1]CHU Hopitaux de Bordeaux, Bordeaux, France, [2]Ctr. Hosp.ier Métropole Savoie, Chambéry, France, [3]Ctr. Hosp.ier Alès-Cévennes, Ales, France, [4]CHU Michallon, Grenoble, France, Grenoble, France, [5]Ctr. Hosp.ier Annecy, Annecy, France, [6]CHU Hopitaux de Bordeaux, Poitiers, France

Abstract Body:

BACKGROUND: Antibiotic administration through subcutaneous (SC) injection is common practice in France, especially with ceftriaxone (CRO). The aim of this study was to determine the tolerance of CRO administrated subcutaneously. **Methods:** This is an ancillary study focusing on CRO use from a large prospective non-interventional multicentre study including every adult patient treated at least one day with SC CRO from May to September 2014 in 50 French hospitals. Data on local adverse effects (AE) and clinical evolution were collected until the end of treatment.**RESULTS:** 163 patients, median age 86 (19-104), treated with CRO were included. Main indications were urinary [n=78 (48%)] and respiratory [n=45 (28%)] infections. Thirty-three patients (21.5%) experienced at least one AE: pain (n=21, 13%), induration (n=11, 7%), hematoma (n=13, 8%) and erythema (n=5, 3%). No cutaneous necrosis was observed. Local AE were mostly reversible, only one patient had a persistent pain associated with transient hematoma and induration contributing to his transfer from rehabilitation unit to acute yard. An injection > 5 min (p=0.005) and the use of non-rigid catheter (p=0.0021) were protective factors against AE. In 137 cases (84%), CRO was successfully injected until the scheduled end. CRO was switched to another more convenient antibiotic in 16 patients (10%). A clinical or bacteriological failure or death were observed in 4% (n=6). AE led to discontinuation of the SC infusion for 4 patients (2%).**CONCLUSIONS:** In a recent report, the European Medicines Agency noticed that data were lacking to recommend a subcutaneous administration of CRO. This original study supports the hypothesis that SC CRO administration may represent an interesting safe alternative to IV route, especially in some peculiar patient settings, such as elders. However this route needs to be further assessed especially for its efficacy and PK/PD data.

Assessing Viral Populations and Predicted Proteins in Coprolites Via Ancient Dna Scaffolding

Author Block:

J. I. Rivera-Perez[1], R. J. Cano[2], Y. Narganes[1], L. Chanlatte[1], G. A. Toranzos[1]; [1]Univ. of Puerto Rico, Rio Piedras Campus, San Juan, PR, [2]California Polytechnic State Univ., San Luis Obispo, CA

Abstract Body:

We recently described for the first time DNA fragments (average length=220bp) obtained from coprolites belonging to two pre-Columbian Caribbean cultures. However, fragment lengths were too small for further analyses. In this study we used additional scaffolding and identified protein-coding viral genes in these paleofeces, a portion of the microbial community commonly ignored by paleomicrobiome studies. Briefly, DNA was extracted from the coprolite cores of each culture and subjected to shotgun sequencing. Quality-filtered DNA fragments underwent scaffolding via Omega (Minimum overlap = 100bp; Insertion and Deletion cost = 3; Mismatch cost = 2) and were submitted to METAVIR for protein analyses (e-value $\leq 10^{-7}$.)Approximately 8% and 25% of Saladoid and Huecoid contigs, respectively, were identified. The majority were dsDNA viruses, although a portion was from ssDNA viruses; retroviral DNA was also detected. Caudovirales, Phycodnaviridae and Mimiviridae, dominated both viromes. Caudovirales protein-coding genes detected included those associated to Siphoviridae, among others. In fact, Siphoviridae-like genes constituted 41% and 39% of the identified Huecoid and Saladoid contigs, the majority of which were from phages infecting *Bacillus sp*, followed by *Rhizobium*, *Staphylococcus*, *Streptococcus*, *Lactococcus* and *Mycobacterium sp*. Bacillus phage genome-coverage was the most complete, including genes encoding for potential replication proteins, a helix-turn-helix domain protein, tail proteins and several site-specific integrases. Interestingly, in Huecoid samples we obtained excellent coverage of possible Mimiviridae genomes, specifically from Acanthamoeba polyphaga moumouvirus and mimivirus. Genes detected from these giant viruses included those encoding for DNA topoisomerases, N-acetyltransferases, epimerases, DNA mismatch repair proteins, as well as several helicase and stomatin family proteins.In conclusion, this study emphasizes the importance of scaffolding in metagenome analyses pipelines, as alignments of ancient DNA sequences <400bp are likely to give refutable results. It also supplements currently limited data on the viromes of pre-Columbian ancient cultures in the Americas.

Presence of a Prophage Determines Temperature-Dependent Capsule Production in &Lt/&Gtstreptococcus Pyogenes&Lt/I&Gt Hsc5

Author Block:

K. CHO; Indiana State Univ., Terre Haute, IN

Abstract Body:

Hyaluronic acid capsule is a major virulence factor in the pathogenesis of *S. pyogenes*. It acts as an adhesin to keratinocytes and anti-phagocytic agent. The expression of the capsule is primarily regulated by the two-component regulatory system CovRS, which acts as a repressor of capsule transcription. The *covRS* genes are frequently mutated in many clinically isolated invasive strains, and this mutation confers visible capsule production on agar plates. We previously reported that capsule production of some invasive strains with *covRS* mutation was dependent on environmental temperature. These strains produce a large amount of capsule only at sub-body temperature, and this thermoregulation occurs at a post-transcriptional level. Here, we report that a prophage has a crucial role in capsule thermoregulation. The lab strain, HSC5, contains three prophages in the chromosome and the prophage ΦHSC5.3 is involved in capsule thermoregulation. In all the spontaneous capsule thermoregulation mutants generated by passaging cells in the lab, only ΦHSC5.3 was cured. Disruption of a gene in ΦHSC5.3 also abolished capsule thermoregulation and caused capsule overproduction in a temperature-independent manner, suggesting that a prophage gene product or products in ΦHSC5.3 participate in capsule thermoregulation. Taken together, these results indicate that the prophage ΦHSC5.3 plays a crucial role in capsule thermoregulation most likely by repressing capsule production at 37°C at a post-transcriptional level.

Phage-encoded Molecules Regulate Stec Virulence

Author Block:

D. Chakraborty, G. Koudelka; State Univ. of New York, Buffalo, NY

Abstract Body:

Background: Shiga toxin-encoding *Escherichia coli* (STEC) cause food poisoning in humans and have been the source of many outbreaks dating back to 1982, when *E. coli* O157:H7 was first isolated. More recent outbreaks of Shiga toxin (Stx) poisoning have been caused both by O157 and non O157 STEC strains. Although primary symptoms of STEC infections are caused by Stx, it is at yet unclear what factors modulate the severity of STEC-mediated disease. In STEC, Stx is encoded by lambdoid prophages. The population structure of *E. coli* O157:H7 lineage is highly homogenous, but the identities and gene content of Stx-encoding phages in these strains are highly variable. Since Stx production, and thus disease, depends on phage lytic growth, our central hypothesis is that induction is primarily regulated by phage-encoded molecules, which subsequently regulates the severity of STEC infections. Our work focuses on determining and comparing the role of Stx-encoding phage repressors affecting induction frequency in Stx-encoding (Φ272 and 933W) and -non encoding phages (434 and λ). We also examine the potential role of a phage-encoded methylase in modulating STEC virulence. **Methods:** UV induction was performed to determine susceptibility of induction in Φ272, 933W, 434 and λ. qRT-PCR was performed to quantify P_{RM} transcripts. In vitro transcription was performed to determine the effects of repressor binding on P_{RM} transcriptional activity. *Acanthamoeba* viability was assessed using a trypan blue exclusion test.**Results:** Stx-encoding phages, Φ272 and 933W, have a higher frequency of spontaneous induction and lower P_{RM} transcript levels than non Stx-encoding phages, 434 and λ. In Φ272 and 933W, the difference in repressor concentration needed to activate versus repress P_{RM} transcription is much smaller than in 434 and λ. Stx-encoding PA8 prophages kill *Acanthamoeba* more efficiently than PA2 prophages, despite both PA2 and PA8 producing similar amounts of Stx when exposed to an SOS inducer. Restoring methylase function increased the killing efficiency of PA2 prophages and affected induction frequency.**Conclusion:** Φ272 and 933W synthesize less P_{RM} transcripts owing to altered binding characteristics by the repressors. This implies lower levels of intracellular repressor, which leads to a higher susceptibility to induction. A phage-encoded specific methylase is responsible for Stx-mediated *Acanthamoeba* killing difference between PA2 and PA8.

Myophage as an Effective Antimicrobial in a Gut-Derived Model of Bacteremia

Author Block:

S. Green, L. Ma, F. Ramig, B. Trautner, A. Maresso; Baylor Coll. of Med., Houston, TX

Abstract Body:

E.coli is a leading cause of gram-negative bacteremia and is an increasing threat due to the prevalence of multi-drug resistant strains in the population. Often arising from a patient's own gastrointestinal tract, strains referred to as ExPEC (extraintestinal pathogenic *E.coli*) are opportunistic organisms capable of translocating across the intestinal barrier into major organ systems and causing life-threatening infections. While immunocompromised patients are at high risk for these infections, chemoprophylaxis with antibiotics, a common treatment, invariably leads to resistant strains and is damaging to the GI microflora. Thus, new treatment avenues are needed. Bacteriophage therapy is an alternative treatment that has not been tested against multi-drug resistant strains in animal models that faithfully recapitulate these types of infections. Here, we report the discovery of a novel series of myoviruses that efficiently kill a panel of multi-drug resistant clinical isolates of ExPEC. These viruses were laboratory evolved using a host range expansion procedure to be further selective against a prominent globally circulating lineage of ExPEC known as ST131. Myophage are effective a reducing ExPEC translocation and levels in tissues and organs while improving health scores of the host in a murine model of neutropenia and gut-derived ExPEC bacteremia. In addition, we demonstrate myophage are safe and can penetrate major organ systems, highlighting their potential desirable qualities as therapeutics. Our results suggest therapeutic phages have potential as effective antimicrobials against MDR ExPEC during bacteremia in compromised hosts.

Publishing Title:

Investigating Impact of Mycobacterial Physiology on Mycobacteriophage Life Cycles by Mass Spectrometry

Author Block:

Y. Li, K. L. Clase; Purdue Univ., West Lafayette, IN

Abstract Body:

Phage lyse bacteria and can be used to design new antibacterial therapies and combat the growth of antibiotic resistant bacteria. Indeed, many current applications in food safety and antibacterial treatment exploit the lytic life cycle of the phage. Therefore, it is necessary to obtain better understanding of phage life cycles, especially the requirements for maintaining different life cycles in order to improve the efficiency of phage's lytic activity.A temperate phage has lytic and lysogenic life cycles. Lytic cycle is preferred when the phage infects exponentially growing bacteria, while the lysogenic cycle is preferred when the phage infects stationary bacteria [1]. Nutrient level of the growth medium impacts the transition of bacterial growth phase and subsequent alteration of bacterial protein expression pattern [2, 3]. Divalent cations may also assist in phage lytic cycle [4]. Thus, the phage life cycle is affected by the physiology of the host bacteria and the content of the growth medium. To explore how the bacterial physiology affects phage life cycles, the phage-host interaction epitomized in the protein expression patterns of both phage and bacteria needs to be investigated.In order to test this hypothesis, we selected three different phages to infect *Mycobacterium smegmatis* (*M. smegmatis*) in different growth phases for subsequent protein extraction. The protein expression patterns were analyzed by high performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS) with an in-house database. Our overall objective is to identify the phage proteins mediating phage lytic and lysogenic cycles and the corresponding bacterial proteins expressed during key transition points in the phage life cycles. The findings will provide a better understanding of phage-host interactions over time and contribute towards novel applications in biotechnology.

Characterizing Parb of Mycobacteriophage Redrock

Author Block:

W. L. Ng, J. Cervantes, R. M. Dedrick, V. Villanueva, T. N. Mavrich, D. Jacobs-Sera, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Plasmids, bacteria, and some phages encode segregation systems for chromosomal partitioning at cell division. One of several such systems is *parABS*, in which ParB DNA-binding protein binds to conserved *parS* sites on the chromosome, and ParA-ATPase segregates ParB-bound DNA. We identified *parABS* systems in forty-six Cluster A bacteriophages belonging to *mycobacteria* and *gordonia* host species. All Cluster A bacteriophages are either temperate or recent derivatives of temperate parents, and most encode an integration system. *Par* phages are predicted to form circularly permuted extrachromosomal prophages and require the *parABS* system for prophage maintenance and stability. Characterization of ParB binding sites in phage *parABS* systems may provide valuable insights into phage diversity and contribute to the development of a potential research tool for the transformation and replication of large or potentially cytotoxic DNA into bacterial cells. To this end, we constructed consensus sequences for *parS* sites of the aforementioned phages and predict that there are at least four specificity groups. Representatives from each group, namely RedRock and Gladiator, which belong to the same group, and Alma, KatherineG, and Echild from each of the remaining three groups, were selected for further study. In support of our predictions, binding assays show RedRock ParB binds more tightly to Gladiator *parS* than to Alma, KatherineG, and Echild *parS*; these data are also consistent with phylogenetic analyses of ParB protein sequences. Contrary to predictions based on *parS* consensus sequences and phylogenies of ParA and ParB proteins, binding studies with Alma ParB demonstrate tight binding to RedRock *parS*, followed by Echild, Gladiator, and KatherineG *parS*. All three components of the *parABS* system can contribute to incompatibility, so further work is needed in order to directly assess *par* cassette compatibility.

Characterizing the Replication System of Extrachromosomal Mycobacterial Prophages

Author Block:

R. E. Rush, T. N. Mavrich, R. M. Dedrick, D. A. Russell, D. Jacobs-Sera, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

When studying mycobacteria, there is an ongoing need for the development of new biotechnological tools. Currently, there are only a few characterized mycobacterial replication systems that can be used for cloning. However, we have identified a group of over forty genetically related, temperate mycobacteriophages (phages) that may aid in the expansion of available genetic tools. Temperate phages have two life cycles, lytic and lysogenic. Typically, during lysogeny the phage's genome is integrated into the host chromosome where it can be passively replicated by host replication systems. However, our mycobacteriophages of interest do not have any apparent integration machinery and instead contain putative partitioning systems. Partitioning systems are used to ensure that DNA is stably inherited during replication. The observed substitution of partitioning machinery for integration machinery suggests that these phages are maintained as extrachromosomal prophages and may utilize novel replication systems as well. The identification and characterization of these replication systems would enable further development of mycobacterial genetic tools. In order to investigate the replication systems used by these prophages, we first employed whole genome sequencing and double lysogenization tests to determine if these prophages are extrachromosomal. Additionally, we conducted standard molecular cloning to determine if the partitioning locus is sufficient for replication. Our results confirm that these phages are indeed extrachromosomal, but that the partitioning locus is not sufficient to confer the ability to replicate. Further characterization of these mycobacteriophages is needed to facilitate the development of new tools and to provide valuable insight into phage biology.

This Chaperone Can Dance - A New Role for Phage Tail Fibre Assembly Proteins

Author Block:

O. Ivantsiv, A. R. Davidson; Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Background: Bacteriophages (phages) possess remarkable specificity for their hosts. In phages containing contractile tails this specificity is determined primarily by tail fibres - elongated trimeric proteins that mediate the initial physical interactions between a phage and a bacterium. In phage T4, the formation of the distal portion of these fibres requires a specific phage-encoded tail fibre assembly protein (TFA; product of gene 38), which is widely believed to act as a chaperone (Leiman, 2010). Genes encoding putative TFAs can be identified in at least 15% of all tailed phage genomes, however, their mechanism of action remains unknown. In this study, we investigated the role of the TFA in assembly of the tail fibres of *E. coli* phage Mu. **Methods & Results:** Through a series of protein expression, purification and *in vitro* binding assays we found that the TFA binds to the C-terminal portion of the monomeric fibre and triggers its oligomerization, preventing the tail fibre from forming intracellular aggregates. Intriguingly, analytical size exclusion chromatography revealed that the TFA does not dissociate from the complex with the fibre after oligomerization or after the assembly of the phage baseplate wedge. A stable complex between the fibre and the TFA is also formed in *E. coli* phage P2, and *Salmonella* phages ST64b and Fels-2, suggesting that the TFA may be a part of the mature tail fibre. Our receptor binding assays further support this idea. When Mu or P2 phages are premixed with their purified bacterial receptors they are subsequently blocked from infecting their bacterial hosts. This inhibition is relieved when the purified receptors are incubated with Mu or P2 TFAs prior to the phage addition. This data as well as our full cell-binding assays reveal that Mu and P2 TFAs are able to specifically bind receptors on bacterial cells. These TFAs share 93% amino acid sequence identity and yet demonstrate different receptor-binding preferences, consistent with those of full phage particles. **Conclusions:** Taken together, our data demonstrates that the TFA assists in tail fibre oligomerization, and that, either in combination with the tail fibre or alone, likely plays a role in determining host specificity in the phages studied. Utilizing TFAs as receptor-binding proteins may represent an evolutionarily conserved mechanism for determining the host range of tailed phages.

Investigation Of The Accessory Region Of Bacteriophage Lambda's p_L Operon

Author Block:

K. Cascino, L. Thomason, N. Costantino, D. Court; NIH, Frederick, MD

Abstract Body:

Bacteriophage lambda is a temperate phage able to undergo both lytic and lysogenic cycles in its host *E. coli*. The p_L operon of lambda, expressed early after infection, contains an "accessory region" composed of eight open reading frames (ORFs) that are non-essential to lambda plaque formation, but are known to contribute to alterations in host cell physiology and cell cycle regulation. Previous work in this laboratory has shown that expression of the accessory region causes pleiotropic effects including a decrease in cAMP levels, an increase in ppGpp levels, and a block to initiation of *E. coli* DNA replication. The goal of this study is to precisely map the ORFs responsible for the changes observed in *E. coli* physiology and cell cycle regulation to gain insight into fundamental viral-host interactions. In order to identify the ORF(s) responsible for these changes, an isogenic set of strains containing nested deletions in the accessory region was constructed using recombineering technology. The effect on cAMP was monitored by assaying β-galactosidase (β-gal) activity. Strains containing both wild-type p_L and the proximal five ORFs of the accessory region inhibit β-gal levels sevenfold compared to strains deleted for the entire region, which do not inhibit β-gal levels. Therefore, the decrease in cAMP can be attributed to a function within the first five ORFs of lambda's accessory region: *orf62*, *orf63*, *orf61*, *orf29*, and *orf73*. In addition, we have previously shown through flow cytometry experiments that strains expressing the distal four ORFs of the accessory region, *orf73*, *ea22*, *ea8.5*, and *orf55*, produced distinct peaks of 4, 8, or 16 complete chromosomes, indicating a block to initiation of replication due to expression of these ORFs. Interestingly, of the eight ORFs composing the accessory region, *orf73* alone contains a recognizable motif. It has a C4-type zinc finger domain similar to TraR and DksA, which modulate gene expression by interacting with the secondary channel of RNA polymerase. Both the decrease in cAMP levels and block to initiation of DNA replication appear to require *orf73*, and we speculate that this gene product may be at least partially responsible for some of the effects observed from the accessory region.

Investigation of Two Putative Integrases Within *Gordonia terrae* Bacteriophages

Author Block:

B. R. Brown, M. Montgomery, University of Pittsburgh SEA-PHAGES Students, D. Jacobs-Sera, D. A. Russell, W. H. Pope, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Comparative genomic analysis of a 1000+ actinobacteriophage collection at the University of Pittsburgh provides a rich source for understanding phage diversity and evolution. (Hatfull, 2010.) One of the hosts used in this endeavor is Gordonia terrae, a soil microbe known to degrade environmental pollutants. To date, 129 phages have been isolated using this host, with 44 genomes being sequenced. The robust diversity that has been found in the mycobacteriophage was also present amongst these Gordonia phages having 13 clusters and 16 singletons. Analysis of these genomes has identified two bacteriophages that contain two integrases each. The integrase gene enables the phage to integrate into the host genome, replicating along with the host. These phages, Bowser and Howe, contain two distinct integrases each, one of which they share in common. The other two integrases are found in 2 other phage genomes, Kita and Schwabeltier. While phages Bowser and Schwabeltier share 92% nucleotide similarity, they only share one of the 2 integrases. Comparing Howe, Kita, and Bowser, they share less than 50 % nucleotide identity placing them into distinct clusters. While functional studies have not been performed yet, the identity of each integrase, shared with Kita and Schwabeltier would suggest that they are functional. It is not yet known why a phage genome would contain two integrases, but this may suggest that Howe and Bowser were recently in an alternative host. In addition, two integration sites may provide additional integration vectors that can be propagated to use as genetic tools in the future.

***Tetrahymena* Phagosomes: Platforms for Bacterial Gene Transfer**

Author Block:

I. Aijaz, G. Koudelka; Univ. at Buffalo, Buffalo, NY

Abstract Body:

Background: The microbial community in natural environments such as soil, pond water or animal rumen is comprised of a diverse mixture of bacteria and protozoa such as ciliates or flagellates. In such microbiota, the main source of bacterial mortality is currently considered to be grazing by phagotrophic protist. Many protists are omnivorous heterotrophs, i.e., they can feed on a range of different bacterial species. Due to this indiscriminate feeding, different bacterial species are assembled together in the food vacuoles of the protists, where they can potentially exchange genetic material. Earlier investigations have used a voracious bacterivore ciliate, *Tetrahymena thermophila*, to demonstrate gene transfer via conjugation within protozoan phagosomes. In this study, we explore the transfer of a bacteriophage 933W, and an *E. coli-Corynebacterium* plasmid shuttle vector pECTAC-*gfp* from one bacterial strain to another within protozan phagosomes. **Methods:** To focus on ingested bacteria and bacteriophage we used differential centrifugation to separate bacteria encapsulated in *Tetrahymena* from planktonic bacteria. We monitored the bacterial population inside *Tetrahymena* using confocal microscopy and measured cfu to determine bacterial survival within *Tetrahymena* phagosomes. Bacteriophage induction within *Tetrahymena* phagosomes was measured using Selectable In-Vivo Expression Technology (SIVET). Bacteriophage activity within phagosomes was monitored *via* spot assay. Bacteriophage transfer was detected *via* PCR and quantified by qPCR. The transfer frequency of shuttle vector pECTAC-*gfp* was measured by counting cfu. **Results:** Bacterial strains, engulfed in the vesicles of protozoa, assemble together. A large fraction of the bacteria are not digested and are expelled to the outside environment. The bacteriophage contained within engulfed bacteria1) induces as early as the first 15 minutes post- ingestion 2) a large fraction of the release bacteriophage remains active, for up to 2 hours and 3) infects recipient strain at higher frequency within *Tetrahymena* phagosomes. Moreover, we found high frequency transfer of a bacteriophage, 933W, and a bacterial shuttle vector pECTAC-*gfp*, from one bacterial strain to another within *Tetrahymena* phagosomes.**Conclusion:** *Tetrahymena* phagosomes, serve as platforms for bacterial gene transfer, providing microbes with the means to evolve and adopt to changing environment.

Incidence and Characterization of Type II Crispr1-Cas and Crispr2 Systems in *Enterococcus*

Author Block:

C. Lyons[1], N. Raustad[2], M. A. Bustos[1], M. Shiaris[1]; [1]Univ. of Massachusetts Boston, Boston, MA, [2]The Charles Stark Draper Lab., Cambridge, MA

Abstract Body:

CRISPR-Cas systems, a specific and adaptive immune response in prokaryotes, obstruct both viral infection and incorporation of mobile genetic elements by horizontal transfer. As horizontally-acquired genes may provide rapid adaptation to habitat change, and thus increase survival, antiviral CRISPR protection may represent a fitness cost to its host. To date, investigations into the prevalence of CRISPR have primarily focused on pathogenic and clinical bacteria, while less is known about CRISPR dynamics in commensal and environmental species.New PCR primers and DNA sequencing were used to detect the presence of *cas1*, a universal CRISPR-associated gene, in environmental and non-clinical *Enterococcus* isolates. Type II CRISPR1-*cas1* was detected in approximately 33% of the 275 strains examined, and significant differences in CRISPR1 carriage between species was observed. Incidence of *cas1* in *E. hirae* was 73%, nearly three times that of *E. faecalis* (23.6%) and 10 times more frequent than in *E. durans* (7.1%). This is the first report of CRISPR1 presence in *E. durans*, as well as in the plant-associated species *E. sulfureus* and *E. casseliflavus*. Significant differences in CRISPR1-*cas1* incidence among *Enterococcus* species support the hypothesis that there is a tradeoff between protection and adaptability. Differences in the habitats of these enterococcal species may exert varying selective pressure, resulting in a species-dependent distribution of CRISPR-Cas systems.Additionally, previously designed primers were used to detect and characterize the CRISPR2 array in isolated *E. faecalis* strains. CRISPR2 is presumed to be an inactive system, due to its lack of associated *cas* genes, and is thus referred to as an "orphan" locus. CRISPR2 loci were detected in 95% of the 99 *E. faecalis* strains analyzed, and 39 of these arrays were fully sequenced for spacer content. Of these, 14 strains contained at least one spacer identifiable as either phage or plasmid, suggesting a past immune role for the presumptively inactive CRISPR2 array. However, further work is needed to ascertain a function for these highly conserved orphan CRISPRs in *E. faecalis*.

Phenotypic Observations Upon Deleting a *Toxoplasma gondii*-Specific Expanded Locus

Author Block:

G. W. Alfonse, A. L. Borges, A. N. Klinghoffer & J. P. Boyle; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Disseminating throughout host cell types and species with intact capacity to cause disease in warm-blooded animal and human hosts, the interaction of the eukaryotic protozoan parasite *Toxoplasma gondii* with its host is in dynamic flux mediated by stage-specific protein effectors. Unlike microbes which have one mode of host cell entry: being endocytosed by the host cell, *T. gondii* also actively facilitates its entry into the host cell through a subset of protein effectors, for instance. On the genome level *T. gondii* matches its closest protozoan relatives by over 80%, yet its transmission across intermediate host organism species and virulence within each of several species studied surpasses theirs. Aside from varied transcriptional expression, an array of differentially diversified protein effectors could account for the transmission-and-virulence advantage of *T. gondii*. We report the genetic deletion of a tandem duplicated-and-diversified gene cassette present in *T. gondii* and not in its closest protozoan relatives which we have termed a *Toxoplasma gondii*-specific expanded locus (TSEL), one known gene of which encodes for a KRUF (Lysine-Arginine rich unidentified function) family protein with a putative role in translation. Through the generation of independent *T. gondii* knockout clones, the removal of the reported TSEL did not prevent parasite growth in tissue culture (human foreskin fibroblasts). Further tissue culture growth assays and *in vivo* studies are impending.

***Toxoplasma gondii* Infections Alter Host Neuronal Gabaergic Signaling**

Author Block:

I. Blader[1], J. Brooks[1], M. Fox[2]; [1]Univ. at Buffalo, Buffalo, NY, [2]Virginia Tech, Roanoke, VA

Abstract Body:

BACKGROUND: Patients suffering from microbial infections of the central nervous system often develop seizures. Breakdown of the blood brain barrier, inflammatory cell influx, altered ionic homeostasis, and glial cell activation are amongst the changes that occur during infections that have been proposed to contribute to seizure development. But how these changes impact neuronal structure and function to cause seizures is not understood. Gamma-aminobutyric acid (GABA) is the primary inhibitory neurotransmitter that regulates the flow and timing of excitatory neurotransmission and when this pathway is altered, seizures develop. We therefore hypothesized that neuronal infections alter GABAergic signaling and tested this in mice infected with the protozoan parasite *Toxoplasma gondii*. **METHODS:** We used immunohistochemistry and electroencephalography/electromyography to assess GABAergic synapses and seizure activity in *Toxoplasma*-infected mice. **RESULTS:** Here, we show that infection with type II *Toxoplasma* tissue cysts led to global changes in the distribution of GAD67, a key enzyme that catalyzes GABA synthesis in the brain. The effect of *Toxoplasma* on GAD67 was specific since excitatory presynaptic markers were unaltered by infection. Alterations in GAD67 staining were not due to decreased expression but rather a change from GAD67 clustering at presynaptic termini to a more diffuse localization throughout the neuron. Consistent with a loss of GAD67 from the synaptic terminals, *Toxoplasma*-infected mice develop spontaneous seizures and are more susceptible to drugs that induce seizures by antagonizing GABA receptors. Interestingly, GABAergic protein mislocalization and the response to seizure inducing drugs were observed in mice infected with type II but not type III strain parasites indicating a role for polymorphic parasite factor(s) in regulating GABAergic synapses. We are currently examining the role that *Toxoplasma*-induced neuroinflammation plays in GAD67 mislocalization and seizure development. **CONCLUSIONS:** Taken together, these data support a model in which seizures and other neurological complications seen in *Toxoplasma*-infected individuals are due, at least in part, to changes in GABAergic signaling.

Exploring the Host Targets of MPR1, a Fungal Metalloprotease That Facilitates the Transmigration of *Cryptococcus neoformans* Across the Blood-Brain Barrier

Author Block:

S. Na Pombejra[1], C. Zhang[2], M. Salemi[1], B. S. Phinney[1], A. Gelli[1]; [1]Univ. of California, Davis, CA, [2]Second Military Med. Univ., Shanghai, China

Abstract Body:

Cryptococcus neoformans can cause a life-threatening fungal infection in immunocompromised patients. The high mortality of cryptococcosis is associated with cryptococcal invasion of the central nervous system (CNS) via the blood brain barrier (BBB). By examining the extracellular proteome of *C. neoformans*, we identified a novel secreted metalloprotease, Mpr1 that facilitates the migration of *C. neoformans* across the BBB. We sought to identify the host targets of Mpr1 and resolve the molecular mechanism of Mpr1 during BBB crossing.Remarkably, we found that *Saccharomyces cerevisiae* (Sc - normally cannot cross the BBB) expressing Mpr1 (Sc<CnMPR1>) gained the ability to attach to brain endothelial cells and migrate across the in vitro BBB model. The transmigration of Sc<CnMPR1> occurred without tight junction disruption confirmed by transendothelial electrical resistance (TER) and FITC-dextran permeability. This suggested that Sc<CnMPR1> penetrated through the BBB transcellularly similar to *C. neoformans*. Moreover, SEM imaging of both wild type Sc (ScWT) and Sc<CnMPR1> strains showed no morphological difference on the yeast cell surfaces. Based on these observations, we hypothesized that instead of altering the fungal cell surface Mpr1 might interact with surface proteins of the BBB and thereby facilitate the transmigration of fungal cells. We exploited the gain function of Sc<CnMPR1> to identify specific host targets of Mpr1. Cell surface proteins of hCMEC/D3 cells (human brain endothelial cell line) were labeled with sulfo-NHS-SS-biotin and then isolated via magnetic beads coupled to a biotin antibody. The labeled proteins were incubated with Sc<CnMPR1> or ScWT (control). Following incubation, yeast were washed to remove non-specific binding & unbound proteins. Host proteins that remained attached to the yeasts were eluted and identified by MALDI-TOF MS/MS. Proteomics analysis revealed hits corresponding to surface proteins of brain endothelial cells with roles in cytoskeleton-plasma membrane rearrangement and endosomal trafficking – process that mediate transcellular migration of *C. neoformans*.

An Eph-Tyrosine Kinase Receptor-Activated Pathway Mediates Transmigration of *C. neoformans* across the Blood-Brain Barrier

Author Block:

M. Jamklang, **P. A. Robins**, A. Gelli; Univ. of California, Davis, Davis, CA

Abstract Body:

Cryptococcus neoformans is the leading cause of fungal meningoencephalitis, a devastating disease that occurs primarily in immunocompromised individuals and claims more than 600,000 deaths per year. Colonization of the brain occurs because *C. neoformans* manages to breach the blood-brain barrier (BBB) and although mounting evidence supports a transcellular mechanism of crossing, the genes and gene products that mediate this process remain largely unknown. Given that the initial association and attachment of cryptococcal cells to the BBB is a key step in the development of meningoencephalitis, we sought to resolve the transcriptome of the BBB during this early stage of transcytosis. To do this we exposed human brain microvascular endothelial cells (hCMEC/D3) to *C. neoformans* and performed high-throughput sequencing on the Illumina platform (RNA-seq). Among the many canonical signaling pathways identified as mediating molecular interactions during the association of *C. neoformans* with brain endothelial cells, we found that the EPH tyrosine kinase receptor-activated pathway is a key player. The EPH receptors and their membrane-tethered ligands (ephrins) mediate several different cellular processes including modulation of the cytoskeleton, cell-substrate adhesion and activation of signaling. Using siRNA to silence the gene encoding an EPH tyrosine kinase receptor in hCMEC/D3 cells, we found that the transmigration of *C. neoformans* in the *in vitro* model of the BBB was significantly reduced. Accordingly, the addition of a chemical agonist (doxazosin) known to activate the EPH pathway promoted greater transmigration of *C. neoformans* across the BBB. Similar transmigration results were observed upon the addition of an EPH ligand (ephrinA1). Our results also suggest that the enhanced transmigration of cryptococci observed upon activation of the EPH receptor did not alter the integrity of the tight junctions consistent with a transcellular mechanism. Taken together our results suggest that the EPH receptor may serve as a link that couples *C. neoformans*' penetration to cytoskeleton–remodeling by serving as an entry and intracellular signaling receptor for *C. neoformans*.

Understanding The Murine Immunological Susceptibility To Candida Albicans

Author Block:

D. P. Agustinho[1], F. Sedlazeck[2], M. Oliveira[3], A. L. Bocca[3], A. A. H. Tavares[3], I. Silva-Pereira[3]; [1]Albert Einstein Coll. of Med., New York, NY, [2]Simons Ctr. for Quantitative Biology, Cold Spring Harbor Lab., New York, NY, [3]Univ. of Brasilia, Brasilia, Brazil

Abstract Body:

The commensal fungal pathogen *Candida albicans* can cause lethal systemic infections in immunocompromised patients. Macrophages and monocytes are the inate immune cells that represent the first line of defense against *C. albicans* infection, and they recognise pathogens via Pattern Recognition Receptors (PRRs). Activation of these receptors induces a signaling pathway that culminates in specific cytokine production, that orchestrates a specific immune response. Understanding the patterns of gene expression that results in resistance to this pathogen could be key in unraveling the infection process and in elaborating novel and more efficient treatments for this disease.In this study we focused on analyzing the molecular patterns of susceptibility to *C. albicans* by investigating the differences in gene expression response of macrophages from two mouse strains, one susceptible and the other resistant to this fungus. This is the first study analyzing the global gene expression in different models of suscetibility to *C. albicans*, and the first to investigate both host macrophage and pathogen cell at the same time. Bone marrow-derived macrophages from the susceptible and resistant strains (DBA/2J and BALB/c, respectively) were co-cultured with *C.albicans* yeasts for different time points and RNA from both pathogen and host cells were extracted and sequenced by Dual RNA-seq. Differential expression analysis showed that many PRR pathways are altered between the resistant and the suceptible mouse strain. The resistant strain (BALB/c) shows a more defined inflamatory response, while the suceptible strain (DBA/2J) shows a down-regulation of TLR and MAPK signalling pathways elements, as well as pro-inflamatory cytokines. The pathogen, on the other hand, shows distinct metabolic differences when interacting with both mouse strains. Theses results led thus to formulate a model of the differences of interaction between macrophages from these two mouse strains and *C. albicans*, possibly highlighting possible new targets for *C. albicans* infection therapy.

***Cryptococcus neoformans* Releases Proteins into Macrophages That Are Associated with Host Cell Metabolic Changes**

Author Block:

E. H. Jung, L. Huang, L. Santambrogio, A. Casadevall; Albert Einstein Coll. of Med., Bronx, NY

Abstract Body:

Cryptococcus neoformans is a facultative intracellular pathogen that can persist and replicate in macrophages. The outcome of the *C. neoformans*-macrophage interaction is a key determinant contributing to the outcome of infection. Previous studies have shown that vesicles released by *C. neoformans* under normal laboratory growth conditions contain polysaccharide and protein components associated with virulence[1]. In this study we analyzed fungal and host proteins in macrophages infected with *C. neoformans*. We used two cell types to study mammalian interaction with *C. neoformans*; an immortalized murine macrophage-like cell line (J774.16) and primary bone marrow macrophages derived from C57BL/6 mice to identify proteins released from cryptococcal cells into macrophages. Mass spectrometry and proteomic analysis allowed us to identify one hundred and twenty six proteins of fungal origin in the lysate of *C. neoformans* infected macrophages. The functions of these proteins ranged from transcription factors to virulence factors like urease. In addition, we analyzed macrophage proteome in macrophages infected with *C. neoformans* and found significant differences in the protein expression of multiple pathways including cell death. These results indicate that quantifiable amounts of proteins are secreted by *C. neoformans* during infection and that host macrophages alter their expression patterns based on the viability of the pathogen.

***Candida parapsilosis* Cell-wall Adhesins Similar to Agglutinin-like Sequence (Als) Proteins are Involved in Binding of Fibronectin and Adhesion to Human Epithelial Cells**

Author Block:

A. Kozik, D. Zajac, G. Bras, J. Karkowska-Kuleta, O. Bochenska, M. Rapala-Kozik; Jagiellonian Univ., Faculty of Biochemistry, Biophysics and Biotechnology, Krakow, Poland

Abstract Body:

Background: Adhesion to host tissues, mediated by pathogen surface-exposed molecules is a critical step in the pathogenesis of infections caused by fungal pathogens of humans. At the cell surface of *Candida parapsilosis*—a widespread commensal commonly isolated from human skin, but also an emerging infectious agent that causes systemic candidiasis in immunocompromised individuals—several proteins similar to *C. albicans* agglutinin-like sequence proteins (Als) have recently been identified and considered as potentially important virulence factors. However, their actual interactions with the host surfaces such as the epithelium or extracellular matrix (ECM) has not been satisfactorily characterized. **Methods:** In this work two Als-like *C. parapsilosis* proteins—Cpar2_404780p and Cpar2_404800p—were isolated from a fraction of beta-1,6-glucanase-extractable cell-wall proteins and purified by ion-exchange and gel filtration chromatography. Adhesive properties of these proteins towards an ECM protein—fibronectin—were characterized with the use of surface plasmon resonance measurements, and their ability to bind to human epithelial cells of the A-431 line was tested by microtiter assays with the use of pre-labeled fungal proteins.**Results:** The dissociation constants determined for the complexes of Cpar2_404780p and Cpar2_404800p with human fibronectin were of 7.76×10^{-10} M and 5.54×10^{-9} M, respectively, suggesting a very high affinity of these fungal proteins to the host ECM. Moreover, both fungal proteins strongly adhere to the surface of epithelial cells, to a capacity of 0.1 and 0.05 pmoles of Cpar2_404780p and Cpar2_404800p bound per 1×10^{6} of human cells.**Conclusion:** Characterization of the interactions of two Als-like fungal adhesins with fibronectin, as well as evidence for their adherence to the human epithelium, deepen our understanding of the mechanisms of host-pathogen interactions during candidiasis caused by *C. parapsilosis*.

Biological Control of *Eichhornia crassipes* Using Fungal Plant Pathogens

Author Block:

J. P. B. Abengaña, G. R. Dedeles; Res. Ctr. for Natural and Applied Sci., Univ. of Santo Tomas, Manila, Philippines

Abstract Body:

Eichhornia crassipes (Mart.) [Solms] or commonly known as water hyacinth is an aquatic weed, found in lakes, rivers, and ponds of countries with temperate climates. Apart from environmental problems arising from water hyacinth infestation, it also impose a negative impact on the socioeconomic status of infested areas.Thus, In this study, fungal plant pathogens were tested for their potential as biological control agents to prevent the rapid proliferation of water hyacinth.Healthy water hyacinth plants with no trace of any disease were collected from aquatic weed-infested areas and were cultivated in greenhouse conditions. Fungal pathogens used in the experiment were isolated from water hyacinth plant parts with observable disease manifestation or necrosis using tissue plating and moist chamber technique. Purified cultures of all emergent fungi were subjected to pathogenicity testing on healthy water hyacinth plants using two inoculation methods, namely, agar block and spore suspension method. Ratings for the infection were measured using a grid method to calculate for total percentage of infected surface area. After 2 weeks of incubation period, all fungal isolates which exhibited disease manifestation were further tested for host-specificity test.Out of 92 isolated fungi, 17 of which exhibited a potential for use as biological control agents. And of the 17, 6 isolates exhibited the most promising results. The six of which with tentative identification are coded as isolates BL1 with a 39% infected leaf surface, BL2 with a 68% infected leaf surface, BL3 with a 45% infected leaf surface, BL6 with a 19% infected leaf surface, WH1 with a 55% infected leaf surface, WH4 with a 38% infected leaf surface, and WH5 with a 64% infected leaf surface. On the other hand, host-specificity test conducted on aquatic plants *Pistia stratiotes* and *Ipomoea aquatica* revealed that isolates WH1 and WH5 are not host-specific for water hyacinth which is an undesirable characteristic for fungal pathogens to be considered as an effective biological control agent. The results indicated that isolates BL1, BL2, BL3, BL6, and WH4 may have a potential as effective biological control agents for water hyacinth. Further experiment is recommended to see if there will be an increased in the effectivity of these fungal pathogens when applied in combinations.

A New Murine Model of Cutaneous Aspergillosis in a Large Skin Defect

Author Block:

A. M. Tatara[1], N. D. Albert[2], A. G. Mikos[1], D. P. Kontoyiannis[2]; [1]Rice Univ., Houston, TX, [2]The Univ. of Texas MD Anderson Cancer, Houston, TX

Abstract Body:

Background: Cutaneous aspergillosis is a clinically challenging condition to resolve. In part, this is due to the ability of *Aspergillus* to invade local blood vessels and suppress host angiogenesis, resulting in large necrotic ulcers with poor innate regenerative capacity[1]. In order to better understand this disease process, as well as build a platform for developing improved therapeutic strategies, we have created a new murine model of cutaneous aspergillosis featuring a large skin defect.**Methods:** Chemically immunosuppressed BALB/c mice[1] were inoculated with subcutaneous injections of either saline or $1.75x10^6$ conidia/mL *A. fumigatus* Af293. After 72 hours, a full-thickness surgical wound of 5mm was created with a sterile biopsy punch and the wound was re-inoculated at the same dosage. Every 3 days, the size of the wound bed was measured. Mice were euthanized at Day 9 (n=5 per group, performed in duplicate) and Day 18 (n=5 per group). After euthanasia, the wound bed was harvested subjected to histologic analysis for host inflammation and presence of fungi.**Results:** As early as day 9, the rate of cutaneous wound healing was significantly inhibited by the presence of *Aspergillus* infection (wound area reduction of 13.5%, p=0.55), whereas saline groups demonstrated significant reduction of wound area (39.0%, p=0.017). Viable *A. fumigatus* could still be recovered from the wound bed at least two weeks after the initial infection. Histology revealed the presence of hyphae and inflammation in infected wound beds at time of euthanasia.**Conclusions:** We have successfully created a murine model of chronic cutaneous aspergillosis infection of a large tissue defect with impaired wound healing. This model reproducibly recapitulates the impaired wound healing seen in immunocompromised patients. Unlike previous work, this model allows for 1) real-time macroscopic assessment of healing of a large cutaneous *Aspergillus*-infected wound, 2) chronicity of infection, and 3) the ability to test novel local therapies for fungal-infected wound beds in the future.

Immune Recognition of *Candida albicans* in Zebrafish

Author Block:

M. E. Theriault, R. T. Wheeler; Univ. of Maine, Orono, ME

Abstract Body:

Candida albicans is an opportunistic fungal pathogen that causes diseases ranging from oral thrush to candidemia in immunocompromised individuals. Recognition of pathogens, like *C. albicans*, during infection is poorly characterized primarily due to the difficulties in visualizing the host/pathogen interaction without killing the host. Transparent animal hosts, such as *Danio rerio* (zebrafish), are necessary to accomplish the task of imaging pathogen recognition while maintaining host viability. For pathogen recognition, zebrafish likely use immune receptors similar to mammalian receptors including C-type lectin receptors. Human C-type lectin receptors have already been shown to be crucial in recognition of fungal pathogens like *C. albicans*, and our goal was to identify and characterize cognate receptors crucial for fungal recognition in zebrafish. Fusion proteins of recently identified receptors were expressed via cell culture and purified with HiTrap Protein A columns. Characterization of receptor binding was conducted using fluorescence microscopy as well as with a high-throughput luminescence binding assay. Recognition by the purified zebrafish receptors of *C. albicans* was observed using fluorescence microscopy. Optimization of the luminescence assay has proved a highly efficient way to detect receptor-ligand binding *in vitro*. Due to its efficiency, this assay will be used to determine the binding affinities of the purified receptors to various other microbes to allow for increased characterization. These studies have contributed to a better understanding of fungal pathogen recognition in zebrafish, an animal model widely used to study disseminated *C. albicans* infection.

Human Gingival Fibroblasts from Patients Infected with Periodontal Pathogens are Less Sensitive to *Candida albicans* Infection

Author Block:

M. Rapala-Kozik[1], D. Ostrowska[1], J. Sykut[1], O. Bocheńska[1], J. Karkowska-Kuleta[1], K. Seweryn[1], W. Aoki[2], M. Ueda[2], A. Kozik[1]; [1]Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian Univ., Krakow, Poland, [2]Div. of Applied Life Sci., Graduate Sch. of Agriculture, Kyoto Univ., Kyoto, Japan

Abstract Body:

Background: Within the gingival tissue, fibroblasts not only constitute the most common cell type that regulate the homeostasis of the connective tissue but are also involved in contacts with periodontal pathogens that form a network of mutualistic or antagonistic interactions at the site of infection. *Candida albicans*—an opportunistic fungal pathogen—is present in the oral cavities of significant part of the population. In particular, it has been identified in gingival tissues and periodontal pockets where it may interact with bacteria to colonize the host. The analysis of the responses of bacteria-infected fibroblasts to the virulence factors of *C. albicans* can provide novel insights into the regulation of host responsiveness to fungal infections.**Methods:** Primary gingival human fibroblasts, obtained from healthy donors and chronic periodontitis patients, were treated with whole *C. albicans* cells or selected aspartic proteases (Saps), glucans, mannans and the whole mixture of isolated cell wall proteins. Lipopolysaccharide served as a positive control. After incubation for different time interval, RNA and protein were extracted and the transcript or protein levels were determined for interleukins and myofibroblast markers**Results:** Two aspartic proteases—Sap3 and Sap6—were identified as the main *C. albicans* factors that activated gingival fibroblasts to produce cytokines and induced the myofibroblast formation. The cell wall proteins and glucans or mannans were less effectively recognized by these cells. Fibroblasts isolated from patients with chronic periodontitis were less sensitive to contact with *C. albicans* cells and Sap treatment.**Conclusions:** Determination of the nature of cytokine influence on the interactions between *C. albicans* and bacteria-stimulated gingival fibroblasts as well as possible changes of the proteome of these host cells may lead to the development of novel strategies to prevent or treat oral candidiasis.

***in Vitro* Dopamine Activity On Gram Negative Bacilli (Gnb) And *candida* spp Biofilm (Bf) From Urogenital Infections (Ugti)**

Author Block:

A. E. FARINATI, Sr., R. Villanueva, M. Marques, C. Layño; SALVADOR Univ., MARTINEZ, BUENOS AIRES, Argentina

Abstract Body:

Background: The majority of microbial endocrinology investigations have focused on the bacteria interaction of stress-associated molecules. Some authors affirm and others denied that dopamine (DA) can modulate growth and virulence factors production in planktonic *E. coli* but they have not assayed with microorganisms (MO) in BF. Aim: to study the DA influence on GNB and *Candida* biofilms from UGTI.**Methods:** We used 8 clinical isolates; 2 GNB: *Escherichia coli* (EC) and *Proteus mirabilis* (PM); yeast: 3 *Candida albicans* (CA) and 3 Non *albicans Candida* (NAC). The BF was investigated using a glass coupon (GC). GNB isolates were inoculated in Trypticase Soy Broth (TSB) and Peptone Broth (PB) with GC. CA and NAC isolates were inoculated in Sabouraud Broth with GC. We used DA (6.0 ± 1.1 ng/ml) that simulate plasma concentration and 12.0 ± 1.1 ng/ml (elevate DA levels) as stress agents. The controls without DA were used with similar techniques. Assays were performed in triplicate; everything was read by optical microscopy previous crystal violet tinction after 6, 12 and 24 hours. To evaluate and compare the results we used a scoring system (SS) based on BF growth (BFSS) from 0 to 5. A 0 is given for the absence of BF, 1 to 5 are given to different growing BF phases.**Results:**DA at plasma level increased the EC BF at early formation (BFSS 2 *vs* control 1) and the increasing is more evident at 24 hours (BFSS 4 vs control 2). There is not variation with TSB and PB. Under influence of elevate DA the BFSS are 3 and 5 respectively vs 1 and 3 of controls. The influence over CA BF is not evident in early stages and at 24 hours. In NAC BF appears a variation of 3 to 5 in the score vs 1 to 3 in 24 hours controls under the two DA levels. **Conclusions:** The present data suggests that DA increased the GN BF growth at least in EC and PM but the influence on *Candida* BF is different. The interaction between DA and *Candida* spp BF is not evidenced in some CA isolates, even though the highest concentration was used. The BF increased in NAC under influence of DA. The association between stress hormones and urogenital infections are well known. Most of them have been related to the suppressing immune function. It is important to take into consideration the influence of DA on microorganisms BF, mainly under stress condition.

Induction of Th2 Responses to Ingested Antigen Following *Candida albicans* Colonization/Infection of the Gastrointestinal Tract

Author Block:

H. E. Lust, N. R. Falkowski, E. M. Hunter, R. A. McDonald, G. B. Huffnagle; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: The interplay between the microbiome and the gastrointestinal (GI) immune system protects against pathogenic organisms, while concurrently providing an environment tolerant to the indigenous microbiota and dietary antigens. Thus, major alterations in the microbiome ("dysbiosis") have the potential to dysregulate GI mucosal immunity and lead to the development of immune responses to ingested antigens. The goal of this study was to investigate the development of Th2 immunity to oral antigen exposure following broad spectrum antibiotic treatment and subsequent *Candida albicans* colonization.**Methods:** Two groups of C57BL/6 mice were given ovalbumin (OVA) in their drinking water and via oral gavage. One group (OCC) was treated with ceftriaxone in the drinking water and subsequently inoculated orally with *C. albicans* CHN1; the other group (OUU) was untreated. The mice were followed over a 3-week period.**Results:** In the OCC mice, *Candida* was cultured from the stomach, throughout the intestinal tract and in the feces. Histologically, there was *Candida* colonization in the limiting ridge of the stomach with the presence of yeast, hyphae and neutrophils. In contrast, there was no detectable tissue inflammation or fungal invasion of the intestinal tract, suggesting that *Candida* was colonizing the lumenal/mucus layer. Following exposure to OVA, there was a 5 log increase in microaerobic bacteria in the feces of OCC mice. Additionally, there was a 1 log increase in lactic acid bacteria and a 7 log increase in *C.albicans* in the feces. By the end of the three week study, there was a >100 fold increase in serum IgE levels and evidence of T cell activation in the spleens of OCC mice.**Conclusions:** These results indicate that *C.albicans* infection of the stomach mucosa and colonization of the intestinal tract can modulate mucosal immunity to an oral antigen.

A Role of *Candida albicans* Als3 in Gut-Derived Fungal Sepsis

Author Block:

Y. Nanjo, A. Yamamoto, Y. Ishii, K. Tateda; Toho Univ., Tokyo, Japan

Abstract Body:

Background: *Candida albicans* is one of the most common causes of nosocomial bloodstream infections. Especially in cancer patients undergoing immune suppression, translocation of *C. albicans* from gut to bloodstream is reportedly a major cause of fungemia. However, there is limited information available to explain the mechanisms of *C. albicans* entry and virulence factors involved. In the present study, we compared occurrence of *C. albicans* translocation and lethality in several clinical isolates in mice model. The presence and expression of *C. albicans* virulence factors were determined by quantitative RT-PCR (qRT-PCR). **Methods:** A total of 68 clinical isolates of *C. albicans* (Toho University Hospital) and 2 standard strains were used. *C. albicans* was administered via the drinking water (approximately $1.0x10^7$ CFU/mL) to mice for 5 days, and mice were treated with cyclophosphamide to induce translocation through the gut to systemic infection. Total 16 virulence genes in *C. albicans* were examined in clinical isolates by qRT-PCR. An association between virulence gene expression and fungal translocation was analyzed to identify the virulence factor responsible for the fungemia. **Results:** Immne suppression in addition to mucosal damage induced systemic *C. albicans* translocation in the gut in varying degrees of challenged organisms. The number of fungi in the livers undergoing immume suppression and endogenous fungemia was varied in clinical isolates examined. Among 16 virulent genes examined in *C. albicans*, the most striking association was observed in Als-3 (the agglutinin-like sequence-3) between translocation from gut and virulence factors expressed. **Conclusions:** The present data demonstrated that colonization of virulent *C. albicans* may be a prerequisite of endogenous gut-derived *C. albicans* fungemia, although wide range's of mortalitiy differences were observed in strains examined. Among *C. albicans* virulence factors investigated, Als-3 was strongly associated with translocation from gut in mice model of C. *albicans* fungemia. Our data refocused endogenous *C. albicans* translocation in the gut of immunocompromised individuals. Also, Als-3 gene expression was closed up as a responsible virulence factor for gut-derived *C. albicans* sepsis.

Immune Responses in *"Candida"* Vaginitis and Vaccine Development

Author Block:

F. De Bernardis, S. Graziani, S. Norelli; ISTITUTO SUPERIORE DI SANITA', Rome, Italy

Abstract Body:

Vulvovaginal candidiasis affects at least 75% of women. the recurrent forms of the disease (RVVC) has a prevalence of 7-15% and devastates the quality of life, causes high cost of medical visits and large use of drugs with possible subsequent upsurge of drug resistance. The aim of our work was to investigate the host defence mechanisms in vaginal candidiasis and to identify "*Candida"* molecules potentially useful for vaccination or immunotherapy of this disease. **"***Candida"* vaginitis has been reproduced in mice and rats. Animals were injected subcutaneously with of estradiol and were inoculated intravaginally with *C.albicans* strains To characterize the interaction between innate and adaptative immunity, the role of the Toll like receptors (TLRs) and C-type lectin like receptors (CLRs) in vaginal candidiasis was evaluated in mice with different TLR knocked out genes. The results suggest that TLRs and CLRs have a role in protection to "*Candida"* at vaginal level. In particular, TLR4 and Dectin 1 are both required for the induction of acquired protective immunity to the fungus.The evidence of an immune response in the vaginal compartment was very encouraging to identify the proper targets for new strategies for vaccination or immunotherapy of vaginal candidiasis. We were working with a recombinant protein: an aspartyl-proteinase (Sap2) which is an important immunodominant antigens and virulence factors of "*C.albicans"* acting in mucosal infections. The recombinant protein Sap2 was assembled with virosomes and a vaccine PEV7 was obtained. The results evidenced that the vaccine PEV7, intravaginally administered, confers protection against "*C. albicans"* vaginal infection as exemplified by the accelerated clearance of the fungus from the vagina and resolution of the infection at least one week before infection in controls (administration of empty virosomes).The results evidenced the contribution of innate and adaptive immune responses in vaginal candidiasis. The vaccine PEV7 has an encouraging therapeutic potential for the treatment of recurrent vulvovaginal candidiasis. This opens the way to a modality for anti-"*Candida"* protection at mucosal level.

The Entomopathogenic Fungus *Aspergillus sclerotiorum* as a Potential Biocontrol Agent of Western Subterranean Termites (R*eticulitermes hesperus*)

Author Block:

T. S. Laird, S. M. Richart; Azusa Pacific Univ., Azusa, CA

Abstract Body:

Termites have an important ecological role in regards to nutrient cycling and soil quality. However, termites, especially subterranean termites, are pests that cause billions of dollars in structural damage worldwide. Methods of termite control typically involve the use of hazardous pesticides. However, alternative methods exist, including the use of entomopathogenic fungi. Our previous work showed that *Aspergillus sclerotiorum* was pathogenic to western drywood and western subterranean termites. This study establishes that in Petri dish bioassays, spores of *A. sclerotiorum* were able to be transmitted between exposed and unexposed subterranean termites (*Reticulitermes hesperus*) which affected termite survivability. With 50%, 27%, and 10% of termites initially exposed to spores, survivability was reduced by 80%, 71%, and 35% respectively compared to the control. Further experimentation was conducted in conical tubes filled with wet sand, whereby only 10% of termites were exposed to fungal spores. In this model, however, which better mimics the trap and treat field application of fungus, there was only 16% reduction in survivability compared to the control.. This suggests that *A. sclerotiorum* may not be an ideal biocontrol agent for use against western subterranean termites in pest control scenarios, but still has potential as a model for understanding insect host-pathogen interactions.

Fumarate and Nitrate Reduction Regulatory Protein-Dependent Proliferation of *V. vulnificus* in Intestine Is Required for Effective Dissemination to Further Organs

Author Block:

T. Kado, T. Kashimoto, K. Yamazaki, S. Ueno; Kitasato Univ., Towada, Aomori, Japan

Abstract Body:

Vibrio vulnificus (*V. vulnificus*) causes a severe sepsis for human after ingestion of sea foods or direct exposure of a wound to seawater. Fatal cases in *V. vulnificus* infection mostly associate with underlying diseases such as chronic liver diseases, immunological dysfunction, and diabetes. The average of incubation period in primary septicemia is only about 36 h. Besides being a short time incubation period, the mortality rate is quite high (exceed 50%). Such fast growing and disseminating abilities of *V. vulnificus* in vivo are bring into a poor clinical outcome in patients. Therefore, elucidation of the proliferation mechanisms of this organism in vivo may lead to development of an effective therapeutic strategy. In our previous study, the significantly higher numbers of *V. vulnificus* were detected from the intestine in the dead mice than that of the surviving mice after orogastric challenge of *V. vulnificus*, suggesting that proliferation of *V. vulnificus* in intestine is the initial critical event for lethal sepsis in oral infection. In this study, we focused on the low oxygen concentration in intestinal milieu because of a drastic change from that of in the air. FNR has been known as the global transcriptional regulator for adaptation to anaerobic condition in various bacteria. When the *fnr* deletion mutant of *V. vulnificus* (*fnr*::*erm*) was tested in competition assay against its isogenic parent (WT) in vivo, the competitive index of *fnr*::*erm* to WT were 0.378±0.096 (Mean±S.E.M) and 0.243±0.0615 in the intestinal loop and liver respectively. Thus, we found that the FNR-dependent proliferation of *V. vulnificus* in intestine is required for effective dissemination to further organs.

The Effect of Oxygen On Acid Tolerance of Listeria Monocytogenes

Author Block:

H. N. Jenkins, D. McClung, B. Roberts, J. R. Donaldson; Mississippi State Univ., Mississippi State, MS

Abstract Body:

Background: *Listeria monocytogenes* is a gram-positive facultative anaerobe that is responsible for the foodborne illness listeriosis. This bacterium is resistant to the broad pH range and oxygen availability encountered within the gastrointestinal (GI) tract. Several virulence factors are known to facilitate this pathogen's survival in these conditions. Recent evidence has indicated that anaerobic conditions can influence the expression of virulence genes, suggesting that oxygen availability impacts virulence potential. Therefore, the purpose of this study was to determine if anaerobiosis impacted the acid tolerance of *L. monocytogenes* using conditions that mimic those encountered within the GI tract. The hypothesis was that tolerance to acidic pH would be enhanced under anaerobic conditions, particularly in regards to strains isolated from listeriosis cases. **Methods:** In order to test this hypothesis, 20 strains of *L. monocytogenes* representing various serotypes and isolation sources were cultured in tryptic soy broth (TSB) to mid-logarithmic phase in aerobic or anaerobic conditions and then cultured in media at a either a pH of 7 or 3 for 2 hours in the same aerobic or anaerobic conditions. Viable plate counts were determined. Fold changes in the expression of putative oxygen sensors were determined by RT-qPCR.**Results:** The results showed an increase in viability at a pH of 3 when strains were cultured under anaerobic conditions in comparison to aerobic conditions. Several virulent strains showed remarkable increases in survival (<1% aerobically to >30% anaerobically). The expression of *resD* was also found to increase anaerobically among these strains.**Conclusions:** These data suggest that oxygen availability influences acid tolerance, but the impact varies among strains of *L. monocytogenes.* Further research is needed to determine the mechanism by which anaerobiosis impacts the stress response of *L. monocytogenes.*

Defining the Genetic Basis of Growth Promotion of *Staphylococcus lugdunensis* by Hemoglobin, Stress Hormones, and Siderophores

Author Block:

J. R. Brozyna, D. E. Heinrichs; Univ. of Western Ontario, London, ON, Canada

Abstract Body:

Staphylococcus lugdunensis is capable of causing an array of serious infections reminiscent of the highly virulent *S. aureus*. Iron is an essential nutrient and the host restricts its access as a form of nutritional immunity. Success of *S. lugdunensis* as a pathogen must be, in part, attributable to its success at stealing iron from the host. Uniquely for staphylococci, *S. lugdunensis* does not produce siderophores - small iron-chelating molecules that strip iron from host glycoproteins, including the major iron source in serum (transferrin). Rather, *S. lugdunensis* can pirate siderophores from other bacterial species and can use heme/human hemoglobin (Hb) as an iron source. It may be metabolically favourable to simply use exogenous siderophores or obtain heme-iron to support *S. lugdunensis* growth in the host. We have demonstrated that serum is growth inhibitory to *S. lugdunensis*, unless it is supplemented with heme, Hb, siderophores or catecholamine stress hormones (e.g. epinephrine, dopamine). We have identified the genetic basis of these transport processes through construction and characterization of genetic deletion mutants, which are impaired for growth with the various metabolites. These mutants allow us to assess whether *S. lugdunensis* preferentially steals iron from transferrin via exogenous siderophores and circulating catecholamines, or whether it prefers to scavenge heme-iron in various host niches. We have coupled mutations into a single strain that is incapable of using heme, hemoglobin, siderophores and stress hormones as sources of iron. This mutant is impaired in its ability to cause subcutaneous lesions, and significantly impaired for its ability to colonize the kidneys of mice. This research provides insight into the utility of various iron acquisition strategies employed by *S. lugdunensis*, and ongoing work will elucidate the role of the various mechanisms in organ-specific infection niches.

Between-Patient Evolution of Sepsis *Escherichia coli*

Author Block:

D. Kisiela[1], S. Paul[1], M. Aziz[2], S. Shevchenko[1], K. Polukhina[1], T. Johnson[3], J. R. Johnson[4], L. B. Price[2], E. Sokurenko[1]; [1]Univ. of Washington, Seattle, WA, [2]George Washington Univ., Washington, DC, [3]Univ. of Minnesota, Saint Paul, MN, [4]Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Escherichia coli is one of the major causes of bloodstream infections and death due to sepsis. However, the virulence traits promoting systemic dissemination of *E. coli* are not known. To investigate the evolution of virulence of sepsis strains we performed whole-genome/transcriptome comparative analysis of two within-household transmitted isolates of *E. coli* associated with vividly different clinical illnesses, i.e. fatal sepsis and chronic UTI. We showed that genomes of these two isolates differed only by 8 SNPs, of which three occurred in the cystitis strain and five occurred in the blood strain, with the latter additionally having duplicated 47-kbp region comprising the fec operon. Interestingly, the majority of detected SNPs targeted transcriptional regulators involved in control of stress responses and virulence loci, which resulted in abrogation of the transcriptional regulation. While the cystitis isolate acquired a mutation in cold shock protein CspE, the blood isolate carried mutations in RpoS, LacI, DeoR-family type regulators and LrhA. LrhA is known to be a major repressor of type 1 fimbriae and flagella, with the latter being critical for invasion of renal ducts leading to bacterial systemic dissemination. Interestingly, the RNAseq studies revealed that inactivation of LrhA was not only associated with increased transcription of flagellar genes in urine but also the activation of the temperate phage integrated in the bacterial genome. Thus, LrhA inactivation might be associated with increased lysis of bacterial cells during infection and higher likelihood of sepsis. Indeed, as detected for other *E. coli* strains, the inactivation of LrhA appeared to be a frequent signature of blood isolates. Taken together, the results indicate that *E. coli* undergoes evolutionary changes in the host that might be niche-specific and the inactivation of transcriptional regulator, LrhA, might be of an adaptive nature for blood isolates.

The Adaptation of *Pseudomonas aeruginosa* in Non-Cystic Fibrosis Bronchiectasis (Ncfb) Patients

Author Block:

T. Woo, J. Duong, H. R. Rabin, M. D. Parkins, D. G. Storey; Univ. of Calgary, Calgary, AB, Canada

Abstract Body:

Background: *Pseudomonas aeruginosa* is a major pathogen in suppurative lung diseases like cystic fibrosis (CF) and non-cystic fibrosis bronchiectasis (nCFB) patients. Colonization of these individuals with *P. aeruginosa* is linked with a decline in respiratory function and an increased risk in morbidity and mortality. While the natural history of *P. aeruginosa* in CF has been well studied, much less research has been done on *P. aeruginosa* from nCFB. As such, we set out to directly investigate the adaptation of *P. aeruginosa* in nCFB. **Methods:** We characterized 84 nCFB and 83 CF isolates for virulence potential which included protease, lipase, and elastase production, 'mucoidy', swarm and swim motility, biofilm production, and for the presence of *lasR* mutants. Of the 84 nCFB isolates we then examined 40 early (defined as the earliest isolate in the biobank) isolates to 41 late (defined as the latest available isolate in the biobank) isolates to observe the natural history of adaptation in nCFB patients.**Results:** Interestingly, we found that the natural history of *P. aeruginosa* remained similar in both chronic lung diseases, with a decline in virulence factor production between early and late time points. Within our cohort, we observed heterogeneity in production of virulence factors both within and between isolates from each disease. We also observed similar average virulence factor production with the exception of lipase and elastase expression, which were significantly lower in *P. aeruginosa* found in nCFB patients relative to CF patients.**Conclusion:** Overall, our data suggests that *P. aeruginosa* adapts similarly to the nCFB lung environment as that in CF with a few notable exceptions. In particular, *P. aeruginosa* from nCFB patients seems to down regulate elastase and lipase production more than that in CF patients. Differential expression of these enzymes may allude to the unique selective pressures within the lung environment of each disease.

***Pseudomonas aeruginosa* Co-Regulates a Bifunctional, Bactericidal Chitinase/Lysozyme with Virulence Factors**

Author Block:

J. Flynn[1], K. Kelly[2], R. Hunter[2]; [1]Univ. of Minnesota, Saint Paul, MN, [2]Univ. of Minnesota, Minneapolis, MN

Abstract Body:

The opportunistic pathogen *Pseudomonas aeruginosa* is a causative agent of wound and chronic airway infections. Within these environments, *P. aeruginosa* secretes a number of proteins that have been implicated in their pathogenicity. For example, ChiC, an endochitinase, has been shown to be expressed and secreted during exposure to mucus from cystic fibrosis patients. However, the specific role(s) that a chitinase may play in lung disease is unclear given the lack of chitin in the airways. In this study, we sought to determine the means by which *chiC* expression is regulated and characterize its activity in an effort to determine its role in infection. Using a transposon mutagenesis screen, we found a number of genetic determinants, including the master virulence regulator, MvfR, to be responsible for the regulation of *chiC* expression. Additionally, with enzymatic techniques we confirmed the endochitinase activity of ChiC and found it that it also has lysozyme activity against *Micrococcus lysodeikticus*. Based on these results, we hypothesized these activities were consistent with the bactericidal activity of other 'virulence factors' (*i.e.* pyocyanin, cyanide, proteases) expressed by *P. aeruginosa*. This hypothesis was supported by the ability of purified ChiC to inhibit a number of other bacteria found within the lower airways during chronic CF lung infections. The work presented here suggests the reason for the existence of ChiC in the 'virulence' repertoire of *P. aeruginosa* is to prevent competition for resources in the lower airway environment.

Potential Diversity of Pneumococcal Capsule Based on O-Acetyltransferase Functionality

Author Block:

B. L. Spencer, K. A. Geno, J. S. Saad, M. H. Nahm; Univ. of Alabama-Birmingham, Birmingham, AL

Abstract Body:

Background: Since anti-capsular antibodies confer serotype-specific protection against *Streptococcus pneumoniae* (pneumococcus), understanding capsular diversity is important for anticipating emerging serotypes following vaccine implementation. One mechanism of capsular diversity is O-acetylation, which alters epitopes and may allow evasion of vaccine-elicited antibodies. Serotype 33A has two O-acetyltransferase genes: *wciG* and *wcjE*. A serotype 33A variant, 33F, is *wcjE*-deficient and occurs naturally, but no *wciG*-deficient variants have been reported. Serotype 33F will be included in the next pneumococcal conjugate vaccine, and we hypothesize that vaccine pressure will select for *wciG*-deficient 33F variants in nature. **Methods:** We created three 33A variants by inactivating *wciG* (serotype 33X), *wcjE* (serotype 33F), or both *wciG* and *wcjE* (serotype 33Y) in the serotype 33A strain TIGR33A. Sequencing confirmed O-acetyltransferase gene inactivation. Bacterial cells were stained with serological reagents and analyzed by flow cytometry. Purified capsules were studied with ^{1}H-NMR.**Results:** All variants have serologically-distinct capsules based on rabbit antisera and Hyp33FG1 (monoclonal antibody) binding. ^{1}H-NMR confirmed that TIGR33A capsule has one WciG- and two WcjE-mediated O-acetyl additions (2.14 ppm and 2.10, 2.18 ppm, respectively) and that TIGR33AΔ*wcjE* (functionally 33F) capsule lacks both WcjE-mediated O-acetyl additions. Finally, ^{1}H-NMR showed that TIGR33AΔ*wciG* lacks WciG-mediated O-acetylation (2.14 ppm).**Conclusions:** We conclude that TIGR33AΔ*wciG* and TIGR33AΔ*wciG*Δ*wcjE* express novel serotypes (termed 33X and 33Y, respectively) which can be distinguished by our in-house monoclonal antibody Hyp33FG1. These serotypes are not differentiated by currently used serotyping techniques like Quellung or PCR, and therefore may be present, but undetected in nature. This study describes a possible mechanism of capsular diversity via O-acetylation and highlights the importance of sensitive serological tools in uncovering novel variants.

Strain (serotype)	**O-acetyltransferase genes**	**fs33b**	**fs20b**	**Hyp33FG1**

Ftsh Function Is Essential to Survival of the Lyme Disease Spirochete B*orrelia burgdorferi* *In Vivo* and *In Vitro*

Author Block:

P. E. STEWART, C. Chu, A. Bestor, B. Hansen, P. Rosa; ROCKY MOUNTAIN LABORATORIES, NIAID, NIH, HAMILTON, MT

Abstract Body:

In many bacteria, the protease FtsH and its modulators, HflK and HflC, form a complex that contributes to membrane quality control and regulation of the cellular response to environmental stress. All three proteins have chromosomally-encoded homologs in *Borrelia burgdorferi*, the Lyme disease spirochete. An obligate pathogen, *B. burgdorferi* depends on crucial membrane functions to infect and persist in both the mammalian host and the *Ixodes* tick. Using an inducible promoter system to control expression, we demonstrate that FtsH is essential for *B. burgdorferi* survival in vitro and in vivo. Depletion of FtsH protein in vitro resulted in arrested cell growth and morphological defects. Overexpression of FtsH did not have detectable adverse effects on spirochete growth in vitro, suggesting that FtsH does not proteolytically overwhelm its substrates. In vivo infection studies demonstrated that FtsH was also required for survival of the spirochete in both the mammalian host and the tick vector. Surprisingly, analysis of the *B. burgdorferi* HflK/C double-mutant in vitro did not identify any defect in morphology, growth rate or growth under stress conditions. The phenotype of the HflK/C double mutant in vivo, including the ability to complete the mouse-tick infectious cycle and ID_{50}, were indistinguishable from wild type. These results demonstrate that FtsH provides an essential function for *B. burgdorferi* survival both in vitro and in vivo, but that the modulators HflK and HflC do not detectably affect FtsH function.

Characterization of Bile Induced Membrane Damage in Listeria Monocytogenes

Author Block:

O. Paul[1], D. Clark[2], A. Thopmson[1], J. Wilson[1], J. R. Donaldson[1]; [1]Mississippi State Univ., Mississippi State, MS, [2]Tougaloo Coll., Tougaloo, MS

Abstract Body:

Background: *Listeria monocytogenes* is a Gram positive, facultative intracellular organism responsible for the foodborne disease listeriosis. *Listeria monocytogenes* must survive a variety of stressors encountered within the gastrointestinal (GI) tract, including variations in pH, oxygen availability, and bile. Though it is known that bile induces oxidative damage under aerobic conditions, it is not known whether this differs under anaerobic conditions. **Methods:** Previous studies from our laboratory indicated extensive membrane damage occurs in the presence of bile salts and that the damage is significantly different under anaerobic conditions. To characterize these differences, membrane induced damage was analyzed by transmission electron microscopy (TEM) and fatty acid analysis in strains representing three different serovars of *L. monocytogenes*: F2365, 10403S, and HCC23.**Results:** TEM observations indicated that the size of all strains under both aerobic and anaerobic conditions decreased following bile exposure. However, no differences in cell envelope width were observed with HCC23 under aerobic or anaerobic conditions; 10403S increased under both conditions and F2365 width increased only under anaerobic conditions. Analysis of fatty acid profiles indicated that saturated fatty acids palmitic acid and stearic acid, as well as the unsaturated fatty acids linoleic acid and oleic acids, increased under aerobic and anaerobic culture conditions following bile exposure. Pre-treatment of strains to a commercial lipid mixture containing palmitic acid, oleic acid, stearic acid, and linoleic acid increased the survival of HCC23 and 10403S to bile, but not F2365 under aerobic conditions. Interestingly, an impact on survival was not observed under anaerobic conditions.**Conclusions:** These data suggest that incorporation of exogenous lipids induces alterations to the cell membrane and may improve bile survival under aerobic conditions in a strain dependent manner. Additional research is needed to determine the mechanism by which *L. monocytogenes* is resistant to bile induced membrane damage under anaerobic conditions.

***Vibrio cholerae* toxr Increases Cyclic Di-Gmp Levels in Response to Bile**

Author Block:

J. C. Shook[1], B. J. Koestler[2], C. M. Waters[1]; [1]Michigan State Univ., East Lansing, MI, [2]The Univ. of Texas at Austin, Austin, TX

Abstract Body:

Vibrio cholerae, the causative agent for the disease cholera, survives in a wide range of environments from aquatic reservoirs to animal digestive tracts. In order to survive in these different environments, *V. cholerae* responds to various cues to appropriately regulate downstream phenotypes. One mechanism by which *V. cholerae* adapts to an ever-changing environment is through the second messenger signal cyclic dimeric guanosine monophosphate (c-di-GMP). *V. cholerae* has over 60 enzymes that are predicted to synthesize and degrade c-di-GMP; however, the environmental signals controlling the activity of these enzymes are poorly understood. Bile is a major component of the human intestinal tract encountered by *V. cholerae* during infection. We recently showed that bile increases c-di-GMP levels and promotes biofilm formation. This is partially due to the repression of the HD-GYP VC1295, which degrades c-di-GMP, in the presence of synthetic human bile (SHB). Bioinformatic analysis of the VC1295 promoter predicted four putative binding sites for ToxR, the master virulence regulator of *V. cholerae.* We therefore hypothesized that ToxR represses the transcription of VC1295 in the presence of SHB. Deletions from the upstream region of the VC1295 promoter were constructed to define the active promoter. Repression of VC1295 by SHB is abolished in a **Δ***toxR* mutant, while complementation with ToxR restores SHB-mediated repression. Site-directed mutagenesis of the four putative ToxR binding sites allows for the expression of luciferase regardless of the presence of SHB. Our results show that ToxR further enhances *V. cholerae* adaptation to the intestinal environment by modulating the levels of c-di-GMP in response to bile.

Regulation of *Coxiella burnetii* Type IV Secretion by the Pmrab Two-Component System

Author Block:

S. C. O. Reed, C. R. Roy; Yale Sch. of Med., New Haven, CT

Abstract Body:

Coxiella burnetii encode a Type IV secretion system (T4SS) that translocates bacterial effector proteins into the host cell as the phagosome matures into a lysosome-like compartment, remodeling the lysosome to creating a fusogenic, replicative *Coxiella*-containing vacuole. Expression of the T4SS and subsequent intracellular growth requires the PmrAB two-component system. We hypothesized that the PmrB histidine kinase senses and responds to changes in pH and ion concentration in the maturing lysosome. We assayed light production by axenically grown *Coxiella burnetii* Nine Mile Phase II strains expressing bacterial luciferase under the control of PmrAB-dependent (icmW, cig2) and independent (311, TetRA) promoters. PmrAB-dependent promoters were strongly expressed during early exponential phase growth (2-4 d post-inoculation or post-infection of HeLa cells). Surprisingly, there was no relationship between relative PmrAB-dependent promoter activity and changes in pH or composition of axenic growth media, suggesting that the Coxiella PmrB-activating signal is distinct from other iron or pH-responsive bacterial *pmrB* genes. Further screening may reveal the host-derived signal necessary for activation of this critically important regulator of intracellular growth.

Investigation of the High Rates of Extra Pulmonary Tuberculosis in Ethiopia Reveals No Single Driving Factor and Minimal Evidence for Zoonotic Transmission of *Mycobacterium bovis* Infection

Author Block:

G. E. Degu, **G. E. Degu**; St. Paul's Hosp. Millennium Med. Coll., Addis Ababa, Ethiopia

Abstract Body:

Background: Ethiopia has one of the highest burdens of human tuberculosis (TB) in the world, and reports one of the highest incidence rates of extra-pulmonary TB, dominated by cervical TB lymphadenitis (TBLN). Infection with Mycobacterium bovis, usually associated with extrapulmonary disease, has previously been excluded as the main reason for the high rate of extrapulmonary TB in Ethiopia.**Methods:** Here we examined demographic and clinical characteristics of 953 pulmonary and 1198 TBLN patients visiting 11 health facilities in distinct geographic areas of Ethiopia. Clinical characteristics were also correlated with genotypes of the causative agent, Mycobacterium tuberculosis.**Results:** No major patient or bacterial strain factor could be identified as being responsible for the high rate of TBLN, and there was no association with HIV infection. Regular direct contact and sharing a household with live animals and drinking raw milk were more associated with TBLN than with pulmonary TB, although no M. bovis was isolated from patients with TBLN.**Conclusions:** The study suggests a complex role for multiple interacting factors in the epidemiology of extrapulmonary TB in Ethiopia, including possible zoonotic transmission of M. tuberculosis and genetic features of the pathogen and/or the host population.

Genomic Effects of Host-Specific Specialization in *Mycobacterium shottsii*

Author Block:

J. H. Doss[1], A. Biswas[1], R. Karls[2], F. Quinn[2], M. Ryan[1], D. Ranjan[1], M. Zubair[1], D. T. Gauthier[1]; [1]Old Dominion Univ., Norfolk, VA, [2]The Univ. of Georgia Coll. of Vet. Med., Athens, GA

Abstract Body:

Striped bass (*Morone saxatilis*) is a finfish species of importance to both commercial and recreational fishing on the US east coast. Mycobacterial infections in this species have been observed in striped bass since 1997, and the impacts of mycobacteriosis in this species may result in profound economic and ecological impacts. Two novel mycobacteria, *Mycobacterium shottsii* and *Mycobacterium pseudoshottsii*, have been described in infected striped bass. Whereas most fish-infecting mycobacteria including *M. pseudoshottsii* are environmental residents and facultative pathogens, *Mycobacterium* appears to be specialized to infect only moronids, and may be an obligate pathogen. A comparison of the *M. shottsii* genome to those of its closest relatives (*M. marinum* complex bacteria) has revealed that approximately 500 genes of their common ancestor have deteriorated into pseudogenes, presumably in order to promote this host-specific specialization. Many of these pseudogenes are the result of insertion sequences that have functionally disrupted the genes; these insertion sequences are comprised of eight different varieties, most unique to *M. shottsii*. Other genomic adaptations in *M. shottsii* are similar to those of the human adapted specialists *M. ulcerans* and *M. tuberculosis*, indicating common patterns of vertebrate specialization in this bacterial group.

Identification and Genomic Characterization of a Novel *Pseudomonas* Species (*Pseudomonas galenii* sp. Novus) Associated with Human Lung Disease

Author Block:

B. S. Scales, J. R. Erb-Downward, R. P. Dickson, N. R. Falkowski, J. J. LiPuma, G. B. Huffnagle; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

There are over 52 *Pseudomonas* species that taxonomically group within the *Pseudomonas fluorescens* species-complex. Members of this complex are gram-negative bacteria (gammaproteobacteria) that have the ability to flourish in many environmental niches due their metabolic adaptability. Using culture-independent analysis, our laboratory has identified abundant levels of *P. fluorescens*-related species in lungs of individuals with chronic lung disease. To further investigate the genomic characteristics of *P. fluorescens*-species complex bacteria from clinical samples, we sequenced a collection of *P. fluorescens*-related strains isolated from individuals with chronic lung disease. This included 28 strains that taxonomically grouped within the *P. fluorescens*-species complex by 16S rRNA gene homology and multi-locus sequence analysis with housekeeping genes. Full genome sequencing, assembly and annotation was performed on all 28 strains. Twelve of the 28 strains grouped within previously defined subclades I, II and III of the *P. fluorescens* species- complex. However, the other 16 strains were distinct and clustered on a phylogeneticlly unique branch that lacked any representative genomes (clinical or environmental) in Genbank. The 16 strains also displayed phenotypic differences *in vitro* from the other subclades. Additional comparative genomic analysis found that its members displayed significant reductions in genome size, gene diversity and GC content compared to other *P. fluorescens* strains. Average nucleotide identity (ANI) analysis between the 16 strains and previously sequenced *Pseudomonas* strains revealed that their shared ANI was below the cutoff required to be grouped within any previously defined species. Despite being most phylogenetically similar to members of the *P. fluorescens* species-complex, the 16 unique strains contained all the elements of a Ysc family type III secretion system, most homologous to that found in *P. aeruginosa.* Analysis of the flagellin gene also revealed structural differences that support the concept that the 16 strains represent a distinct species within the *P. fluorescens* species-complex. We have designated these 16 unique strains as the new *Pseudomonas* species- *Pseudomonas galenii* sp. novus.

Profile-Based Comparison of *Salmonella* Genomes Reveals Signatures of Host Adaptation

Author Block:

N. E. Wheeler[1], L. Barquist[2], P. P. Gardner[1]; [1]Univ. of Canterbury, Christchurch, New Zealand, [2]Univ. of Würzberg, Würzberg, Germany

Abstract Body:

Comparative genomics investigations have yielded an abundance of information on the genetic variation between organisms, however understanding the consequences of this variation for protein function has proved challenging. A small non-synonymous change to or a short indel within a coding sequence can have varying effects on protein function, depending on both the nature of the change and the context of the change within the protein. These effects can range from maintaining native protein function to a complete abrogation of function, or even in rare cases altering protein function. The increasing availability of complete genome sequences for collections of closely related bacteria presents an opportunity to study the fine-grain functional evolution of protein sequences in nature. We present a profile HMM-based method for assessing the functional significance of mutations in protein coding sequences. We demonstrate an application of the method to comparative analysis of bacterial genomes to scan for functionally significant genetic variation. As a model system, we have chosen the well-studied species *Salmonella enterica*, of which several lineages are known to have undergone host-restriction events characterized by a narrowing of host tropism with a concurrent accumulation of pseudogenes. We show that our method is able to detect functional degradation of genes associated with host-adapation that are not detected by conventional pseudogene analysis, and suggest that this approach offers a sensitive measure of the loss-of-function mutations that may occur as a result of adaptation to a new niche.

Measuring Differential Growth Rates of Uropathogenic *Escherichia coli* Strains *In Vitro* and During Experimental Murine Urinary Tract Infection

Author Block:

S. N. Smith, C. Armbruster, A. Springman, S. Himpsl, H. L. T. Mobley; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Uropathogenic *Esherichia coli* (UPEC), the causative agent of most uncomplicated urinary tract infections (UTIs), is a member of a subset of bacteria broadly known as *extraintestinal pathogenic E. coli* (EXPEC). EXPEC infections include urinary tract infections, meningitis, sepsis, pneumonia and surgical site infections. The versatility of EXPEC isolates may be due, in part, to differences in their ability to grow and survive in different host environments. While measurement of growth *in vitro* has been routinely determined for as long as scientists have studied bacteria, the growth rate of bacteria during experimental infections has only been cursorily examined. In this study, we used a previously constructed marker plasmid (pGTR902) (a gift of Paul Gulig) that replicates only in the presence of arabinose, to investigate growth rates of various EXPEC isolates *in vitro* and in a murine model of ascending urinary tract infectionUTI. The average copy number of pGTR902 was determined to be ~26 by differential plating to verify segregation of the plasmid under non-permissive (arabinose-negative) conditions. Female mice were transurethrally inoculated at a dose of 10^8 CFU/ mouse and sacrificed after 48 hours to compare infecting doses (ID_{50}) between EXPEC isolates. Subsequent infection studies were conducted to compute doubling time of each isolate by determining the proportion of bacteria that maintained the marker plasmid over time. Our data indicate that UPEC isolates, such as CFT073, have much higher colonization levels and faster growth rates during experimental UTI than asymptomatic bacteriuria (ABU) and commensal isolates, indicating that UPEC strains have an enhanced ability to colonize and grow at a faster rate within this particular host niche. Closer examination of the dynamics of growth and colonization rates between EXPEC strains will give us deeper insight into the differences of these closely-related strains and their abilities to cause infection.

Transposon Insertion Sequencing to Identify *Proteus mirabilis* Fitness Factors for Murine Catheter-Associated Urinary Tract Infection

Author Block:

V. S. DeOrnellas, C. E. Armbruster, S. N. Smith, H. L. T. Mobley; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

The most common healthcare-associated infections are urinary tract infections (UTI), ~80% of which are associated with indwelling catheters. Long term catheter use inevitably results in bacteriuria, which can lead to the development of fever, cystitis, pyelonephritis, bacteremia. Historically, *Proteus mirabilis* commonly causes catheter-associated UTI (CAUTI), present in up to 44% of cases. During CAUTI, bacteria colonize the bladder to cause infection of the lower urinary tract, but may ascend to the kidney causing infection of the upper urinary tract. The ability to cause infection in two different environments likely requires expression of organ-specific fitness factors. Identification of the full complement of *P. mirabilis* virulence and fitness factors is required to elucidate novel therapeutic targets for treatment of CAUTI. The classical virulence factors of *P. mirabilis* include fimbrial adhesins, flagellar-mediated motility, hemolysin and urease. Previously a library of 2,088 signature-tagged mutants was used to identify additional fitness factors during non-catheterized infection, including genes for nutrient and iron acquisition. These findings are not likely to represent a comprehensive list of fitness factors since ~34,000 mutants are required for full genome coverage, and it does not account for potential differences in infection with an indwelling catheter. In this study, we utilized transposon directed insertion site sequencing (TnSeq), which makes use of a modified mariner transposon, to generate a saturating transposon mutant library and capture flanking chromosomal DNA for identification. A random library of 50,000 transposon mutants was generated and validated. CBA/J mice were infected by transurethral inoculation through an indwelling catheter with pools of 10,000 transposon mutants at $1x10^5$ CFU/mouse, resulting in a median bacterial burden of $2.7x10^7$ CFU/g tissue in the bladder and $9.3x10^5$ CFU/g tissue in the kidneys at 4 d.p.i. Application of next-generation sequencing of mutants harvested from bladders and kidneys after CAUTI infection allowed determination of the relative abundance of individual mutants. The subpopulation of mutants underrepresented in each site following infection represent genes required to colonize bladder and kidneys of catheterized mice.

Ethanolamine Utilization Genes are Novel Virulence Determinants of Uropathogenic *E. coli* During Human Urinary Tract Infection

Author Block:

A. Sintsova[1], S. Subashchandrabose[2], S. Smith[1], H. Mobley[1]; [1]Univ. of Michigan, Ann Arbor, MI, [2]Wake Forest Univ., Winston-Salem, NC

Abstract Body:

Uropathogenic *Escherichia coli* (UPEC) is the major causative agent of uncomplicated urinary tract infections (UTIs). The high incidence of UTIs makes them a global heath concern that is further exacerbated by the rise of antibiotic-resistant strains. Accordingly, identification of novel virulence factors and research aimed at understanding UPEC pathogenesis is of the utmost importance in our drive to discover new therapeutic strategies. To this end, we recently compared the gene transcription profiles of UPEC isolated directly from UTI patients to those of the same strains cultured in sterile urine, and identified genes specifically up-regulated during human UTI. Intriguingly, this led to identification ethanolamine utilization (*eut*) genes as important host-specific virulence factors. Using a well-established mouse model of UTI, we show that a UPEC construct in which *eut* genes were deleted has a severe defect in bladder colonization, and is outcompeted by wild type UPEC strain 20-fold in the murine model of ascending UTI. Ethanolamine utilization has been linked to the pathogenesis of a number of bacterial species, including *Salmonella typhimurium* and *Listeria monocytogenes*. In these bacteria, all *eut* genes are up-regulated during intestinal infections, and various *eut* mutants have attenuated virulence *in vivo*, however, the exact role of *eut* operon in facilitating colonization remains enigmatic. While in some instances ethanolamine seems to serve as a useful source of nutrition for *E. coli*, our preliminary data show no growth defect in a *eut* mutant strain cultured under conditions that mimic the *in vivo* environment. This suggests that the ethanolamine utilization pathway might function to impede proper functioning of the innate immune response and help UPEC evade detection and clearance.

A. J. McCarthy[1], R. A. Stabler[2], B. W. Wren[2], P. W. Taylor[1]; [1]Univ. Coll. London, London, United Kingdom, [2]London Sch. of Hygiene & Tropical Med., London, United Kingdom

Abstract Body:

Background: *Escherichia coli* K1 is a major causative agent of neonatal bacterial meningitis and associated sepsis. The genes important for initial colonisation of the gastrointestinal tract, entry and survival in the blood and invasion are poorly understood. **Objective:** to construct an *E. coli* K1 A192PP-*Tn5* mutant library for high-throughput screening, to identify genes essential for growth in nutrient broth, for gastrointestinal (GI) colonization in the neonatal rat and for survival in serum using transposon insertion site sequencing. **Methods:** A library of >280,000 unique mutants was constructed using the EZ-Tn5 transpome kit. Transposon insertion sites were sequenced using the Illumina MiSeq platform, and bioinformatics analyses used to assess the distribution of mutants across the genome. Single gene mutants were created using lamda-red recombineering, and their fitness was assessed using *in vitro* and/or *in vivo* rat models of colinsation/infection. **Results:** Analysis identified 370 genes in *E. coli* K1 A192PP essential for growth *in vitro*; 113 of these genes were not considered essential for the growth of *E. coli* K12. A library of 50,000 distinct mutants was also screened for genes that decreased the capacity of *E. coli* A192PP to colonize the GI tract of neonatal rats and to survive in human serum. A short-list of >200 genes was identified as important for colonisation and serum survival. A subset of newly identified genes was selected for further characterisation and deletion mutants were constructed in A192PP. Each mutant was tested *in vitro* and/or *in vivo* to confirm their attenuated phenotypes. **Conclusions:** We have developed and validated a large robust *E. coli* K1-A192PP Tn*5* library for the study of physiology and pathogenesis of this neonatal pathogen. Our data has revealed genes not previously considered essential for *in vitro* growth and identified genes important for colonization and serum survival. Further characterisation of the genes will improve understanding of physiology and pathogenesis, and may aid the identification of novel targets for therapeutic intervention.

Demonstration of the Effect of pH on Competition within a Vaginal Co-culture

Author Block:

D. W. Koenig[1], P. Anunson[1], R. Bartell[1], L. Peed[2], J. Li[2], R. Vongsa[1]; [1]Kimberly Clark Corp., Neenah, WI, [2]Kimberly Clark Corp., Roswell, GA

Abstract Body:

Background: Human microbiome research has revealed that interspecies interactions play an important role in influencing host health. We have developed a simplified *in vitro* co-culture model to assess the ecological impact of growth factors on the key members of the vaginal microbiome. Vaginal microflora of healthy women are dominated by *Lactobacillus* spp. Changes in the vaginal environment will reduce the dominance of *Lactobacillus* to favor harmful bacteria. The aim of this study was to use a vaginal co-culture model to demonstrate pH regulation of bacterial growth. **Methods:** Cultures of two bacteria, *Lactobacillus crispatus* ATCC 33820 and *Escherichia coli* ATCC 10798 were grown in batch bio-reactors to evaluate the change in cell yields as a function of medium type and pH. Growth was recorded by plate count and OD 800nm. The pH was controlled for multiple pH sets between 4.5 and 6.0. Finally, two lactobacilli media were used, LAPT-G (yeast extract, peptone, tryptone, and Tween without glucose) which enhances *E. coli* growth and LAPT-G plus sucrose which enhances *Lactobacilli* growth. **Results:** In LAPT-G single and co-cultures, *E. coli* did not grow when held at pH 4.5, and both *E. coli* and *L. crispatu*s grew when pH was held at 6.0. The pH of unregulated co-cultures grown in LAPT-G did not lower with growth, staying at 6.5. In unregulated pH LAPT-G single cultures, L. *crispatus* dropped the pH from 6.6 to 5.6, while the pH remained at 6.4 with *E. coli*. In LAPT-G plus sucrose single and co-culture, both organisms grew when the pH was held at 6.0. *E. coli* did not grow when pH was held at 4.5 in either single or co-culture and did not grow when pH was unregulated in co-culture with a starting pH of 6.4. *L. crispatus* grew slowly at pH 4.5 and required 50 hrs to reach max cell yield in co-culture. In unregulated pH single cultures of LAPT-G plus sucrose, *L. crispatus* dropped the pH from 6.7 to 4.2 and remained at 6.4 for *E. coli*. **Conclusions:** The binary system described here confirms the reported *in vivo* observations of the effect of pH on vaginal community structure. pH drives the selective growth of *L. crispatus* over *E. coli* in a co-culture system. Use of this model will allow for the pre-clinical assessment of prebiotics and other biologicals that have the potential to alter the vaginal consortium.

Plant Cell Wall Xyloglucans are Utilized by Human Gut Colonizing Bifidobacteria as a Sole Carbon Source

Author Block:

E. Özcan, D. A. Sela; Univ. of Massachusetts, Amherst, MA

Abstract Body:

Human-associated bifidobacteria are beneficial members of gut microbial community and capable of using dietary and host-derived glycans (e.g. milk oligosaccharides and mucins) that are impervious to host digestion. The genomes of *Bifidobacterium infantis* and *Bifidobacterium longum* encode an array of glycosyl hydrolases and oligosaccharide transporters to utilize dietary oligosaccharides that are encountered in their respective ecological niches. These phylogenetically near-neighbors use divergent mechanisms to utilize oligosaccharides, while both secrete acetate and lactate as end-products of fermentative metabolism. In this study, we tested the hypothesis that *B. longum* and *B. infantis* utilize plant-derived xyloglucans extracted from the cranberry cell wall using the characteristic phosphoketolase pathway common to the genus *Bifidobacterium*. Accordingly, we observed strain-level phenotypic variation with respect to growth phenotype while utilizing xyloglucans as a sole carbon source. Interestingly, bifidobacterial strains subsisting on xyloglucans varied in the theoretical yield of 3:2 acetate to lactate sectered in contrast to glucose catabolism. Xyloglucan utilization results in carbon shunted towards 1C metabolism as higher concentrations of formate is secreted at the expense of lactate. In order to determine if overlapping mechanisms are deployed to capture xyloglucans, we characterized the expression of several target genes previously implicated in oligosaccharide transport. Previous comparative genomics and functional experiments have indicated that *B. longum* has likely adapted to utilize plant-derived products. However, our results indicate that *B. infantis* strains that are typically associated with infants are highly competent for plant xyloglucan metabolism.

Interactions between Two Human Gut Symbionts in Coculture

Author Block:

M. Smith, N. Buan; Univ. of Nebraska Lincoln, Lincoln, NE

Abstract Body:

The human gut is home to 10^{14} microorganisms. They digest polysaccharides we are unable to and exist symbiotically with our cells. Though not an abundant phyla, methane producing archaea are ubiquitous in the human gut. One species, *Methanobrevibacter smithii*, can be detected in 95.7% of individuals. The *M. smithii* genome encodes adhesion like proteins predicted to bind to chondroitin sulfate (CS), a component of the luminal intestinal extracellular matrix. Because CS is not a known carbon source for methanogens, I hypothesize that *M. smithii* uses the proteins in order to co-localize with fermenting bacteria such as *Bacteroides thetaiotaomicron*. *B. theta* has been demonstrated to use CS as a sole carbon and energy source, and is also known to associate with gut epithelia. To test my hypothesis, I developed a coculture of *B. theta* and *M. smithii*.In the syntrophic coculture, the end products excreted by *B. theta* (H_2, CO_2, acetate, and formate), are carbon and energy sources for *M. smithii*. This benefits *B. theta* by removing waste, allowing cells to continue to proliferate. Samples of the coculture at stationary phase were observed using an EVOS confocal microscope. Large aggregates of *M. smithii* and *B. theta* cells could be seen. Whole granules appeared to have coenzyme F_{420} fluorescence diffusing from *M. smithii* cells. Putative F_{420} dehydrogenase genes were found in *B. theta* suggesting a possibility of how the two organisms coordinate their metabolisms.To determine if *M. smithii* binds CS directly, or uses the adhesion like proteins to bind dietary polysaccharides or to other microbial cells, a carbohydrate binding assay was developed using *B. theta*. Carbo-bind plates were coated with glucose or CS. Stationary-phase *B. theta* cells were added and binding was measured using a Coommassie stain on bound protein. When grown on glucose, *B. theta* cells have decreased binding from 57% on a glucose coated plate to 19% on a CS coated plate ($p<0.01$). However, CS grown cells experienced no change in binding (18.5% to 16.3%, $p=0.2$). The assay will be used to measure carbohydrate and *B. theta* binding by *M. smithii*. Should *M. smithii* and/or *B. theta* influence polysaccharide binding of each other, it would support my hypothesis that *M. smithii* attaches itself to polysaccharides to co-localize with *B. theta*, and the idea that *M. smithii* actively seeks syntrophic partners for growth.

Horizontal Gene Transfer of Accelerated Protein Evolution in the Human Gut Microbiome

Author Block:

Y. Wang[1], K. Sasaninia[1], X. Yu[2], B. Paul[3], C. Wei[2], S. Mazmanian[4], J. F. Miller[1]; [1]Univ. of California-Los Angeles, Los Angeles, CA, [2]Shanghai Jiaotong Univ., Shanghai, China, [3]Univ. of California-Santa Barbara, Santa Barbara, CA, [4]California Inst. of Technology, Pasadena, CA

Abstract Body:

The human gastrointestinal (GI) tract houses approximately 10^{14} microbes of more than 1500 species, and represents one of the most diverse and complex microbial ecosystems in the biosphere. The mechanisms by which these microbes interact, exchange genetic information, and evolve new traits remain largely unknown. Diversity-generating retroelements (DGRs) are a novel family of genetic elements that diversify protein-encoding genes and accelerate protein evolution. Bioinformatic analysis discovered numerous DGRs in the human gut microbiome, including within the genome of *Bacteroides fragilis* 638R. In this study, we have characterized the functionality and dissemination of a model retroelement *B. fragilis* 638R DGR, which encodes a diversified target protein, BdtA, with a lipoprotein signal sequence. Proteinase K sensitivity and immunostaining studies showed that BdtA is localized in the outer leaflet of the outer membrane and surface-exposed, supporting the hypothesis that *B. fragilis* has exploited DGRs to generate new ligand-binding specificities. Further examination of the 638R DGR locus and flanking regions suggested that it is carried on an integrative and conjugative element (ICE) subject to tight and complex regulation. *In vitro*, upon induction by BdiA (BF638R_2082), an AraC-like transcriptional regulator, the DGR-containing ICE was readily excised as detected by PCR assays. During colonization of gnotobiotic mice, ICE excision was also detectable in 638R cells even in the absence of BdiA. During *in vitro* mating, the ICE was horizontally transferred to *B. fragilis* 638R or *B. thetaiotaomicron* VPI5482 at a frequency of 10^{-6} to 10^{-7}, and next-generation sequencing (NGS) successfully detected DGR activity in 638R cells grown *in vitro* or during colonization of the mouse GI tract. Colon tissue-associated 638R cells demonstrated the highest DGR activity, followed by mucus-associated cells. Thus far, we have elucidated a molecular mechanism underlying the wide distribution of DGR-mediated protein evolution cassettes, which has the potential to increase bacterial fitness within the dynamic environment of the host gut.

A Reduced Response to Bacterial Muramyl Dipeptide: Comparison of Nod2 Mutations Associated with Crohn's Disease and Blau Syndrome

Author Block:

E. R. Stiles, R. Ewer, C. P. Bocian, L. Nguyen, **A. M. Domina**; Husson Univ. Sch. of Pharmacy, Bangor, ME

Abstract Body:

NOD2 is a human pattern recognition receptor for muramyl dipeptide (MDP), a component of the bacterial peptidoglycan layer of Gram positive and Gram negative bacteria. MDP binding to NOD2 results in the activation of several intracellular signaling pathways, including the NF-κB and MAP kinase pathways. Some mutations in the NOD2 gene predispose individuals to Crohn's Disease, while other NOD2 mutations cause Blau Syndrome, which is associated with childhood onset of granulomatous dermatitis, arthritis, and uveitis. It has been proposed that the Crohn's-associated mutations result in decreased NOD2 activation, perhaps due to its instability, while the Blau-associated mutations result in constitutive NOD2 activation; however, some studies have called into question the clinical relevance of constitutive NOD2 activation in Blau syndrome. Therefore, the goal of this work is to compare the effects of Crohn's- versus Blau-associated NOD2 mutations on its activation. To achieve this goal, Crohn's-associated NOD2 mutations (R702W, G908R), Blau-associated mutations (R334W, E600A, T605N, T605P), and appropriate controls were constructed and transfected into HEK-Blue cells, which are HEK 293 cells containing a gene for secreted embryonic alkaline phosphatase (SEAP) under the control of multiple NF-κB binding sites and AP-1 sites. Transfected cells were treated with or without MDP, followed by quantification of SEAP activity, which is reflective of NOD2 activation. The results indicated that all Blau-associated and Crohn's-associated NOD2 mutations exhibited a reduced ability to respond to MDP compared to wild type NOD2. These results indicate that Crohn's- and Blau-associated NOD2 mutations induce a common cellular effect in that they have a reduced ability to respond to MDP. Future work will explore the possibility that the Blau-associated mutations result in an activation-induced NOD2 inactivation.

Enteroviruses in the Pancreas of Live Adult Patients Newly Diagnosed with Type 1 Diabetes - The DiViD Study

Author Block:

A. Q. Toniolo[1], A. P. Genoni[1], D. Campani[2], S. Sansonno[1], L. H. Krogvold[3], K. Dahl-Jorgensen[4]; [1]Univ. of Insubria, Varese, Italy, [2]Univ. of Pisa, Pisa, Italy, [3]Oslo Univ. Hosp., Oslo, Norway, [4]Univ. of Oslo, Oslo, Norway

Abstract Body:

Background: The DiViD study aims at assessing whether viral agents are present in the pancreas at the onset of type 1 diabetes (T1D). Pancreas samples of 6 DiViD cases and 11 nondiabetic controls were analyzed for 20 groups of viruses, including enteroviruses (EVs). **Methods:** Detection methods combining cell culture and gene amplification were used. Frozen pancreas was obtained from 6 adult T1D cases (University of Oslo, Norway) and 11 cases of pancreatic carcinoma without diabetes (University of Pisa, Italy). Tissue homogenates were produced in DMEM supplemented with antimicrobials. Cell lines (AV3, RD, HEp-2, LLC-MK2) were exposed to pancreas homogenates. DNA and RNA were extracted from cell cultures. DNA viruses (6 herpesviruses, parvovirus B19, HBV) and RNA viruses (HCV, GBV-C, rubella, influenza A/B, parainfluenza 1-4, RSV, astrovirus, norovirus, rotavirus, HAV, EVs, poliovirus) were searched for by real time PCR. End-point EV PCR was performed with four primer pairs targeting the 5'UTR region of the A, B, C, D species. Amplicons were directly sequenced. Expression of EV VP1 capsid protein was evaluated by immunofluorescence (mAbs 5D-8.1 and 9D5) in cultured cells exposed to pancreas homogenates. **Results:** EV genomes were detected in the pancreas of 6/6 T1D cases vs. 2/11 control carcinoma cases ($p<0.05$). In the T1D group, sequences of 5'UTR amplicons were compatible with EVs of the A and B species. One EV of the B and one of the C species were found in controls. Clear cytopathic effects were not perceived in EV-carrying cell cultures. Signals of viruses other than EVs were rare (occasional positivity for EBV, HHV6, parvovirus B19). Cytoplasmic expression of VP1 in cells exposed to pancreatic extracts was concordant with results of PCR assays. **Conclusion:** Results demonstrate that detection of EVs in the pancreas is a constant finding in T1D cases at the clinical onset and a possible finding in cases of pancreatic carcinoma. This study could not establish the location of EVs within the pancreas. However, previous investigations of DiViD cases pointed to infection of islets of Langerhans as the virus source (Krogvold et al., 2015). The findings reinforce the idea of a non-chance association of EV infections with the origin of T1D.

Infectobesity and Cancer Risk: Could Adenovirus 36 Infection Increase Your Risk for Breast Cancer?

Author Block:

T. Gray, W. C. Webley; Univ. of Massachusetts Amherst, Amherst, MA

Abstract Body:

Obesity is linked to a higher risk of recurrence of breast cancer despite optimal treatment. Recent studies confirm that obesity increases the risk of recurrence in women with hormone receptor-positive breast cancer. More recently, studies confirmed a significant increase in adiposity, and subsequent obesity, in chickens, mice, rats, and non-human primates infected with human adenovirus 36 (Adv36). These viruses are thought to increase the replication, differentiation, lipid accumulation, and insulin sensitivity in fat cells while reducing leptin secretion. Adv36 is the only human adenovirus to date that has been directly linked with human obesity; however, Adv37 and Adv5 have also been suspected. The current study sought to determine the prevalence of obesogenic adenovirus serotypes in breast tissue and blood from patients undergoing breast biopsy or mammoreduction surgery.**Methods:** We utilized serotype-specific PCR amplification to determine the presence of adenovirus species in patient samples obtained from human mammary epithelial cells (HMEC), buffy coat, and formalin-fixed paraffin-embedded (FFPE) breast tissue.**Results**: The average BMI of the patient cohort was 31.45, average age 37.2 years old and there was no significant association between the presence of obesogenic adenovirus and parity. Adv36 DNA was isolated from the breast tissue and blood of 55% (25/45) of all HMEC and buffy coat samples. Adv37 was found in 13% (6/45), Adv5 in 71% (32/45) and Adv2, 9 and 37 in one patient each. Since archived FFPE breast tissue biopsy samples are more readily available, we also evaluated these for the presence of obesogenic adenoviruses. Twenty nine percent (11/44) FFPE samples were positive for Adv36 and 76% (32/44) for Adv5. Data from the FFPE samples suggest an association between the prevalence of Adv36 and BMI in this patient cohort. The average BMI of patient samples positive for Adv36 was 33.83 compared to 30.8 for Adv36 negative samples.**Conclusion:** Our data shows, for the first time, that Adv36 DNA was present more frequently in breast tissue of women with higher BMI. We also confirmed previously published serological data that Adv5 is prevalent in the population and now demonstrate that its DNA is readily detected in breast tissue and white blood cells. Our initial findings support a role of infectobesity in the risk for breast cancer development.

A Cluster of Cases with Melioidosis Following Chennai Floods

Author Block:

A. Rajalakshmi[1], A. Ghafur[2], D. Vidya[2], P. Senthur Nambi[1], V. Ramasubramanian[1], D. Suresh Kumar[1], R. Gopalakrishnan[1]; [1]Apollo Hosp., Chennai, India, [2]Apollo Specialty Hosp., Chennai, India

Abstract Body:

Background: Devastating floods were recorded in the city of Chennai and surrounding areas, South India, on November 8-9 and December 1, 2015; We describe a case series of melioidosis following these floods.**Methods:** Retrospective chart review of patients with melioidosis to analyze the clinical profile and association with flood water exposure. All patients with blood or any other sterile site specimen growing *Burkholderia pseudomallei* between 9th November 2015 to 8th January 2016 were studied. Blood cultures were performed using the BacT-Alert automated blood culture system (BioMerieux).**Results:** 11 patients with blood culture growing *B. pseudomallei* were identified during this 2 month period. All were from the flood affected area. 9 cases (81 %) had flood water exposure. Only 3 had occupational risk in the form of farming. Majority were diabetics (81%), 2 had skin lesions (eczema and diabetic foot infection). All presented with fever, 2 with pneumonia, 4 had septic foci elsewhere. All had bacteremia, 3 had one other site culture positivity as well. 36% mortality was noted. **Conclusions:** In a previous study done from this institution, between 2005-2010, out of 32 cases, only 11 were from South India. Thus there is definite increase in number of cases of meliodosis post flood. Understanding the epidemiology, rainfall and flood exposure as risk factors for meliodosis will help early recognition and starting appropriate therapy.

Epidemiology of the cases				
	Place of flood exposure	Date of flood exposure	Date of onset of symptoms	Outcome
Case 1	Neyveli	Nov 10	Nov 15	expired
Case 2	Karaikal	Nov 9	Nov 14	expired
Case 3	Nellore	Nov 10	Nov 16	improved
Case 4	Neyveli	Nov 11	Nov 18	improved
Case 5	Kadappa	Nov 11	Nov 25	improved
Case 6	Chennae	no	Dec 12	improved
Case 7	Chennai	Dec 1	Dec 6	expired
Case 8	Neyveli	Dec 2	Dec 16	improved
Case 9	Nellore	Dec 3	Dec 27	improved

Neuroendocrine Factors Dictate *Streptococcus pneumoniae* Serotypes-Specific Responses

Author Block:

C. G. Ngo Ndjom, H. P. Jones; Univ. of North Texas Hlth.Sci. Ctr., Fort Worth, TX

Abstract Body:

Background: Among the 92 known serotypes of *Streptococcus pneumoniae (S. pneumoniae)*, few are considered virulent. Moreover, invasive serotypes are not contagious (e.g. pneumonia, otitis media and sepsis). Rather, transmission of disease stems from the reservoir of resident asymptomatic pneumococci along the nasal passages. Previous studies have shown that hormonal factors may be influential in regulating *S. pneumoniae's* transition from a non-pathogen to a pathogenic state. The current study investigated the effects of corticotropin-releasing hormone (CRH) and Norepinephrine (NE), on the virulence properties across *S. pneumoniae* serotypes. **Methods:** *S. pneumoniae* serotypes 3 and 19 were treated with either Corticotropin-releasing hormone (CRH) or Norepinephrine (NE) and allowed to grow in the incubator at 37º C, 5% CO_2. *S. pneumoniae's* response to CRH and NE was quantified by colony forming units, fluorescence analysis of metabolic activity and capsule staining using Congo red.**Results:** We demonstrated serotype-specific responses to both CRH and NE in terms of metabolic activity, bacterial growth and capsular formation. Specifically, CRH significantly increased the metabolic activity of serotypes 3 and 19. In contrast, NE significantly decreased their activity. Bacterial growth of serotype 3 was significantly increased by CRH. However, CRH did not influence the growth of serotype 19. In contrast, NE significantly decreased bacterial growth of serotype 19. NE did not influence the bacterial growth of serotype 3. Both CRH and NE promoted capsule formation of serotype 19 but had no significant effect on serotype 3.**Conclusion:** These results demonstrate the potential diversity of pneumococcal responsiveness to neuroendocrine factors that in turn may influence serotype phenotype with potential implications of pathogenicity.

Methicillin-Resistant *Staphylococcus aureus* in People Living with HIV/Aids Visiting a Tropical and Infectious Disease Hospital in Nepal

Author Block:

B. Rayamajhee[1], J. Aacharya[2], L. Ghimire[3], S. B. Pun[4]; [1]Kathmandu Univ. High Scool, Dhulikhel, Nepal, [2]Natl. Publ. Hlth.Lab., Kathmandu, Nepal, [3]SANN Intl. Coll., Kathmandu, Nepal, [4]Sukraraj Tropical and Infectious Disease Hosp., Kathmandu, Nepal

Abstract Body:

The emergence of Methicillin-resistant *Staphylococcus aureus* (MRSA) infections in people living with HIV/AIDS (PLWHA) has become a major challenge in clinical settings worldwide. MRSA infections in PLWHA is more frequently acquired in the community, may lead to increase risk of multi-drug resistance to opportunistic infections. Early identification of pathogen and proper antibiotic treatment can play a significant role in reducing the disease burden among PLWHA. Studies on MRSA infections in PLWHA in Nepal are, however, scarce. The objective of this study, hence, was to understand antimicrobial resistance of MRSA infections in patients living with HIV/AIDS in Nepal.A total of 324 nasal swabs were extracted from PLWHA through September 2014 to February 2015 in Sukraraj Tropical and Infectious Disease Hospital according to the protocol of Clinical Laboratory Standard Institute. Antibiotic susceptibility test was performed by using modified Kirby-Bauer disk diffusion technique and agar dilution method was performed for oxacillin. CD4 cell counting was done using computerized GeneQuant spectrophotometer. Of these, 91 were found positive for *S. aureus,* of which 38 were MRSA (41.76%) isolates. 76.3% (29/38) of them, had CD4 counts less than 500 cells/mm^3. D-test shown that inducible clindamycin resistant MRSA were 28.94 %. All of the isolated *S. aureus* were sensitive to vancomycin while 100% resistance to penicillin. *S. aureus* isolates were susceptible to cephalosporin (94%), tetracycline (89%), clindamycin (87%), gentamicin (53%), and erythromycin (45%) while ciprofloxacin (21%) and cotrimoxazole (10%) were less effective. Multidrug resistance (MDR) was significantly distributed with methicillin resistance where 22 MSSA (41.5%) and 35 MRSA (92.1%) were MDR. Clindamycin is a reserve option and decreed in severe MRSA infection. D-test is a simple laboratory method to portray inducible and constitutive clindamycin resistance *S.* aureus. Low CD4 cell count may increase incidence of MRSA in PLWHA and cause difficulties in treating opportunistic infections. The present study would be useful in bridging knowledge gap on MRSA infections in PLWHA in Nepal.

Ctr., King Abdulaziz Univ., Jeddah, Saudi Arabia, [3]Biology Dept., Faculty of Sci., King Abdulaziz Univ., Jeddah, Saudi Arabia, [4]Physiology & Immunology, Technical Univ. Munich, Munich, Germany

Abstract Body:

Background: Obesity is a modern global epidemic and is a risk factor for diabetes and cardiovascular diseases (CVD). The prevalence of overweight and obesity in Saudi Arabia is on the rise, placing a huge burden on health and economic resources. Recently, gut microbiota has been reported to be involved in the pathogenesis of many metabolic disorders and diseases, including obesity, diabetes, and CVD.**Objective:** The objective of this study was to identify obesity-associated gut microbiota dysbiosis and their relationship to body mass index (BMI) among healthy Saudi females with different degrees of obesity.**Methodology:** A total of 120, below the age of 30 years, healthy females with different degrees of obesity were recruited. All those filled out a questionnaire related to their nutritional habits, health conditions and demographics. Their height, body weight, hip and waist circumference were measured (BMI and age). Stool samples were collected and genomic DNA was extracted from those samples. The 16S rRNA were amplified and sequenced via next generation sequencing (MiSeq), sequencing reads were trimmed, analyzed and filtered and assigned to taxonomic units.**Results:** The results indicated the presence of various bacteriological groups including Firmicutes, *Actinomyces odontolyticus*, *Escherichia coli* and *Ruminococcus obeum* and others. Work is in progress to correlate the prevalence of those bacterial groups with BMI.**Conclusion/Recommendations:** The results indicated that a variety of bacterial strains and microbiota populations are present among our study subjects. Bioinformatical data analysis will help to identify certain microbiota marker populations to be associated with different stages of obesity among the female Saudi population. Final goal is an early prediction of obesity and to target those patient groups to treat obesity.

Immune Response to Bk Virus in Renal Transplant Recipients

Author Block:

D. DeWolfe, 02215[1], J. Gandhi[1], M. Mackenzie[1], T. A. Broge, Jr[1], E. Bord[1], D. A. Mandelbrot[1], R. Viscidi[2], F. Cardarelli[1], M. Pavlakis[1], **C. S. Tan**[1]; [1]Beth Israel Deaconess Med. Ctr., Boston, MA, [2]Johns Hopkins Univ., Baltimore, MD

Abstract Body:

Background: The adaptive immune characteristics associated with BK Virus (BKV) infection and control remain incompletely described. In this study we further elucidate the immune response to BKV.**Methods:**29 patients undergoing renal transplantation from two institutions were followed prospectively for one year to evaluate the recipients' BKV specific humoral and cellular immune responses. ELISA assay detected IgG antibody titers against BKV 1 and 4 and intracellular staining for interferon gamma (IFN-γ) determined BKV-specific $CD4^+$ and $CD8^+$ T lymphocytes. We quantified T lymphocyte phenotypes and expression of activation and exhaustion markers to demonstrate lymphocyte functions.**Results:**7 patients developed BK viruria and 3 progressed to BK viremia. There were no clinical differences between BKV positive and negative patients. Viremic patients had an increase in IFN-γ producing $CD8^+$ T Cells with time (P= 0.034) and a trend toward increased IFN-γ positive $CD4^+$ T Cells. Prednisone was associated with fewer BKV specific $CD8^+$ T Cells (P=0.027). Viremic patients had an increase in IgG titers against both BKV 1 and 4(P= 0.044). Viremic patients also had higher titers against BKV 4 at 6 (P=0.035) and 12 months (P=0.004) and a similar trend toward higher BKV 1 titers. Viremic patients had fewer $CD4^+$ central memory cells expressing activation markers CD38 (P=0.042) and HLA-DR (P= 0.027) at 1 month. Viremic patients had more $CD8^+$ effector cells at baseline (P = 0.002) and 12 months (P = 0.009).**Conclusions:**The response to BK virus includes both a BKV specific humoral and cellular component, dominated by $CD8^+$ T lymphocytes, and may be impaired by prednisone. Viremia was associated with fewer activated $CD4^+$ central memory cells at 1 month, perhaps indicating an early memory deficit; and significantly more $CD8^+$ effector cells at 12 months, potentially reflecting the cytotoxic response to viremia. Monitoring and modulating specific immune factors against BKV post transplant could help identify risk of BKV infection and factors to harness as immunotherapy against BKV.

Antibiotic Disruption of a Fish Model Microbiome with Negative Host Effects

Author Block:

J. M. Carlson, T. P. Primm; Sam Houston State Univ., Huntsville, TX

Abstract Body:

Human and veterinary medicine practices the application of broad spectrum antibiotics because of their robust ability in fighting an assortment of bacterial infections. Yet in clinical settings, patients can exhibit serious side effects, including antibiotic-associated enterocolitis, which presumably results from dysbiosis of the microbiome. Study utilizing a well-controlled system is needed. Therefore, we observed the compositional changes within the skin and gut bacterial communities from an antibiotic and how this treatment affects the host. Samples of the two mucosal microbiomes, skin and gut, were collected from *Gambusia affinis* before, during, and after exposure to rifampicin, a broad spectrum antibiotic. In both the skin and gut microbiomes, 16S rRNA profiling revealed a decrease in community evenness and diversity, and dominance of the genus *Myroides*. This was followed by a recovery period resulting in a drop in *Myroides* and stabilization to a taxonomic distribution different than pre-exposure. Several host effects were measured on fish with altered microbiomes. Treated fish given a standardized diet gained less weight over the duration of a month than control fish. Susceptibility to the fish pathogen *Edwardsiella ictaluri* increased in treated fish rather than in the control. In contrast, polymicrobial water challenges from feces and soil, or with addition of the toxin nitrate, observed no survival differences between fish groups. A novel observation was that treated fish became more sensitive to high salinity concentration. Findings from this study reveal a tractable system that can be used to determined mechanisms of confirmed antibiotic-derived negative host effects.

Acute *Montipora W*hite Syndrome and Its Potential Causative Agents, Environmental Drivers, and the Importance of Coral Health

Author Block:

S. Beurmann[1], A. M. Smith[1], B. Ushijima[1], C. M. Runyon[1], P. Videau[1], S. M. Callahan[1], G. S. Aeby[2]; [1]Univ. of Hawaii at Manoa, Honolulu, HI, [2]Hawaii Inst. of Marine Biology, Kaneohe, HI

Abstract Body:

Disease is a threat to coral reefs and exacerbates the widespread impacts of climate change. Prevalence of a number of coral diseases are increased by environmental stressors including elevated water temperatures, pollution, and runoff, which can lead to destructive outbreaks. Numerous outbreaks of the tissue loss disease acute *Montipora* white syndrome (aMWS) have occurred in *Montipora capitata*, a major reef-building coral in Kaneohe Bay, Hawaii, which may have been triggered by sewage runoff associated with winter rainfall and pre-existing stress from a chronic tissue loss disease (cMWS). One of the potential etiological agents of aMWS is *Pseudoalteromonas* sp. OCN003, a strain isolated from diseased *M. capitata*. Under controlled conditions, 20% of the healthy *M. capitata* fragments exposed to OCN003 developed acute tissue loss within three weeks post-inoculation. When fragments already compromised by cMWS were exposed to OCN003, 60% of the fragments developed acute tissue loss within four days post-exposure. Thus, OCN003 is more successful as a secondary pathogen in laboratory experiments. Chronic MWS infections are observed year-round in Kaneohe Bay, while aMWS outbreaks have only occurred during the rainy winter months. The bacterial communities of samples from healthy and diseased *M. capitata* during an aMWS outbreak were analyzed with high-throughput sequencing. Bacteria from the family Enterobacteriaceae dominated all samples, healthy and diseased, and the most abundant OTU was similar to species that inhabit the human gastrointestinal tracts, suggesting sewage and/or freshwater input. This study describes the first *Pseudoalteromonas* sp. pathogenic to coral, evidence for OCN003 as a secondary pathogen, and possible bacterial communities consistent with anthropogenic stressors associated with a fatal coral disease.

Identification of Urine Metabolites as Novel Biomarkers of Early Lyme Disease

Author Block:

A. Pegalajar-Jurado[1], L. v. Ashton[2], J. T. Belisle[2], K. Webb[2], G. P. Wormser[3], C. R. Molins[1]; [1]Ctr.s For Disease Control and Prevention, Fort Collins, CO, [2]Colorado State Univ., Fort Collins, CO, [3]New York Med. Coll., Valhalla, NY

Abstract Body:

Over 300,000 cases of Lyme disease (LD) are reported annually in the United States. Current diagnostics for LD are antibody-based and test patient serum samples. Limitations of this approach include a sensitivity that is dependent upon the stage of infection (low in early LD and high for late LD), the utilization of immunoblotting that requires advanced training for proper execution and interpretation, and the inability to distinguish between current and past infections. As an innovative diagnostic approach, we applied metabolomics to determine the presence of dysregulated metabolites in urine from patients with early LD. Urine samples (n=42) were obtained from well-characterized patients diagnosed with early LD (EL), 1 month treated early LD (1mthEL) and healthy controls (HC). Urine samples were analyzed using liquid chromatography-mass spectrometry (LC-MS) in positive- and negative-ion mode, resulting in the resolution of several thousand metabolites. Comparisons between EL, 1mthEL and HC were performed using the Agilent Mass Profiler Professional software. Metabolites that significantly differed ($p<0.05$) between the comparative groups, and were consistently observed in multiple LC-MS analyses, were selected to establish group-specific metabolic profiles. Specifically, biosignatures that differentiated EL vs HC, and EL vs 1mthEL were produced. These biosignatures consisted of 327 to 548 metabolites. Currently, *in silico* analyses are being performed with the METLIN database and the web-based Pathos software to provide a structural identity for the metabolites and predict metabolic pathways altered during EL and 1mthEL. Further refinement of the biosignatures and structural conformation of the selected metabolites is currently undergoing. This evaluation offers an opportunity for the identification of early LD and 1mthEL biomarkers that can be applied towards the development of novel diagnostic tools that utilize a non-invasive patient specimen. These studies will also provide insight into the host response of early LD.

Association of *Staphylococcus aureus* Exotoxin Antibody Concentrations to Clinical Outcomes in Patients with Bacteremia

Author Block:

W. Rose[1], R. P. Adhikari[2], R. Koralkar[3], S. Krishnan[2], R. Proctor[1], M. J. Aman[2], S. Shukla[3]; [1]Univ. of Wisconsin-Madison, Madison, WI, [2]Integrated Biotherapeutics, Inc., Gaithersburg, MD, [3]Marshfield Clinic Res. Fndn., Marshfield, WI

Abstract Body:

Patients with *Staphylococcus aureus* bacteremia (SaB) have variable clinical responses attributed to multi-drug resistance, virulence, and immune evasion organism characteristics. These factors contribute to a dysregulated host immune response during the initial infection course. This study correlates the staphylococcal exotoxin (SE) antibody response to primary clinical outcomes in patients with confirmed SaB. Adult patients with SaB at a single academic medical center were included prospectively. Serum samples were collected on the initial day of patient presentation. Serum antibody to 10 SEs were measured using an electrochemiluminescence based multiplex immunoassay. Patients were compared according to outcomes of rapid bacteremia clearance ($\leq$ 4 d), persistence (> 4 d), and in-hospital mortality. Patient demographics, severity of illness, source of infection, and initial antibiotic treatment were collected. SE concentrations were compared by patient outcome (Mann Whitney U) and adjusted for collected covariates (logistic regression). Consecutive patients (n=98) were included in the study for analysis. 39 patients (39.8%) had persistent bacteremia > 4 days and 14 (14.3%) died during the hospital course. Patients with prolonged SaB often had lower antibody responses. Of interest, antibodies to staphylococcal enterotoxin A (SEA) were significantly lower with prolonged SaB compared to the rapid clearance (median 1.95 vs 2.37 log Ab U/ml; p=0.046). Duration of SaB was inversely related to SEA (Pearson coefficient 0.249; p=0.013). A similar trend was observed with SED in prolonged versus rapid SaB (0.88 vs 1.09; p=0.069). Patients who died also had lower SE antibody responses, most strikingly with alpha hemolysin (death vs survival 3.14 vs 3.33, respectively), but none of these comparisons were statistically significant. The SE antibody responses in SaB are lower in patients with poor outcomes of prolonged SaB and mortality. This is consistent with earlier studies demonstrating lower SE antibodies in patients with sepsis. These results provide further data on the dysfunctional host immune response in SaB and may be a potential biomarker for a precision approach to treatment.

Mokdong Hosp., Seoul, Korea, Republic of

Abstract Body:

Background: Toll-like receptor 2 (TLR2) is the main pattern recognition receptor recognizing pathogen-associated molecular patterns in *Staphylococcus aureus* infection, playing an important role in innate immune response. The cytokines released by TLR2 signaling are either beneficial or detrimental. We aimed to examine the relationship of TLR2 expression and cytokines with prognosis in patients with *S. aureus* bacteremia (SAB).**Methods:** Whole blood samples were collected at several time points (≤ 5 days, 6-9 days, 10-13 days, 14-19 days and ≥ 20 days) after the onset of bacteremia, from patients with SAB in 2 teaching hospitals in Korea. The relative mRNA expression of TLR2 and the concentration of IL-6 and IL-10 were measured to identify associations with 30-day mortality and severity.**Results:** The level of TLR2 expression during the clinical course after the onset of bacteremia was variable among the 62 patients with SAB. In 10 patients with 30-day mortality, TLR2 expression was down-regulated and showed less dynamic changes throughout the whole period than in 52 survivors. Within 7 days of bacteremia, the mortal group showed significantly elevated IL-6 level (755.8 vs. 97.8 pg/mL, P=0.017) and more patients (90%, 9/10) in the mortal group showed measurable IL-10 (>2.49 pg/mL) compared with the survived group (40%, 20/50). IL-6/IL-10 ratio tended to be either low or high in patients with 30-day mortality, which implies excessive immune response of either pro-inflammation or anti-inflammation. The level of TLR2 expression within 5 days of bacteremia was higher in patients with complicated bacteremia or septic shock.**Conclusion:** Down-regulated TLR2 expression and elevated level of either IL-6 or IL-10 at early stage of bacteremia were associated with 30-day mortality in SAB patients. TLR2 expression within 5 days of bacteremia was higher in patients with severe presentations. Host immune response including TLR2 expression and secretion of cytokines may be a potential prognostic factor in SAB.

Dysregulation of Bile Acids Occurs at Different Stages of Lyme Disease

Author Block:

L. V. Ashton[1], C. R. Molins[2], K. Webb[1], G. P. Wormser[3], J. T. Belisle[1]; [1]Colorado State Univ., Fort Collins, CO, [2]Ctr.s for Disease Control, Fort Collins, CO, [3]New York Med. Coll., Valhalla, NY

Abstract Body:

Lyme disease (LD) is the most common tick-borne disease in the United States. Early disease is characterized by the presence of an erythema migrans (EM) lesion and general symptoms of malaise. However, multiple EMs, cardiac involvement or neurological symptoms may develop as the infection disseminates, and Lyme arthritis presents in the late stage of LD. Liquid chromatography-mass spectrometry-based metabolomics was applied to sera obtained from well-characterized patients diagnosed with various stages of LD (early localized and disseminated LD, late LD, and one month treated early LD) as well as from healthy controls (HC), to elucidate metabolic pathways perturbed for LD. This effort resulted in the resolution of 2,027 unique molecular features (MFs) that significantly differed in abundance with at least a two-fold change between early LD and HC, or between the various disease states. Although individual metabolic biosignatures were discovered for the various LD stage comparisons, an overlap (44 to 66%) in the molecular features that comprised these biosignatures was observed. *In silico* analyses using the METLIN database and the web-based Pathos software were applied to predict metabolic pathways altered in LD. Within the predicted pathways, bile acid metabolism and secretion, among others, was found to be perturbed in LD. A total of 38 MFs with putative structural identifications aligned to this pathway, and seven of these metabolites have been confirmed. These data are consistent with previous clinical findings demonstrating abnormal liver function in LD patients, and the frequency of these abnormalities being greater in early disseminated LD versus early localized LD. The structural conformation of additional bile acid metabolites is currently being performed, as well as investigation of LD stage-specific differences in the bile acid pathway.

Comparison and Characterization of Usa300 Clones by Whole Genome Sequencing and Mice Pneumonia Model

Author Block:

S. Sonoda[1], T. Yamaguchi[2], K. Aoki[2], C. Kajiwara[2], S. Kimura[2], Y. Akasaka[2], Y. Ishii[2], K. Tateda[2]; [1]Tokyo Med. and Dental Univ., Tokyo, Japan, [2]Toho Univ. Faculty of Med., Tokyo, Japan

Abstract Body:

Background: Highly virulent community-acquired MRSA, especially USA300 clone, has become epidemic in the world. Types and severities of diseases by USA300 clones varied from mild skin infection to fetal necrotizing pneumonia, although the exact mechanisms still remained unknown. In the present study, by applying whole genome sequence (WGS) analysis, we compared genetic backgrounds of virulence factors in several USA300 clones, such as isolates from severe pneumonia (IP) and mild skin diseases (IS). In vivo comparative virulence was characterized in bacterial burdens, cytokine responses, pathological changes in the lung and the survival in mice model of pneumonia.**Methods:** IP and IS isolates, in addition to two reference strains (BAA-1556, USA300; N315, USA100), were used. In pneumonia model, mice (BALB/c, 6-8 weeks old) were intra-tracheally challenged with $1\text{-}3\times10^8$ CFU/mouse of bacteria, and sacrificed at 12 hours after infection for bacterial burdens, cytokine responses and pathological analysis in the lungs. WGS analysis of IP and IS was performed, and transcriptional levels of several virulence factors (ex. α-toxin) were examined in several conditions.**Results:** In pneumonia model, IP strain demonstrated significantly stronger virulence than that of IS strain (mortality rate of IP 100% vs IS 0%). Well correlated with the mortality, significantly stronger cytokine productions and bacterial burdens (IP 1.6×10^9 vs IS 2.7×10^7 CFU/lungs) were observed in the lungs of IP-challenged group. Interestingly, strong bacterial aggregation and tissue destructions were exhibited in the lungs of IP-group. WGS analysis showed that the IP isolate possessed 16 additional ORFs, comparing to IS isolate. Although not all genes were examined yet, we observed higher expressions of α-toxin in IP isolate than that of IS isolate.**Conclusions:** The present data demonstrated that USA300 IP isolate was more virulent than IS isolate in pneumonia model. WGS analysis showed presence of 16 additional ORFs in IP isolate, although remaining genes detected were similar to those of IS isolate. Our data suggested that gene expression experiments directing several virulence factors, such as α-toxin, are warranted for better understanding a virulence difference observed among USA300 clones.

Transcription Factor Efg1 Regulates Biofilm Formation and Contributes to Palatal Tissue Damage in *Candida albicans* Associated Denture Stomatitis

Author Block:

J. Yano, A. Yu, D. Stoute, P. L. Fidel, Jr, M. C. Noverr; LSU Hlth. Sci. Ctr. Sch. of Dent., New Orleans, LA

Abstract Body:

Background: Denture stomatitis (DS), a condition characterized by inflammation of the oral mucosa in direct contact with dentures, affects a significant number of denture wearers. The disease is a fungal infection predominantly caused by *Candida albicans,* which readily colonizes and form biofilms on denture materials. While evidence for biofilms on abiotic and biotic surfaces initiating *Candida* infections is accumulating, a role for biofilms in DS remains unclear. Using an established animal model incorporating a novel intraoral denture system, the purpose of this study was to determine the role of biofilm formation in mucosal damage during pathogenesis of DS *in vivo*. **Methods:** Denture materials or rat palatal tissues were inoculated with wild-type *C. albicans* or mutants defective in morphogenesis (*efg1*$^{-/-}$) or biofilm formation (*bcr1*$^{-/-}$) and evaluated for the presence of biofilms by scanning electron and confocal microscopy. For *in vivo* analyses, rats fitted with custom dentures, consisting of fixed and removable parts, were inoculated with wild-type *C. albicans,* mutants or reconstituted strains and monitored weekly for fungal burden (denture and palate), body weight and tissue damage (LDH) for up to 8 weeks. **Results:** *C.albicans* wild-type and reconstituted mutants formed biofilms on dentures and palatal tissues under *in vitro, ex vivo* and *in vivo* conditions as indicated by microscopy demonstrating robust biofilm architecture and colocalization of extracellular matrix (ECM) and *C. albicans*. In contrast, both *efg1*$^{-/-}$ and *bcr1*$^{-/-}$ mutants exhibited poor biofilm growth with little to no ECM . In addition, quantification of fungal burden showed reduced colonization on dentures and palates of rats inoculated with *efg1*$^{-/-}$ mutant throughout the infection period compared to rats inoculated with wild-type, reconstituted mutants or *bcr1*$^{-/-}$ mutant. Finally, rats inoculated with *efg1*$^{-/-}$ had minimal palatal tissue damage/weight loss while those inoculated with wild-type, reconstituted mutants or *bcr1*$^{-/-}$ mutant showed elevated levels of tissue damage and substantial weight loss. **Conclusions:** These data suggest that biofilm formation is not required to induce damage during DS; however, regulation by *C. albicans* Efg1, a central regulator of virulence, has a pivotal role in pathogenesis of DS.

A Quorum Sensing Signal Promotes Host Tolerance Training Through Chromatin Modifications

Author Block:

A. Bandyopadhaya, A. Tsurumi, D. Maura, K. L. Jeffrey, L. G. Rahme; Massachusetts Gen. Hosp. & Harvard Med. Sch., Boston, MA

Abstract Body:

The quorum sensing excreted volatile small molecule 2-aminoacetophenone (2-AA), amply produced by the human opportunistic pathogen *Pseudomonas aeruginosa* (PA), dampens host innate immune responses, modulates host metabolism, while promoting host tolerance against high bacterial burden, ultimately rescuing mice from PA induced mortality. The biological mechanisms by which pathogens act upon hosts to maintain their burden without affecting host fitness, and the causes and consequences of variation in tolerance are still underdeveloped. Similarly, the precise underlying mechanisms by which innate immune training can be triggered and the outcome of this "training" for the pathogen remains elusive. Here, we have used 2-AA molecule paradigmatically to uncover the mechanism by which bacterial molecules may "train" the host to become tolerant to high bacterial burden, while having a positive effect on host fitness. The training was induced by 2-AA pretreatment and the training capacity was investigated following exposure to the specific or non-specific molecule and/or PA itself *in vitro* and *in vivo*. Chromatin modifications were analyzed by biochemical, molecular assays and ChIP-PCR. We show that 2-AA regulates histone deacetylase (HDAC)1, resulting in H3K18 hypoacetylation at proinflammatory cytokine loci. 2-AA was capable of reprogramming the innate immune cells via the induction of specific alterations in histone acetylation at critical immune cytokines *in vivo* and *in vitro*. The host epigenetic reprograming generated by 2-AA, maintained for up to seven days, resulted in a significantly dampened response to subsequent exposure to 2-AA or other pathogen-associated molecules, lipopolysaccharide or peptiodoglycan. This process is a distinct molecular mechanism of host chromatin regulation by a QS excreted small molecule. Genetic and pharmacological inhibition of HDAC1 prevented the immunomodulatory effect of 2-AA. These observations provide the first mechanistic example of a QS excreted small molecule that trains the host tolerance against infection via epigenetic reprogramming. A solid understanding of patho-epigenetic changes following host-pathogen interactions will benefit the development of therapeutic interventions for acute and chronic infection.

Of Texas Hlth.Sci. Ctr. at San Antonio (UTHSCSA), San Antonio, TX, [3]Inst. for Genome Sci., Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

Streptococcus pneumoniae, (the pneumococcus) is a leading cause of opportunistic diseases such as community-acquired pneumonia, bacteremia, and meningitis. During severe infections the pneumococcus also contributes towards cardiac complications such as arrhythmia and heart failure. Along such lines, we previously reported that pneumococci invade the myocardium during invasive pneumococcal disease (IPD) forming bacteria-filled microlesions that disrupt cardiac functionality. Herein we expand upon our previous microscopic observations and detail changes in the number and size of microlesions within the ventricular tissue. Fluorescent and electron microscopic analysis revealed equidistantly spaced non-encapsulated pneumococci with a striking absence of infiltrating immune cells; a finding that is suggestive of biofilms as described in the nasopharynx. A biofilm-like phenotype was confirmed by the presence of extracellular matrix components poly-N-acetylglucosamine and both eukaryotic and prokaryotic extracellular DNA within the microlesions. Furthermore, pneumococci isolated from the myocardium were more resistant to antibiotics, a hallmark of the biofilm phenotype. Pneumococci isolated from the heart were found to retain unique properties following their isolation. These included an increased capacity to adhere and invade cardiomyocytes *in vitro*, and increased tropism for the heart on subsequent infections. Comparative gene expression profiling of the pneumococci within the myocardium using RNA-Seq identified numerous differentially expressed genes including established virulence determinants. Ongoing studies are focused on examining the requirement for these determinants in experimentally challenged mice and are intended to provide a deeper insight into the host-pathogen interactions *in vivo*, identify new strategies to prevent pneumococcal invasion of the myocardium, and allow development of treatment strategies for IPD- associated cardiac complications.

Cystic Fibrosis and Immunodeficiency Disease

Author Block:

R. Harbeck, K. Lucey; Natl. Jewish Hlth., Denver, CO

Abstract Body:

Chronic, pulmonary infections are the most prominent cause of the increased morbidity and mortality in cystic fibrosis (CF). In immunodeficiency diseases, an individual is often unable to mount an immune response to microorganisms. Common variable immune deficiency (CVID) is a frequently diagnosed immunodeficiency, especially in adults, characterized by low levels of serum immunoglobulins and antibodies, which causes an increased susceptibility to infection. In this study we examined the immune profile of patients diagnosed with immunodeficiency and CF to determine if an immunodeficiency influenced the profile of microorganisms recovered from the respiratory secretions of CF patients.Between the years of 2008 and 2015 we identified ten patients with a diagnosis of CF and an immunodeficiency. Two of these patients were diagnosed with CVID. All patients had immunoglobulin levels performed and some also were tested for pneumococcal polysaccharide and tetanus antibody titers. In addition CD4, CD8, CD19 and memory B cells were determined. We compared the different organisms that were identified in this population to the organisms recovered from our population of patients diagnosed with only cystic fibrosis.Four of the ten patients had multiple organisms identified in their respiratory cultures including *Pseudomonas aeruginosa,* methicillin resistant *Staphylococcus aureus, Staphylococcus aureus, Haemophilus influnzae, Candida albicans* and mold. One patient was only positive for *Pseudomonas aeruginosa* in multiple cultures that were collected. The other five patients had cultures with normal flora present or had no cultures performed. The profile of organisms compares with those recovered from patients with only cystic fibrosis where predominately *Pseudomonas aeruginosa* and *Staphylococcus aureus* were identified. In most cases the immunological profile of these patients support the diagnosis of immunodeficiency or CVID.Patients diagnosed with both cystic fibrosis and immunodeficiencies have many of the same pathogens recovered as do patients diagnosed only with cystic fibrosis. It does not appear that an immunodeficiency alters the microbial populations in the airways of CF patients.

Human Genetic Variation in *vac14* Regulates *S. typhi* Invasion and Typhoid Fever Susceptability

Author Block:

M. Alvarez[1], S. Dunstan[2], P. Luo[1], S. Oehlers[1], E. Walton[1], L. Glover[1], L. Wang[1], D. Tobin[1], D. Ko[1]; [1]Duke Univ., Durham, NC, [2]Univ. of Melbourne, Melbourne, Australia

Abstract Body:

Background: Human genetic variation influences many aspects of our lives including susceptibility to infectious diseases. Our lab has developed a novel cell-based screen of human genetic variation (Hi-HOST: High-throughput human in vitro susceptibility testing) for identifying genetic differences that impact host-pathogen interactions. Specifically, we examined genetic variation in *S.* Typhi invasion of cells and the impact this has on risk of typhoid fever in people.**Methods and Results:** We carried out a Hi-HOST screen of genotyped cell lines from 351 individuals for invasion by *S.* Typhi. A human single nucleotide polymorphism (SNP) in the gene encoding the phosphoinositide scaffolding protein VAC14 was associated with invasion (p=0.0006). While this association suggested that VAC14 regulates invasion, we experimentally tested this with RNAi, CRISPR knockouts, and plasmid complementation. RNAi against VAC14 in HeLa cells caused an increase of *Salmonella* invasion (p=0.02). CRISPR knockout of VAC14 completely abolished protein expression and nearly doubled invasion (p=0.005). To determine the mechanism by which VAC14 alters invasion, assays of membrane docking, actin-based ruffling, and early intracellular survival were carried out on *vac14*$^{-/-}$ cells. Of these steps in early *S.* Typhi infection, only docking was increased in *vac14*$^{-/-}$ mutant cells (p=0.0002). Cellular lipid measurements suggest the *vac14*$^{-/-}$ cells have an altered plasma membrane composition that then impacts *Salmonella* docking and invasion. To extend these studies *in vivo*, mutant *vac14* zebrafish are being evaluated for *Salmonella* dissemination and outcome. Finally, the *vac14* SNP was tested for association with typhoid fever in a case-control study (n=500 cases, 496 controls). Remarkably, the allele that decreases invasion is associated with protection against typhoid fever (p=0.0098, OR=1.4).**Conclusion:** Through this multi-disciplinary project, we discovered VAC14 to be an inhibitor of *Salmonella* invasion. We propose that this effect on invasion is mediated by VAC14 regulation of phosphoinositides that impact plasma membrane lipid composition. Ultimately, we hope to use these findings to develop new therapeutic options.

Integrative Analysis of Gwas, Transcriptomices, Metabolites, and Cytokines Reveals Methylthioadenosine Is a Prognostic Biomarker for Death in Sepsis

Author Block:

L. Wang[1], E. Ko[1], J. J. Gilchrist[2], A. Rautanen[2], S. Jaslow[1], A. V. S. Hill[2], E. T. Tsalik[1], D. C. Ko[1]; [1]Duke Univ., Durham, NC, [2]Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Background: Sepsis is a systemic, deleterious inflammatory response to infection. Sepsis is a leading cause of death, and identifying sensitive and specific biomarkers could improve diagnosis, prognosis, and treatment. This study reports a novel and robust biomarker for sepsis death based on analysis combining multiple "omics" datasets.**Methods:** Three patient datasets were used to examine the association between genetic, transcriptional, metabolite, and cytokine markers and sepsis: A GWAS analysis was performed from 218 cases of non-typhoidal Salmonellae (NTS) bacteremia patients and 3000 controls. Metabolites, RNA-seq, and cytokine levels were examined in SIRS patients from the previously published CAPSOD study and an independent cohort with temporal data, the VAP study (157 samples).**Results:** A pathway-based GWAS of NTS bacteremia showed a strong statistical enrichment for SNPs near genes of the methionine salvage pathway. Measurement of the pathway's substrate, 5'-methylthioadenosine (MTA), in two independent cohorts of sepsis patients demonstrated that plasma levels are increased in nonsurvivors compared to survivors and controls. High plasma MTA was correlated with high levels of inflammatory cytokines (IL-6 and IL-8), suggesting elevated MTA could mark a subset of patients with excessive inflammation. Finally, we evaluated a machine-learning model by combining MTA and other clinical variables and measured approximately 80% accuracy (based on AUC) in cross-validation and testing of independent samples. Notably, MTA alone was nearly as successful in predicting sepsis outcome.**Conclusions:** Based on integrative analysis of panomics approaches, we identified and validated that MTA is a robust prognostic biomarker of sepsis death. Our approach combining genetic association data with biomolecule measurements can shape our understanding of sepsis and lead to the development of accurate biomarkers.

Semen-Derived SEM1 Amyloid Fibrils Modify Immune Responses to Vaginal Anaerobes

Author Block:

S. N. Ryan[1], H. S. Yamamoto[1], N. R. Roan[2], R. N. Fichorova[1]; [1]Brigham and Women's Hosp., Boston, MA, [2]Univ. of California, San Francisco, San Francisco, CA

Abstract Body:

Semen harbors amyloids fibrils, including those made up of peptide fragments from semenogelin 1 (SEM1).The physiologic function of SEM1 is unknown, but it has been shown to increase HIV infectivity *in vitro*. Because the majority of HIV infections in women occur through vaginal sexual contact, it is of significant interest to study how factors in semen, such as SEM1, interact with the genital immune environment and the vaginal microbiota, which plays an important role in the formation of the mucosal barrier against sexually-transmitted diseases. The disturbance of the vaginal microbiota leads to replacement of beneficial *Lactobacillus* species with anaerobic bacteria, and inflammation, which in turn facilitates HIV. Whether SEM1 fibrils affect the vaginal microbiota and influence vaginal immunity has not been studied. We treated female genital tract epithelial cells treated with SEM1 fibrils at doses previously demonstrated to enhance HIV infection followed by incubation with *Lactobacilli* or with anaerobes representing the disturbed vaginal microbiota (*P. bivia* and *A. vaginae).* Vaginal colonization was determined by colony forming units attached to the epithelial cells. Inflammatory responses were measured by NF-κB activation and chemokine secretion. Both lactobacilli and pathogenic bacteria colonized the vaginal epithelium in the presence of SEM1 fibrils, which did not affect immune responses to *Lactobacilli* but induced NF-κB activation and enhanced the proinflammatory activities of *A. vaginae*. The fibrils increased levels of the neutrophil chemoattractant GRO-α, decreased levels of the dendritic cell chemoattractant MIP-3α, and did not affect levels of RANTES, which is known to block HIV entry. Our experiments support our hypothesis that SEM1 fibrils may increase the risk of HIV acquisition in part by inducing an inflammatory response and enhancing the proinflammatory activities of vaginal bacteria that thrive in a disturbed vaginal environment. The proinflammatory activities of the SEM1 fibrils are in line with the beneficial effects of semen-induced inflammation on reproductive success; however, these activities present a problem to women at high risk of HIV who seek pregnancy.

Adjuvant Hyperbaric Oxygen Therapy Augments Tobramycin Treatment in Left-Sided *Staphylococcus aureus* Endocarditis in an Experimental Rat Model

Author Block:

C. J. Lerche, L. Christophersen, M. Kolpen, P. O. Jensen, N. Høiby, C. Moser; Clin. Microbiol., RigsHosp.et, Copenhagen, Denmark

Abstract Body:

Background: *Staphylococcus aureus* endocarditis (SA IE) still presents a clinical challenge and remains a disease with high mortality. SA IE is a rapid evolving and complex infectious disease. Tobramycin single agent antibiotic therapy in SA IE has been shown to be suboptimal. We hypothesized, that hyperbaric oxygen therapy (HBOT) could enhance the efficacy of tobramycin treatment in experimental SA IE. **Methods:** SA IE was established in male Wistar rats (n=47). Animals were randomized in two groups: 1. group received a combination of HBOT and tobramycin (n=23) and 2. group received tobramycin as monotherapy (non-HBOT, n=24). Animals exposed to HBOT were treated for 90 minutes at > 99% O_2 at a pressure of 280 kPa (2.8bar) in a hyperbaric chamber (OXYCOM 250 ARC, Hypcom). Tobramycin was given s.c. 20 mg/kg once a day. Treatments were initiated 1 day post infection (DPI) and cardiac valves were evaluated at 3DPI or 4DPI. The animals of the two treatment groups were divided into two subgroups a low-grade IE and a high-grade IE, defined by bacterial valve burden at the time of evaluation with a cut-off at 10^7 and 10^6 CFU/g valve at 3DPI and 4DPI, respectively. Low-grade IE < and high-grade IE > cut-off. **Results:** HBOT was well-tolerated and no adverse effects were observed. In the group of low-grade IE there was a significant reduction of bacterial load in valve vegetations in the HBOT group (3.4 ± 0.2, n=5) as compared to the non-HBOT group (4.8 ± 0.2, n=5)(p=0.03) already at 3DPI, but only a trend at 4DPI (p=0.06). In the high-grade IE group a significant reduction in bacterial load in the HBOT group (7.2 ± 0.3, n=8) was not observed until 4DPI as compared to the non-HBOT group (8.2 ± 0.4, n=6)(p=0.03). Animals, in the high-grade IE group exposed to HBOT, showed significantly reduced bacterial load in valve vegetations from 3DPI (8.4 ± 0.28, n=5) to 4DPI (7.2 ± 0.3, n=8)(p=0.014). The group treated with tobramycin alone was stationary in bacterial load in valve vegetations, from 3DPI (n=8) to 4DPI (n=6). **Conclusion:** Consecutive HBOT reduced the bacterial load in valve vegetation in experimental SA IE in tobramycin treated rats. The effect was postponed in animals with high-grade IE. The present results suggests HBOT may prove beneficial as adjunctive treatment of IE.

Evidence of Bacterial Genomic Variation Contributing to Invasive Pneumococcal Disease Manifestation

Author Block:

Y. Li, B. Metcalf, S. Chochua, P. A. Hawkins, R. William, T. Pilishvili, L. Mcgee, B. W. Beall, Active Bacterial Core Surveillance Team; CDC, Atlanta, GA

Abstract Body:

Background: Bacteremia without focus (BwoF) and pneumonia with bacteremia (PB) are the two most common invasive pneumococcal disease (IPD) manifestations in children. It remains unclear whether specific bacterial factors contribute to the development PB over BwoF. Here we aim to identify pneumococcal variants associated with PB among pediatric IPD patients. **Methods:** Blood isolates from patients aged 5 or younger with either BwoF (n=665) or PB (n=346) were obtained through the Active Bacterial Core surveillance in years 1998, 1999, 2009, 2012, and 2013. Short reads from Illumina whole genome sequencing were mapped onto 3225 non-redundant pneumococcal coding DNA sequences (CDSs) to identify single nucleotide polymorphisms (SNPs), insertion/deletions, and gene absence. Association between PB and each variant was assessed by a Mantel-Haenszel (MH) test conditioned on patient age and sample year. Frequency of candidate variant was also examined in 17 pleural fluid (PF) isolates from the same patient population.**Results:** After Bonferroni correction, 5 non-synonymous SNPs in 3 CDCs showed p-value<0.05 in the MH test, hence identified as candidate variations. Two candidate SNPs were found in the polar amino acid ABC uptake transporter substrate binding protein gene (*paat*) and they exhibited strong linkage disequilibrium (r^2=0.98). In a multivariate analysis, patient age, surveillance year, and serotype were significant predictors of IPD syndrome. After controlling for these covariates, snp2401844A allele in *paat*, and no variant in other genes, showed association with PB (OR=2.25, 95% CI 1.08-4.67). The frequency of snp2401844A allele in the 17 PF isolates (0.29, 95% CI 0.10-0.56) was also significantly higher than that of the BwoF isolates (0.03, 95% CI 0.02-0.05).**Conclusion:** Genomic variation in pneumococcus appears to contribute to IPD manifestations among patients aged 5 years or younger. Serotype was a major but not the only pneumococcal determinant of IPD syndrome. How the snp2401844A allele in *paat* may facilitate lung infection deserves further investigation, including confirmation of this association.*The findings and conclusions in this report are those of the author(s) and do not necessarily represent the official position of the Centers for Disease Control and Prevention.*

Inhibition of Epithelial-Mesenchyme Transition Prevents Genital Chlamydia-Induced Complications

Author Block:

J. U. Igietseme[1], Y. Omosun[2], O. Stuchlik[1], M. Reed[3], C. M. Black[3], J. Pohl[3], J. Pohl[3], F. O. Eko[1], Q. He[2]; [1]CDC/NCID, Atlanta, GA, [2]Morehouse Sch. of Med., Atlanta, GA, [3]CDC/NCEZID, Atlanta, GA

Abstract Body:

Chlamydia trachomatis genital infection in women causes severe reproductive complications and is a strong co-factor for human papilloma virus (HPV)-associated cervical carcinoma. We have recently showed that chlamydia infection induces epithelial-mesenchyme transition (EMT) through caspase-mediated miRNA dysregulation that drives the development of complications. We tested the hypothesis that EMT inhibitors will prevent the key complications of chlamydial infection, especially reproductive tract inflammation, fibrosis, infertility, and promotion of HPV-related cervical carcinoma. Here we report that caspase inhibitors prevented chlamydia-induced EMT and the associated pathologies, including inflammation and infertility. Additionally, we found that, similar to estrogen, chlamydial infection promoted cervical epithelial hyperplasia in the HPV 16 E6/E7 transgenic mouse model of cervical carcinoma, which requires estrogen as co-factor for accelerated development of invasive cervical carcinoma. Therefore, the use of EMT antagonists provides a therapeutic strategy against the complications of genital chlamydial infections, as well as against HPV-related cervical carcinoma. Furthermore, EMT components are potential biomarkers for monitoring the development of complications of chlamydia genital infection and for assessment of the therapeutic efficacy of candidate treatment regimens.

High Dietary Salt Intake Exacerbates *helicobacter pylori*-induced Iron Deficiency Anemia And Gastric Ulceration

Author Block:

A. C. Beckett, M. B. Piazuelo, J. M. Noto, R. M. Peek, Jr., H. M. S. Algood, T. L. Cover; Vanderbilt Univ. Sch. of Med., Nashville, TN

Abstract Body:

Background: Iron deficiency is the most prevalent nutritional disorder in the world, and often results in iron deficiency anemia (IDA). Human epidemiologic and animal studies suggest that *H. pylori* is linked to iron deficiency, but data regarding IDA are conflicting. High salt and low iron diets augment *H. pylori* virulence and are known to be risk factors for gastric cancer. Therefore, we hypothesized that *H. pylori*-associated IDA is promoted by increased dietary salt concentrations. **Methods:** Mongolian gerbils (either *H. pylori*-infected or uninfected) received one of four diets: normal, high salt, low iron, or combination high salt/low iron. Hematologic parameters and gastric histology were analyzed at 14 weeks post-infection. **Results:** *H. pylori*-infected animals had significantly lower hemoglobin values than their uninfected counterparts ($P<0.0001$). The greatest reduction in hemoglobin occurred in infected animals consuming a combination diet, indicating a role for both dietary iron and salt concentrations ($P<0.05$). Mean corpuscular volume (MCV) and serum ferritin values were also significantly reduced among *H. pylori*-infected animals when compared to uninfected cohorts. ($P<0.0001$). IDA (defined based on analyses of hemoglobin and serum ferritin) occurred only in infected animals, and increased in a diet-dependent fashion among the infected cohorts. Infected animals maintained on a combination diet experienced the highest rate of IDA (90%). A subset (30%) of the *H. pylori*-infected animals maintained on a normal diet developed IDA, indicating that *H. pylori* infection alone can cause IDA. Interestingly, gastric ulceration was detected in 67% of infected animals on a high salt diet compared to 30% of infected animals on a normal or low iron diet. Uninfected animals did not develop gastric ulcers, demonstrating an essential role for *H. pylori* in this process. Gastric pH was elevated in all infected cohorts. **Conclusions:** *H. pylori* infection promotes the development of IDA, and the risk of IDA is influenced by composition of the diet. We propose a model in which *H. pylori* promotes development of IDA through multiple mechanisms, including iron loss through bleeding ulcers and reduced absorption of dietary iron due to increased gastric pH.

Does Repeated Administration and Accumulation of Nanoparticles Increase Susceptibility of Mice to *Listeria monocytogenes*?

Author Block:

S. A. KHAN[1], K. Sung[1], B. Marasa[2], M. Nawaz[1], C. Cerniglia[1], A. Paredes[1], T. Ingle[1], P. Howard[1], A. Patri[1], Y. Jones[1], K. Tyner[2]; [1]Natl. Ctr. for Toxicological Res., JEFFERSON, AR, [2]Ctr. for Drug Evaluation and Res., Silver Spring, MD

Abstract Body:

It has been previously demonstrated *in vitro* that the accumulation of gold, silver, and silica nanoparticles (NPs) within macrophages reduces their ability to phagocytize bacteria. Impaired macrophage function may lead to an increased risk of infection. Whether this reduction in macrophage activity was preserved *in vivo* in non-clinical models and/or has a potential clinical impact has not been established to date. The focus of this study was to determine whether animals exposed up to 8-weeks to pharmacologically-relevant levels of gold (10 nm), silver (50 nm), and silica (10 nm) nanoparticles are more susceptible to *Listeria monocytogenes* (LM) infection. Eighty female BALB/c mice were divided in to 5 groups of 16 mice each. Animals in the vehicle control, silver and gold NP groups were subjected to weekly injections with 5% dextrose water, or 5 or 10 mg/kg body weight (BW) of NPs via tail vein for up to 8 weeks; the animals in silica NP group received weekly injections at 5 mg/kg BW for two weeks. This was followed by intraperitoneal injections of cyclophosphamide (CY) (80 mg/kg) in the positive control group of animals. All the animals were injected with 2,500 colony forming units (CFU) of LM via tail vein at 24 h after CY injections. On day 3 and 10 after LM injections, the animals were sacrificed and their livers, lungs, and spleens were collected for elemental analysis, electron microscopy, and viable LM count determination. The infection with LM resulted in an enlargement of spleen, liver, and lung. On day 3, the highest LM counts ($1\text{-}10^6$ CFU/gm tissues) were observed in spleen followed by liver and lungs. On day 10, most animals cleared *Listeria* from all the tissues suggesting that repeated administration and bioaccumulation of NPs in macrophages did not increase animal's susceptibility to bacterial infections. The data from this *in vivo* study is important to determine the impact of nanoparticle-based therapeutics and the immunological impact of accumulation of the nanoparticle-carrier. This will assist regulatory agencies in determining (i) the impact of nanomaterials and (ii) methodological approaches to evaluate the biological impact and risk.

Differential Characterization of Gene Expression Patterns in Pbmc of Children Who Have Recurrent Middle Ear Infections Compared to Non-Otitis Prone

Author Block:

R. Kaur[1], R. Kennedy[2], J. Casey[3], M. E. Pichichero[1]; [1]Rochester Gen. Hosp., Rochester, NY, [2]Mayo Clinic, Rochester, MN, [3]Legacy Pediatrics, Rochester, NY

Abstract Body:

Background: We used transcriptomic high-dimensional Next-Generation Sequencing to characterize the profile of peripheral blood mononuclear cells (PBMCs) from children who got recurrent middle ear infections called otitis-prone (OP) and non-OP during their healthy stage and during acute otitis media (AOM) episodes.**Methods:** RNA was extracted from PBMC of 12 children age between 9-15 months and sequenced using the Illumina HiSeq 2000 platform. Differential expression analysis comparing the OP subjects relative to the non-OP subjects was done using the edgeR package in R.**Results:** Results are reported within the healthy and AOM visits, as $\log_2$ of the fold change for the OP relative to the NOP, with corresponding p-values and false discovery rates. Following normalization 13,528 genes in healthy and 13248 genes during AOM visits were analyzed for differential expression between OP and NOP children respectively. Despite the relatively small sample size we identified significant expression differences in 39 and 31 genes ($p < 0.0003$ and $q \leq 0.1$) in OP children during healthy and AOM state respectively. A KEGG pathway enrichment analysis identified the complement and coagulation cascades pathway as being differentially downregulated (p=0.0006) in OP children during healthy state including genes C1, C2, C1qA and C3AR1. This pathway is a mediator of innate immunity leading to opsonization of pathogens, the recruitment of inflammatory and immunocompetent cells, and the direct killing of pathogens. Chemokine signaling pathway also showed differential trend (p=0.08) with the analysis. During the AOM state only one pathway, "Pathogenic Escherichia coli infection" emerged as different in OP (p=.08). Long Intergenic Non-Protein Coding RNA gene and some ubiquitin (USP32) encoding genes showed downregulation. Gene DSP encode for Desmoplakin was 10 fold upregulated that has shown to regulate the functions of chemical signaling pathways, cell differentiation and apoptosis.**Conclusions:** OP children are characterized by differential expression of selected genes in PBMC in both their healthy as well as during AOM state. The differential genes are mostly related to innate immune system.

Nutritional Cues And Genetic Determinants For Biofilm Formation By An *acetobacter* Isolate From The Fruit Fly *drosophila Suzukii*

Author Block:

P. D. Newell, S. Magalhães Moreira; Oswego State Univ. of New York, Oswego, NY

Abstract Body:

The fruit fly *Drosophila melanogaster* has proven to be a successful model animal for studying host-microbiota interactions, thanks in part to a gut microbiota that is easily cultured and manipulated *in vitro.* While substantial progress has been made in characterizing the composition and function of the gut microbiota in this model animal, less is known about that of its cousin *Drosophila suzukii* (a.k.a Spotted-wing *Drosophila*), an emerging agricultural pest that infests fresh and ripening soft fruit. To explore the biology of bacteria associated with *D. suzukii*, *Acetobacter* sp. DsW_54 was isolated from the gut of a fly caught on raspberries in the field and its genome sequenced. In this study we characterized its growth and capacity for biofilm formation in dilute media amended with various carbon sources. Next, the bacteria were subjected to transposon mutagenesis followed by screening and enrichment strategies to isolate mutants with reduced or increased biofilm formation *in vitro*. Of 3,000 mutants screened, 19 showed a reduced ability to form a biofilm while 7 showed increased levels compared to wildtype. Transposon insertion sites were mapped by arbitrarily primed PCR and found within genes predicted to affect numerous cellular processes, including some typically associated with biofilm formation, e.g. flagellar motility. Finally, we utilized the newly isolated mutants to examine whether the capacity for biofilm formation *in vitro* correlates with the ability of *Acetobacter* to colonize and persist within *Drosophila.* The results show that some but not all biofilm-deficient mutants are affected for these phenotypes, and suggest that colonization is influenced by the diet of the host. In summary, *Acetobacter* sp. DsW_54 is useful strain for investigating the genetic requirements for colonization of abiotic surfaces as well as interactions between fruit flies and their gut microbiota. Future studies will investigate the mechanisms of colonization as well as the role that switching between sessile and motile lifestyles might play during the various life stages of the host.

Manipulating the Host-Microbe Phenotype in *Nasonia* Through Environmental Stressors

Author Block:

R. Brucker; Harvard Univ., Cambridge, MA

Abstract Body:

Background: The innate immune system functions to protect the animal from complications arising from injury, combating disease, and regulating the microbial community. A dynamic environment can influence the regulation of the host immune system by stimulating or suppressing regulation during stressful conditions; however, when the environment stresses the microbial community, how does the host respond? Do phenotypic traits arise when host-microbe relationships are stressed by the environment? Using the model system *Nasonia*, we use xenobiotics to stimulate changes to‘ the microbial community and determine host immune response and adaptation across host generations due to the changes in the microbial community.**Methods/Results:**Successive generations of xenobiotic-exposed animals were used to observe changes in microbial communities and innate immune regulation. Using NGS approaches, we determine that microbial community changes as well as variations in host immune expression are responding to acute and long-term exposure to environmental stresses. Likewise, metabolite production, mating behavior, and fitness were compared between populations. Furthermore, we compare immune regulation in germfree experiments from derived populations of xenobiotic and control *Nasonia* to conventional and artificial microbiota inoculated wasps and observe clear adaptation of the microbiome to prolonged exposure to environmental toxins.**Conclusion:**We observe heritable changes in the microbial community in response to xenobiotic exposure. The link between host microbiota and innate immunity during successive generations of xenobiotic exposure can result in positive adaptation by the host to environmental stressors.

Antimicrobial Activity in Actinobacteria Associated with Monarch Butterflies (*Danaus plexippus*)

Author Block:

D. J. Desautels, A. J. Book, C. R. Currie; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

There is a current crisis involving the evolution of antibiotic resistance in human bacterial and fungal pathogens. Multi-drug resistant pathogens are emerging at an alarming rate and the discovery of new antimicrobial compounds is slowing. Thus, discovery of novel antibiotic compounds is essential for maintaining health standards across the world. One major problem with the classic discovery pipeline is that it relies heavily on free-living soil microbes and the discovery of novel compounds from this source is increasingly rare. Previous research from our lab has shown that insects such as leaf-cutter ants and bark beetles harbor microbial symbionts that protect them from pathogens by producing antimicrobial compounds, some of which may are effective against human pathogens. The migratory lifestyle of the Monarch butterfly (*Danaus plexippus*) makes it an ideal candidate for symbiotic association with a protective symbiont. Each year the Monarch embarks on a long migration to Mexico, where millions of butterflies overwinter in trees in extremely dense populations. We propose this is an evolutionary pressure to select for microbial symbionts that protect the dense population from infection. Currently, little is known about the microorganisms associated with Monarch butterflies. We collected Monarch butterflies in Eastern Wisconsin after their migration north and used culture-dependent methods to obtain over 60 Actinobacteria isolates based on 16S sequencing. We will utilize bioassays with these Actinobacteria against ecologically relevant pathogens of monarch butterflies along with human pathogens to test for antimicrobial activity. Priority strains will be analyzed by LC-MS metabolomics and whole genome sequencing to identify novel secondary metabolites and gene clusters. This work will provide insight into the role of symbiotic Actinobacteria and Monarch hosts, as well as identifying antimicrobial compounds that may be useful treatments for human pathogens.

AI-2 Mediated Quorum Sensing by Microbial Symbionts within the European Honey Bee (*Apis mellifera*)

Author Block:

K. I. Miller, I. L. G. Newton; Indiana Univ., Bloomington, IN

Abstract Body:

Background: The European honey bee (*Apis mellifera*) is a charismatic species that plays a critical role in the pollination of agriculturally important crops and native flora. The recent and dramatic decline in colony numbers maintained in the United States has spurred researchers to both examine potential causes of the decline and identify factors that contribute to the health and well-being of the honey bee. One emerging field of research is that of the host-associated honey bee microbiome: a group of bacterial phylotypes consistently found within the honey bee and are thought to play critical roles such as protection from pathogens and nutrient acquisition. In other model systems, host-associated microbial communities are known to participate in a form of bacterial communication known as quorum sensing. This type of communication allows a bacterial community to sense their environment and respond with changes in gene expression, controlling a number of factors including virulence, biofilm formation, and cell motility. **Methods:** For the first time, we have investigated the production of quorum sensing molecules from honeybee specific microbiota *in vivo* and *in vitro*. We specifically looked for the presence of an important type of communication molecule: the inter-species autoinducer-2 (AI-2). To determine this, we used genetic data from the honey bee meta- genome and transcriptome and biosensors to look for the production of AI-2 both *in vivo* and *in vitro*. **Results:** The metagenome and the metatranscriptome showed the presence and transcription of the LuxS gene, respectively. Using biosensors, we confirmed the production of AI-2 both *in vivo*, using whole gut sections, and *in vitro*, using honey bee specific bacterial isolates. Additionally, using honey bee specific bacterial isolates, we have shown an increase in biofilm production when isolates are exposed to increased levels of AI-2. **Conclusions:** Together, these data provide multiple lines of evidence for the presence of quorum sensing inside the honey bee host. The effect of AI-2 on biofilm formation from honey bee specific bacteria shows one potential avenue for quorum sensing to affect host health. Future research will further investigate these interactions and their impacts on honey bee health.

Characterization of the *Trachymyrmex septentrionalis* Fungus Garden Microbial Community

Author Block:

K. M. Lee, J. L. Klassen; Univ. of Connecticut, Storrs, CT

Abstract Body:

The multi-partite fungus-growing ant symbiosis of *Trachymyrmex septentrionalis* is an established model for coevolution and secondary metabolite ecology. Like all fungus-growing ants, *Trachymyrmex* cultivate and maintain a "fungus garden" consisting primarily of a specific *Leucoagaricus sp.* (cultivar) fungus. The ants provide food for this fungus in the form of fresh leaf cuttings, oak seed pods (catkins), and frass (feces) from caterpillars. In return, the fungus produces specialized hyphal swellings that the ants consume as their primary food source. Such a rich nutrient source is not without predators, mainly other fungal species. To combat predation, the ants host a bacterial symbiont from the genus *Pseudonocardia* within specialized crypts that chemically defends the cultivar fungus. The cultivar fungus itself also hosts its own microbial community. What is less well understood is the composition and potential function of this microbial community. Using the *Trachymyrmex septentrionalis* fungus-growing ant system we are characterizing the composition, diversity, and potential interaction networks of the fungus garden microbial community. Because most of the food items incorporated into the fungus garden are either plant based (leaves and catkins), or derived from plant material (frass), the garden material contains many potential inhibitors of enzymes used in PCR. To overcome this difficulty, we have adapted previous methods to separate fungus garden bacteria from the fungus garden matrix to reduce and overcome PCR inhibition. Our community amplicon sequencing data generated from these techniques suggest that the microbial community associated with the fungus garden may be partitioned into two main fractions, one being highly transient and the other persistent. The sampled "microbiome" may therefore be a composite of"symbionts" that are important for fungus garden growth and immigrants that have neutral or detrimental effect on community function.

Microbe Vs. Microbe: Bacterial and Fungal Cultivar Interactions in a Fungus-Farming Ant System

Author Block:

S. M. Kopac, J. Klassen; Univ. of Connecticut, Storrs, CT

Abstract Body:

Microbes live in close association with one another in the *Trachymyrmex septentrionalis* fungus-farming ant system, providing a framework for potentially undiscovered and understudied microbial interactions. Leafcutter ants, which belong to the same tribe as *Trachymyrmex*, are characterized by evolutionarily conserved interactions between pathogens and protective bacteria carried by the ants; similar dynamics might exist in the *T. septentrionalis* system. Interestingly, the role of bacteria living in the fungus garden (the cultivar) are not well characterized in either system. From a preliminary survey of 33 strains of fungus garden bacteria we identified over a dozen species, including Actinomycetales, Enterobacteriaceae, Lactobacillales and Bacillales. We found that many of these microbes have negative or positive effects on each other's growth. In the present study we focus on the interactions between these bacteria and with that of the cultivar.We characterized bacterial isolates to the species level and determined if they are persistent or transient members of the cultivar community by identifying conserved clades in a phylogeny of isolates from multiple fungus gardens. Conserved clades could be the result of bacterial-bacteria or cultivar-bacteria interactions on the assembly and maintenance of the fungus garden bacterial community or the result of abiotic conditions.Interactions between microbes from our system were assessed by growth assays; cross-streak growth assays for inhibition and spot plate co-cultures for beneficial and mutually beneficial interactions. The effect of bacteria on cultivar growth was tested using pour plate assays with an overlay. We tested for coevolution at the colony level by comparing the number of interactions between bacteria and bacteria/cultivar from the same colony vs. from different colonies. We also tested close relatives of bacterial isolates to determine if specialization to fungus gardens occurs at the clade level.In collaboration with JGI, the genomes of several isolates were sequenced using SMRT technology developed by PacBio. Genome content comparisons were made, with specific focus on genes associated with secondary metabolites and other forms of microbial interaction and communication. Secondary metabolites possess a variety of functions including antibacterial, antifungal, anti-malarial and anti-cancer properties.

Diversity, Ecology, and Evolution of *Trachymyrmex septentrionalis* Associated *Pseudonocardia*

Author Block:

S. L. Goldstein, J. L. Klassen; Univ. of Connecticut, Storrs, CT

Abstract Body:

The discovery of antibiotics was one of the chief scientific breakthroughs of the 20th century. However, the indiscriminate use of antibiotics has lead to antibiotic resistance becoming one of the greatest scientific crises of the 21st century. Although the natural diversity and function of these compounds remains largely unknown, an improved understanding of the natural functions of antibiotics will allow us to target discovery efforts and understand how antibiotic resistance is overcome in the natural environment. Here, we use the *Trachymyrmex septentrionalis* fungus-growing ant as a model system to study the diversity, ecology and evolution of antibiotics in their natural environment. *T. septentrionalis* participates in a multipartite mutualism consisting of the ants, a specific "cultivar" fungus used as the ants' main food source, and the antibiotic producing bacterium *Pseudonocardia*. *T. septentrionalis* nurtures its fungal cultivar in underground "fungus gardens. *Pseudonocardia* symbionts reside on the propleural plates of the ants and act as "crop sprayers" that use antibiotics to protect the fungus garden from pathogen infection. The antagonistic relationship that exists between *Pseudonocardia* and its target parasites that is mediated by secondary metabolites suggests that *Pseudonocardia* might be a valuable untapped source of natural products. We sampled ~100 *T. septentrionalis* colonies along a transect following the Atlantic coast of the USA. We isolated strains of *Pseudonocardia* from each of these colonies and identified these bacteria using 16S rRNA gene sequencing and phylogenetic analysis. These results indicate that all *T. septentrionalis*-associated *Pseduonocardia* fall within one clade, and were confirmed by genomic data having higher phylogenetic resolution. Together, these data suggest that *Pseudonocardia* symbionts are propagated between generations of their ant hosts with high fidelity. Our results also suggest that secondary metabolite biosynthetic genes differ between geographic locations. These differences in secondary metabolite biosynthetic gene clusters indicate a geographically localized response to pathogen pressure. Tapping into this evolutionary dynamic will grant a better understanding of how antibiotics evolve in the presence of their natural pathogens, and reveal novel chemical diversity that can be exploited for human use.

Abstract Body:

Symbioses between bacteria and eukaryotic hosts are widespread in nature and are found in all realms from the deep-sea to the human gut. In most cases the bacterial partners have essential roles being involved in e.g nutrition, niche adaption, and detoxification. Yet, only few symbioses and the involved host-microbe interactions are well understood. Here we investigated a so far unknown association between bacteria and the water scorpion *Ranatra fusca*, an insect that is very common in freshwater and brackish ecosystems in North America. The R. fusca specimens originated from Trunk River, a brackish, sulfide and methane-rich pond close to Woods Hole, MA. We observed that the insects had a thick biofilm on their carapace, which is uncommon for this species, and hypothesized that it could be a layer of sulfur-oxidizing bacteria. To analyze bacteria and host in detail we used cultivation approaches, 16S rRNA gene libraries, fluorescence *in situ* hybridization as well as high-resolution fluorescence and scanning electron microscopy. Our results show that the biofilm indeed consists of aggregates of sulfur-oxidizing *Gammaproteobacteria*, most likely of the genus *Thiothrix*, that are embedded in a matrix of algae and other bacterial assemblages. Considering the very high sulfide concentrations in the ecosystem and the predatory life-style of the insect we propose the following mutually beneficial association: The bacteria are involved in sulfide detoxification for the host, while being attached to the insect enables them to hitch rides between oxic and sulfidic layers, having the ideal niche for sulfur oxidation. Although further investigation is needed our results indicate a novel association between bacteria and insects that may be widespread in brackish ecosystems along the American East Coast.

Acetogenesis and Fermentation in the Gut of the Methane-Emitting Earthworm Eudrilus Eugeniae

Author Block:

S. Hunger[1], C. Bruss[1], R. Conrad[2], H. L. Drake[1]; [1]Univ. Bayreuth, Bayreuth, Germany, [2]MPI für terrestrische Mikrobiologie, Marburg, Germany

Abstract Body:

The earthworm gut represents a saccharide rich and anoxic habitat. The earthworm *Eudrilus eugeniae* emits H_2 and methane, indicating that anaerobic processes such as fermentation and methanogenesis are ongoing in the earthworm gut. Based on the occurrence of strictly anaerobic processes, we hypothesized that acetogenesis might also be an ongoing process in the gut of *E. eugeniae*. This hypothesis was addressed by (a) RNA-based stable isotope probing with [^{13}C]-glucose as a model saccharide in anoxic slurries with gut contents of *E. eugeniae*, (b) molecular analysis of bacterial 16S rRNA and *fhs* (encoding formyl-H_4F synthetase), and (c) cultivation-dependent methods. The degradation of [^{13}C]-glucose yielded various fermentation products that were enriched in ^{13}C (such as acetate, CO_2). Methane was produced in similar amounts in unsupplemented and [^{13}C]-glucose-supplemented slurries, and was enriched in ^{13}C during the degradation of [^{13}C]-glucose. H_2 and CO_2 that were added as co-substrates to [^{13}C]-glucose-supplemented slurries drove the production of acetate and decreased the enrichment of ^{13}C in acetate (in comparison to [^{13}C]-glucose-supplemented slurries without H_2), indicating that acetate was derived in part from H_2-dependent acetogenesis. An acetogenic enrichment that was obtained from gut contents converted H_2 to acetate in a stoichiometric ratio that was indicative for acetogenesis. Taxa most closely related to fermenters (*Robinsoniella peoriense*, *Citrobacter murliniae, Erwinia persicina*) were labeled by glucose-derived carbon, indicating that those taxa were involved in the anaerobic metabolism of glucose. *Fhs* sequences closely related to acetogens (*Clostridium glycolicum*, *Blautia producta*) were detected in [^{13}C]-glucose-supplemented slurries, suggesting that these taxa were participants in the methanogenic wood web in the gut of *E. eugeniae*.

Inactivation of the Major Hemolysin Gene Influences Expression of Nonribosomal Peptide Synthetase *swra* in the Insect Pathogen *Serratia* sp. Strain Scbi

Author Block:

T. J. Koloski[1], L. M. Petersen[1], K. LaCourse[1], R. Audette[1], T. A. Schöner[2], H. Bode[2], L. S. Tisa[1]; [1]Univ. of New Hampshire, Durham, NH, [2]Goethe Univ. Frankfurt, Frankfurt, Germany

Abstract Body:

A novel *Serratia* sp. (termed SCBI) forms a mutualistic association with South African *Caenorhabditis briggsae* nematodes isolated through bait trapping within the greater wax moth, *Galleria mellonella.* This association represents a newly identified microbe-nematode relationship and shows potential as a nascent entomopathogenic system. Genetic and genomic approaches were used to understand the physiology of the insect pathogen *Serratia* sp. strain SCBI. Screening a strain SCBI fosmid library in *Escherichia coli* EPI300 cells revealed that several fosmids were virulent to our insect model system, *Manduca sexta*, the tobacco hookworm. One fosmid, A1-A8, was lethal to 73% of injected *M. sexta* and conferred hemolytic activity. Deletion of the major hemolysin gene in this fosmid removed the phenotype. A previously generated SCBI transposon library was screened and five hemolytic transposon mutants were identified with inserts within the major hemolysin gene. Inactivation of this hemolysin gene resulted in the loss of hemolysin activity, but did not attenuate insecticidal activity. Unexpectedly, these hemolysin mutants showed increased motility and antimicrobial activity. qPCR analysis of the hemolytic mutants showed an increased in mRNA levels of the nonribosomal peptide synthetase *swrA*, whose product produces serrawettin W2. Mutation of the *swrA* in strain SCBI resulted in highly variable antibiotic activity, motility, and hemolysis phenotypes dependent on the site of the disruption within the 17.75 Kb *swrA* gene. RT-PCR and qPCR analysis revealed differential expression patterns of the *swrA* gene for the three *swrA* transposon mutants. Two mutants with insertions in later portions of the gene showed expression of the gene up to the disruption site. However, one mutant with an insertion in the initial portion of the gene allowed expression of the gene downstream of insertion site, suggesting an internal regulatory element enhancing gene expression. While it is unclear how inactivation of the major hemolysin gene influences *swrA* expression, these results suggest that *swrA* plays an important role in motility and antimicrobial activity in *Serratia* sp. strain SCBI.

ahpc* Expression in *Vibrio fischeri

Author Block:

A. Sánchez Peña, W. X. Torres Pérez, Z. Flores-Cruz; Univ. of Puerto Rico, Río Piedras Campus, San Juan, PR

Abstract Body:

Vibrio fischeri is a bioluminescent marine bacterium that forms a beneficial symbiosis with the Hawaiian bobtail squid, *Euprymna scolopes*. During the interaction, *V. fischeri* experiences oxidative stress when exposed to host derived reactive oxygen species (ROS). This bacterium contains a high abundance of Alkyl hydroperoxide reductase (AhpC), which is predicted to degrade peroxides, suggesting that it may be important during host interaction. In this study we investigated *ahpC* expression in different *V. fischeri* mutant backgrounds, different growth phases and oxidative stress conditions caused by methyl viologen. The mutant backgrounds used were *ahpC* mutant, catalase mutant and an *ahpC*/catalase double mutant. *ahpC* expression increased as the growth phases progressed, was significantly higher in the mutant backgrounds than in the wild-type parental strain, and was further induced when grown in the presence of methyl viologen. Among the mutant backgrounds, on average, *ahpC* expression was highest in the *ahpC* mutant strain. Together, these results suggest that the mutant strains are experiencing oxidative stress and that this stress induces the expression of *ahpC*. Future work will include expression studies of catalase gene.

The Symbiotic Microbiome of Staghorn Coral *A. cervicornis* is Affected by Solar Radiation

Author Block:

A. Rivera[1], B. Cabera[1], F. Godoy-Vitorino[1], C. Toledo[2]; [1]Inter American Univ. of Puerto Rico, San Juan, PR, [2]Univ. of Puerto Rico, San Juan, PR

Abstract Body:

Background: Coral reefs are the most diverse ecosystems in the marine realm and among them, *A. cervicornis,* plays crucial services to an array of different species. In recent years however, this coral has suffered unprecedented mortality with no significant recovery across its entire range. The causes are variable and included diseases and climate change related stresses such as bleaching. Based on this, *A. cervicornis* is considered a threatened species under the US Endangered Species Act. In this project we aim to address the effect of depth-associated factors such as solar radiation, on the microbiome of *Acropora cervicornis* at two water depths. **Methods:** Six *A. cervicornis* fragments from different individuals at two depths (three at 1.5 and three at 11m) were collected from Palomino an island 3.2km off the northeast coast of Puerto Rico. Each fragment was used for genomic DNA extractions and the 16S rRNA gene region V4 was sequenced with the Illumina platform. Data analyses was done using the QIIME pipeline with the Greengenes database. **Results:** A total of 1,314,293 good-quality sequences were binned into 2,427 OTUs. Overall we found a total of 16 Phyla with a dominance of *Proteobacteria (Rhicketsiales)* (90%), followed by *Firmicutes* (4%), *Planctomycetes* (2.5%) among other taxa at lower abundance. Considering taxa with <10% relative abundance, we found that corals receiving at shallower depths had 11 phyla with a higher amount of Proteobacteria (Pseudomonas, Acinetobacter and Rhodobacteraceae)(~50%), Planctomycetes (Pirellulaceae) (19%) and Cyanobacteria (Oscillatoria and Rivularia)(~8%); while those at higher depths had 15 phyla with a dominance of Proteobacteria (*Psychrobacter, Acinetobacter* and unclassified Campylobacterales) (~43%), Firmicutes (*Streptococcus* and *Lactobacillus* mainly) (~33%), and Actinobacteria (*Corynebacterium* and *Micrococcus*) (10%). **Conclusion:** The microbiome of *A. cervicornis* is dominated by a Rickettsiales-like bacterium with changes in low dominance taxa according to water depth. Corals at shallow depths have a higher abundance of ammonia oxidizers and nitrogen-fixing taxa revealing bacterial-mediated nitrogen cycling in the coral-microbiome holobiont which may confer an advantage over the depth zone individuals in restoration procedures.

Genomic and Metabolite Divergence in Cyanobacterial Symbionts of Dysideidae Sponges

Author Block:

J. M. Blanton, S. Podell, V. Agarwal, B. S. Moore, E. E. Allen; Univ. of California San Diego, La Jolla, CA

Abstract Body:

Certain members of the tropical marine sponge family Dysideidae have co-evolved with strains of cyanobacteria identified as *Oscillatoria spongeliae* living within their tissues. These sponges are of interest as natural sources of potentially toxic polybrominated diphenyl ethers (PBDEs). Here we investigate the relationship between host genotype, symbiont genotype and PBDE biosynthesis using targeted gene sequencing and shotgun metagenomics. Samples from 17 sponges initially identified as *Dysidea granulosa* and *Lamellodysidea herbacea* were collected from Guam coastal reefs and evaluated for the presence and composition of PBDEs by LC-MS/MS. Ribosomal gene markers were amplified and sequenced to reconstruct host and symbiont phylogenies. As *Oscillatoria spongeliea* has yet to be cultivated, whole sponge samples were sequenced using shotgun metagenomic methods. Symbiont genomes and PBDE biosynthetic gene clusters were reconstructed through de novo metagenome assembly and phylogenetic binning analyses. Sponge-symbiont chemotypes, including the absence of PBDE chemistry, were identified and correlate strongly with both host and symbiont clades. Analysis of binned metagenomic assemblies indicate that the PBDE biosynthetic cluster is of cyanobacterial origin, not derived from the host sponge. Comparison of the symbiont genomic data analyzed to date shows varying degrees of divergence between strains (95-99% average nucleotide identity). The chemical variability of Dysideidae sponges is linked to diversification of the sponge-bacteria holobiont. While the *Oscillatoria* symbiont is responsible for production of polybrominated diphenyl ethers in sponges, host sponge phylogeny is a stronger predictor of the primary chemotype. This work demonstrates the utility of metagenomic methods in performing comparative genomic analysis on uncultured microbial symbionts of metazoan hosts.

Unprecedented Diversity of Myxotroph Communities in Three Species of Crabs in Puerto Rican Red and Black Mangroves

Author Block:

Y. Diaz[1], G. Ortiz[1], M. Cafaro[2], F. Godoy-Vitorino[1]; [1]Inter American Univ. of Puerto Rico, San Juan, PR, [2]Univ. of Puerto Rico, Mayaguez, PR

Abstract Body:

Background: The karst region of Puerto Rico contains mature forests of red (*Rhizophora mangle*) and black (*Avicenia germinans*) mangroves with a diversity of crabs that are distributed according to salinity and tree diversity. Red mangroves harbor *Goniopsis cruentata in their flooded roots,* and *Aratus pisonii* in the canopy, while black mangroves sustain *Uca rapax fiddler* crabs. Mangrove leaves and derived detritus are an important food source for these macroinvertebrates and their foraging and feeding activities directly influence the availability of organic carbon and nutrient cycling. The present study was carried out to understand the microbiome community composition and functional diversity among three different species of crabs in response to their feeding behaviors and trophic niches. **Materials:** A total of 10 samples were obtained from *Aratus pisonii*, *Goniopsis_cruentata* and *Uca_rapa*x, which underwent genomic DNA extractions and the 16S rRNA gene region V4 was sequenced with the Illumina platform. Data analyses was done using the QIIME pipeline with the Greengenes database. **Results:** A total of 3,953,258 good-quality sequences were binned into 411,484 OTUs. Overall we found a dominance of Proteobacteria and Tenericutes in *A. pisonii* and *G. cruentata with other 20 and 29 phyla respectively. U. rapax* crabs had a dominance of Tenericutes (~80%) (unclassified Mollicutes family), Gammaproteobacteria and Planctomycetes (Pyrellulaceae) with 58 other rarer phyla. A total of 3,800 archaeal OTUs were found with 90% belonging to *Uca* rapax with a dominance of *Nitrosopumilus* and *Cenarchaeum,* while *Aratus* and *Goniopsis* had abundant *Nitrosphaera* OTUs. **Conclusion:** Preliminary results indicate that the zonation recognized for the mangrove crabs is mimicked by the crab-associated microbiome that is species-specific, very diverse with dominant and novel Tenericute-associated taxa. Overall red mangrove crabs had dominant halotolerant bacteria with carbohydrate degrading taxa as well as ammonia oxidizers. Black mangrove associated *U. rapax* had a very high microbial diversity with a dominance of sulfate reducers, nitrate reducers and ammonia-oxidizers suggesting and adaptation of the crab microbiomes to high sulfate and low ammonia concentrations and a possible mixotrophic lifestyle.

Multilocus Sequence Typing Analysis of the *Francisella*-like Endosymbiont of Ixodid Ticks

Author Block:

Z. C. Holmes, M. J. Pung, M. L. Zambrano, J. R. Hensley, G. A. Dasch; Rickettsial Zoonoses Branch, CDC, Atlanta, GA

Abstract Body:

The *Francisella*-like endosymbionts (FLE) of Ixodid ticks have been detected and distinguished from free-living *Francisella* (FLA), primarily by sequencing of the 16S rRNA gene. In some populations of ticks, a number of single nucleotide polymorphisms (SNP) have been detected; however, only 4 of 11 FLA multilocus sequencing typing assays (MLST) gave products with *Dermacentor variabilis* FLE, and their sequences differed greatly from FLA. We developed primers for nine FLE MLST targets and sequenced those amplicons in order to define the population diversity of FLE in *Amblyomma maculatum* from Georgia and Oklahoma, *D. occidentalis* from California, *D. andersoni* from Montana, and three populations of *D. variabilis* from Georgia, Ohio, and California. In order to select MLST sites, we performed a sliding window analysis of the nine MLST targets and determined the most informative 400 bp window from each gene. The sliding window analysis was performed with the R package "spider" on sequence alignments of FLA for which whole genome sequences were available and our FLE data. This approach informed us of the sites which exhibited the greatest rates of polymorphisms in FLA and therefore had a higher probability of exhibiting polymorphisms in the FLE. Analysis of 2048 bp of sequence from five of these MLST targets detected 59 SNPs, 13 of which occurred in more than one tick FLE sample and were therefore phylogenetically informative. Each species of surveyed tick harbors a specific dominant genotype of FLE, and the FLE from East Coast populations of *D. variabilis* (GA and OH) are distinct from FLE from West Coast populations (CA). A 408 bp region of the *fop*A1 outer membrane protein and a 257 bp region of the *atp*G ATP synthase gamma chain genes contained 14 and 7 SNPs, respectively. All sequenced FLE populations were distinguishable from the others by a minimum of two SNPs in both gene regions. Across all five gene regions, each FLE population is distinguishable from all others by a minimum of 7 SNPs and up to 41 SNPs. FLE in California *D. occidentalis* differed from those of *D. variabilis* collected from the same site. The inferred phylogeny of the FLE suggests that different species of ticks harbor distinct genotypes of FLE which are not shared, even when two species occur sympatrically, and that some ticks contain more than one genotype of FLE.

Assessing Exchange of *Rickettsia, Coxiella,* and *Francisella* Agents Between *Amblyomma Americanum* and *Amblyomma maculatum* Ticks in Georgia

Author Block:

J. R. Hensley, M. L. Zambrano, A. J. Williams-Newkirk, G. A. Dasch; CDC, Atlanta, GA

Abstract Body:

Two abundant species of aggressive ticks commonly feed on humans in Georgia: the Gulf Coast tick (*Amblyomma maculatum*) and the lone star tick (*A. americanum*). *A. maculatum* is the primary vector of *Rickettsia parkeri*, *Candidatus* Rickettsia andeanae, and a *Francisella*-like endosymbiont (FLE), whereas *A. americanum* is the primary vector for *R. amblyommii*, *Ehrlichia chaffeensis*, *E. ewingii*, and a *Coxiella*-like endosymbiont (AmCox). Horizontal transmission of *R. parkeri* from *A. maculatum* to *A. americanum* via co-feeding has been described, and *R. amblyommii* has been found infrequently in *A. maculatum* ticks. We assessed whether exchange of tick-associated bacteria is common between *A. maculatum* and *A. americanum* from the same site.Unengorged ticks were collected May-August 2014 in central Georgia from a 4.14 acre site by flagging and from humans and canines. Ticks were identified, washed, and their DNA extracted with the Wizard SV 96 Genomic DNA Purification System (Promega). All DNA samples were screened with qPCR assays for these bacteria found in both ticks, and the species of *Rickettsia* was identified by species-specific TaqMan assays or by sequencing of the *ompA* gene using the BigDye Terminator v3.1 Cycle Sequencing Kit (Applied Biosystems) on an ABI 3130xl Genetic Analyzer.Only *R. amblyommii* (14) and AamCox (39) were detected in 39 *A. americanum*, while the 74 *A. maculatum* only contained *R. parkeri* (30), *Candidatus* Rickettsia andeanae (3), and FLE (74). Neither tick species had either *Ehrlichia*.Consequently, we obtained no evidence for the frequent exchange of these tick-borne agents in a natural setting despite high levels of carriage of each agent and the common observance of infestation with both tick species of dogs and humans at this site. Based on these data, exchange of these *Rickettsia*, *Coxiella*, and *Francisella* agents between *A. maculatum* and *A. americanum* is not common, and if it occurs, it does so at low frequencies, undetectable except with much larger sample sizes.

***Aedes aegypti* Midgut Microbiota May Affect Mosquitoes' Dengue Virus Refractoriness**

Author Block:

E. Molina Henao, Y. Graffe, E. De La Cadena, I. Serrato, A. Correa, C. Ocampo; CIDEIM, Cali, Colombia

Abstract Body:

Dengue is a tropical disease with major distribution in the world, principally transmitted for the mosquito *Aedes aegypti*. We do not have a vaccine for dengue yet, so efforts for decreasing its incidence have been focused in mosquito populations' control. A new promising field has begun to explore vector competence manipulation for endosymbiont microorganisms, which influences mosquito's biology, immune response and the capacity to infect with the virus. So, we looked for identifying culturable A. aegypti midgut microorganisms in three selected strains (susceptible to dengue virus, Cali-S; refractory, Cali-BIM; and wild, Paso del Comercio). We evaluated whether there are differences between their microbial communities, and whether those differences affect mosquitoes' vector competence. In order to do that, we dissected adult mosquitoes midgut from the three strains, plated pools of 5 guts into LB broth and, after 72 hours, isolated bacterial colonies in blood, chocolate and McConkey agars. Bacteria identification was carried out using MALDI-TOF, Vitek, BD Phoenix and 16S rRNA gene sequences. Also, we fed 30 individuals from each strain with a mix of water, sugar and antibiotics and other 30 individuals without antibiotics during 10 days, and then we fed them with blood and dengue virus, and finally we tested vector competence by indirect immunofluorescence in the midgut and salivary glands. The highest bacterial diversity was presented in CALI-BIM with the genera *Pseudomonas*, *Serratia*, *Stenotrophomonas* and *Escherichia*. Meanwhile, Cali-S presented only *Bacillus* and a predominance of *Candida* yeasts. Paso del Comercio strain had also poor diversity and presented only *Bacillus megaterium*. Additionally, the refractory strain (Cali-BIM) was the only one that presented significant differences between the control and antibiotics treated population regarding dengue susceptibility. There were also differences between microbial communities in Cali-S and Cali-BIM, possibly due to a higher antimicrobial immune response in Cali-S; then, elimination of the midgut microbiota probably increases dengue susceptibility in CALI-BIM. Thus, this work suggests that the presence of bacteria in the midgut is influencing the vector competence of *A. aegypti*.

Contribution of SopB, SptP and PphB in the Intracellular Survival of *Salmonella* Typhimurium in *Dictyostelium discoideum* and RAW264.7 Macrophages

Author Block:

I. M. Urrutia, C. A. Santiviago; Univ. de Chile, Santiago, Chile

Abstract Body:

Recently, we demonstrated that *Salmonella* Typhimurium is able to survive in the amoeba *Dictyostelium discoideum*. However, the molecular mechanisms involved in this process have not been characterized. In this work, we evaluated the contribution of SopB, SptP and PphB in the intracellular survival of *S.* Typhimurium in *D. discoideum* and RAW264.7 macrophages. SopB and SptP are well known *Salmonella* virulence factors. SopB is a phosphatidyl phosphatase required for invasion of epithelial cells. SptP is a bifunctional protein harboring a GAP domain involved in Rho GTPases inactivation, and a tyrosine phosphatase domain that contributes to intracellular replication of *Salmonella*. On the other hand, PphB is a putative serine-threonine phosphatase not characterized in pathogenicity. We constructed Δ*sopB*, Δ*sptP* and Δ*pphB* derivatives of the *S.* Typhimurium virulent strain 14028s using the Red Swap method. Then, we evaluated the intracellular survival of the wild-type and mutant strains by means of an infection assay *in vitro* using *D. discoideum* AX4 and RAW264.7 macrophages. The infections were carried out for 1 h at 22°C (*D. discoideum*) or 37°C (RAW264.7) using a MOI of 100 bacteria/cell. Infected cells were lysed with 0,2% Triton X-100 and the number of intracellular bacterial at 0, 1, 3 and 5 hours post-infection was determined by serial dilution and plating on LB agar. Our results showed that the three mutants are defective for intracellular survival in *D. discoideum* at 1, 3 and 5 h post-infection, as compared to the wild-type strain. The phenotype of the mutants was complemented *in trans*. On the other hand, we observed that the mutant strains present wild-type levels of intracellular survival in RAW264.7 macrophages. Thus, virulence factors SopB, SptP and PphB contribute to intracellular survival of *S.* Typhimurium in *D. discoideum*, but not in RAW264.7 macrophages.

Publishing Title:

Salmonella* Typhimurium Δ*sopB* and Δ*sifA* Mutants are Impaired in Intracellular Survival in the Amoeba *Dictyostelium discoideum

Author Block:

C. Valenzuela, A. Sabag, S. Riquelme, C. A. Santiviago; Univ. de Chile, Santiago, Chile

Abstract Body:

The ability of *Salmonella* to survive intracellularly in eukaryotic cells is explained, in part, by the modification of the intracellular niche within the cell in a compartment called the *Salmonella* containing vacuole (SCV). For this purpose, *Salmonella* employs a number of effector proteins secreted by the type-three secretion systems encoded in *Salmonella* pathogenicity island 1 (T3SS $_{SPI-1}$) and 2 (T3SS $_{SPI-2}$). Previously, we reported a role for these T3SS in the survival of *Salmonella* Typhimurium in the social amoeba *Dictyostelium discoideum*. In this work, we evaluated the role played by two effector proteins in this process. SopB (secreted by T3SS $_{SPI-1}$) is a phosphoinositide phosphatase that in other models acts increasing the PI(3)P species in newly formed SCV. SifA (secreted by the T3SS $_{SPI-2}$) is involved in the formation of *Salmonella*-induced filaments (Sifs), a complex network of membrane filaments that extends from the SCV. We performed phagocytosis assays using axenic cultures of *D. discoideum* strain AX2 co-cultured with *S.* Typhimurium wild-type strain 14028s or derived mutants Δ*sopB* and Δ*sifA*. Viable bacterial cells were recovered from *D. discoideum* at 0, 3 and 6 hours post-infection and titrated by serial dilution and plating in selective media. In parallel, viable cell counts of infected *D. discoideum* were obtained by Trypan blue exclusion. Our results show that Δ*sopB* and Δ*sifA* mutants are recovered ~10-fold less than the wild-type strain at 6 hours post-infection, indicating that these mutants are defective in intracellular survival in the amoeba. These results are in accordance with their reduced intracellular survival in murine macrophages *in vitro*. Altogether, our results suggest that the modification of a SCV-like compartment by SopB and SifA is required for *S.* Typhimurium to survive within *D. discoideum.*

Identification of Regulatory Mechanisms That Contribute to Novel Cell Cycle Outcomes During Host-Microbe Symbiosis

Author Block:

C. Puerner[1], C. Sadowski[2], K. Schallies[1], K. Gibson[1]; [1]Univ. of Massachusetts Boston, Boston, MA, [2]Symbiota Inc., Cambridge, MA

Abstract Body:

Sinorhizobium meliloti has emerged as a key model organism for understanding the link between cell cycle regulation and chronic host colonization because it undertakes novel cell cycle outcomes during symbiosis within the root nodules of legumes. The DivJ-like histidine kinase CbrA is a necessary regulator for both symbiosis and cell cycle progression. CbrA indirectly regulates the activity and degradation of CtrA, a master cell cycle transcription factor. We isolated a spontaneous Δ*cbrA* symbiosis suppressor strain from a rare phenotypically wild type root nodule, which contains a mutation that suppresses both symbiotic and free-living cell cycle defects of the Δ*cbrA* mutant. Whole genome sequencing identified the mutation responsible for Δ*cbrA* suppression to be located within a PAS domain of *divL* (*divL*^{Q362P}), which encodes a modified kinase that likely mediates CbrA regulation of CtrA by serving a bridge between the CbrA cognate response regulator DivK and the CckA/ChpT phosphorelay. The *divL*^{Q362P} allele shows temperature-sensitivity, a slow-growth defect, and importantly has a drastic reduction of endogenously expressed CtrA in an otherwise wild-type background. Genetic experiments are underway to further characterize the nature of *divL*^{Q362P} function. Recently, ten additional Δ*cbrA* symbiosis suppressor strains were isolated. These ten strains fall into three linkage groups and have been characterized further. Preliminary observations suggest that one group also suppresses Δ*cbrA* cell cycle defects, while the other two do not and appear to be symbiosis-specific. Specifically, Western blot analysis has revealed these symbiosis-specific suppressors do not restore CtrA levels to that of wild type and retain cell morphology defects. We plan to use whole-genome sequencing of these strains in order to identify the genes responsible for suppression. Through this study, I aim to better characterize the role DivL plays in symbiosis and regulation of the cell cycle and identify additional symbiosis-specific mechanisms of cell cycle regulation in *S. meliloti*.

Packaging of *Campylobacter jejuni* into Multilamellar Bodies by the Ciliate *Tetrahymena pyriformis*

Author Block:

H. Trigui[1], V. E. Paquet[2], S. J. Charrette[2], S. P. Faucher[1]; [1]McGill Univ., Montréal, QC, Canada, [2]Laval Univ., Quebec, QC, Canada

Abstract Body:

Background: *Campylobacter jejuni* is a foodborne pathogen recognized as the major cause of human bacterial enteritis. The survival and persistence *of C. jejuni* in food processing environments are poorly understood. Some amoebae and ciliates ingest pathogenic bacteria, package them into multilamellar bodies (MLBs) and release them in the milieu. Packaged bacteria are protected from various stresses and are more able to survive than free bacteria. **Hypothesis:** We propose that *C. jejuni* could be packaged after internalization and then expelled into MLBs by protozoa known to be able to package other pathogens. **Results:** Co-cultures of *C. jejuni* strain 81116 with *Acanthamoeba castellanii* or the ciliate *Tetrahymena pyriformis* were processed for epifluoresence and transmission electron microsopy. *A. castellanii* did not expel packaged bacteria even when we tested multiplicity of infections higher than those reported in previous studies. In contrast, *T. pyriformis* is able to package *C. jejuni* into expelled spherical vesicles in less than one hour after internalization. According to their size and structures these MLBs were reminiscent to those excreted by ciliates as already described for *Salmonella enterica*, *E. coli* and *L. pneumophila*. Live/dead staining and CFU counts indicate that *C. jejuni* were present as viable cells in MLBs for up to 60 hours, and that this packaging increased the survival of *C. jejuni*. **Conclusions:** Our study suggests that *T. pyriformis* may increase the risk of persistence of *C. jejuni* in the environment and that the packaging could be involved in the transmission from farm water distribution systems or slaughterhouse chillers to the final product.

***biomphalaria Havanensis* (Syn. *obstructa*) Identified As New Snail Host For *drepanocephalus Auritus* (Digenea: Echinostomatidae) In Catfish Aquaculture**

Author Block:

N. R. Alberson[1], T. G. Rosser[1], L. H. Khoo[2], S. K. Buddenborg[3], E. S. Loker[3], T. D. Richardson[4], E. T. Woodyard[1], L. M. Pote[1], M. J. Griffin[5]; [1]Mississippi State Univ. Coll. of Vet. Med., Starkville, MS, [2]Thad Cochran Natl. Warmwater Aquaculture Ctr., Mississippi State Univ., Stoneville, MS, [3]Univ. of New Mexico, Albuquerque, NM, [4]Univ. of North Alabama, Florence, AL, [5]Thad Cochran Natl. Warmwater Aquaculture Ctr., Mississippi State Univ., Starkville, MS

Abstract Body:

Digenetic Trematodes are considered a major impediment to catfish aquaculture in the southeastern United States. Catfish production ponds make an ideal feeding ground for piscivorous birds due to the constant availability of a confined food source and are the perfect habitat for a variety of aquatic snails. These characteristics provide an optimal environment for the propagation of digenetic life cycles. In July 2014, two endemic snail species (*Planorbella trivolvis* and *Biomphalaria* sp.) were collected from two separate catfish production ponds in East Mississippi. Both snail species were observed shedding cercariae morphologically consistent with *Drepanocephalus auritus*, a parasite of the double crested cormorant, *Phalacrocorax auritus,* and channel catfish *Ictalurus punctatus*. Sequencing of five different gene targets (SSU, ITS, LSU, ND1, and CO1) confirmed these cercariae to be *D. auritus*. Sequencing of the mitochondrial cytochrome c oxidase subunit 1 (CO1) and nicotinamide adenine dinucleotide dehydrogenase subunit 1 (ND1) genes showed the snails in this study released cercariae belonging to both North American and South American genotypes. Juvenile channel catfish were challenged with ~275 *D. auritus* cercariae shed from *Biomphalaria havanensis* (syn. *obstructa*). Few mortalities (2 out of 10 fish) were observed, and surviving fish were euthanized 7 days post-challenge. Histology confirmed the presence of metacercariae, and pathology was consistent with previous studies. This work identifies a second snail species endemic to catfish aquaculture ponds that release cercariae pathogenic to juvenile channel catfish and is the first report of a *Biomphalaria* sp. being an intermediate host for *Drepanocephalus* sp. in North America.

Symbiont Communities in Submerged Cave Ecosystems: Molecular and Microscopical Investigations of Shrimp-Associated Bacteria

Author Block:

J. P. Nelson[1], L. M. Ortiz[2], G. Rouse[3], C. C. Cavanaugh[1]; [1]Harvard Univ., Cambridge, MA, [2]Univ. of Quintana Roo, Cozumel, Cozumel, Mexico, [3]Scripps Inst. of Oceanography, UCSD, La Jolla, CA

Abstract Body:

Dark, submerged caves contain complex habitats and endemic fauna. Several studies have suggested that in anchialine caves, in which landlocked marine water is often overlain by groundwater, chemosynthetic microbial communities support invertebrate dominated food webs. Yet, while chemosynthetic symbiosis in an anchialine cave shrimp has been reported based on electron microscopy and stable isotope enrichment experiments, symbiont identity and diversity have not yet been investigated. This study aims to identify the bacteria associated with members of the blind cave shrimp genus *Typhlatya* from 12 caves in the Yucatan Peninsula, Mexico. Sequencing of bacterial 16S rRNA genes and fluorescence in situ hybridization were employed to determine symbiont phylotypes and the diversity of the microbial community in the gills of several host species (N=5). These data were compared with geochemical analyses (salinity, dissolved oxygen, temperature, pH) of sampled shrimp habitats in order to assess whether environmental factors might correlate with symbiont association. Analyses of 16S rRNA sequences revealed that the dominant phylotypes were *alphaproteobacteria*, gammaproteobacteria, or spiroplasma and varied between host species. Proportions of proteobacterial clades and firmicutes that were associated with shrimp differed by cave site based on Illumina Miseq data. These findings give us insight into how host-associated microbes vary within and between anchialine shrimp species. The integration of geochemistry, microbial community structure, and symbiont studies in these shrimp will help to elucidate the roles of environment vs. host phylotype in determining symbiont composition. In particular, these investigations will add to recent reports of microbial niche partitioning in a variety of chemosynthetic symbioses.

Presence of Virulence Factor-Associated Genes in *Aeromonas* Pathovars, Cell Cytotoxicity and Nematode Lethality

Author Block:

W. Almonte, P. Kim, D. J. McGarey; Kennesaw State Univ., Kennesaw, GA

Abstract Body:

Background: Aeromonads are Gram-negative, chemoheterotrophic bacteria globally distributed in aquatic environments with some species, particularly *Aeromonas hydrophila*, able to cause various diseases including gastroenteritis, septicemia, soft tissue infections and acute necrotizing fasciitis. The severity of disease may be dependent on expression of specific virulence factors, which vary among species and strains within species (pathovars).**Methods:** Polymerase chain reaction was used to detect the presence of 16 genes encoding specific enzymes, toxins, surface components and secretion system components reported to contribute to virulence in clinical and environmental isolates of *A. hydrophila* (n = 22), *A. bestiarum* (n = 4), and *A. salmonicida* subsp *salmonicida* (n = 3). Based on gene amplification profiles the isolates were assigned into pathovar groups with representative members tested for cell cytotoxicity (rainbow trout gonad cells; RTG-2) and lethality using *C. elegans* challenge.**Results:** Eighty-three percent of strains inducing significant ($p < .05$) cell cytotoxicity were positive for genes encoding major surface adhesion (*aha1*), type VI secretion system (T6SS) effectors valine-glycine repeat G protein (*vgrG1*) and hemolysin co-regulated protein (*hcp*), and repeat in toxin exotoxin (*rtxA*). Genes for Type III secretion system (T3SS) toxins AexT and AexU (*aexT*, *aexU*) were present in 40% of highly cytotoxic strains, and 50% of strains with no significant cytotoxicity. Nematode lethality was greatest (43-53% lethal) in strains positive for *ashA* (S-layer) and toxin genes *vgrG1*, *hcp* and/or *rtxA*, and moderate (25-39%) when the same toxin genes were present without the *ashA*. It is likely the S-layer (gene expression confirmed) provided protection against clearance and lysis by the host's innate immune factors. Virulence factor genes common to all strains tested included elastase (*ahyB*), serine protease (*ser*), lipase (*lip*), and hemolysin (*ahh1*). Although these factors may contribute to disease, they did not appear to be correlated to cytotoxicity or nematode lethality.**Conclusions:** Based on these results, a multiplex PCR was developed for the simultaneous amplification of genes encoding toxins *rtxA*, *hcp*, *vgrG1*, *aexT*, and *aexU* and surface components *aha1* and *ashA* to differentiate potentially high virulence pathovars from those less virulent.

Recovery of a Diverse Gut Microbiota Occurs Gradually Following Fecal Microbiota Transplantation

Author Block:

J. J. Farrell[1], D. K. Martin[2], S. V. Thompson[3], A. Bogner[2], J. Bonello[2], H. Holscher[3]; [1]Univ. of Illinois Coll. of Med., Peoria, IL, [2]OSF Med. Ctr., Peoria, IL, [3]Univ. of Illinois, Urbana, IL

Abstract Body:

Background: Fecal microbiota transplantation (FMT) for treatment of *Clostridium difficile* infection (CDI) is associated with success rates >90%. The presumed mechanism of action is restoration of intestinal microbial diversity, but the time course and process of evolution to restoration of gut microbiota following FMT is not well understood. **Methods:** IRB approved FMT for patients with CDI who failed conventional treatment. FMT began November 2013, and in October 2014, patients submitted a stool sample or rectal swab prior to FMT. Designated donors (DD) also provided stool samples. Fecal DNA was extracted followed by generation of archaeal, bacterial, and fungal amplicon pools using a Fluidigm Access Array, sequencing on an Illumina MiSeq, and QIIME 1.8 analysis. Successful treatment was defined as resolution of symptoms of CDI following FMT. Failure was defined as diarrhea with > 3 stools/day or retreatment (either oral vancomycin or a 2nd FMT) within 30 days.**Results:** Between November 2013 and May 2015 48 FMT patients were enrolled: 38 women, 10 men; mean age=68 (median=69). CDI resolved for 44/48 (91.7%) patients following FMT (2 patients required a second FMT to achieve resolution of symptoms). There was no significant change in patient weight following FMT. Microbiome analysis was performed on stool from both of the DD, as well as 8 patients at day 0, 4/8 patients at day 30, and the same 4/8 patients at day 90 (only 2/4 patients that failed FMT provided follow-up stool specimens). Fecal bacterial operational taxonomic units (OTUs) and phylogenetic diversity (PD) were greater in DD than patients at day 0 ($p<0.05$). Patient OTUs and PD increased from day 0 to day 90 ($p<0.05$). OTUs and PD were not different in DD vs. patients at day 90 ($p>0.05$). Among the 4 patients that submitted stool at baseline, 30, and 90 days, PD was significantly greater at 90 days compared to baseline (27 vs. 13; $p=0.006$). Principal coordinates analysis (PCoA) of UniFrac distances between samples based on their 97% OTU composition and abundances indicated the enteric bacterial communities changed over time ($p=0.001$).**Conclusions:** Gut microbiota recovery following FMT was not instantaneous, but appeared to be a process of evolution following FMT that occurs over ≥ 3 months.

The Gut Microbiome Drives Individual Differences in Metabolism of Anti-Cancer Drugs

Author Block:

L. Guthrie, S. Gupta, J. Daily, L. Kelly; Albert Einstein Coll. of Med., Bronx, NY

Abstract Body:

The ways in which the human gut microbiome shapes drug metabolism, efficacy and adverse drug responses (ADRs) is understudied and merits urgent investigation. As an example, severe diarrhea is a dose-limiting side effect of the colorectal cancer (CRC) chemotherapeutic and prodrug Irinotecan (CPT-11). Damage to intestinal epithelial cells and diarrhea can occur when a dominant, inactive metabolite of the drug, SN-38G, is converted to the active form by microbial β-glucuronidases (BGs) in the gut. ADRs to CPT-11 are variable in patient populations, potentially reflecting inter-individual variation in gut microbiota, which contribute to metabolism of the excreted drug. We find that diverse and mobile BGs populate the healthy human gut. We hypothesize that patterns of BG gene abundance, expression, and variability in the gut microbiome are linked to distinct metabolic phenotypes and may therefore be used to predict patient responses to drugs that are glucuronidated as a part of their metabolism. To assess the variation in functional activity of BGs among healthy individuals, we used LC-MS/MS to quantify microbiota-generated metabolites during ex-vivo drug administration of SN-38G to fecal samples. We found that microbial metabolism drives variable turnover phenotypes. We are further addressing the variation in functional activity of BGs between individuals using metatranscriptomic analysis to determine 1) whether BGs are expressed in response to drug administration and 2) to identify novel genes involved in drug metabolism. Integrating metabolomic, biochemical, evolutionary, and meta'omic data may identify new links between microbial metabolism and variable drug response. Finally, we compared the phylogenetic diversity and abundance of BGs in individuals with CRC and healthy controls and found distinct patterns of BG abundance and phylogeny in CRC patients in comparison to healthy individuals. BGs, and potentially other carbohydrate active enzymes may therefore be indicative of disease states. An overlapping set of microbial carbohydrate active enzymes mediate the metabolism of dietary substrates and xenobiotics, and, as a secondary consequence of metabolism, exert both protective and detrimental effects on carcinogenesis. Metagenomic assessment of CAZymes represents a novel and non-invasive approach to developing biomarkers for CRC diagnosis and progression.

Drug Metabolism Potential of the Human Microbiome Varies by Age

Author Block:

T. D. D. LeBlanc, M. G. I. Langille; Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Background: The human microbiome is the collection of bacteria living in and on the human body. Several studies have demonstrated that the gut microbiome can alter the metabolism of commonly used medications. However, there has yet to be a broad-scope analysis to determine the presence and variance of microbial genes with drug metabolizing potential. The aim of this study is to survey the drug metabolising potential of the human microbiome. We examine what drug metabolising genes are present in these microbes, and how the abundance of these genes changes based on body site, gender, and age. **Methods:** A subset of 50 microbial genes with the potential to metabolize drugs was manually curated from the Kyoto Encyclopedia of Genes and Genomes. These genes were annotated for two publicly available metagenomic data sets, including the Human Microbiome Project dataset with 118 gut microbiome samples[1], and a study examining type 2 diabetes and age in Chinese individuals with 370 gut microbiome samples[2] . Relative gene abundance were compared across body site, gender, and age of the individuals with ANOVA using Benjamini-Hochberg FDR multiple test correction.**Results:** All 50 genes were found to be present in the human microbiome, and 46 were different in proportion within the gut compared to other body sites. Although there were no significant differences based on gender, we identified 22 genes that were significantly different based on the individual's age, including alcohol dehydrogenase, azoreductase, and several methyltransferase genes. Varying levels of these genes in the microbiome could have clinical implications for a wide array of therapeutic treatments.**Conclusions:** The ability of the human microbiome to alter drug metabolism is diverse and variable across the human population and changes with age. Future studies will test other factors that could alter the drug metabolising potential of the gut microbiome, and this knowledge will be incorporated into personalized medicine applications.

Metatranscriptome Analysis to Study the Response of the Human Gut Microbiota to Live Oral-Attenuated Vaccines and Subsequent Challenge with Wild-Type *Salmonella typhi*

Author Block:

Y. Zhang[1], A. Brady[1], C. Jones[1], Y. Song[1], A. J. Pollard[2], M. B. Sztein[1], C. M. Fraser[1]; [1]Univ. of Maryland Sch. of Med., Baltimore, MD, [2]Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Successful development of oral attenuated vaccines against *Salmonella* Typhi (*S.* Typhi) requires a better understanding of host immunity and its interaction with the resident microbiota in the human gastrointestinal tract; the combined responses of the microbiota and host immunity are likely to determine host susceptibility to or protection from typhoid disease (TD). This study was directed to characterize the structure and function of the gut microbiota in a human challenge model of TD in order to identify associations between the gut microbiota and host immune responses.Healthy adult volunteers received orally Ty21a (a licensed live attenuated typhoid vaccine, strain Ty21a), M01ZH09 (an attenuated live typhoid vaccine candidate strain) or placebo, followed by a subsequent challenge with wild-type (wt) *S.* Typhi and monitoring of clinical symptoms and immune responses. A total of 331 longitudinal stool specimens from 30 volunteers were collected. Messenger RNA were extracted from stool and sequenced on the Illumina HiSeq 2000 platform. Analysis of taxa abundances revealed that the gut microbiota was clustered into three enterocommunities dominated by *Ruminococcus*, *Methanobrevibacter* or *Firmicutes*. Enterocommunities were stable within an individual over the collection period, regardless of treatments or clinical outcomes. In contrast, differential gene expression analysis revealed that flagella genes, mainly from *Eubacterium* and *Roseburia*, were up-regulated in the volunteers who developed TD after 24 hr and 6 days following challenge with wt *S.* Typhi. In volunteers who did not develop TD, genes from COG group O (post-translational modification, protein turnover, chaperones) were up-regulated 24 hr after challenge with wt *S.* Typhi, consistent with activation of general defense mechanisms. This is the first study that investigates the functional responses of the human gut microbiota to challenge with wt *S.* Typhi. Future work will correlate changes in the gene expression profile of the gut microbiota with immune responses measured in the same volunteers over time.

Effects of Two Polyphenols on the Gut Microbiome and Associated Weight Gain in Mice

Author Block:

J. E. Wilkinson[1], J. D. Hanson[2], C. D. Phillips[1], E. J. Rees[2], G. D. Mayer[1]; [1]Texas Tech Univ., Lubbock, TX, [2]RTL Genomics, Lubbock, TX

Abstract Body:

Recently, changes in gut microbial assemblages are being investigated as underlying causes of many health issues. Even minuscule changes in gut bacterial population structures have been correlated to conditions such as glucose intolerance, diabetes, and autism. We studied two polyphenols that are regularly consumed by humans and examined their effects on the gut microbiome and weight gain, using mice as a model. Natural sweeteners (Stevioside) are derived from plants (*Stevia rebaudiana*), and have sweetening effects ~300-fold greater than sucrose. Sugar substitutes are known to play a pivotal role in both obesity and diabetes and are consumed regularly as an alternative to sugar. Epigallocatechin-3-gallate (EGCG) is a polyphenol found in green tea that has been reported to impact health, including involvement in gut microbial metabolism and weight loss. However, no DNA sequencing studies to date have documented the gut microbial composition after the regular consumption of Stevioside or EGCG. C57BL/6J mice were divided into 5 groups: control, EGCG treatment (12.5 mg/kg bw/day, and 3 Stevioside treatments (10, 25, and 50 mg/kg bw/day). Mice were weighed and feces was collected daily. Four mice were sacrificed upon arrival to the lab and 6 mice at the start of the study (after a 3-day acclimation). All groups were divided 50/50 male and female. 16S amplicon sequencing was performed on gDNA of collected fecal and colon samples. We observed shifts in Firmicutes and Bacteroidetes ratios. Differences were noted between fecal and colon samples, which is to be expected. Trends in weight gain were present between groups, and between sexes within groups. We also observed a shift in OTU numbers from arrival until day 30, even in controls. Our results indicate that both Stevioside and EGCG affect the gut microbiome and weight gain. This was dose dependent for Stevioside. Notably, change of habitat from arrival until the start of the study (no treatment) altered the gut bacterial composition dramatically, which should be noted for other studies that only report changes before and after treatment without pre- and/or post-acclimation sampling. The findings of this study will inform people of potential health effects of these two polyphenols, and provide researchers knowledge of how acclimation and change in habitat affect gut microbial communities of mice.

Antibiotics Indirectly Disrupt Gut Microbiota Through Environmental Shifts

Author Block:

A. T. Reese[1], H. Durand[1], E. H. Cho[1], M. M. Villa[1], S. Nimmagadda[1], M. A. Deshusses[1], S. P. Nichols[2], N. A. Wisniewski[2], B. Klitzman[1], L. A. David[1]; [1]Duke Univ., Durham, NC, [2]Profusa, South San Francisco, CA

Abstract Body:

Antibiotic use can lead to major shifts in composition of the gut microbiota that persist after treatment has ceased. It is unknown, however, whether abiotic conditions also change, and, if so, whether such changes contribute to community dynamics. The microbiota are known to alter the environment of the gut, including maintaining the anoxic state of the distal lumen, so feedbacks between the community and environment after disturbance are predicted. Specifically, we hypothesized that changes in composition due to differential mortality would result in abiotic changes that induce further changes in composition. We sought to test this hypothesis with mouse and *in vitro* models. **Methods:** We measured colonic oxygen tension *in vivo* and redox potential in fecal pellets daily during treatment of C57BL-6 mice treated with a broad-spectrum antibiotic cocktail for five days. Oxygen was measured with a novel fluorescent biosensor inserted rectally. Redox potential was measured using a microelectrode. An *in vitro* bioreactor model of the human colon was subjected to increased oxygen and/or antibiotic treatment. Composition was evaluated by high-throughput sequencing of bacterial 16S ribosomal RNA using the Illumina MiSeq platform. Total bacterial load was estimated with qPCR of the 16S rRNA gene. **Results:** Antibiotics resulted in a two-fold decrease in bacterial load that persisted throughout treatment, with a significant reduction apparent within 12 hours. We observed an increase in reduction potential within 16 hours of the first dose of antibiotics *in vivo*, and reduction potential remained elevated (258±72mV) throughout treatment. In contrast, oxygen increased only transiently roughly one day after the initial dose. These changes coincide with a shift to a community dominated by Proteobacteria. A similar transient increase in oxygen is observed *in vitro*, coinciding with an increase in facultative anaerobes, including Proteobacteria, even in the absence of antibiotics. Treatment with antibiotics alone was not sufficient to recapitulate the changes in composition observed *in vitro*. **Conclusions:** Treatment with antibiotics results in a major environmental change that causes compositional shifts beyond those resulting from antibiotic-induced mortality.

Beta-Glucans As Novel Prebioitcs And Their Effects In Mouse Microbiome Modulation

Author Block:

K. LAM, H. Kwan, P. C. K. Cheung; The Chinese Univ. of Hong Kong, Shatin, Hong Kong

Abstract Body:

Background: Bifidobacteria are gram-positive, hetero-fermentative, non-motile, non-spore forming rods. Nowadays, many research projects have demonstrated that bifidobacteria constitute a healthy and balanced microbiome in human guts. In consideration of having evolved as a successful competitor in human gastrointestinal tract (GIT), which harbors at least 160 common bacterial species, bifidobacteria are believed to have specific mechanism in the utilization of carbohydrate, especially prebiotics for survival. Beta-glucans are complex non-digestible carbohydrates of D-glucose monomers linked by beta-glycosidic linkages. Structurally, beta-glucans are non-starch polysaccharides with repeating glucose residues with a linear chain having none or multiple side branches. Beta-glucans have long been shown to have health promoting effects including anti-tumor, immuno-stimulatory, and anti-obesity. More recently, beta-glucans are considered to have the potential to be used as novel prebiotics. **Methods:** Balb/c mouse were used as the animal model for the investigation of the effects of microbiome modulation by beta-glucans. Beta-glucans were used as prebiotic, *Bifidobacterium longum* subsp. *infantis* was used as probiotics and a combination of two used as synbiotics. The animals were randomly assigned to four groups, control, prebiotic, probiotic, and synbiotic. Prebiotics, probiotics and synbiotics were administered to the respective animal groups by intra-gastric gavage. After two weeks of gavage, fecal contents were collected. DNA from the fecal samples was extracted and the 16S rDNA region was sequenced. Sequences were analyzed with the QIIME pipeline to find out the alpha and beta diversity.**Results:** Our finding suggests that beta-glucans can shift the mouse gut microbiome with a slight increase of Bifidobacterium population. Beta-glucans could potentially be one of the novel prebiotics that not only confer beneficial effects to host via direct action such as immune-stimulatory effects, but also via an indirect route as the modulation of gut microbiome, bringing health benefits to host.**Conclusions:** Beta-glucans could potentially be one of the novel prebiotics.

Increased *Akkermansia muciniphila* and *Bacteroides fragilis* Group Abundance After Islamic Fasting

Author Block:

C. Erdogdu[1], M. Y. Cirak[2], T. Karakan[2]; [1]Hacettepe Univ., Ankara, Turkey, [2]Gazi Univ., Ankara, Turkey

Abstract Body:

Metabolic disorders such as obesity is often associated with the changes in microbiota composition and quantity. It has been well known that dietary habits also effects intestinal microbiota. Here we hypothesized that long-term fasting may have a distinct effect on intestinal microbiota. Since the experimental design in human subjects is hard to perform for this purpose, we thought that Islamic fasting before-after specimens may give clues about the effect of long term fasting on intestinal microbiota. Total of 8 subjects were included in this study during Ramadan between the dates June 18 and July 16, which is approximately 17 hours of fasting per day during a 29 day period.The stool samples from volunteers were collected the day before the beginning of Islamic fasting and the day end of the Ramadan. 16S rRNA qPCR assay has been performed for quantification of *Akkermansia muciniphila, Faecalibacterium prausnitzii, Bifidobacterium spp, Lactobacillus spp, Bacteroides fragilis group, Enterobacteriaceae*. Blood samples were also collected to test for metabolic and nutritional parameters. The before and after Islamic fasting results were statistically analyzed using Wilcoxon Signed-Rank test.All of the subjects were normal weight according to the calculated BMI. The overall bacterial count did not significantly change over time in none of the subjects. However significantly increased abundance of *A. muciniphila* and *B. fragilis* group was observed in all subjects after Islamic fasting when compared to the baseline levels ($p=0.0078$ and 0.0156; respectively). Serum fasting glucose and total cholesterol levels in all subjects is also significantly reduced in all of the subjects ($p<0.001$ and $p=0.009$; respectively).Islamic fasting which has been approximately 17 hours of fasting for each day lead to a change in microbiota members.Figure 1. Increased levels of A. muciniphila and B. fragilis group before and after Islamic fasting

***Faecalibacterium prausnitzii* Prevents from the Non-Alcoholic Fatty Liver- Underlying Mechanisms**

Author Block:

E. Munukka[1], A. Rintala[1], R. Toivonen[1], A. Hänninen[1], S. Jalkanen[2], P. Huovinen[1], S. Pekkala[3]; [1]Univ. of Turku, Turku, Finland, [2]Medicity, Univ. of Turku, Turku, Finland, [3]Univ. of Jyväskylä, Jyväskylä, Finland

Abstract Body:

Current worldwide epidemic of obesity associates with an increase in the non-alcoholic fatty liver disease (NAFLD). The causal mechanisms of NAFLD are not entirely clear. We have previously shown in humans that the high liver fat content associates with a low fecal abundance of *Faecalibacterium prausnitzii* and a higher abundance of enterobacteria. To investigate *in vivo* the effect of *F. prausnitzii* (ATCC 27766) and *Enterobacter cloacae* subspecies *cloacae* (ATCC 13047) that served as a candidate enterobacteria, on NAFLD, experimental liver fat accumulation was induced by a high-fat diet (HFD) over 13 weeks in C57BL/6N female mice (n=6/group). Control group received normal chow. During the intervention mice received either live bacteria or PBS twice a week every two weeks via intragastric administration. After the intervention, subcutaneous and visceral adipose tissue, liver and *gastrocnemius* muscle were collected. All the tissues were pulverized in liquid nitrogen for the subsequent analyses of protein and gene expression and fat content measurements. Serum glucose and glycerol were analysed and liver sections were imaged by neutral lipid dying and confocal microcopy (Carl Zeiss). Gut microbiota composition was profiled with Illumina MiSeq 16S sequencing. The overall fat mass was heavier in *F. prausnitzii*-treated mice compared to HFD control. However tissues were metabolically healthier namely more insulin sensitive and less inflamed than in HFD control. *F. prausnitzii*-treated HFD mice were protected from fatty liver through the mechanisms involving increased fatty acid oxidation and adiponectin signaling. *E. cloacae* did not increase the liver fat content. Interestingly, *F. prausnitzii* also increased *gastrocnemius* muscle mass, which refers to an enhanced mitochondrial respiration. In addition, *F. prausnitzii* improved the intestinal integrity by increasing the expression of *Tjp1* mRNA, which may be to some extent due to the increased intestinal *TLR5* mRNA expression in response to *F. prausnitzii* and adjusted the gut microbiota composition, which may be to some extent due to the increased intestinal *TLR5* mRNA expression in response to *F. prausnitzii*. These findings show that *F. prausnitzii* prevents NAFLD induced by HFD.

Probiotic Supplementation Alters Gut and Systemic Immune Activity and Energy Consumption of Growing Chickens

Author Block:

A. Ballou, R. Ali, M. Koci; North Carolina State Univ., Raleigh, NC

Abstract Body:

Probiotics have been the focus of considerable scientific and public interest as we learn how manipulation of the gut microbiome impacts host health and physiology. Previous research in our lab has demonstrated supplementation with a lactic acid bacteria probiotic product results in shifts in microbial colonization of the gut as measured by 16s rDNA sequencing. Reduced abundance of pro-inflammatory species like *Candidatus Savagella*, increased expression of IL-10 and decreased expression of IL-12RB2 in the ileum suggests this probiotic affects the host immune system. Further study of this relationship reveals probiotics stimulate circulating immune cells as well. Probiotic-treated animals generate antigen specific antibodies faster than control animals, and their circulating lymphocytes generate and consume more ATP. To better understand how oral administration of a probiotic leads to changes in systemic immune cells serum was collected at days 7, 14, 21 and 28 from animals fed control or probiotic diets (approximately $3x10^5$ CFU probiotic containing *Lactobacillus acidophilus, Lactobacillus casei, Enterococcus faecium,* and *Bifidobacterium thermophilus*/g of feed). Serum from treated and control animals was used to supplement RPMI media (10% v/v) in which chicken T-cell line CU205s were cultured for 2 or 4 days. Cells were assessed for changes in viability, proliferation and ATP content. Cells exposed to serum from probiotic-treated animals show consistently higher levels of ATP ($P < 0.05$). Partial size fractionation of the serum suggests the lymphocyte ATP-inducing factor is below 30 kDa in weight, and may be lipid associated. A study of cellular metabolism in these cells indicated the increased ATP may be a result of increased glycolytic activity. To begin to understand the specific effect of probiotics on lymphocytes cells, serum from control and treated animals was used to stimulate CU205 cells in triplicate and total RNA was isolated for transcriptional analysis. Transcript sequencing was performed on the Illumina Hi-Seq and data were processed using tools available from Galaxy. Analysis of differentially expressed genes networks will help identify the source of the metabolic stimulation, as well as other cellular processes affected by probiotics. These genes and gene pathways could serve as novel therapeutic targets for future microbial products.

H. Kunishima[1], N. Ishibashi[2], K. Wada[3], M. Hirose[1], K. Oshima[2], T. Aoyagi[2], S. Endo[2], K. Oka[3], M. Takahashi[3], T. Matsuda[1], M. Kaku[2]; [1]St. marianna Univ., Kawasaki, Japan, [2]Tohoku Univ. Graduate Sch. of Med., Sendai, Japan, [3]Miyarisan Pharmaceutical Co., Ltd, Tokyo, Japan

Abstract Body:

Background: Increase of antibiotic resistant bacteria and its risks has been reported worldwide. Previous reports has shown that the commensal intestinal microbiota may have a role of reservoir of the antibiotic resistant properties. However, it is unclear about correlation between intestinal microbiota including probiotics and antibiotic resistant organisms. Therefore, we examined the effects of intestinal microbiota and/or probiotics on the growth, beta-lactamase activity and resistance gene transfer of antibiotics resistant bacteria.**Methods:** Six strains of *K. pneumoniae* (*bla*$_{\text{IMP-1}}$) and *E. coli* (*bla*$_{\text{CTX-M-15}}$) were used as a resistant bacteria. Type strains of *C. butyricum*, *C. difficile*, *C. perfirngens*, *Enterococcus faecium*, *Bifidobacterium longum*, *Bacteroides fragilis*, *Lactobacillus plantarum* and *C. butyricum* MIYAIRI588 (CBM) were also used. Resistant bacteria was incubated in a liquid medium supplemented with or without culture supernatant of probiotics or intestinal microbiota. Viable counts, beta-lactamase activity, *bla* gene expression and resistance transfer frequency of antibiotic resistant bacteria were evaluated.**Results:** Some of culture supernatant of intestinal microbiota including CBM suppressed the growth and beta-lactamase activity of resistant bacteria and decrease of resistance transfer frequency. In terms of mode of action of the reduction of beta-lactamase activity, CBM supernatant significantly suppressed expression of *bla* gene. However, some of the organism such as *E. faecium* did not affect to those of the properties.**Conclusion:** These results indicate that some certain intestinal microbiota may affect an expression of resistant mechanism and resistant gene transfer of antibiotic resistant bacteria. In addition, probiotics possibly attractive to reduce the risk of antibiotic resistant bacterial infection.

Individual and Combined Administration of Galactooligosaccharide and *Bifidobacteria adolescentis* Ivs-1 During High Fat Feeding Causes Differential Adaptation of the Microbiome and Metabolic Profile

Author Block:

R. R. Segura Munoz; Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract Body:

Human and animal studies have linked disturbances in the gastrointestinal microbiota to the worldwide epidemics of obesity and metabolic syndrome. Consequently, development of dietary strategies that reconstruct a beneficial microbiota has gained much momentum. One such strategy is the parallel administration of a prebiotic fiber with a probiotic bacterium, known as a synbiotic. Synbiotics may synergistically provide benefits to the host. The goal of this study was to systematically compare a novel synbiotic composed of *Bifidobacterium aldolescentis* IVS-1 and galactooligosaccharide (GOS) with its individual components to determine how their interactions impact host metabolism and influence gut microbiota composition. To achieve this goal, we compared the effects of feeding mice a high fat diet alone or supplemented with GOS, *B. adolescentis* IVS-1, or the combination of both. Although feeding IVS-1 had no effect on host metabolic phenotype, administering GOS alone significantly reduced both plasma glucose and insulin levels. Interestingly, feeding IVS-1 together with GOS abrogated the benefits of the prebiotic and adversely affected fat deposition and plasma glucose levels. In addition, feeding IVS-1 together with GOS prevented GOS-induced microbiome shifts that were positively correlated with an improved insulin resistance index. Together, these findings indicate that synbiotic approaches may lead to antagonistic interactions, possibly by the administered strain competing against the health-promoting organisms within the resident microbiota that are supported by the prebiotic.

Effect of Palm Kernel Cake Supplementation on Cecal Bacterial Communities of Pigs

Author Block:

Y. Lee; Natl. Inst. of Animal Sci., Wanju-gun, Korea, Republic of

Abstract Body:

Unpleasant odors in pig slurries have become an issue to resolve in the Republic of Korea because they can affect the health and well-being of people. Production of unpleasant odors in pig slurries is associated with bacterial species producing volatile compounds. Our previous study showed that odor was mitigated in pigpen pits of pigs fed diet supplemented with palm kernel cake. Therefore, intestinal bacterial communities associated with malodor production in pigs remain to be identified. The objective of this study was to examine effect of palm kernel cake supplementation on cecal bacterial communities of pigs. Cecal samples were collected from 24 newly weaned crossbred pigs (Landrace X Large White X Duroc) fed 1 of 3 diets: 1) 8 pigs fed control diet containing no palm kernel cake, 2) 8 pigs fed control diet supplemented with 2% palm kernel cake, and 3) 8 pigs fed control diet supplemented with 4% palm kernel cake. Bacterial communities were investigated from individual cecal samples using next-generation pyrosequencing technology. A total of 13,113 16S rRNA gene sequences were assigned to 22 phyla, where *Firmicutes* was the first dominant phylum and accounted for more than 80% of the total sequences in all 3 diet groups. *Bacteroidetes* was the second dominant phylum and accounted for about 10% of the total sequences in all 3 diet groups. *Peptostreptococcaceae* was the most dominant family in all 3 diet groups and its abundance. Tended to decrease in response to palm kernel cake supplementation, indicating that *Peptostreptococcaceae* may produce odor-causing compounds. Additional efforts to elucidate roles of *Peptostreptococcaceae* in pigs are necessary.

Chenodeoxycholicacid Induces the Synthesis of Intestinal Antimicrobial Peptides and Attenuates Infection by Enteric Pathogens

Author Block:

S. Tremblay[1], G. Romain[1], M. Roux[1], X-L. Chen[1], K. Brown[2], S. Ramanathan[1], D. L. Gibson[2], A. Menendez[1]; [1]Univ. of Sherbrooke, Sherbrooke, QC, Canada, [2]Univ. of British Columbia Okanagan, Kelowna, BC, Canada

Abstract Body:

Background. Intestinal epithelial cells play a critical role in gut homeostasis. One of their major mechanisms is the synthesis and secretion of antimicrobial peptides and proteins (AMPP), which control the number and composition of the intestinal microbiota and protect from infections. Recent data have implicated the nuclear bile acid receptor FXR in the immunity of the small intestine. We hypothesized that bile acids (BA) contribute to the immunological homeostasis of the gut through the global regulation of intestinal AMPP expression.**Methods**. *Ex vivo* intestinal explants were treated with several BA to evaluate the BA impact on the synthesis of AMPP. C57BL/6 mice fed with a chenodeoxycholic acid (CDCA)-supplemented diet for 16 hours were used to determine the effect of CDCA on AMPP synthesis *in vivo*. Alterations in the immune cell populations of the intestinal mucosa were also studied using FACS. Susceptibility of CDCA-fed animals to enteric infections was tested with the BA-resistant pathogens *C. rodentium* and *S. typhimurium*.**Results.** Intestinal explants treated with CDCA demonstrated the highest and most consistent up-regulation of AMPP expression. CDCA feeding increased the base-line synthesis of intestinal AMPP *in vivo*; it also had an effect on the mucosal immune cell populations, inducing a decrease in the abundance of macrophages ($CD68^+$) and neutrophils ($Ly6G^+$) and an increase in the percentage of B cells ($IgG\kappa^+$). Gene expression analyses using DNA microarrays revealed an anti-inflammatory gene expression pattern in the ilea of CDCA-fed mice. Feeding with CDCA promoted a significantly faster clearance of *C. rodentium* and limited the establishment of systemic *S. typhimurium* infection.**Conclusion.** Our results demonstrate the existence of a novel mechanism for the control of intestinal AMPP expression and reveal a new aspect of the antimicrobial nature of bile acids *in vivo*. The regulation of intestinal AMPP synthesis by bile acids is physiologically relevant and seems to facilitate resistance to enteric pathogens, which has the potential to be exploited in therapeutic applications.

Fatty Acid Control of *Salmonella* Virulence

Author Block:

Z. J. Zhang, H. C. Hang; The Rockefeller Univ., New York, NY

Abstract Body:

The challenge to global health imposed by microbial pathogens demands a better understanding of host-microbe interactions, and understanding how small molecules (metabolites) from environmental factors (diet, microbiota) control host immunity and microbial pathogenesis is a major frontier of infectious disease. While metabolites from the diet and microbiota have been reported to directly inhibit pathogen virulence, the direct mechanism(s) are often unclear. Notably, short-chain fatty acids (SCFAs) produced by commensal bacteria and long-chain fatty acids (LCFAs) from the diet have been shown to inhibit key bacterial virulence pathways, such as type III secretion system (T3SS) in enteric microbial pathogens,(1) but the molecular mechanism(s) are not well studied. Chemical reporters of SCFAs and LCFAs developed in our laboratory have enabled the characterization of covalent protein targets of fatty acids in bacteria,(2) yeast,(3) and mammalian cells.(4) With these tools, we identified the protein targets of SCFAs and LCFAs in *Salmonella enterica* serovar Typhimurium (*S. typhimurium*) and discovered that fatty-acylation of a specific transcription factor may control the expression of virulence genes in *S. typhimurium* and attenuate bacterial pathogenesis. The site-specific effects of protein fatty-acylation on this key transcriptional regulator was further evaluated by installing a stable fatty-acylation mimic with genome editing(5) and amber suppression technology(6). Using these chemical approaches, we found that exogenous fatty acids derived from the host microbiota or diet may directly modify specific proteins involved in virulence regulation and control bacterial pathogenesis. These studies are crucial for understanding how key metabolites that are generated in the gut affect specific virulence pathways of enteric Gram-negative bacteria pathogens and may facilitate the design of novel anti-infectives.

Sucralose Produces a Species Specific Dose Dependent Bacteriostatic Growth Attenuation on Members of the Human Microbiota

Author Block:

R. T. Kalyanam, L. S. Manly, D. T. Ha, M. Osmani, V. S. Volante, C. B. Coughlin; Univ. of North FLorida, Jacksonville, FL

Abstract Body:

Sucralose (Splenda®) is widely used as a means to help curb sugar intake. Previous studies in our lab observed concentration dependent bacteriostatic effects of sucralose on select environmental bacteria. It was hypothesized that similar sucralose-dependant inhibition of microbe growth could be measured in key species affecting human health. This experiment used clinically significant human gastrointestinal species: Bacteroides fragilis, Salmonella enterica, Klebsiella pneumoniae, and Akkermansia muciniphila. The species were challenged with incremental concentrations of sucralose within gently agitated Hungate cultures at 37°C; simulating conditions of the human gastrointestinal tract. Turbidity absorbance was utilized as an indirect measurement of the dose-dependent effect sucralose had on culture growth. Growth trends and patterns were analyzed to elucidate any possible impacts of sucralose. Sucralose demonstrated a dose-dependent attenuation of culture growth, especially in concentrations exceeding 6.29mM. At sucralose concentrations approximating Recommended Daily Allowance, results suggest no significant difference on growth rate and on peak absorbance values. Investigation into the metabolic processes hampered by the sweetener would be the next step to understand gut microbes response to sucralose exposures. These results should stimulate reconsideration of sucralose consumption as a dietary aid without knowing its full impact on the human gut microbiome. Additionally, high concentrations of sucralose may have therapeutic applications in addressing antibiotic resistant pathogens such as Klebsiella species.

A Food-Grade Antimicrobial Biopolymer Transiently Perturbs the Community Structure of the Murine Gut Microbiome

Author Block:

X. You, J. Einson, C. Lopez-Pena, M. Song, H. Xiao, D. J. McClements, D. A. Sela; Univ. of Massachusetts, Amherst, MA

Abstract Body:

Dietary components guide the establishment and maintenance of microbial communities and functions within the distal gastrointestinal tract. Antimicrobial compounds are ubiquitous in food systems, though it is unknown to what extent these molecules interact with endogenous gut microbiota once ingested. In this study, we investigated the influence of food-grade biopolymers (i.e. ε-polylysine, pectin, and ε-polylysine-pectin complexes) on composition of the murine microbiota. Accordingly, CD-1 mice were fed biopolymers incorporated into a high-fat diet over a 9-week time course. Microbial phylogenetic diversity present in fecal extracts were ascertained by high-throughput amplicon sequencing of the 16s rRNA gene. In addition, community function was predicted from relative abundances of taxa using PICRUSt. Interestingly, dietary ε-polylysine transiently altered the gut microbiome prior to restoration of the initial microbial population structure observed at the end of the feeding trial. Thus ε-polylysine shifts the murine gut microbiome *in vivo* with the community exhibiting an adaptive response over the course of the feeding trial. Moreover, when the cationic ε-polylysine is associated with an anionic polymer this perturbation is mitigated. Finally, the absolute population structure of these murine gut microbial communities was observed to be sex-dependent, but did not alter the response trajectory to exogenous biopolymers.

Effect of Repetitive Applications of an Alcohol-based Nasal Antiseptic on the Nasal Vestibular Microbiota

Author Block:

E. F. Mongodin[1], L. Hittle[1], P. Nasipuri[2], E. W. Spannhake[2]; [1]Inst. for Genome Sci., Baltimore, MD, [2]Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD

Abstract Body:

Interest in the substitution of non-specific non-antibiotic preparations to reduce nasal carriage of *Staphylococcus aureus* (SA) and other human pathogens is increasing. However, the effect of these broad-spectrum agents on bacterial reduction and subsequent re-growth is not well understood. This study evaluated the effects of repetitive applications of an alcohol-based antiseptic on the bacterial load and composition of the nasal microbiota.SA-positive subjects underwent daily applications of an alcohol-based antiseptic over a 3-day period. Swabs from the anterior nares were collected on the morning (pre) and evening (post-treatment) of each day and on the morning of day 4. Samples were cultured to assess CFU counts. DNA was also extracted, followed by 16S rRNA gene PCR amplification, sequencing on Illumina MiSeq and analyses using the QIIME software.Multi-day applications of alcohol antiseptic resulted in marked and significant reduction in total CFU counts on each treatment day (Table 1). The median decrease in nasal bacterial load on mornings 2-4 was 46%, 60% and 74% respectively, and reached statistical significance on day 4. Comparative analyses of the Gram(+) and Gram(-) bacterial composition showed little changes in bacterial richness (Chao1) and diversity (Shannon) after each treatment. Beta-diversity analyses also revealed minimal bacterial composition differences between time points, with samples primarily clustering by subjects. The relative abundance of the top 15 resident bacterial organisms remained mostly unaltered in response to ethanol application and during re-growth.The use of an ethanol-based nasal antiseptic resulted in effective broad spectrum decrease of total bacterial load in the nasal vestibule and did not lead to shifts in the nasal microbiota over a multi-day treatment regimen.

A Metagenomic Approach to Understanding the Effect of Sugar on the Functional Composition of Gut Microbiome of Drosophila Melanogaster

Author Block:

S. Bhatnagar[1], J. A. Chandler[2], J. M. Lang[1], J. A. Eisen[1], A. Kopp[1]; [1]Univ. of California Davis, Davis, CA, [2]Univ. of California Berkeley, Berkeley, CA

Abstract Body:

The gut microbiome of a host has been correlated with many important functions that are required for the health of host. *Drosophila melanogaster* is a model organism, whose gut microbiome is extensively studied to uncover essential roles. There are multiple factors that play a role in determining the community structure of the microbiome, such host genetics and the environment. Diet is one such important determinant of gut microbiome composition. It is a source of nutrients for the microbiome as well as a reservoir of microbes that the host can sample from. In *D. melanogaster*, diet has been implicated as an important factor in bacterial and yeast community structure. These studies have looked only at diet-correlated differences in taxonomic compositions of the communities. Here we present a metagenomic framework to go beyond the taxonomy and elucidate the role of diet in shaping the functional potential of the gut microbiome in *Drosophila melanogaster*.We reared a colony of *D. melanogaster* on Bloomington diet and split the population onto two different nutrient media, yeast-rich and sugar-rich. For these two treatments, fecal swabs and dissected intestines were collected every day, for four days. An SSU-RNA and metagenomic libraries from these samples were compared to identify the similarities in the microbial community's structure and function. We identified specific taxa with differential abundance that responded to the divergence in diet. These differences were observed in both metagenomic and SSU-RNA libraries. For the same samples, a change in functional potential was also discerned as observed through changes in gene abundances in the metagenomic libraries. Using shotgun metagenomics of fecal swabs, we are able to identify the functional capability of the *Drosophila* microbiome using a non-invasive and cost-effective technique. This technique is easily transferable to other insects and non-laboratory populations, allowing the unexplored functional diversity of host-associated microbiome to be identified.

Commensal Oral Bacteria as Probiotics against *Porphyromonas gingivalis*

Author Block:

P. Balani[1], J. Scott[1], L. Hu[2], M. Duncan[1]; [1]The Forsyth Inst., Harvard Sch. of Dental Med., Cambridge, MA, [2]Tufts Univ., Boston, MA

Abstract Body:

The aim of this study was to identify effective probiotics against a model bacterial system and its target genes and metabolic pathways. Periodontitis is a complex polymicrobial disease affecting up to 40% of the US population (1), but the molecular interactions between species in this community are poorly understood. *Porphyromonas gingivalis (Pg*), an oral anaerobe, is associated with the etiology of periodontitis. We previously reported that non-pathogenic commensal bacteria can modulate *Pg* virulence (2), warranting further study of the mechanisms underlying such interspecies interactions. We screened a library of 300 oral commensal *Streptococcus* and *Actinomyces* strains as potential probiotics that inhibit growth of *Pg*. Of the five different non-pathogenic oral species isolated from healthy adults and children, 70% of the *Streptococci* and 10% of *Actinomyces* species completely inhibited the growth of *Pg*. Supernatants of the inhibitory strains were tested for probiotic activity against growth of *Pg* biofilms. Several *Streptococcus oralis* strains produced an inhibitory activity only after co-culture with *Pg*, suggesting communication between the organisms whereas *Actinomyces naeslundii* produced inhibitory compounds that were byproducts of growth. To systematically identify Pg genes that render it sensitive to the inhibitors, we constructed a *Pg* Transposon (Tn) insertion library to be challenged by coculture with the probiotic strains or their inhibitory metabolites. We expect that among the challenged survivors, *Pg* Tn-mutants defective in inhibitor target genes or pathways will be predominantly represented. These mutants will be identified by Tn-seq (transposon sequencing) analysis. The results of this study will increase our understanding of the molecular mechanisms of probiotics and will allow us to determine the *in vivo* role of probiotics in preventing/eliminating periodonatal disease.

Comparative Analysis of Antiseptic Perturbations and Skin Microbial Community Dynamics

Author Block:

A. SanMiguel, J. Meisel, J. Horwinski, Q. Zheng, E. Grice; Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Antimicrobial drugs are commonly employed to inhibit the growth of pathogenic microorganisms. These treatments are rarely narrow in spectrum, and act upon a range of bacterial species in our commensal microbiota. Only recently have these effects been fully appreciated, as previous research has relied on isolated, culture-based systems. While informative, these studies cannot account for the complex growth environments of most microbial communities, and fail to evaluate the dynamics of previously uncultured bacteria. This is especially relevant when considering the skin surface, where antiseptics are used with the expectation of complete bacterial sterilization. Indeed, many of these treatments boast efficacy rates greater than 99% when used against pathogenic microorganisms in artificial culture studies. Despite these results, few studies have explored the impact of antisepsis on resident, non-pathogenic bacteria. By using hairless mice as a model system and culture-independent 16S rRNA gene sequencing, we report a minimal and conserved effect of antiseptics on resident bacterial populations. We also describe a potential impact of these drugs on transient bacteria such as *Staphylococcus* species. These results were confirmed by human studies in which limited, personalized effects of antiseptic treatment were observed on skin bacterial communities over time. This includes separate biogeographic regions of the skin including the forearm and upper back. In all, these results suggest that skin bacterial inhabitants represent a relatively stable community at the population level, but that particular residents may vary in an individualized manner. It also supports the notion that antimicrobial drugs, while potent *in vitro*, may have more modest effects in the context of resident bacterial populations at the skin surface.

Sadowsky[3]; [1]PacBio, Menlo Park, CA, [2]Univ. of Minnesota, St Paul, MN, [3]Univ. of Minnesota, St. Paul, MN, [4]Univ. of Minnesota, Minneapolis, MN, [5]Brown Univ., Providence, RI, [6]Montefiore Med. Ctr., New York, NY

Abstract Body:

Background: Fecal samples were obtained from human subjects in the first blinded, placebo-controlled trial to evaluate the efficacy and safety of fecal microbiota transplant (FMT) for treatment of recurrent *C. difficile* infection. Samples included pre-and post-FMT transplant, post-placebo transplant, and the donor control; samples were taken at 2 and 8 week post-FMT. Sequencing was done on the PacBio Sequel System, with the goal of obtaining high quality sequences covering whole genes or gene clusters, which will be used to better understand the relationship between the composition and functional capabilities of intestinal microbiomes and patient health. **Methods:** Samples were randomly sheared to 2-3 kb fragments, a sufficient length to cover most genes, and SMRTbell libraries were prepared using standard protocols. Libraries were run on the Sequel System, which has a throughput of hundreds of thousands of reads per SMRT Cell, adequate yield to sample the complex microbiomes of post-transplant and donor samples.**Results:** Here we characterize samples, describe library prep methods and detail Sequel System operation, including run conditions. Descriptive statistics of data output (primary analysis) are presented, along with SMRT Analysis reports on circular consensus sequence (CCS) reads generated using an updated algorithm (CCS2). Final sequencing yields are filtered at various levels of predicted accuracy from 90% to 99.9%. Previous studies done using the PacBio RS II System demonstrated the ability to profile at the species level, and in some cases the strain level, and provided functional insight.**Conclusions:** These results demonstrate that the Sequel System is well-suited for characterization of complex microbial communities, with the ability for high-throughput generation of extremely accurate single-molecule sequences, each several kilobases in length. The entire process from shearing and library prep through sequencing and CCS analysis can be completed in less than 48 hours.

Microbial Interactions in a Model Consortium of the Infant Intestinal Microbiome

Author Block:

A. Ovalle, F. Pinto, **D. Garrido**; Pontificia Univ. Católica de Chile, Santiago, Chile

Abstract Body:

The intestinal microbiome is a complex assembly of microorganisms, that impacts host physiology and health in several ways. The infant gut microbiome starts to develop at birth, where microbes from the fecal and vaginal microbiome of the mother come in contact with the infant and start a colonization process dominated by facultative anaerobes followed by strict anaerobes, especially *Bifidobacterium*. Diet is one the major factors shaping the composition of this community in the first years of life, with clear differences in microbiome composition during breast or formula feeding. It is not known how infant gut microbes respond to other members and how this interaction is shaped by dietary compounds. In this study we aimed to study microbial interactions in a model infant microbiota using a representative culture media containing fructooligosaccharides (FOS), a prebiotic commonly used in infant formula. We defined a model consortium of the infant gut microbiome, consisting of four representative species: *B. longum* subsp. *infantis* (Bi), *Lactobacillus acidophilus* (La), *Escherichia coli* (Ec) and *Bacteroides vulgatus (Bv)*. Using experimental design and surface response analysis, we modified a previously reported chemically defined media (ZMB-1), including variables such as partially degraded proteins, presence of bile salts, and pH of 5.5. This optimized media was used to evaluate the levels of each member of the consortium when given FOS as the sole carbon source. Experiments were performed as monoculture, and co-culture with every other member of the consortium. Bacterial levels were assessed every 12 h during 72 h by qPCR. We found that Bi always dominated each co-culture, supporting the prebiotic effect of FOS, and that Bv and Ec outnumbered La. Interestingly, when accounting for the amount of cells in co-culture over monoculture, this ratio was always higher for Bi, indicating that this bacterium achieves higher cell densities when growing with other members of the consortium than alone. In contrast, Bv numbers were always lower during co-culture than in monoculture. This suggests that while Bi enjoys the benefit of company in a commensalist interaction with other members of the microbiome, Bv instead displays a more competitive relationship with other bacteria. These results indicate that different ecological forces shape the infant gut microbiome and should be considered.

What Is in That Soiled Diaper: A Study on Enumeration and Characterization of *bifidobacterium* and Other Gut Bacteria from an Infant

Author Block:

T. W. Frazer, M. Santos; The Univ. of North Carolina at Pembroke, Pembroke, NC

Abstract Body:

The genus of bacteria *Bifidobacterium* contains over 50 known species with new species and subspecies still being discovered and heavily researched today. *Bifidobacteria* populations in newborns and infants are of particular interest, as these bacteria are among the initial colonizers of the infant gut and comprise the overwhelming majority of the infant's intestinal/gut microbiome. The positive influence of *Bifidobacteria* on infant health has long been noted as the various species within this genus have been shown to prevent allergic diseases, aid in breast-milk digestion, as well as inhibit potentially pathogenic microbes The study attempted to enumerate and characterize the antimicrobial effects of *Bifidobacteria* by collecting fresh fecal samples from soiled diapers during the first eight weeks of an infant's life. The fecal samples were collected using nitrogen enriched culture collection/transport device, were diluted using tryptic soy broth, and plated onto agar media selective for *Bifidobacteria*. The plates were incubated for 48 hours at 37C with and without oxygen. Standard plate counts and optical density readings were used to enumerate bacteria from the fecal sample. *The* antagonistic effects of *Bifidobacterium breve* against the pathogens *Escherichia coli*, *Clostridium difficile*, and *Candida albicans* were tested using the diffusion disk method. Preliminary anaerobic counts showed *Bifidobacteria* numbers were low in the first three days of life and then increased exponentially thereafter within the next 8 weeks to become the major type of microbe in the infant gut. Disk assays showed *B. breve* inhibited all three of the potential pathogens used in the study, while there was no inhibition between *E.coli* and *C. albicans*. The researchers plan to validate the bacterial counts and the identity of the other non-*Bifidobacterium* bacterial colonies from the frozen fecal samples during the months of January and February 2016.

Strain-level Metagenomic Analysis Implicates Uropathogenic *E. coli* in Necrotizing Enterocolitis and Death in Preterm Infants

Author Block:

D. V. Ward[1], M. Scholz[2], M. Zolfo[2], D. H. Taft[3], K. R. Schibler[3], A. Tett[2], N. Segata[2], A. L. Morrow[3]; [1]Univ. of Massachusetts Med. Sch., Worcester, MA, [2]Univ. of Trento, Trento, Italy, [3]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract Body:

Background: Necrotizing enterocolitis (NEC) afflicts approximately 10% of extremely preterm infants with high fatality. One in fourteen infants born prior to 32 weeks of gestation or less than 1500 grams develop NEC, and nearly one-third of NEC cases are fatal. The etiology of NEC is not confidently established, but appears to result from a hyperinflammatory response to the gut microbiota. Inappropriate bacterial colonization with Enterobacteriaceae is implicated but no specific pathogen has been identified. We sought to apply metagenomic approaches to characterize, at the species and strain level, Enterobacteriaceae that may indicate risk for NEC.**Methods:** Metagenomic shotgun sequence data was generated from 144 preterm infants (less than 30 weeks gestational age) and 22 term infants (greater than 37 weeks gestational age) with stool samples collected between days 3 to 22 of life. Novel analysis methods were developed to subtype *E. coli* species present in the infant gut microbiome.**Results:** Metagenomic analysis indicated that function subtypes of *E. coli*, defined by species-specific accessory gene content were associated with development of NEC and death as NEC-outcome. Accessory gene content and metagenomic multi-locus strain typing indicated that risk was associated with uropathogenic *E. coli* strain types (UPEC).**Conclusions:** Colonization by UPEC is a risk factor for development of NEC and (ii) UPEC correlated with death as an outcome. These findings are the first to associate UPEC with NEC and provide a foundation for further investigating the epidemiology of NEC.

Diversity and Variability of the Dominant Enterococci in Human Stool Samples

Author Block:

C. Del Rio-Ramos, L. A. Ríos-Hernández; Univ. of Puerto Rico, Mayaguez Campus, Mayaguez, Puerto Rico

Abstract Body:

The intestinal flora of humans is known to harbour a multitude of microorganisms. One important genus is *Enterococcus*, while it only composes less than 1% of the total gut flora, the ability to harbour a wide array of virulence factors and antibiotic resistance grant it medical importance. However, not much is known about how the species composition behaves in the human gut. In order to fill this gap, the focus of our study was to analyse and compare the dominant enterococci population of two subjects via daily stool sampling for a period of 7 consecutive days. A total of 140 Enterococci per subject were isolated and subjected to antibiotic resistance assays and molecular analysis. Molecular analysis allowed the comparison of isolates at the species level, presence of virulence factors and ultimately at the strain level. Total enterococci population was around 10^6 to 10^8 for both subjects, however species composition and dominance were different. In subject #1, the dominant enterococci vary daily but was limited to *E. faecium* and *E. faecalis*, with two transitions in seven days. Of the two species, *E. faecalis* was the most virulent with vancomycin resistance and gelE virulence factor for 3 days while *E. faecium* only had *gelE*. In subject #2, *E. faecalis* was the only dominant species during the sampling period. Although species dominance was consistent, the strains and the frequency of virulent factors among the dominant species were different and higher than in subject #1. Although Enterococci were always present at similar densities, the dominant population changed daily. One subject had a higher frequency of strains with virulence factors, gelE and esp, while the other had a wider range of antibiotic resistances, vancomycin being the most notable. Screening for colonization of virulent strains during hospital admittance might not safeguard the patient's health because of the high strain transition frequency.

Microbial Transformation of *Populus* Secondary Metabolites By Microbiome Isolates

Author Block:

D. A. Pelletier, J. Morrell-Falvey, A. N. Bible, G. B. Hurst, K. Chourey, M. Denney, K. Kertesz, A. Zinkle, C. Timm, T-Y. Lu, N. Engle, T. Tschaplinski, M. Doktycz; Oak Ridge Natl. Lab., Oak Ridge, TN

Abstract Body:

Populus is a widely studied model woody plant species and a potential cellulosic feedstock for biofuels. These trees host a wide variety of microbial associates within their roots and rhizosphere and thus serve as a useful model to study interactions between plants and microorganisms. One of the defining characteristics of *Populus* is the production of secondary metabolites known as higher-order salicylates (HOS), which are involved in host defense and signaling mechanisms. We are interested in determining the influence of these HOS on the host-microbiome composition and physiology. We have isolated and characterized a number of bacteria from genera (*Pseudomonas*, *Sphigobium*, *Rhizobium*, *Bacillus*, *Pantoea*, *Duganella*, *Burkholderia*, *Caulobacter*, *Streptomyces*, *Bradyrhizobium*, *Rahnella* and *Varivorax)* prevalent in the endosphere and rhizosphere compartments of *Populus* roots and obtained whole genome sequence data. Here we describe physiological characterization of these bacterial isolates with the goals of determining the ability of these strains to transform salicin and other HOS extracted from *Populus* tissues, and measuring the sensitivity and resistance of these bacterial strains to HOS compounds and their degradation products. We present proteomics, metabolomics and comparative genomics data from select strains that have led to identification of potential mechanisms for transformation of the HOS. We hypothesize that the complex nature of these HOS metabolites and their degradation products may be a mechanism for modified plant-bacteria signaling, and may facilitate microbial cross feeding in which has been observed in bacterial co-cultivation experiments. This analysis provides initial insight into the prevalence and diversity of *Populus* microbiota capable of transforming HOS, potential transformation mechanisms, and interactions between microbiome community members.

A Meta-Analysis of Obesity and the Bacterial Microbiome: Is There Common Ground?

Author Block:

M. A. Sze, P. D. Schloss; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: There have been numerous studies investigating the role of the bacterial microbiome on obesity. The evidence in mouse and human studies show the powerful effect that the microbiome could have in obesity. Yet, two recent meta-analyses on different data sets suggest otherwise (Finucane et al. 2014 and Walters et al. 2014). We build on these two studies by incorporating all data sets with body mass index and microbiome data and add additional data from controls in the Great Lakes and New England (GLNE) cohort. By harnessing the increased power provided by combining multiple cohorts we investigate whether there are community or population-level signals that would allow us to differentiate people of varying body mass index (BMI).**Methods:** A total of 10 datasets were/are being analyzed (GLNE (n=172), Human Microbiome Project (HMP) (n=256), Ross et al (n=63), Escobar et al (n=30), MetaHit -Danish only (n=85), Nam et al (n=18), Turnbaugh et al (n=281), Goodrich et al (n=525), Zupancic et al (n=202), and Yatsunenko et al (n=528)). For each dataset we calculated the Shannon diversity, Bacteroidetes/Firmicutes ratio (B/F), and generated Random Forest models using individual operational taxonomic units to differentiate individuals based on BMI or obesity categories based on BMI. We also included demographic data for each subject to determine whether these could be used to strengthen the associations. We used an RE model to generate relative risk (RR) and confidence intervals (CI) for a pooled analysis across studies.**Results:** No difference was found between non-obese and obese groups for Shannon diversity and B/F ratio ($P > 0.05$). There was no significant increase in RR of obesity in high versus low diversity groups (RR = 1.08 (CI 0.92-1.27)). Analyzing the data together, there was a significant loss of diversity in the overweight versus obese group ($P=0.01$). Using continuous and categorized BMI data, each dataset had factors that predicted non-obese from obese with a high degree of accuracy (out of bag area under the curve, 0.71-0.95). The majority of variables that were predictive in a single dataset were not predictive in more than two datasets. Ruminococcaceae (4/7 datasets) and Shannon diversity (3/7 datasets) were the exception to this.**Conclusion:** These data suggest the lack of a consistent taxonomic signal that is associated with variation in a person's BMI.

Dynamic Community Structure Of The Necrobiome Has The Potential To Aid Postmortem Interval Determination

Author Block:

Z. Burcham[1], J. Pechal[2], J. Bose[3], E. Benbow[2], C. Schmidt[4], H. Jordan[1]; [1]Mississippi State Univ., Starkville, MS, [2]Michigan State Univ., East Lansing, MI, [3]Univ. of Kansas Med. Ctr., Kansas City, KS, [4]Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Little is known about the postmortem microbiome (necrobiome) in cadavers, particularly the microbial structure of the microflora residing within the human ecosystem, and their associations with decomposition stages. Recent work suggests that these postmortem bacterial communities are surprisingly dynamic. We describe how the microbiome of a living host changes and transmigrates within the body after death, linking the microbiome of the living to the postmortem necrobiome. These changes have demonstrated promise as usable evidence in criminal investigations for estimating the time since death occurred (postmortem interval). We investigated the postmortem microbial community structure in a mouse model along with the transmigration of the bacterial species present in a highly controlled setting which minimized outside microbial influence not associated with the microbiota. Immunocompetent mice (N=60) were inoculated intranasally with *Staphylococcus aureus*-RFP and *Clostridium perfringens* to introduce controlled aerobic and anaerobic communities, respectively, that have the ability to break down host tissue through protease production. Thirty of the inoculated mice were immediately surface sterilized with a bleach solution following sacrifice, in order to disrupt the influence of the external microbiota. DNA was isolated and purified from tissue samples starting at 1 hour and ending at 7 days postmortem, for use in library preparation and whole genome shotgun sequencing. Sequencing results were analyzed to identify changes in community structures associated with different stages of decomposition. The results from this study could provide insight into how commensal bacterial populations colonize, proliferate, and transmigrate throughout the host following death. Data obtained from this study contributes to our ongoing investigations that aim to identify novel methods that could be used in the field of forensic science to precisely measure time since death.

Mapping the Gastrointestinal Microbiota of a Human Cadaver

Author Block:

J. Coffman[1], M. Sanchez-Gonzalez[2]; [1]Saba Univ. of Med., The Bottom, Netherlands Antilles, [2]Larkin Community Hosp., South Miami, FL

Abstract Body:

Background: Fresh frozen cadavers offer the opportunity to investigate the resident flora of the human gastrointestinal tract as the donated body is quickly frozen in saline to preserve tissue integrity.**Methods:** 13 fecal/mucus samples were collected from the stomach to the descending colon, DNA was extracted and bacterial amplicons from the V1-V3 hypervariable region of the 16S rRNA gene were sequenced using Ion Torrent DNA Sequencing and reads were clustered into operational taxonomic units (OTUs, 3% distance) and taxonomically classified using the Green Gene database.**Results:** The stomach region revealed OTUs with the lowest diversity and similar to the microbiota of the distal duodenum. There was a steady increase in the populations of *Lactobacillus casei*, *Bacillus sp.* and *Kocuria rosea* throughout the small intestine with a dramatic decrease towards the proximal end as diversity increased. The diversity of the ascending, transverse and descending regions of the colon were drastically distinct and highly diverse (Figure 1).**Conclusion:** Mapping the gastrointestinal tract of the human gut revealed distinct eubacterial communities relative to locations and structures within the gastrointestinal tract.

Using the Human Necromicrobiome to Estimate the Postmortem Interval

Author Block:

D. D. Trinidad, N. H. Lents, S. Guzman, J. Parziale, A. Lerer; John Jay Coll. of Criminal Justice, Manhattan, NY

Abstract Body:

The microbiome is the community of microbes that live in, on, and around the human body. In this project, we explore postmortem changes in this community. One goal of this work is to establish new tools for calculation of the postmortem interval (PMI) to aid death investigations. In the first phase of this project, we compared the bacterial communities on both living and deceased subjects to determine whether or not we could identify consistent differences among the microbial communities. We were successful and identified many microbial taxa, particularly genera and species, that allow us to characterize a sample as having come from a decomposing body. In phase two, we are focused solely on cadavers, and how the microbiome changes through the course of decomposition. Specifically we collected swab samples from the nostrils and external ear canals of four cadavers at the Anthropology Research Facility at the University of Tennessee at Knoxville over 4-6 weeks of decomposition. We then extracted DNA from these samples and performed 16S metagenomic sequencing using the miSeq platform from Illumnia. We then identified several dozen bacterial taxa that show a consistent pattern of change in all four bodies. We used these to construct a statistical algorithm with which to predict the PMI and tested it on eight test subjects. The results are both striking and encouraging. We conclude that the postmortem microbiome will be a successful tool in establishing PMI and will present our proof-of-concept study of how it might be done.

Dominant *Bifidobacterium* and *Lactobacillus* Species in Patients with Non-alcoholic Fatty Liver Disease

Author Block:

C. Erdogdu[1], M. Y. Cirak[2], T. Karakan[2]; [1]Hacettepe Univ., Ankara, Turkey, [2]Gazi Univ., Ankara, Turkey

Abstract Body:

Background: Identification of *Lactobacillus* and *Bifidobacterium* species in certain conditions is of critical importance due to their health promoting effects. Here we hypothesized that patients with NAFLD and healthy microflora may have some distinct characteristics in terms of dominant species. Despite the many advantages of next generation sequencing, plasmid library construction still have some superiorities since it makes possible to determine the bacteria in species level. However the disadvantage of this method is being very time consuming and its high cost. In order to determine the *Lactobacillus* and *Bifidobacterium* microflora in species level we choose the metagenomic approach by constructing library from pooled and amplified patients and control stool samples which may be a good approach to analyze high number of samples with a cost-effective strategy.**Methods:** A total of 49 NAFLD patients and 35 control subjects stool DNA samples were pooled within each group in the same concentration. The DNA pools were amplified with specific primers for *Lactobacillus* and *Bifidobacterium* and ligated into PCR 2.1 TA cloning vector. After transformation E.coli clones were cultured in Luria-Bertani Agar containing 100 mg/L ampicillin. Approximately 50 colonies for each group were randomly selected and sequenced.**Results:** All sequences obtained showed more than 98% sequence identity. The most dominant Lactobacillus species was *L. ruminis* in both patients (44.6%) and healthy controls (50%). However *L. reuteri* which was the second dominant *Lactobacillus* member in patients group (21.4%) was not observed in healthy controls. Different from patient microflora healthy microflora contains *L. sakei* and *L. helveticus*. *L.acidophilus* could not be determined in both groups. Patient and healthy microflora has *B. adolescentis* and *B.bifidum* as dominant species. The main difference is patient group has 7.7% of B. infantis which could not be determined in healthy controls.**Conclusion:** Sample pooling before plasmid library construction is a successful cost-effective method for determining dominant species in a community. The dominant *Lactobacillus* and *Bifidobacterium* species seem to be different between healthy controls and NAFLD patients which promote the idea that the certain species may be unique for the disease or health situation.

Gut Microbiota in Patients with Non-Alcoholic Fatty Liver Disease

Author Block:

C. Erdogdu[1], M. Y. Cirak[2], T. Karakan[2]; [1]Hacettepe Univ., Ankara, Turkey, [2]Gazi Univ., Ankara, Turkey

Abstract Body:

Background: The effect of the gut microbiota on several diseases is becoming increasingly important issue. Since there is a close relationship between gut and liver via portal vein, the liver is consistently exposed to bacterial products such as endotoxin. The composition and quantification of microbiota members may be important for gut dysbiosis and subsequent bacterial translocation which may be the major cause of non-alcoholic fatty liver disease (NAFLD). In order to support this hyphothesis we performed qPCR analysis in stool of patients with NAFLD and healthy controls.**Methods:** The stool samples from 52 patients with NAFLD and 38 healthy controls have been collected. NAFLD has been proven by biopsy in 43 of the patients. 16S rRNA qPCR assay has been performed for quantification of *Akkermansia muciniphila, Faecalibacterium prausnitzii, Bifidobacterium spp, Lactobacillus spp, Bacteroides fragilis* group and *Enterobacteriaceae*. Serum IL-6, TNF-α, hs-CRP and **endotoxin levels were assessed.Results:** *A. muciniphila* and *B. fragilis* group were found significantly lower in patients with NAFLD ($p=0.003$ and $p=0.001$; respectively). As expected, the Enterobacteriaceae family members were found to be significantly higher in patients group ($p<0.001$). In consistent with the higher Enterobacteriaceae abundance in NAFLD patients, elevated serum endotoxin levels were also determined. TNF-α and IL-6 levels were not significantly different, however patients have 3 fold higher hs-CRP which is a well-known marker of inflammation. Multiple regression analysis has performed in order to adjust for BMI and gender. A. muciniphila was still significantly lower and Enterobacteriaceae levels were significantly higher in patients group after adjusting for BMI and gender ($p=0.0221$, $p=0.0186$; respectively).**Conclusion:** NAFLD patients were characterized with higher Enterobacteriaceae levels, lower *A. muciniphila* and *B. fragilis* group levels in our study cohort. Elevated endotoxin levels and inflammation are also supporting our hypothesis.

Microbial Occupation of Cecal Crypt Microniches Depends on Host Conditions

Author Block:

A. Zaborin, J. Defazio, S. K. Hyoju, M. Krezalek, **O. Y. Zaborina**, J. C. Alverdy; Univ. of Chicago, Chicago, IL

Abstract Body:

Background: It has been demonstrated that cecal crypts represent a specific microniche that is normally colonized by commensal bacteria providing the host with sustained tonic stimulation. Here we hypothesize that physiological stress in the form of surgical injury can disturb the cecal crypt microbiome providing an opportunism for colonization by pathogens. **Methods:** We used a mouse model in which mice undergo a short period of pre-operative starvation, antibiotic administration (IM cefoxitin) and a 30% hepatectomy that mimics the process of elective surgery. When mice were intestinally inoculated with a pathogen community (PC- *Serratia marcescens, Klebsiella oxytoca, Enterococcus faecalis*, and *Candida albicans*) isolated from the stool of a critically ill patient, mortality rates approached 60-80%. Five groups of mice were studied: untreated controls, starvation + antibiotics (SA), hepatectomy alone (H), starvation + antibiotics + hepatecomy (SAH), and starvation + antibiotics +hepatectomy + PC inoculation (SAHPC). Mice were sacrificed at 48 hours and cecal crypts were analyzed by scanning electron microscopy, hematoxylin and eosin staining, and fluorescent *in situ* hybridization using bacterial universal probe and probes specific for each member of pathogen community.**Results:** Cecal crypts in untreated mice showed dense filling with bacteria. Hepatectomy alone did not influence the crypt microbiota. The SA treatment demonstrated that 20-25% of crypts were empty and the remaining crypts were less packed. Full SAH treatment dramatically decreased crypt microbiota with upto 60% of crypts completely empty and the remaining crypts sparsely occupied by bacteria (n=5 mice, 3 cecal sections per mouse, 4000 crypts total, $p<0.01$ compared to control). SAHPC group displayed crypts sparsely colonized by the three bacterial pathogens with predominance of *S. marcences.* No *C. albicans* was detected in crypts. **Conclusions:** Crypt microbiota are not stable structures and can be readily disturbed during the process of major surgery. Empty crypts may create opportunism for pathogens to colonize with profound implications for disease.

Pan Gi Analysis of *F. nucleatum* Colonized Human Tumors

Author Block:

S. Bullman, C. Pedamallu, M. Meyerson; Dana-Farber Cancer Inst., Boston, MA

Abstract Body:

Studies by our group have implicated an over abundance of Fusobacterium nucleatum (Fn) in association with colorectal cancer1,2. Noting that Fn is primarily an oral pathogen, providing a source of entry to the digestive tract, we set out to determine if Fn colonizes tumors of the gastrointestinal (GI) tract, from the mouth to the rectum via our computational subtraction pipeline, PathSeq3. Our analysis of whole genome and RNAseq data from over 2,000 human tumors from TCGA cohorts demonstrates Fn is associated with a subset of tumors throughout the GI tract. With this we reveal a conserved microbial signature characterized by the enrichment of anaerobic bacteria and depletion of aerobic organisms in tumors that are colonized with Fn. We observe Fn to be significantly enriched in tumors of stomach adenocarcinoma in comparison to matched normal tissue. Together these findings may suggest a Fn specific tumor microenvironment in a subset of tumors along the GI tract. Furthermore, we have comprehensively characterize Fn-associated tumors by correlating host mutation status, transcriptome and epigenetic landscapes, along with clinical information, to reveal site-specific and site-shared features of Fn associated tumors. Comparison of host gene expression signatures between Fn “high” and Fn “low/negative” tumors reveals a hypoxic inflammatory signature in the presence of Fn. We hypothesize that (i) particular Fn strains are associated with GI cancers and (ii) this occurs within a susceptible host population. As such, an ongoing focus of or work, via whole genome analysis of cancer and non-cancer associated Fn strains, is to determine if genomic features are shared specifically between tumor isolates, revealing “high-risk” strains.

Sources of DNA Contamination in a Study of Human Oral Microbial Communities

Author Block:

N. M. Davis, D. M. Proctor, D. A. Relman; Stanford Univ., Stanford, CA

Abstract Body:

Background: Sample contamination by exogenous microbial DNA is an important but understudied problem in sequence-based human microbiome compositional analysis. Low-biomass samples are of particular concern, as contaminant sequences from the laboratory environment, reagents, and other samples can obscure biologically meaningful findings. **Methods:** We collected oral mucosa samples (MS) from 7 distinct sites in each of 3 healthy adults daily for 29 days (n=609), and another set of the same 7 MS once a week in the same period (n=105). We extracted genomic DNA from 25 blank swabs and 5 no-template extraction control samples (EC) alongside biological samples. After PCR-amplifying the V4 region of the 16S rRNA gene using barcoded primers, amplicons were sequenced using Illumina MiSeq. A total of 16,272,135 paired-end, high-quality reads were analyzed.**Results:** Sample type (MS vs. EC) contributed most to the explained variance in Bray-Curtis distances between samples (PERMANOVA: $F=108$, $R^2=0.14$, $P=0.001$). 86 contaminant operational taxonomic units (OTUs) were classified as either oral cross contaminants or environmental contaminants using a k-Nearest Neighbors (k-NN) classifier trained on OTU sequence relative abundances and amplicon yield (PicoGreen dsDNA assay). Classifications were consistent with known contaminating environmental taxa like *Methylobacterium komagatae* and with known members of the oral microbiota like *Haemophilus parainfluenzae*. A pairwise, between-sample correlation matrix showed that removal of 76 putative environmental contaminants resulted in 12 of 30 EC becoming less distinct from MS.**Conclusions:** Our results point to multiple sources of contamination, including the laboratory environment and reagents, and to a lesser extent, biological samples processed alongside EC. Differences in OTU relative abundances across samples help to distinguish cross contaminant OTUs from environmental OTUs, which may allow a classifier like k-NN to identify environmental sequences for removal. A remaining question is exactly which laboratory sources (e.g. surfaces vs. reagents) give rise to environmental sequences. We will address this question by developing a physical model for the study of sample processing.

Determining the Optimal Primers for Studying Microeukaryotic Diversity of the Human Gut

Author Block:

T. A. Auchtung, A. K. Nash, M. C. Wong, N. J. Ajami, J. F. Petrosino; Baylor Coll. of Med., Houston, TX

Abstract Body:

Microeukaryotes are an understudied component of the human gut microbiome — in healthy adults, fungi and protists compose typically 0.01 - 1% of the genetic material. They have been shown to be present at abnormal levels in some diseases. The extent of this diversity is infrequently examined, and it is often unclear whether the detected microeukaryotes are active components that have colonized the gastrointestinal tract, or are simply passing through with consumed food or saliva.To gain insight into the microeukaryotic diversity of the gut, we are amplifying, sequencing, and analyzing ribosomal internal transcribed spacer (ITS) and 18S rRNA genes that are useful for identifying fungi, and other microeukaryotes, respectively. As an initial step, it was necessary to determine which of the many published ITS primer sets was best for use with MiSeq 2x300 sequencing of fecal samples. The most important criteria were which primers had the best amplification efficiency, and which the broadest and least biased taxonomic coverage. We tested those commonly used to target ITS1 (ITS1F and ITS2R) and ITS2 (ITS3F and ITS4R), the published winner of another fungal primer set comparison, ITS2-targeting ITS86F and ITS4R, and as a control, the broad fungal 18S rRNA gene-targeting 775F and 1121R.DNA extracted from five children's fecal samples, five adult fecal samples, and a mock community were used as template in PCR with each the of four primer sets. When the 11 PCR-amplified samples were run on an agarose gel, there was a detectable band from 5/11 for ITS1F-ITS2R, 8/11 for ITS3F-ITS4R and ITS86F-ITS4R, and 9/11 for 775F-1121R. No primer set yielded consistently greater alpha diversity. ITS3F-ITS4R and ITS86F-ITS4R amplicons had no major taxonomic differences, but neither detected *Rhodotorula* (Sporidiobolales). ITS1F-ITS2R missed *Malassezia*, and mock community members *Cryptococcus neosporans* and *Aspergillus fumigatus* completely.Based on the above results, ITS3F-ITS4R was chosen for use in our large scale fungal analysis projects. This ITS primer set, in concert with 18S rRNA gene primers, are now yielding insights into the diversity, activity, and functions of the microeukaryotic portion of the human gut.

Bioinformatics Workflow for Metagenomics Data Analysis

Author Block:

M. Matvienko, S. Prince, Katja Einer, Arne Materna, M. Miyamoto; Qiagen Bioinformatics, Redwood City, CA

Abstract Body:

Background: Next generation sequencing allows for comprehensive analysis of metagenomics samples. Nowadays researchers can examine the microbial species composition from a variety of environmental resources, such as gut and fecal microbiomes, soils, air, various water resources, etc. The existing data analysis tools are not always easy to use and have limited functionalities.**Methods:** We used the CLC Microbial Genomics Module, that supports the metagenomics analyses in CLC Genomics Workbench. The sequencing data were passed through QC, trimming, and alignment to Greengenes OUT reference database. The primary output of the clustering, tallying and taxonomic assignment processes is an OTU table, listing the abundances of OTUs in the samples under investigation viewable through a number of intuitive visualization options. Our secondary analyses included estimations of alpha and beta diversities, in addition to the statistical tests for differential abundance.**Results:** Here we present the analysis results from publically available chicken gut microbiome data. The samples were extracted from two different parts of the intestines (ilea and caeca) from chicks at different ages (7, 14, 21 and 42 days-old). In our analysis, we present the alpha diversity, the bar charts with different level of taxonomy, and the PCoA analysis. Different visualizations options and easy switches between the aggregate taxonomy units significantly speedup the analyses and promote the decision making.**Conclusions:** The described metagenomics workflow allowed for comprehensive analysis of metagenomics data in a user friendly environment.

Metatranscriptome Analysis of Gnotobiotic Mice Harboring the Altered Schaedler Flora During Epithelial Injury Mouse Model of Colitis-associated Cancer

Author Block:

A. Proctor, G. J. Phillips; Iowa State Univ., Ames, IA

Abstract Body:

Background: Colorectal cancer (CRC) is a common type of cancer in both men and women, and individuals with inflammatory bowel disease (IBD) are at a greater risk of developing CRC. Both IBD and CRC are associated with dysbiosis of the gastrointestinal (GI) microbiota. Conventional mice harbor hundreds of species of bacteria in their GI tract, making associations between bacterial taxa and host functions difficult. Using Altered Schaedler Flora (ASF) mice, colonized with only 8 species of bacteria, we can more precisely evaluate how the GI microbiota responds to the GI environment. **Methods:** Gnotobiotic C3H:HeN mice harboring the ASF, as well as conventional C3H:HeN mice, were split into 4 groups each: control, dextran sodium sulfate (DSS) only, azoxymethane (AOM) only, and AOM+DSS. Mice in the AOM groups were given a single intraperitoneal (IP) injection of AOM on day 1, while the control and DSS only groups received an IP saline injection. Throughout a 10-week period, mice in DSS groups were treated with 2% DSS in drinking water for 7 days, with 2 week restitution between treatments. Fecal samples were taken throughout the study. After 10 weeks, mice were euthanized and cecal, colon and fecal pellets were collected, as well as colon tissue and tumors or abnormal lesions. Total RNA was extracted from fecal pellets from ASF mice after the last DSS treatment. RNA was pooled in the control, DSS only, and AOM+DSS groups for library preparation and sequencing of cDNA on the Illumina HiSeq2500 platform. **Results:** All DSS treated mice had shorter colon lengths at necropsy. Gross analysis of the GI tract of conventional mice revealed 30% of the animals had cancerous lesions. In contrast, ASF mice showed no lesions associated with AOM+DSS. Transcriptome analysis of fecal pellets from the ASF mice revealed differences in metabolic pathways associated with both inflammation and carcinogens. **Conclusion:** Our unique gnotobiotic mouse model has allowed us to detail the changes in metabolic pathways of the resident GI community with respect to GI health of the host. The observation that ASF mice displayed no lesions suggests the limited ASF community lacks important triggers of tumorigenesis found in a conventional GI community.

Metabolic Functionality and Interaction of the Altered Schaedler Flora Captured *In Vitro* and *In Silico*

Author Block:

G. Kolling[1], M. Biggs[1], G. Medlock[1], T. Moutinho, Jr.[1], J. Swann[2], H. Lees[2], J. Papin[1]; [1]Univ. of Virginia, Charlottesville, VA, [2]Imperial Coll., London, United Kingdom

Abstract Body:

Background: The Altered Schaedler Flora (ASF) is a model microbial community with both *in vivo* and *in vitro* relevance. Because the ASF has primarily been used to standardize gnotobiotic mice, very little is known about it—particularly as a dynamic, interacting community. This project is the first to characterize the ASF community *in vitro*, independent of a murine host.**Methods:** We performed a comprehensive, functional genetic analysis of all eight species. Furthermore, we developed a chemically-defined medium that supports growth of seven of the eight ASF members. Finally, to elucidate the metabolic capabilities of each ASF species—and the potential for competition and cross feeding—we performed a spent media screen and analyzed the results through dynamic growth measurements and unbiased metabolomics.**Results:** We found that cross-feeding is relatively rare (20 of 1512 possible cases), but is enriched between ASF356 and ASF519. We identified many cases of emergent metabolism (334 of 1512 possible cases), where metabolite consumption or biosynthesis was dependent on interspecies interactions. We validated metabolomics-based predictions by designing minimal media which supports the growth of ASF519.**Conclusions:** These data will inform efforts to understand ASF dynamics and spatial distribution *in vivo*, to design pre- and probiotics that modulate relative abundances of ASF members, and will be essential for validating computational models of ASF metabolism. Furthermore, this novel framework for characterizing microbial communities can be beneficially applied to many other communities of interest. Well-characterized, tractable model communities such as the ASF enable research which will translate into improved human health.

Identification of ABC-JK2, a Small Molecule Inhibitor of Staphylococcal Biofilm Formation

Author Block:

Y. Yoshii[1], K-i. Okuda[1], S. Yamada[1], M. Nagakura[1], S. Sugimoto[1], T. Nagano[2], T. Okabe[2], H. Kojima[2], Y. Mizunoe[1]; [1]The Jikei Univ. Sch. of Med., Tokyo, Japan, [2]The Univ. of Tokyo, Tokyo, Japan

Abstract Body:

Background: *Staphylococcus aureus* is a major causative pathogen of hospital- and community-acquired infections. Especially, methicillin-resistant *S. aureus* (MRSA) is a serious global threat in recent years. Moreover, *S. aureus* attaches to medical device surfaces and forms multilayered communities of bacteria called biofilms. Since biofilm bacteria exhibit much greater resistance to antibiotics than planktonic bacteria, there are still no effective therapeutic agents for combatting biofilm-related infections. In this study, based on the concept that compounds specifically targeting biofilm formation would not exert high selective pressure for resistance, we aimed to identify compounds that inhibit biofilm formation by *S. aureus* without affecting bacterial growth.**Methods:** Biofilms were formed on 96-well flat-bottomed polystyrene plates in the absence or presence of compounds, and were subsequently quantified by the conventional crystal violet-staining method. A high-throughput screening has been employed using 50,000 compounds with characteristic structures stocked at Drug Discovery Initiative of The University of Tokyo. Effects of the hit compounds on metabolic profile, gene expression profile, and cell morphology were evaluated by metabolomic analysis, microarray/quantitative real-time PCR, and thin-sectioning transmission electron-microscopy (TEM) observation, respectively.**Results:** One of the hit compounds, named anti-biofilm-compound JK2 (ABC-JK2), inhibited biofilm formation of several strains of S. aureus including MRSA and Staphylococcus epidermidis at IC_{50} ranging from 12.0 to 22.5 μM. ABC-JK2 decreased intracellular levels of glycolytic metabolites and increased the expression of genes related to peptidoglycan biosynthesis and hydrolysis in *S. aureus*. In addition, aberrant morphologies of *S. aureus* with thick cell walls and abnormal rippled septa were observed in the presence of ABC-JK2.**Conclusions:** Overall, these results indicate that ABC-JK2 inhibits staphylococcal biofilm formation presumably by affecting glycolysis and quality control of cell wall. These findings might lead to innovative drug development for preventing and curing staphylococcal biofilm infections.

Decoupling of Alginate Polymerization from C-Di-GMP Population in *Pseudomonas aeruginosa*

Author Block:

Sh. Ghods, B.H.A. Rehm, **M. Moradali**; Massey Univ., Palmerston North, New Zealand

Abstract Body:

The exopolysaccharide, alginate, is a virulence factor produced by the ubiquitous opportunistic human pathogen *Pseudomonas aeruginosa*. Alg8 and Alg44 are inner membrane proteins and subunits of the multiprotein complex directly involved in alginate polymerization. Activation of polymerization is positively regulated through binding of the secondary messenger c-di-GMP to the cytoplasmic PilZ domain of membrane anchored Alg44. Here, site-specific mutagenesis informed by an *in silico* model of Alg8-$PilZ_{Alg44}$ was applied to analyze the role of individual amino acid residues in the activation mechanism. The three amino acid residues H323, T457 and E460 were identified as critical for Alg8 in order to respond to c-di-GMP mediated activation while replacement of either H323 or E460 led to c-di-GMP mediated inhibition. Alanine substitution of these residues led to decoupling of alginate synthesis from cellular level of c-di-GMP.

Comparative Genetic Analysis of Biofilm Formation by *Pseudoalteromonas* from Deep-Sea Sediment versus from Surface Seawater

Author Block:

X. Cai , P. Wang, B. Li, **X. Wang**; South China Sea Inst. of Oceanology, GuangZhou, China

Abstract Body:

Biofilm is a common lifestyle of bacteria in aquatic ecosystem, including in the in nutrient-deprived deep-sea sediment. Whole genomic studies have revealed genetic features of deep sea bacteria. However, the features and molecular basis of biofilm formation in deep-sea sediment bacteria have rarely been characterized. Two closely related *Pseudoalteromonas* strains, *Pseudoalteromonas* sp. SM9913 (SM9913) derived from deep-sea sediment and *Pseudoalteromonas* sp. SCSIO 11900 (11900) derived from surface seawater, can form both pellicles at the liquid-air interface and submerged biofilms at the liquid-solid interface. They are compared at genomic and gene expression levels during biofilm formation. Compared to SM9913 planktonic cells, genes for growth, cell division and DNA repair were down-regulated during pellicle formation. The lateral flagellar gene cluster and chitinase genes, which located in genomic islands and presented only in SM9913 but not in 11900, were all up-regulated in SM9913 pellicle, suggesting that this strain is capable of utilizing horizontally acquired genes to gain advantages in nutrient acquisition on the deep-sea sediment surface in pellicle lifestyle. Additionally, genes encoding extracellular serine proteases and alkaline phosphatases were highly up-regulated in both strains during the initial stage pellicle formation. The enzymes encoded by *melA* and *hmgA* play key roles in the generation and degradation of homogentisic acid, which can further lead to the production of extracellular pyomelanin. *melA* was substantially induced during SM9913 pellicle formation, and its deletion resulted in a decrease in biofilm formation. In SM9913 pellicle formation, expression of *melA* at a higher level relative to *hmgA* continually, that led to excess homogentisic acid production. Conversely, in 11900, expression of *melA* was relatively lower compared to *hmgA* during the initial stage, and it was enhanced repression of *hmgA* transcription relative to *melA* in the mature stage that resulted in homogentisic acid accumulation. These results suggest that although the same set of genes are present in these bacteria residing in different niches (surface water *vs*. deep-sea), they can be differentially regulated at the RNA levels in response to stress.

***Enterococcus faecalis* Biofilms Reveal Conservation of the Extracellular Matrix Morphology between Multiple *In Vitro* and *In Vivo* Animal Model Systems**

Author Block:

A. M. T. Barnes[1], K. L. Frank[2], J. L. Dale[1], Y. Chen[1], D. A. Manias[1], K. E. Greenwood Quaintance[3], P. C. Kashyap[3], R. Patel[3], G. M. Dunny[1]; [1]Univ. of Minnesota, Minneapolis, MN, [2]Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, [3]Mayo Clinic, Rochester, MN

Abstract Body:

Enterococcus faecalis biofilms are complex microbial communities associated with a surface and encased in a self-derived extracellular matrix (ECM). The matrix is a dynamic developmental structural and is compositionally complex, containing proteins, nucleic acids, and polysaccharides. Here we report work using several complementary light and electron microscopy techniques examining *E. faecalis* biofilm formation in three animal models: rat osteomyelitis, rabbit endocarditis (top), and a germ-free murine model of gut colonization (bottom). In all three models several unusual features were conserved: 1) discrete *E. faecalis* biofilm microcolonies were distributed over the host tissue without evidence of confluent growth days-to-weeks post-infection; 2) cells were covered in an ECM that is morphologically indistinguishable from that seen *in vitro*; 3) there was little to no evidence of an inflammatory host response in any of the *in vivo* model systems. In the rabbit endocarditis model, biofilm microcolonies were also notable for attachment to the host endothelium in the absence of preexisting gross damage, as well as an apparent lack of platelet involvement in initial microcolony development. Finally, pooled competition assays in the murine gut model demonstrated no correlation via sequencing of genes up- or down-regulated in the *in vivo* system and the *in vitro* CDC biofilm reactor highlighting the importance of evaluating mutant fitness in animal model systems. Characterization of the *Vibrio cholerae* Norspermidine-Preferential ABC-type Transporter PotABCD1

Author Block:

E. A. Villa[1], B. Sanders[2], R. Sobe[1], C. Wotanis[1], A. Rutkovsky[3], E. Karatan[1]; [1]Appalachian State Univ., Boone, NC, [2]Virginia Tech, Blacksburg, VA, [3]The Med. Univ. of South Carolina, Charleston, SC

Abstract Body:

Vibrio cholerae, an intestinal pathogen and the causative agent of cholera, is capable of prolonged persistence in aquatic environments in part through formation of biofilms. During biofilm formation, cells aggregate and become encased within a self-produced matrix. Biofilms can provide protection from environmental stressors and unfavorable conditions, and have been implicated in *V. cholerae* pathogenesis by providing protection from the acidity of the stomach. A variety of environmental signals are involved in the switch from the planktonic cell state into the biofilm. Polyamines, small, cationic hydrocarbons that are found in virtually all cells, are one such group of signals. The *V. cholerae* genome encodes a putative polyamine ABC-type transporter, PotABCD1. PotA is annotated as the ATPase, PotB and PotC as the transmembrane channel-forming proteins, and PotD1 as the periplasmic substrate-binding protein. Previously, our lab demonstrated a role of PotD1 in the uptake of the polyamines spermidine and norspermidine. In this work, we aimed to characterize the role of the remaining components of the transport system in polyamine uptake, and subsequent effects on biofilm formation. Through cellular polyamine extraction and HPLC analysis, we show that PotA, PotB, and PotC are all required for uptake of both norspermidine and spermidine, and that this system has a preference for norspermidine. Furthermore, deletion of any gene results in increased biofilm formation in a *Vibrio* polysaccharide-dependent manner. Finally, because bacterial genes involved in a common function are often found in operons, we confirm cotranscription of all *pot* genes. Together, our work indicates that the entire system must function as a whole to facilitate polyamine uptake, which then mediates the biofilm phenotype through an unidentified, VPS-dependent mechanism. This work not only establishes PotABCD1 as the first norspermidine transporter ever reported in any species, but also further elucidates the role of polyamines in *V. cholerae* biofilm formation.

Implications Of Down Regulation Of Rcsa And Rcsa-Regulated Colanic Acid Biosynthesis Genes In Increased Acid Sensitivity And Enhanced Curli And Biofilm Production In Enterohemorrhagic *escherichia Coli* O157:H7

Author Block:

V. K. SHARMA; Natl. ANIMAL DISEASE CENTER, AMES, IA

Abstract Body:

Enterohemorrhagic *Escherichia coli* O157:H7 strain 86-24, originally linked to a disease outbreak in the western USA in 1982, exhibits acid resistance as indicated by its ability to survive exposure to acidic conditions (pH2.5) for several hours. The strain 86-24 is a poor biofilm producer which correlates with the production of low levels of curli fimbriae as assessed by Congo red binding assays, electron microscopy, and the levels of curlin (major structural protein of curli) expression using Western blotting. This parental strain 86-24, however, can produce variants that are highly acid sensitive but show increased biofilm formation and enhanced Congo red binding (CR^+), the latter correlating with increased curli expression. Transcriptomic analysis of the CR^+ variant revealed significantly reduced expression of genes associated with acid resistance, colanic acid production, but enhanced expression of genes encoding flagellar motility compared to the low Congo red binding (CR^-) parental strain. The expression of *rcsA*, which encodes a positive regulator (RcsA) of genes for colanic acid biosynthesis, was highly down regulated in the CR^+ variant. RcsA has been shown to serve as an auxiliary to the RcsB of the Rcs phosphorelay system in controlling colanic acid biosynthesis and expression of genes governing flagellar motility. In this study, we demonstrated that while *rcsA* was required for colanic acid biosynthesis and flagellar motility, findings that are in agreement with the other published reports, the *rcsA* gene did not negate the high levels of curli expression and biofilm formation in the CR^+ variant. RcsB reportedly regulates the expression of acid resistance in *E. coli* by interacting with GadE, which is the major regulator of genes required for the high level acid resistance. Whether RcsA has any role in controlling acid resistance through cooperation with RcsB or some other factors is not yet fully understood.

The *Burkholderia thailandensis*-Encoded MarR Homolog, BifR, Is Redox-Sensitive And Represses Genes Related To Biofilm Formation

Author Block:

S. Fuentes, A. Gupta, A. Grove; Louisiana State Univ., Baton Rouge, LA

Abstract Body:

B. thailandensis locus *BTH_I0541-0542* encodes an EmrB family drug resistance transporter and a MarR family transcription factor named BifR. This operon is divergently oriented to *ecsC*. EcsC has been annotated in *Pseudomonas* as a LasA protease, but its function in *Burkholderia* is unknown. This gene locus is also conserved in *B. cenocepacia*, a serious pathogen of patients with cystic fibrosis (CF). The protease might likewise contribute to the success of *Burkholderia* in the lungs of patients with CF. *B. cenocepacia* forms biofilm, making it less sensitive to antibiotics. BifR has one cysteine per monomer, and SDS-PAGE analyses showed that it is oxidized by ROS. BifR exists as a dimer in the reduced state but as a dimer of dimer in the oxidized state, which is particularly efficiently induced by copper-mediated oxidation. DNA binding studies showed that BifR binds two adjacent palindromes in the *emrB-bifR* promoter. An excess of DNA separates BifR dimers such that one protein dimer binds to one DNA molecule, a binding mode in which protein oxidation is not observed. Mutation C104A significantly reduced binding affinity, yielding a K_d ten times higher than that of WT protein. This suggests that the mutation produces structural changes that are communicated to the DNA recognition helices. *In vivo,* BifR repressed both *ecsC* and *emrB* expression as evidenced by increased expression in a *bifRΔ* strain. This repression was better in the presence of H_2O_2. An *emrB-bifRΔ* gene disruption mutant showed increased biofilm formation when compared to wild type *B. thailandensis*, suggesting that EmrB exports a biofilm dispersal agent. Biofilm formation was also increased in *bifRΔ*, but comparatively less than in *emrB-bifRΔ.* We suggest that BifR links cellular redox state and biofilm formation by differentially repressing genes associated with biofilm formation in its reduced and oxidized states.

Characterization of Key *H. pylori* Regulators Identifies a Role for Arsrs in Biofilm Formation

Author Block:

S. L. Servetas[1], B. M. Carpenter[1], J. J. Gilbreath[1], K. P. Haley[2], J. A. Gaddy[2], D. S. Merrell[1]; [1]Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, [2]Vanderbilt Univ., Nashville, TN

Abstract Body:

*Helicobacter pylor*i causes chronic infection of the gastric mucosa. In order to colonize and persist within this inhospitable niche, *H. pylori* must be able to rapidly respond to changing conditions. Despite this, *H. pylori* encodes few regulatory proteins. The well characterized regulators, Fur (ferric uptake regulator), NikR (nickel response regulator), and ArsR (the response regulator associated with the ArsRS acid response two component system), are paramount to the success of this pathogen. While numerous studies have examined these regulators individually, little is known about their combined effect. Thus, to study the interactions of these key regulatory proteins, a series of isogenic mutants was constructed in the commonly used lab strain, G27. This series includes single, double, and triple deletion strains of each regulator. Growth curve analysis under standard laboratory conditions revealed no outstanding growth defects of the strains. However, an interesting growth phenotype was noted in strains lacking ArsS; after 20 hours of growth, strains lacking ArsS formed large aggregates and a biofilm-like substance at the air liquid interface. Based on this observation, we further analyzed the biofilm-like phenotype in our isogenic mutant strains. In addition to the aforementioned collection, a non-phosphorylatable ArsR D52N mutant strain was also constructed. Phenotypic analysis using crystal violet assays and scanning electron microscopy showed that strains lacking ArsS or containing the ArsRD2N mutation formed significantly more biofilm than wild type G27. Furthermore, the ΔFur and ΔNikR single mutant strains appeared to form biofilms more slowly than wild type G27. Further characterization of the repertoire of regulatory mutants is ongoing and includes characterization of biofilm related properties such as adherence, auto-aggregation, and motility. Preliminary data suggest more pronounced aggregation and an increase in adherence in ΔArsS and ArsRD2N mutant strains as compared to wild type. Conversely, no overt differences in motility have been observed.

Adaption Of *porphyromonas Gingivalis* To *streptococcus Gordonii* Observed Using Time-Coursed Rna-Seq

Author Block:

E. L. Hendrickson[1], R. Lamont[2], D. Miller[2], M. Hackett[1]; [1]Univ. of Washington, Seattle, WA, [2]Univ. of Louisville, Louisville, KY

Abstract Body:

The current view of dental infections is one where, while the proximal cause of the disease may be a pathogen such as *Porphyromonas gingivalis* (Pg), pathogenesis occurs in the context of a multi-species microbial community. Colonization of Pg involves attachment to the antecedent oral community inhabitant *Streptococcus gordonii* (Sg). A combination of Pg and Sg thus provides a simple model of potentially pathogenic oral biofilms. To explore the effect of Sg on Pg biofilms we used RNA sequencing to examine the transcriptome of Pg across the first six hours after shifting from planktonic to sessile in both the presence and absence of Sg. Two or three biological replicates were taken at 5, 30, 120, 240, and 360 minutes for each condition. Comparisons were made using DESeq2 to calculate *p*-values adjusting to *q*-values to account for multiple hypothesis testing. Significant differences were called at a *q*-value cutoff of 0.001 and had an absolute $\log_2$ fold difference of greater than 0.5. Most of the changes compared to planktonic controls were similar for both Pg alone and PgSg, increased levels for ribosomal protein, translational machinery, amino acid energy metabolism, and stress protein transcripts and decreased levels for polysaccharide biosynthesis. However, in the presence of Sg most of the changes were significantly closer to those observed for planktonic cells than for Pg alone. It appeared that the changes needed for Pg to shift to a sessile lifestyle, as would occur during the early stages of biofilm formation, were more extensive without Sg, implying significant support from Sg for Pg biofilms. One exception was oxidative stress protein transcripts. These showed higher increases with Sg presumably due to Sg peroxide production.

The Role Of Quorum Sensing In Biofilm Formation Of The Antibiotic Resistant Gram-Negatives

Author Block:

S. Baho, S. Samarasinghe; De Montfort Univ., Leicester, United Kingdom

Abstract Body:

Background: Quorum sensing (QS) represents a mechanism for multicellular behavior in bacteria and known to regulate virulence and biofilm formation. Urinary tract infection (UTI) represents one of the most public health problems that affect women worldwide. The primary causing agent of this disease is *Escherichia coli* and, to a less extent, *Klebsiella.* Biofilm formation is one of the major health problems due to its difficulty to eradicate. Most studies focus on seeking for new antibiotics to treat biofilms but very little focus on the bacterial communication signals. In our work we are trying to find the relationship between biofilm formation and QS virulence factors genes. This work primarily has analyzed the susceptibility profiles and Biofilm formation ability of Gram-negative UTI causing pathogens. **Methods:** Double Disk Diffusion testing was used to confirm whether the strains are Extended Spectrum Beta Lactamases (ESBL) or Carbapenamases. PCR assay was used for confirmation that the strains has the antibiotic resistant gene. The amount of biofilm formation at different time points was determined using Biofilm Formation Assay (Tissue Culture Plate Assay; TCP). **Results:** Phenotypic characterization using Double Disk Diffusion testing confirmed that *K. pneumoniae* SHV-18, *E.coli* CTX-M-15 and *E.coli* TEM-3 are ESBL, and *K .pneumoniae* NDM-1, *K. pneumoniae* KPC-3 and *E.coli* IMP-type are carbapenemases. Whereas genotypic screening using PCR assay confirmed that *K. pneumoniae* OXA-48 belongs to carbapenemases, in addition for further confirmation of the above strains. Finally, TCP assay showed that amount of biofilm produced varies according to the bacterial growth stage at 6, 12, 24 and 48 hours of growth and culture condition (static or shaking). **Conclusions:** Our results demonstrated that quantity of biofilm produced is affected by the strain type, growth stage and culture conditions. We also demonstrated that double disk diffusion tests and molecular detection are useful for determining the ESBL and Carbapenemases strains. Further work is underway to determine the relationship between QS and biofilm formation and how they contribute to antibiotic resistance.

Genotypic And Biofilm Profiles Of *propionibacterium Acnes* Isolated From Pacemakers Without Clinical Signs Of Infection

Author Block:

K-i. Okuda[1], S. Yamada[1], S. Sugimoto[1], T. Iwase[1], M. Sato[2], C. Sato[2], Y. Mizunoe[1]; [1]The Jikei Univ. Sch. of Med., Tokyo, Japan, [2]Natl. Inst. of Advanced Industrial Sci. and Technology (AIST), Tsukuba, Japan

Abstract Body:

Background: Development of biofilms on medical devices often causes biofilm-associated infections. There is little information about biofilm formation on devices without clinical signs of infection. In this study, colonization of bacteria on the surfaces of cardiac pacemakers explanted from patients without clinical evidence of infection was consecutively analyzed. Additionally, genotypic and biofilm profiles of the isolated bacteria were investigated. **Methods and Results:** Blood agar plates were stamped with explanted pacemakers, and were subsequently incubated anaerobically at 37°C for 7 days. As a result, 8 of the 31 pacemakers were culture-positive. *Propionibacterium acnes* was isolated from 7 of the pacemakers and *Staphylococcus hominis* was isolated from 1 of the pacemakers. The *P. acnes* isolates were categorized into 5 different sequence types (STs) including ST2 (JK5.3 and JK6.2), ST4 (JK18.2), ST53 (JK17.1), ST69 (JK12.2 and JK13.1), and novel ST (JK19.3) by multi locus sequence typing. *In vitro* biofilm formation assay using microtiter plates revealed that all of the *P. acnes* isolates excepting JK6.2 form biofilms depending on glucose supplemented into the culture medium. Next, effects of enzymes on biofilm formation of the isolates were investigated. We used DNase I, RNase A, proteinase K, and dispersin B which degrade DNA, RNA, protein and poly-N-acetyl glucosamine, respectively. DNase I completely inhibited biofilm formation by all of the *P. acnes* isolates tested, on the other hand, susceptibilities to RNase A, proteinase K, and dispersin B were different among the isolates. High-resolution observation of nanostructures in the biofilms by transmission electron microscopy and atmospheric scanning electron microscopy visualized cytoplasmic components leakage along with cell lysis and fiber structures connecting cells. **Conclusions:** *P. acnes* was isolated from pacemakers without clinical signs of infection at high frequency (23%). Biofilm forming capacities of the *P. acnes* isolates and biochemical properties of the biofilms were different among strains regardless of the STs, however, extracellular DNA was suggested to be a factor commonly involved in biofilm formation of diverse strains of *P. acnes*.

Interaction Of Flagellin-Homologous Proteins With Eps And Its Effect On Biofilm Formation Of *vibrio Vulnificus*

Author Block:

Y-C. Jung, M-A. Lee, K-H. Lee; Sogang Univ., Seoul, Korea, Republic of

Abstract Body:

A pathogenic bacterium *Vibrio vulnificus* exhibits an ability to form biofilm, of which initiation is dependent upon swimming motility by virtue of a polar flagellum. The filament of its flagellum is composed of multiple flagellin proteins, FlaA, B, C, and D. The ORFs putatively encoding flagellin-homologous proteins (FHP) are also present in the *V. vulnificus* genomes. Although these FHPs are not involved in filament formation and cellular motility, they were found to be well-expressed and secreted to extracellular milieu through the secretion apparatus for the flagellins. In the extrapolymeric matrix (EPM) of *V. vulnificus* biofilms, significant amounts of FHPs were detected. The major components of its EPM are constituted with diverse extracellular polysaccharides, such as LPS, CPS, and EPS. Thus, the role of FHPs in biofilm formation was investigated using recombinant FHPs. Exogenous addition of FHPs to the FHP-defective mutants resulted in recovery of biofilm formation up to the wild-type level, and the added FHPs were predominantly incorporated in biofilm matrix. The same positive effect of FHP-addition on biofilm formation was apparent in biofilm formation by mutants defective in LPS or CPS. In contrast, biofilm formation by a mutant *V. vulnificus* defective in EPS biosynthesis was not influenced by addition of FHPs. These results raised a possibility that FHPs specifically interact with EPS within the biofilm matrix. To examine whether FHPs directly interact with EPS, EPS fractions were prepared and treated to the resins bound by recombinant FHPs or flagellin. Analyses of the eluted fractions of protein-conjugated resins showed the significantly more EPS was retrieved from the FHP-resins than the flagellin-resins. Taken together, this study demonstrates that FHPs are crucial in biofilm formation of *V. vulnificus*, via directly interacting with EPS that are known to be one of the major factors essential for biofilm formation.

A Rodent-Specific Two-Component System Plays a Key Role in Biofilm Formation of *Lactobacillus reuteri* 100-23

Author Block:

R. M. DUAR, X. B. Lin, M. Bording-Jorgensen, E. Wine, M. G. Gänzle, J. Walter; Univ. of Alberta, Edmonton, AB, Canada

Abstract Body:

Lactobacillus reuteri is a gut symbiont of vertebrates that has diversified into host-specific phylogenetic lineages. The ability of *L. reuteri* to form biofilms in the murine forestomach is a key determinant of host-adaptation. Comparative genomic analysis identified a rodent-specific two component system (TCS) lr70529-30 (Frese et al. 2011). This project aimed to determine the ecological significance of lr70529-30 in gut colonization. For this purpose, isogenic deletion mutants of the histidine kinase (HK) lr70529 and the response regulator lr70530 were generated from a rodent isolate *L. reuteri* 100-23. Forestomach biofilms were quantified by confocal laser scanning microcopy (CLSM), measuring the pixel area in images where bacterial cells were stained with propidium iodide. Cell adherence to tissue culture dishes was determined by optical density and matrix morphology examined in Filmtracer™-stained biofilms visualized by CLMS. Disruption of the response regulator significantly impaired (p <0.0001) biofilm development *in vitro* and reduced biofilm by 50% in gnotobiotic mice. In contrast, disruption of the histidine kinase resulted in more robust biofilms (p = 0.001) than the ones formed by the wild type *in vitro,* without significantly influencing biofilm formation *in vivo.* Current experiments are ongoing to determine the mechanisms by which two proteins organized in the same TCS exert highly different effects on biofilm formation. Overall, our findings demonstrate that lr70529-30 TCS is involved in regulatory pathways driving biofilm formation in *L. reuteri* 100-23. Functional characterization of these pathways will contribute to our understanding of the molecular mechanisms underlying host-adaptation of rodent isolates and will offer new insights into the strategies governing symbiotic bacterial adaptation to the vertebrate gut.

Regulation of EPS Production and Biofilm Formation by Synergistic Interation of DctD and IIA^{Glc}

Author Block:

S. Kang, H. Park, K-J. Lee, J-A. Kim, M-A. Lee, K-H. Lee; Sogang Univ., Seoul, Korea, Republic of

Abstract Body:

A previous study showed that the mutant strains of *Vibrio vulnificus* defective in the components of carbon-PTS exhibited decreased ability to form biofilms (Kim *et al*., 2007 Mol. Microbiol. 63:559) To further investigate the role of glucose-PTS in biofilm formation, a mutant defective in IIA^{Glc} (*crr* mutant) was examined in its ability to form biofilm. The mutant was severely impaired in biofilm formation due to minimal biosyntheses of exopolysaccharides (EPS), which are essentially required for the maturation of biofilm structure. In the absence of IIA^{Glc}, the expression of the gene clusters for EPS biosynthesis (EPS-clusters) were significantly decreased. To elucidate how the transcription of the EPS-clusters was regulated by IIA^{Glc}, a transcription factor was isolated from a pool of the proteins bound to the recombinant IIA^{Glc}. DctD, one of the sigma N-dependent transcription factors, was identified as an activator for the EPS-clusters' expression. Deletion of *dctD* gene in *V. vulnificus* resulted in reduced levels of EPS production and biofilm formation. The abilities of a *dctD*/*crr* double-mutant to produce EPS and to form biofilm were almost the same as those of single mutants, suggesting that IIA^{Glc} and DctD act together in inducing the EPS-clusters. Two forms of IIA^{Glc}, a phospho- and a dephospho-IIA^{Glc} (d-IIA^{Glc}), have been shown to interact with diverse proteins. Both *in vitro* and *in vivo* assays for protein-protein interaction showed that d-IIA^{Glc} was able to specifically bind DctD. *In silico* analysis of nucleotide sequences revealed the presence of the DctD-binding consensus sequence in the upstream regions of EPS-clusters. Binding affinity of DctD to these upstream regions was increased when d-IIA^{Glc} was included in the binding assay. *In vivo* expression of the EPS-clusters were induced when cells entered the mid-exponential phase, at which the cellular contents of IIA^{Glc} and DctD reached the maximal levels. Therefore, this study demonstrates that the EPS-clusters' transcription is highly induced by the d-IIA^{Glc}-DctD complex and then the resultant EPS accumulation facilitates the maturation of *V. vulnificus* biofilms.

Bacterial Extracellular DNA Contributes to *Streptococcus mutans* Biofilm Formation on the Damaged Valve in the Experimental IE Rat Model

Author Block:

C-J. Jung, J-S. Chia; Coll. of Med., Natl. Taiwan Univ., Taipei, Taiwan

Abstract Body:

Background: Host factors like platelets enhance biofilm formation of oral commensal streptococci for inducing infective endocarditis (IE), but the bacterial components contribute directly to biofilm formation *in vivo* is still not clear. We demonstrated earlier that the autolysin Atl contributes to the colonization of *Streptococcus mutans* on injure heart valves in an experimental endocarditis rat model, but the role of Atl in the biofilm formation *in vivo* is unknown.**Methods and Result:** By using confocal laser scanning confocal analysis, we found that *atl*-defective mutant strain significantly reduced the ability to form biofilm *in situ* along with the loss of extracellular DNA (eDNA) embedded inside bacterial floes. In accordance with the maturation and autolysin activity of the Atl, the amount of eDNA released or biofilm formed by *S. mutans in vitro* was also enhanced dose-dependently by plasma and calcium ions and was significantly reduced in *atl*-deficient strain. In addition, an Atl-like protein (All) also modulates bacterial eDNA release contributing bacterial biofilm formation.**Conclusions:** Our data suggested that Atl and All-mediated eDNA release contributes directly to *S. mutans* biofilm formation *in vivo* to induce IE.

Identification of a Novel Regulator Controlling *Staphylococcus epidermidis* Biofilm Formation in the Presence of Serum

Author Block:

A. Both[1], C. Wiechmann[1], N. Hector[1], H. Büttner[1], M. Christner[1], C. Heinze[1], P. Valentin-Weigand[2], H. G. Rohde[1]; [1]Univ. Clinic of Hamburg-Eppendorf, Hamburg, Germany, [2]Univ. of Vet. Med. Hannover, Hannover, Germany

Abstract Body:

Background: *Staphylococcus epidermidis* is a leading cause of implant associated-infections, and biofilm formation is thought to significantly contribute to the species' success in this clinical setting. Previous work has shown that the presence of serum induces biofilm formation in some *S. epidermidis* strains. **Hypothesis:** The aim of this study was to characterize serum-induced *S. epidermidis* biofilm formation in more detail, and to identify genes contributing to biofilm assembly under this growth condition.**Results:** PIA-producing *S. epidermidis* reference strain 1457 formed strong biofilms in TSB as well as TSB containing 50 % serum. In contrast, *S. epidermidis* 1585 was biofilm-negative in TSB, but became biofilm-positive in the presence of serum. Screening of a Tn*917* transposon mutant bank derived from *S. epidermidis* 1585 identified four mutants exhibiting a biofilm-negative phenotype after growth in serum. Sequencing of Tn-flanking chromosomal regions showed that all mutants carried insertions within an open reading frame encoding for a so far uncharacterized transcriptional regulator, preliminarily referred to as serum response regulator (Srr). Growth in serum induced *srr* expression in *S. epidermidis* 1585, indicating that Srr is relevant for adaptation to this condition. *In trans* complementation of *srr* fully rescued the biofilm positive phenotype, unambiguously linking the biofilm-negative phenotype with inactivation of *srr*. Further analysis of 1585*srr*::Tn917 identified changes in AtlE- and Embp-production. Consistent with phenotypic assays, these changes indicate that *srr* is crucial for expression of mechanisms involved in adherence as well as intercellular adhesion and biofilm accumulation. **Conclusion:** This is the first systematic approach to identify genes relevant to serum-induced biofilm formation. *srr* is a novel regulator, influencing biofilm accumulation through pleiotropic effects on adherence properties and intercellular adhesion. In depth analysis of regulatory circuits and functional molecules depending on *srr* expression will provide important insights into mechanisms allowing *S. epidermidis* to adopt to hostile environments to cause device-related infections.

Co-cultivation Models Reveal Xip to be an Intercellular Communication Molecule for *Streptococcus mutan*s

Author Block:

J. Kaspar, A. Reyes, R. A. Burne; Univ. of Florida, Gainesville, FL

Abstract Body:

Streptococcus mutans, the etiological agent of human dental caries, displays complex behaviors in response to short hydrophobic peptides, often called pheromones. Development of genetic competence is initiated via activation of transcription of an alternative sigma factor, encoded by *comX*, by the *comX*-inducing peptide (XIP) and the transcriptional regulator ComR. It has been proposed that XIP may function in an autocrine-like manner to control onset of competence, and not as a quorum sensing molecule. Here, we designed a co-culture system that utilizes a *comS*-overexpressing strain (*comS* encodes the precursor for XIP) that is marked with a dsRed fluorescent protein, in combination with an otherwise-wild-type strain of *S. mutans* carrying a *gfp* gene fused to the *comX* promoter (PcomX::*gfp*). The two strains were simultaneously inoculated in a co-culture biofilm system and *comX* expression was monitored over time using a Synergy 2 plate reader. In addition, at selected time points the biofilms were observed using confocal microscopy, or dispersed and subjected to analysis by flow cytometry to obtain quantitative data at the single cell level. Our results showed that the co-culture system could be used to measure and monitor XIP-dependent signaling in maturing biofilms and 1) there was evidence of co-operation and influences on fitness between the donor (*comS* overexpresser) and responder (PcomX::*gfp*); 2) differences in spatial organization of the donor and responder within the biofilm were evident; and 3) growth in sucrose, which allows for the production of an adhesive exopolysaccharide matrix, as opposed to glucose, had a profound influence on the distribution and proportion of responsive cells (GFP-positive). Notably, as the proportions of sucrose to glucose were increase, the positive feedback from intracellular XIP signaling (autoactivation of PcomX::*gfp*) increased. This study clearly demonstrates that XIP can signal between cells, but importantly it also highlights the unusual dynamics of XIP signaling within biofilm populations, both at the single cell and population levels, and how environmental factors can influence intercellular communication in a way that may modify the virulence and persistence of the organism.

Arginine Treatment Re-engineers Oral Microbial Community *In Vitro* and Prevents Sucrose-induced Ph Drop

Author Block:

L. Cen[1], **M. Agnello**[1], J. S. McLean[2], X. He[1]; [1]Univ. of California, Los Angeles, Los Angeles, CA, [2]Univ. of Washington, Seattle, WA

Abstract Body:

Background: The human oral cavity is home to a complex microbial community. Dysbioses of the oral microbiota can lead to diseases such as dental caries and periodontitis. Dietary sucrose increases the risk of dental caries through induction of acid production by acidogenic bacteria, which in turn promotes demineralization of tooth enamel and further selects for acidogenic and aciduric bacterial species. Arginine has been shown to induce alkali production in oral bacteria, which may inhibit caries formation. The aim of the current study was to evaluate the response of an *ex vivo*-derived oral bacterial community to pre-treatment with arginine and subsequent sucrose exposure. **Methods:** *In vitro* oral microbial communities were generated by inoculating pooled saliva collected from 6 dental patients into specialized media developed in our laboratory (SHI media) that has been shown to preserve up to 80% of the species diversity present in the original inoculum. Cultures were grown anaerobically overnight, and subsequently grown as biofilms in 24-well plates in chemically-defined media at a starting pH of 5.5 or 7. Arginine (75mM) was added at time 0, followed by the addition of 0.5% sucrose after 0, 3, 6, 12, 20, 48, or 54 h. At each time point, pH was measured and biofilms were collected for 16S sequencing and GC-MS metabolomics analysis. Results were compared to media-only, sucrose-only, and arginine-only controls. **Results:** The addition of sucrose at time 0 led to a pH drop to 4.5 after 3h regardless of starting pH (5.5 or 7). pH did not drop in biofilms pre-incubated with arginine 6, 8, 12, 20 or 48 hours prior to the addition of sucrose (pH=8 at 48 h). 16S sequencing revealed a shift in the microbial community structure of biofilms pre-incubated with arginine, specifically an increase in arginine-metabolizing species and a decrease in acid-producing *S. mutans*. GC-MS analysis revealed an increase in arginine secondary metabolites by the arginine-treated biofilms, indicating active uptake and metabolism. **Conclusion:** Treatment with arginine re-engineers the oral microbial community by selecting for less acid-producing bacteria, leading to protection against the sucrose-induced pH drop seen in non-treated biofilms. This suggests that arginine may potentially be used as a method of caries prevention.

The Role of Fatty Acids in Biofilm Formation by *Streptococcus mitis*

Author Block:

C. O'Brien, A. Higgins, D. Lenehan, P. Donovan, S. McCarthy, C. Ward, **J. Mitchell**; Univ. Coll. Dublin, Dublin, Ireland

Abstract Body:

Streptococcus mitis is a member of the normal human oral microflora. However it can make the transition from a harmless commensal to a pathogen and is a leading cause of infective endocarditis and bacteremia in immunocompromised individuals. The ability of *S. mitis* to form biofilms is a major virulence factor in the pathogenesis of these infections and may contribute to the resistance of *S. mitis* to many commonly used antibiotics. The aim of this study was to identify the factors, both genetic and environmental, that influence the ability of the organism to form biofilm. We firstly assessed the role of genes involved in temperate phage replication on the ability of *S. mitis* to form biofilm. These genes were not found to influence the biofilm forming capacity of *S. mitis* strains tested. Following this several growth conditions that *S. mitis* encounters in the oral environment were tested for their ability to influence the biofilm forming capacity of *S. mitis*. Growth of *S. mitis* in glucose promoted biofim formation, while NaCl, ethanolamine and ethanol all inhibited biofilm formation. Each of these growth conditions were found to have a distinct effect on autolysis of *S. mitis*.We then tested the impact of a panel of fatty acids for their ability to influence biofilm formation by *S. mitis*. Growth of *S. mitis* in the presence of eicosapentanoic acid (EPA) and docosahexanoic acid (DHA), which are found in fish oils, were found to have an inhibitory effect on biofilm formation whereas arachadonic acid promoted biofilm formation. The other fatty acids tested did not significantly impact biofilm formation. These results indicate that EPA and DHA represent a starting point to develop compounds to target biofilm formation and potentially infections by this increasingly antibiotic resistant pathogen.

Gyia Is an Sos- and Heat-Shock Induced DNA Gyrase Inhibitor in *Escherichia coli*

Author Block:

Yunxue Guo, Xiaoxiao Liu, T. Wood[1], **X. Wang**[2]; [1]Dept. of Chemical Engineering, University Park, PA, [2]South China Sea Inst. of Oceanology, Guangzhou, China

Abstract Body:

DNA gyrase introduces negative supercoils into DNA, coupling the reaction to ATP hydrolysis. DNA gyrase inhibitors induce relaxation of negative supercoiled DNA by inhibiting gyrase activity, and this relaxation is required for transcription, replication, repair and recombination. Here we demonstrate that chromosomally-encoded YfbC from *Escherichia coli* blocks the formation of a negative supercoiled plasmid DNA, and the activity of GyiA is enhanced by Mg^{2+} and it is ATP independent. Overproduction of GyiA causes extensive filamentous growth. GyiA interacts with the DNA gyrase subunit GyrA but not GyrB. We propose to rename YfbC as GyiA (Gyrase Inhibitor A). Additionally, deletion of *gyiA* greatly decreases cell viability during the SOS response and heat shock stress, and *gyiA* expression is induced upon the SOS response. Notably, different from the previously identified gyrase inhibitor gene *gyrI*, *gyiA* expression is not induced by the stationary phase sigma factor RpoS, but it is induced by heat shock sigma factor RpoH via direct binding to the promoter region. Furthermore, deletion of *gyiA* increased swimming motility and early biofilm formation, indicating an important role of GyiA during biofilm formation. Hence, we show GyiA is a DNA gyrase inhibitor in *E. coli* and it is beneficial to cells when they encounter SOS response and heat shock stress to which bacteria must adapt.

***Pseudomonas fluorescens* Integrates Environmental Information Across a Large C-Di-Gmp Network**

Author Block:

K. M. Dahlstrom[1], A. Collins[1], C. E. Harty[1], T. Gauvin[1], J. Rudd[1], C. Greene[2], G. A. O'Toole[1]; [1]Geisel Sch. of Med. at Dartmouth, Hanover, NH, [2]Univ. of Pennsylvania, Perelman Sch. of Med., Philadelphia, PA

Abstract Body:

Cyclic diguanylate (c-di-GMP) is a near-universal second messenger used by bacteria to control a large array of cellular decisions. Proteins called diguanylate cyclases (DGCs) produce c-di-GMP while phosphodiesterases (PDEs) degrade it, and any given bacterial species may contain up to several dozen DGCs and PDEs. To dissect the involvement of DGCs and PDEs in a given cellular process, previous studies have often focused on a single laboratory medium to assay the desired phenotype. While these efforts have associated many DGCs with cellular functions, they have left many more as orphan enzymes, without an obvious regulatory role. This raises two important questions: what is the role of these additional DGCs/PDEs, and how does the cell sort the signals from a large c-di-GMP network into meaningful outputs?To address these questions, our lab studies the c-di-GMP network in *Pseudomonas fluorescens*. *P. fluorescens* has several dozen potential DGCs, but only four were previously found to impact biofilm formation in our standard group medium. We hypothesized that when tested under other conditions, the function of more DGCs would be elucidated. To this end, we made deletion or insertion mutations of all known DGCs, PDEs, and c-di-GMP receptors of *P. fluorescens*. We utilized a systems-level approach to test each of our 53 mutant strains for biofilm formation in 192 carbon source conditions, examine transcript levels in a subset of these conditions, and test each member of the network for interaction with other members of the network using a bacterial two-hybrid assay. Our findings indicate that nearly half of DGCs act on biofilm formation through a series of nodes at the inner-membrane organized around effector proteins where physical interaction is utilized. Further, although several classes of organic molecules emerged as promoters or inhibitors of biofilm formation, few molecules of the same class utilized the same DGCs or PDEs indicating a surprising lack of redundancy among the dozens of enzymes. Collectively, our results support a model whereby bacteria may utilize a large c-di-GMP network in order to exquisitely regulate important life-style decisions, and that environmental context is a critical factor in organizing functional nodes of DGCs.

The Role of Serine Metabolism in *Bacillus subtilis* Biofilm Formation

Author Block:

J. Greenwich, G. Di Cecco, Y. Chai; Northeastern Univserity, Boston, MA

Abstract Body:

Bacillus subtilis is a Gram-positive bacterium used to study biofilm formation. It has recently been shown that serine plays a role in biofilm formation in *B. subtilis*, but the exact mechanism has yet to be determined. Under serine starvation, translation of SinR, the master biofilm repressor, is decreased. The *sinR* gene has an above average number of TCN serine codons (N stands for A,G,T,C) and ribosomes have been shown to preferentially pause on TCN serine codons under serine starvation, relative to AGT and AGC codons. Small changes in SinR levels can have drastic effects on the genes it regulates, suggesting that this decreased translation rate may partially regulate the transition to biofilm formation.We hypothesize that *B. subtilis* is using serine as a sensor of its overall nutrient state, and that low serine levels indicate low nutrient availability, triggering biofilm formation. Because exogenous addition of serine to a culture delays biofilm formation, the next step was to assess the effect of manipulating intracellular serine levels. An increase in intracellular serine levels led to decreased biofilm formation. Overexpression of *serA*, the key structural gene in serine biosynthesis, as well as deletion of the two-protein serine dehydrogenase complex (encoded by *sdaAA/sdaAB*) reduces biofilm formation relative to wild type in biofilm-inducing media based on a transcriptional reporter for *yqxM*, the gene encoding a protein component of the biofilm.Additionally, tRNA isoacceptor levels may be important in this regulation. The genes for the serine tRNA isoacceptors are downregulated in stationary phase relative to exponential phase, based on qPCR analysis. Overexpression of *trnD-ser* does not alter biofilm formation in the wild type strain, but does reduce biofilm formation in a hyper-biofilm producing strain. This supports the hypothesis that increased tRNA isoacceptors allows for increased read through and translation of the *sinR* transcript, leading to increased protein synthesis of the master regulator of biofilm formation. Taken together, these results suggest that *B. subtilis* uses serine as a signal for its overall nutrient availability. This simple sensor allows bacteria to quickly adapt to their changing environments and provides new insights into bacterial physiology.

Designing of a Chimeric Protein for Specific Diagnosis of *Mycoplasma hominis* Infection

Author Block:

S. Saadat[1], R. Yousefi Mashouf[1], M. Y. Alikhani[1], **Z. Rikhtegaran Tehrani**[2]; [1]Hamadan Univ. of Med. Sci., Hamadan, Iran, Islamic Republic of, [2]Pasteur Inst. of Iran, Tehran, Iran, Islamic Republic of

Abstract Body:

Background: Molecular and serological diagnosis of heterogeneous and antigenic variable *Mycoplasma hominis*, a multi-potential pathogen, is usually a controversial issue. Designing of reliable recombinant antigens containing specific immunodominant epitopes selected from different proteins exposed on the bacterial membrane can be useful in immunoassay based methods. The aim of this study is prediction and rational selection of specific epitopes from p120 and p80 and designing of a chimeric protein based on a combinational algorithm. **Methods:** Antigenic epitopes was predicted by Immune Epitope Database and Analysis Resource using "Kolaskar and Tongaonkar Antigenicity Scale" and "Bepipred Linear Epitope Prediction" methods. The peptides with more than 80% similarity to species other than *M. hominis* were removed after BLASTP search at UniProt. The specific peptides were scored with weighted scoring based on different parameters including conservation, flexibility, hydrophilicity, length and position of epitope. The selected peptides were sorted and the specificity of the final protein was evaluated again. **Results:** Among 26 predicted epitopes, 11 peptides were nonspecific and excluded. The score of 15 specific peptides were calculated and eight of them with score of equal or more than 3.0 were selected. The final protein, with 247 amino acids, is composed of conserved, specific and highly antigenic epitopes. **Conclusions:** The inherent polymorphism of *M. hominis* makes its surface proteins unreliable targets for immunoassays. p120 is an abundant surface lipoprotein containing hyper-variable N-terminal region which is the target of human antibodies. p80, a membrane anchored protein, has an N-terminal cytoplasmic signal peptide and can be released after cleavage. The proposed algorithm used in this study increases the probability of finding of conserved, specific and immunoreactive epitopes within p120 and p80 proteins. Such peptides will increase the sensitivity and specificity of diagnosis methods based on immunoassay. We plan to experimentally evaluate the efficiency of this chimeric protein in diagnosis of individuals infected by *M. hominis*.

Computational Identification and Characterization of Promiscuous T Cell Epitope on Extracellular Protein 85B of *Mycobacterium* spp. for Peptide-Based Subunit Vaccine Design

Author Block:

M. Hossain, M. Wakayama; Ritsumeikan Univ., Kusatsu, Japan

Abstract Body:

Tuberculosis (TB) is a re-emerging disease that remains one of the leading causes of morbidity and mortality in humans. Bacille Calmette Guerin (BCG) vaccine for TB become complicated and in trouble more in TB endemic countries, particularly for pulmonary TB patients. We herein conducted an in silico study to identify and characterize a suitable T cell epitope, which might be an efficient target for epitope vaccine against Mycobacterium spp.We have assessed all the antigenic proteins of *Mycobacterium* spp recorded to date in Protegen database with Vaxign server and found that extracellular protein antigen 85B (Ag85B) was superior among all others. Analysis with NetMHCII 2.2 server and NetCTL 1.2 servers for identification of T cell epitope predicted an epitope 181-QQFIYAGSLSALLDP-195. These servers predicted that the epitope could bind with at least 13 major histocompatibility complex (8 MHC II and 5 MHC I molecules) and it revealed promiscuous nature of epitope. We increased the accuracy of our analysis by using multiple prediction servers for each DRB allele. Analysis with bioinformatics tools revealed that this epitope was highly stable. To validate the identification of the epitope with the computer aided programs, the *in silico* approaches were applied to identify the epitope on a positive control protein, an influenza viral antigen nucleoprotein peptides that has successfully used as peptide vaccine. We also analyzed HLA frequency of high burden TB endemic countries for the respective allele in the allele frequency database and found epitope has covered almost all TB endemic areas of populations. Finally, molecular docking simulation showed that epitope could bind with the binding groove of MHC II and MHC I molecules with numerous significant hydrogen bonds. Molecular docking analysis showed that the epitope had distinctive binding patterns to all DRB1, A and B series of MHC and presented almost no polymorphism in their binding site.Physico-chemical, alleles coverage and binding properties analyzed in this study revealed that the polypeptide '181-QQFIYAGSLSALLDP-195' is the novel epitope. This epitope is ~90% identical in all the non-identical Ag85B sequences available in the protein database. Therefore, Ag85B might be the universal candidate to produce efficient peptide or epitope- based vaccine for TB.

Recognition of Supercoil Handedness by *Mycobacterium tuberculosis* Gyrase

Author Block:

R. Ashley[1], T. Blower[2], J. Berger[3], N. Osheroff[4]; [1]Vanderbilt Univ. Sch. of Med., Nashville, TN, [2]Durham Univ., Durham, United Kingdom, [3]Johns Hopkins Univ. Sch. of Med., Baltimore, MD, [4]VA Tennessee Valley Hlth.care System, Nashville, TN

Abstract Body:

The coiled structure of DNA creates numerous topological issues. Transcription and replication require the strands to be unwound, resulting in significant DNA overwinding ahead of the moving forks. Recombination and replication also create knots and tangles that must be removed for proper chromosome segregation. Type II topoisomerases resolve these issues by creating a transient double-strand break in DNA, passing another segment through the break, and religating the cut strands. The hallmark of this process is the cleavage complex, in which the cut DNA is covalently attached to the enzyme. Bacterial type II enzymes are the targets of quinolones, which are highly effective broad-spectrum antibacterials. *Mycobacterium tuberculosis* encodes one type II topoisomerase, gyrase. Gyrase is a unique enzyme that can actively underwind DNA to facilitate access to the genome. As quinolone use to treat tuberculosis increases, it is critical to understand how DNA topology affects gyrase activity and its interactions with these drugs. Thus, we investigated the ability of *M. tuberculosis* gyrase to distinguish between overwound (positively supercoiled) and underwound (negatively supercoiled) DNA. Gyrase maintained 3-4-fold lower levels of cleavage complexes on overwound DNA than it did on underwound DNA in the absence or presence of quinolones. However, the enzyme established cleavage-religation equilibria on both isoforms at equal times. Gyrase bound positively supercoiled DNA more tightly than it did negatively supercoiled molecules and could only form stable interactions with underwound DNA if a divalent cation was present. Finally, gyrase rapidly and processively removed positive supercoils to generate relaxed DNA, but introduced negative supercoils much more slowly and distributively. These results indicate that gyrase is uniquely adapted to work on positively supercoiled DNA. We propose that its critical function is to quickly and safely remove positive supercoils to maintain genome accessibility while minimizing the risk of permanent double-strand breaks.

Analyzing Novel Components Of Developmentally-Associated Genome Segregation For Streptomyces Coelicolor

Author Block:

M. Hasipek, R. Dedrick, **J. R. McCormick**; Duquesne Univ., Pittsburgh, PA

Abstract Body:

There are five known components of the partition (*par)* system needed for developmentally-associated chromosome segregation in *Streptomyces coelicolor*: the centromere-like *parS* sites and ParA, ParB, ParJ and Scy. Chromosome segregation in bacteria generally involves a ParA ATPase and centromere-binding ParB complexes. The purpose of this study was to characterize the function of a ParA homologue ParH, investigate interactions between ParH with known segregation proteins and screen a genomic library to find novel interacting proteins.A *parH* null mutant was isolated and strains containing ParH-EGFP, and ParB-EGFP in a *parH* strain were constructed and analyzed by fluorescence microscopy. Site-directed mutagenesis of *parH* was used to change a conserved lysine residue (K99E) in the ATPase Walker A box. To determine if ParH interacts with known segregation proteins, an *E. coli* bacterial two-hybrid system was used. Plasmids carrying *parH*, *parH* variants, and target genes fused with T25 and T18 fragments of *cyaA* and were screened on MacConkey indicator plates. A random genomic library of *S. coelicolor* was constructed to screen for novel ParH interacting proteins using ParH as bait.In aerial hyphae of the Δ*parH* mutant, 4% of spores were anucleate compared to 24% for a *parA* null mutant. In predivisional aerial filaments, ParH-EGFP occasionally localized into a bright band or bands of fluorescence in apical compartments or as increased diffuse fluorescence toward the tip in these filaments. As judged by two hybrid analyses, ParH interacts with itself and ParB. However, the Walker A motif K99E mutation in ParH and N-terminal in-frame deletion in ParH impaired the two-hybrid interaction between ParH and ParB. No evidence was obtained to indicate there was a heterodimer interaction between ParH with ParA. By screening a random genomic library, the highly conserved actinobacterial signature protein HaaA (ParH and ParA-associated protein A) was found as a novel interacting partner of ParH. Interestingly, HaaA, also interacts with ParA in a bacterial two-hybrid system. This pattern of interaction was also conserved for homologs of *Mycobacterium smegmatis* and *Corynebacterium glutamicum.* Preliminary characterization indicates that a *haaA*-null mutant has no overt segregation defect, but exhibits a slight developmental defect.

Elucidating the Role of Rhomboid Proteases in *Streptomyces coelicolor*

Author Block:

N. Carmona, R. Argawal, W. E. Nieves, L. Lara, M. Trujillo; Queensborough Community Coll., Bayside, NY

Abstract Body:

Background: Cell membranes are controlled borders with the outside world and serve as organizers of cell signaling, metabolic pathways and ultra-structure assembly. Proteases that reside within the cell membrane play an important role in regulating these events but it is still not clear how intramembrane proteases function. Rhomboids are intramembrane proteases found in all forms of life that have been implicated in human diseases. *Streptomycetes* are gram positive soil bacteria that produce secondary metabolites with biological activities. The production of these natural products relies on a cell signaling system, not fully understood, that integrates environmental, physiological and stress signals. We propose rhomboid proteases play a role in these signaling mechanisms.**Methods:** Bioinformatics tools were used to identify rhomboid genes in *Streptomycetes*. Reverse transcription showed that four rhomboid genes from *Streptomyces coelicolor*, the model organism for this genus, were transcribed under normal growth conditions. A *Providencia stuartii* rhomboid mutant (XD37.A) was complemented with rhomboid A (SCO3855) and D (SCO2139) from *S. coelicolor*. Furthermore, a SCO3855 knock out (KO) was constructed using CRISP technology. Additionally a plasmid with SCO3855 under the *erm* promoter was conjugated into *S. coelicolor*. The phenotypes of the constructs are being characterized. Currently, SCO3855- green fluorescent protein fusions are being constructed.**Results:** Five families of putative rhomboid genes were identified in *Streptomycetes*. SCO3855 fully complemented XD37.A demonstrating this is a functional rhomboid enzyme; it can cleave the substrate of aarA, the rhomboid enzyme from *P. stuartii*. SCO2139 only partially complemented XD37. A proving this enzyme has a different substrate. Preliminary results suggest that the deletion and/or overexpression of SCO3855 affects sporulation in *S. coelicolor*.**Conclusion:** Of the five families of rhomboid genes in *Streptomycetes*, two (A and D) are highly conserved. A and D play different biological roles as shown by the complementation experiments with XD37.A. Initial results from deletion and overexpression of SCO3855 support our hypothesis that rhomboids are involved in cell communication as it is well known that sporulation is influenced by external and internal signals.

Biochemical Characterization of Two Aldoxime-forming, Flavin Dependent *n*-Hydroxylases Involved in Phosphonocystoximic Acid Biosynthesis

Author Block:

M. N. Goettge, J. P. Cioni, K-S. Ju, W. W. Metcalf; Univ. of Illinois Urbana-Champaign, Urbana, IL

Abstract Body:

Phosphonocystoximic acid (PnCys) and its hydroxylated congener (hPnCys) are two recently discovered natural products produced by *Streptomyces* sp. NRRL WC-3744 that contain an unusual oxime moiety. A related organism, *Streptomyces* sp. NRRL S-481 produces only PnCys. Bioinformatic analyses identified a novel FAD-NAD(P)H-dependent *N*-hydroxylase that we hypothesized would install this oxime moiety during biosynthesis. The putative flavin-dependent *N*-hydroxylase protein is found in both organisms and is significantly longer in length (750 vs. 450 amino acids) than known oxime-forming flavin-dependent *N*-hydroxylases. We previously showed that formation of hPnCys involves an α-ketoglutarate-dependent dioxygenase that converts 2-aminoethylphosphonic acid (AEPn) to 1-hydroxy-2-AEPn (HAEPn). Notably, this enzyme is absent from *Streptomyces sp.* S-481, which only produces PnCys. Thus, we expected that AEPn and HAEPn would be the substrates for the putative N-hydroxylases, while the enzyme from WC-3744 would show a preference for HAEPn and the enzyme from S-481 would preferentially oxidize 2AEPn. To test these hypotheses, both enzymes were purified after expression in *Escherichia coli*. UV-Vis spectroscopy was used to follow the consumption of the required nicotinamide cofactor, NADPH, allowing kinetic studies to identify the cofactor and substrate preferences of each enzyme. NMR spectroscopy and mass spectrometry were used to follow substrate consumption and product formation, allowing identification and assignment of the products, including *E* and *Z* aldoxime isomers and a nitro-containing product. Both enzymes catalyzed NADPH-dependent oxime formation with both AEPn and HAEPn as substrates, while the S-481 *N*-hydroxylase also showed activity with phosphonoalanine. As expected, the S-481 *N*-hydroxylase preferentially oxidized AEPn, while the preferred substrate for the WC-3744 *N*-hydroxylase is HAEPn, with k_{cat}/K_M values *ca.* 100 fold higher for the preferred substrate. Accordingly, these unique enzymes are members of a novel subclass of oxime-forming *N*-hydroxylases involved in the formation of the oxime moiety during PnCys biosynthesis.

Design and Application of Novel Multicatalytic Cellulases for Improved Microbial Degradation of Cellulosic Biomass

Author Block:

K. O. Duedu[1], C. E. French[2]; [1]Univ. of Hlth.& Allied Sci., Ho, Ghana, [2]Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract Body:

Background: In naturally occurring cellulose degrading microbes, bioconversion is catalyzed by a battery of enzymes with different catalytic properties. We have reported construction and characterization of an endoglucanase-exoglucanase fusion protein (CxnA) which improves microbial degradation of cellulosic biomass.**Methods:** In order to investigate the capabilities of recombinant multimeric fusion proteins in improving cellulosic biomass conversion, we constructed six additional fusions of cellulases from *Cellulomonas fimi* (endoglucanases CenA, CenB and CenD, exoglucanase Cex, and β-glucosidase) and *Cytophaga hutchinsonii* (cellodextrinase CHU2268). The fusions were made using flexible proline-threonine linkers. Enzyme activity was tested by expressing fused and non-fused devices in *Escherichia coli*. All fusions retained catalytic activity of both parental enzymes. To investigate the benefits of fusion, Citrobacter freundii ATCC8090 was transformed with either fused or non-fused enzymes and cultured with cellulose blotting papers (Whatman® GB003, 0.8 mm, 300 gsm or Ford 428 mill 0.2 mm, 148gsm) as main carbon source.**Results:** Cells expressing the fusions of Cex with CenA or CenD reproducibly showed higher growth than cells expressing non-fused versions, as well as more rapid physical destruction of paper. The opposite was observed for the other combinations. A newly constructed Cex/CenA fusion (CxnA2) which contains two CBMs degraded the GB003 paper faster than the previously reported Cex/CenA fusion (CxnA1) which contains only one CBM and led to improved cell growth.**Conclusions:** Our results demonstrate that use of fusion proteins can improve biomass conversion in vivo, and could potentially substitute cloning of multiple enzymes and improve product yield. Our procedure for generating fusion proteins from existing libraries of constructs is simple and may be useful in other applications.

Deciphering the Mechanism of Flavoprotein Mediated Tellurite Reduction

Author Block:

F. Arenas[1], M. Arenas[2], C. Muñoz[1], C. Vasquez[1], J. Vargas[1], F. Cornejo[1]; [1]Univ. de Santiago de Chile, Santiago, Chile, [2]Univ. de Talca, Talca, Chile

Abstract Body:

Tellurite is extremely toxic to most organisms at very low concentrations. However, tellurite can be enzymatically reduced to its elemental non-toxic form in a reaction coupled to NAD(P)H oxidation (Tellurite Reductase activity, TR), which is described as a mechanism of resistance. In the present work, different proteins with TR activity were evaluated *in silico* by using various databases of protein classification, showing that the majority belong to the "FAD/NAD(P) fold binding domain" (flavoprotein family), are related by the PFAM structural domains PF00070, PF02852 and PF07992, and all have cysteine residues at their active site. Bioinformatic analysis identified six *E. coli* flavoproteins (TrxB, AhpF, YkgC, GorA, E3 and NorW) which were characterized. All have NADH- and/or NADPH-dependent TR activity *in vitro*, an optimum pH of 8-9, a temperature of 42°C. The generation of tellurium-derived nanostructures from the *in vitro* and *in vivo* TR activity of these enzymes was evaluated. To date, the amino acids involved in reducing TeO_3^{-2} are unknown. Using E3 as a model, the importance of cysteine residues in these enzymes was tested by using specific inhibitors and site-directed mutation of C45A. The role of FAD was analyzed by removing and incubating E3 with FAD and by mutating residue E354K in the FAD binding domain. Finally, mutant H322Y was constructed, since this amino acid is directly involved in binding NADH. In all cases tested, TR activity was affected, allowing to infer that residues C45, H322 and E354 are key for the TR activity of these enzymes.

Impact of Thioredoxin System Deletion Mutations on Sulfur Metabolism and Heavy Metal Reduction in Sulfate Reducing Bacteria

Author Block:

E. L. W. Majumder[1], G. M. Zane[1], T. R. Juba[1], K. B. De Leon[1], S. D. Smith[1], G. P. Butland[2], M. W. W. Adams[3], A. P. Arkin[2], P. D. Adams[2], J. D. Wall[1]; [1]Univ. of Missouri, Columbia, MO, [2]Lawrence Berkeley Natl. Lab, Berkeley, CA, [3]Univ. of Georgia, Athens, GA

Abstract Body:

Thioredoxins are small proteins that facilitate reduction of other proteins and small molecules in cells with a dithiol/disulfide exchange. Thioredoxins are thought to be ubiquitous in nature and have established roles in dealing with oxidative stress, redox signaling and supplying electrons for nucleotide synthesis. While well characterized in plants and animals, the role(s) of thioredoxins in anaerobes and particularly Sulfate Reducing Bacteria have not been well established. The sulfate reducing bacterium (SRB) *Desulfovibrio vulgaris* Hildenborough (DvH) is an obligate anaerobe that has the ability to reduce Uranium (VI) to Uranium (IV) and has been shown methylate mercury. DvH does not have glutathione, common in eukaryotes, and relies on thioredoxin as the main low molecular weight sulfide compound. A phylogenetic analysis showed that only 14 of 38 phyla of bacteria and archaea have glutathione, but all 38 have type I thioredoxin. DvH has two thioredoxins and four thioredoxin reductases in the genome. All six thioredoxin system genes are expressed *in vivo,* but with different fitness values. Recent work by Li and Krumholz (Ecotoxicology **23**(4): 726-733. 2014.) has implicated a non-canonical thioredoxin as necessary for the uranium reduction process. Five of the six single and multiple deletion mutants of the thioredoxins and thioredoxins reductases have been generated and are being characterized with growth curves and uranium reduction assays. We will also test these strains for oxygen sensitivity, effect of thioredoxin inhibitors and screen various electron acceptors and donors. Thioredoxin deletion mutants will also be generated in the *Desulfovibrio desulfuricans* ND132 strain capable of mercury methylation and be assayed for growth and methylation of mercury. Tagged copies of thioredoxins and thioredoxin reductases will be overexpressed on *Escherichia coli,* purified and assayed for direct interactions with metals, small molecules or other proteins. These results will begin to elucidate the function of the thioredoxin system in SRB.

An Intestinal Bacterium Degrades Carnitine by a Novel Pathway That Avoids Generation of Known Precursors to Proatherosclerotic TMAO

Author Block:

D. J. Kountz, L. Zhang, J. Krzycki; The Ohio State Univ., Columbus, OH

Abstract Body:

Background: Microbial degradation of quaternary amines, such as L-carnitine and glycine betaine, generates trimethylamine (TMA) in the intestines. Once in the bloodstream, liver enzymes oxidize TMA to TMAO, which promotes atherosclerosis and increases risk of stroke, heart attack, and death. We recently described MtgB, a glycine betaine:corrinoid methyltransferase that permits *Desulfitobacterium hafniense* to produce N,N-dimethylglycine, rather than TMA, from glycine betaine. MtgB is a member of the largely uncharacterized TMA methyltransferase (MttB) superfamily, members of which are found in the genomes of multiple intestinal isolates. Important active site residues are not conserved across the MttB/MtgB superfamily, which raises the possibility of substrate diversity beyond betaine. **Methods and Results:** By performing BLASTp searches that used MtgB as a query, we identified a candidate organism, *Eubacterium limosum* ATCC 8486. This organism is the type strain of a species that is found in the intestines of approximately 7% of individuals with western diets. We found *E. limosum* demethylated carnitine to norcarnitine with the production of acetic, butyric and caproic acids. Cell extracts from carnitine-grown cells exhibited significant carnitine:cob(I)alamin and carnitine:tetrahydrofolate methyltransferase activities, suggesting involvement of a corrinoid methyltransferase in carnitine catabolism. Proteomic data indicated that genes encoding an MttB homolog, a methyl-tetrahydrofolate:corrinoid methyltransferase homolog, and two corrinoid proteins were upregulated during growth on carnitine compared to growth on lactate. The MttB homolog (designated MtcB) was shown to be a carnitine:cob(I)alamin methyltransferase while the MetH homolog (MtcA) demethylates methylcob(III)alamin to produce methyl-THF. This novel corrinoid dependent pathway thus fuels both oxidative and reductive branches of the Wood-Lundahl pathway for generation of acetyl-CoA. **Conclusions:** These data have revealed the first such pathway that is both directly and indirectly incapable of generating TMA, and raise the possibility that benign and potentially detrimental pathways may compete for quaternary amines in the human intestine.

Mutation Network Based Understanding of Pleiotropic and Epistatic Effects of Double Mutations on *Enterococcus faecalis* FMN-Dependent Azoreductase

Author Block:

H. Chen[1], J. Sun[1], O. Kweon[1], J. Jin[1], G-X. He[2], X. Li[2], C. E. Cerniglia[1]; [1]Natl. Ctr. for Toxicological Res./U.S.FDA, Jefferson, AR, [2]Univ. of Massachusetts Lowell, Lowell, MA

Abstract Body:

Background: AzoA from *E. faecalis*, a homodimeric FMN-dependent NADH-preferred azoreductase, cleaves the azo bonds (R-N=N-R) of diverse azo dyes. A recently reconstructed mutation network of AzoA has systematically explained the pleiotropic effects of the 13 residues on the functional interaction among the three substrates (FMN, NADH, methyl-red). The residues, Arg-21 and Asn-121 have been considered as mutational hotspots with positive pleiotropic effects. Here we report the experimental network-based pleiotropic and epistatic mutational effects of double mutations at positions Arg-21 and Asn-121 on AzoA from *E. faecalis*.**Methods:** Site-directed mutagenesis; recombinant protein expression and purification; azoreductase assays; network analysis.**Results:** In addition to the previous R21G and N121A, six more mutants were made and characterized: two single mutants (R21K and N121A) and four double mutants (R21G/N121A, R21G/N121Q, R21K/N121A, R21K/N121Q). Using the K_m^{MR}, K_m^{NADH}, FMN, and relative specific activity of the mutants, we reconstructed an AzoA-mutational network, showing a general correlation between enzyme activity and connection distance. Single mutation of Arg-21 and Asn-121 with Lys and Gln, respectively, yielded mutant enzymes with properties very similar to those of the wild-type enzyme; they shared a very similar network connection in shape and distance. Out of the 4 double mutants, the two double mutants R21G/N121A and R21G/N121Q showed enhanced enzyme activity, whereas the other (R21K/N121A and R21K/N121Q) showed decreased enzyme activity. R21G/N121A and R21G/N121Q show apparently different network connection shapes with a relatively short distance, indicating some striking kinetic differences from the wild-type enzyme and the double mutants with decreased activity.**Conclusions:** Mutational network-based analysis of the double mutations not only proves the position Arg-21 as a hotspot with positive mutational effects but also suggests that rational control of the epistatic mutational interaction between the two residues is necessary for productive enzyme engineering of AzoA.

YbtT is a Virulence-associated Siderophore Biosynthetic Repair Enzyme in Uropathogenic *E. coli*

Author Block:

S. I. Ohlemacher, J. P. Henderson; Washington Univ. Sch. of Med., St. Louis, MO

Abstract Body:

Iron limitation is an important aspect of the host innate immune response. Consequently, pathogens often produce multiple siderophores, or small molecule Fe(III) chelators, to acquire this essential nutrient. Uropathogenic *E. coli* (UPEC) can produce up to four chemically distinct siderophores: yersiniabactin (Ybt), enterobactin (Ent), salmochelin (Sal), and aerobactin (Aero). Ybt is unique because it is a metallophore that interacts with iron and copper. Both Ybt and Ent/Sal are produced by nonribosomal peptide synthetases (NRPS), a class of multimodular enzymes that use phosphopantetheine (ppant) cofactors to covalently attach substrates and intermediates to the enzymes. With multiple siderophore pathways operating inside a single bacterial cell, it remains unclear how biosynthetic integrity is maintained when the starting substrates are chemically similar. One possibility is the existence of a proofreading enzyme. YbtT is a thioesterase encoded amongst the Ybt biosynthetic genes that has homology to editing enzymes from other NRPS systems. We constructed a knockout of *ybtT* in UPEC and used mass spectrometry to directly observe a 90% reduction in Ybt production. Therefore, we hypothesized that YbtT removes incorrect substrates from the Ybt biosynthetic machinery to promote siderophore production. To identify YbtT binding partners, we performed a pull down with UPEC lysate. YbtT pulled down the two major Ybt biosynthetic proteins, HMWP1 and HMWP2, and did not pull down other siderophore biosynthetic enzymes. We next used fluorescence polarization to examine protein-protein interactions between YbtT and individual domains of HMWP1 and HMWP2. These studies revealed the importance of the ppant posttranslational modification for YbtT binding to carrier protein domains. Finally, we demonstrated that YbtT is an active thioesterase that can cleave a range of acyl groups from N-acetylcysteamine (SNAC) substrates, which mimic the native ppant. Together, the results of this study suggest a mechanism where YbtT binds HMWP1 and HMWP2 carrier protein domains, with significant engagement of the ppant, and hydrolyzes covalently attached, non-native small molecules. This activity may prevent incorrect substrates from acting as suicide substrates during Ybt biosynthesis. The elucidation of this mechanism could lead to novel methods of inhibiting Ybt biosynthesis.

Siderophore Biosynthesis as a Model System for Dissecting the Role of Mbth-like Proteins in Natural Product Biosynthesis

Author Block:

R. A. Schomer[1], H. Park[2], M. G. Thomas[1]; [1]Univ. of Wisconsin-Madison, Madison, WI, [2]Massachusetts Inst. of Technology, Cambridge, MA

Abstract Body:

Nonribosomal peptides (NRPs) are a structurally diverse class of natural products that comprise a significant portion of our current medicinal arsenal. In nature, microorganisms have evolved to use these molecules for a wide range of physiological roles from nutrient acquisition to virulence. NRPs are constructed by nonribosomal peptide synthetases (NRPSs) that use a mechanistically repetitive and modular enzymology. NRPS enzymology has been extensively studied, but until recently it was unappreciated that many NRPSs are dependent on the presence of an MbtH-like protein (MLP) for function and solubility. This incomplete understanding of the role of MLPs in NRP biosynthesis implies there is more to be learned about the basic enzymology of NRPSs. Further investigation of MLPs may lead to an understanding of how to disrupt their function, opening up the possibility of using MLPs as new drug targets. Structural and genetic studies indicate that MLPs do not have a catalytic site, leading to the hypothesis that a complex protein-protein interaction between the NRPS and MLP is required. Using enterobactin biosynthesis in *E. coli* as a model system, we have identified several residues in the cognate MLP, YbdZ, required for *in vivo* metabolite production. Analysis of YbdZ variants and other noncognate MLPs *in vitro* and *in vivo* will be presented here. These data have led to the generation of hypotheses for how MLPs interact with NRPSs and enable optimal NRPS enzymology. A detailed understanding of what dictates functional MLP/NRPS interaction is essential to the successful engineering of NRPs for medicinal or other applications.

Trimeric Spa47 is an Active Type Three Secretion System (T3SS) ATPase from *Shigella flexneri*

Author Block:

J. L. Burgess[1], H. B. Jones[1], P. Kumar[2], R. T. Toth, IV[2], C. R. Middaugh[2], E. Antony[3], **N. E. Dickenson**[1]; [1]Utah State Univ., Logan, UT, [2]Univ. of Kansas, Lawrence, KS, [3]Marquette Univ., Milwaukee, WI

Abstract Body:

Many Gram-negative pathogens, including *Shigella* spp., use conserved type three secretion systems (T3SS) as key virulence factors. The *Shigella* T3SS relies on an associated needle-like type three secretion apparatus (T3SA) which penetrates the host cell membrane and provides a unidirectional conduit for injection of effectors into host cells. A great deal is now understood about the complex structure of the *Shigella* T3SA, however, the specific mechanisms of formation, secretion activation, and regulation remain unclear. Sequence homology of the *Shigella* protein Spa47 to other known T3SS ATPases and its location within the sorting platform of the T3SA suggest that perhaps it is an ATPase responsible for providing the energy for T3SA formation and secretion. We have recently overcome the long standing hurdle of producing active recombinant Spa47 and report here the details of the intein fusion based purification protocol along with the first direct evidence that Spa47 is in fact a *bona fide* ATPase. Biophysical characterization of the recombinant Spa47 identified multiple discrete oligomeric species with the highest order representing a unique Spa47 trimer exhibiting >10 fold higher ATP hydrolysis activity over the monomeric form. This increase in activity by the oligomer is consistent with observations for other T3SS ATPases, but represents an active trimeric intermediate that is either unique to *Shigella* or has yet to be observed in other systems. Additionally, access to active recombinant Spa47 permitted investigation of the influence on Spa47 oligomerization and activity by several factors, including active site Walker motif residues, the protein N-terminus, and key interactions with other T3SS proteins. Together, these results identify Spa47 as a *Shigella* T3SS ATPase and suggest that its activity is linked to oligomerization, perhaps as a regulatory mechanism controlled through interaction with chaperone proteins such as MxiN. The *in vitro* characterization of Spa47 structure and function described here provides a strong platform for additional studies dissecting its role in virulence and identifies an attractive target for much needed anti-infective agents against *Shigella* spp.

Ribosome-Dependent Growth Inhibition by YhaV in *Escherichia coli*

Author Block:

J-H. Park, W. Choi; Korea Res. Inst. of BioSci. and Biotechnology, Cheongju-si , Chungbuk, Korea, Republic of

Abstract Body:

Background: Most of bacteria have toxins which inhibits cell growth and may lead to cell death when overproduced. They are located in one operon with their cognate antitoxins and neutralized in normal growing cells. Antitoxins are readily degradable under stress conditions, leading cytotoxicity. mRNA interferases are one of the well-known toxins which cleave cellular mRNAs. They are classified into two different types based on their dependence on ribosome. Here, we showed that YhaV binds to ribosomal subunits and it does not show its toxicity without ribosome.**Methods:** YhaV was overexpressed in *E. coli* deletion strain which PrlF(YhaV's antitoxin) and YhaV genes are deleted. DNA, RNA and protein synthesis were compared with deletion strain by incorporating [35S]methionine, [3H]thymidine, [a-32P]UTP , respectively. Northern blot analysis was carried out in ompA, ompF and lpp genes with YhaV incubation. Ribosome profiles fractions were detected by Western blotting. For identifying the ribosome dependence of YhaV toxicity, it was incubated with CAT expression vector in both prokaryotic and eukaryotic *in vitro* translation system.**Results:** Protein synthesis was almost completely inhibited within 5min after YhaV induction while DNA and RNA synthesis were not blocked, suggesting that YhaV is a general inhibitor of all protein synthesis. When the cellular mRNAs of *E. coli* carrying pBAD-YhaV were analyzed at different time points after induction of YhaV, intact mRNAs were observed only at the 0-time point, suggesting that YhaV has endoribonuclease activity and inhibits protein synthesis by cleaving mRNA. When measured cell-free protein synthesis using an *E. coli* T7 S30 extract system, the synthesis of CAT fusion protein was almost completely inhibited by higher concentration of YhaV. However, in eukaryotic *in vitro* translation, the synthesis of luciferase protein did not show any changes unlike MazF_bs, which is ribosome-independent and its higher concentration showed complete inhibition in this system.**Conclusions:** This study indicates that YhaV binds to ribosomal subunits and inhibits protein synthesis depending on ribosome like RelE toxin, which is different from ribosome-independent mRNA interferase, such as MazF. Therefore, we showed that YhaV is a ribosome-dependent toxin in contrast to previous study that concluded YhaV as a ribosome-independent toxin.

Mutational Analysis to Explore the Essential Residues for the Linkage Mechanism of the Remote Allosteric Regulation of NAGK

Author Block:

Y. Huang, Female, W. Ao, N. Zhao, S. Zheng; South China Univ. of Technology, Guangzhou, China

Abstract Body:

Background: *N*-acetyl glutamate kinase (NAGK) catalyzes the phosphorylation of the γ-COO^- group of *N*-acetyl-L-glutamate (NAG) by the γ-PO_4^{3-}group of ATP. The NAGK from *Corynebacterium glutamicum* (C.g NAGK) is allosterically inhibited by L-arginine, and is considered to be the key enzyme that regulates the production of L-arginine (Sakanyan et al. 1996). In pre-study, the docking results of the mutants indicated a linkage mechanism for the remote allosteric regulation of NAGK activity (Huang et al. 2015). In order to further explore the linkage mechanism, the amino acids in substrate binding region of NAG are mutated to explore the proposed signal transduction pathway of the feedback inhibition. **Methods:** The potential binding sites of substrates and the residues essential for the inhibition and catalysis are identified by homology modeling, molecular docking and site-directed mutagenesis. **Results**: The docking result shows that G69 and G71 directly interact with NAG and are closed to the β3-β4 hairpin. The mutants G71R and G69W have a severe impact on the catalytic activity, which only retain approximately 2.3% specific activity relative to that of wild-type CgNAGK (Fig. 1a). The wild-type CgNAGK, which is strongly inhibited by arginine, is half inhibited in 3.3 mM L-arginine. The mutants G69W and G71R can retain 34%, 59% activity in the presence of 10 mM L-arginine (Fig. 1b). Comparison the structure of G71R and G69W with the wild-type CgNAGK found that the β3-β4 hairpin is changed, which also indicate the residues G69 and G71 play an essential role in the signal transduction pathway of arginine inhibition. **Conclusions**: The amino acids G69 and G71 play an essential role in the catalysis of CgNAGK and the signal transduction pathway of the arginine inhibition.

Structure-Function Analysis of Site-Specific Protease PRP: A New Target for Antibiotic Design in *Staphylococcus aureus* and Related Pathogens

Author Block:

E. A. Wall, A. L. Johnson, D. Peterson, G. E. Christie; Virginia Commonwealth Univ., Richmond, VA

Abstract Body:

Ribosomal protein L27 is a component of the eubacterial large ribosomal subunit that has been shown in *E. coli* to play a critical role in substrate stabilization during protein synthesis. In *Staphylococcus aureus* and other Firmicutes, L27 is synthesized with an N-terminal extension of nine amino acids that must be removed post-translationally to expose the conserved residues important for tRNA stabilization at the peptidyl transferase center. We identified the novel cysteine protease that performs this cleavage, Prp, and found that it represents a new clade of uncharacterized proteases, now designated as C108 in the MEROPS database. In this work, we demonstrate L27 cleavage to be essential in *S. aureus*; un-cleavable L27 could not complement an L27 deletion. A truncated variant of L27 beginning at the cleavage site also failed to complement, indicating an essential regulatory role for the cleavage event. L27 cleavage by Prp is thus a new target for development of antimicrobials against *S. aureus* and many related pathogens. We developed an assay based on the cleavage of a fluorogenic peptide derived from the conserved L27 motif, and found that the enzyme demonstrates tight binding and high substrate specificity. Molecular modeling and site-directed mutagenesis support a structural model in which rearrangement of a flexible loop upon binding of the peptide substrate is required for the active site to assume the proper conformation for catalysis. This research lays the foundation for the design of protease inhibitors that target this novel, essential pathway.

Detection of Small Molecule Effectors of Pyruvate Carboxylase via the Development of a Novel High-throughput Screen

Author Block:

B. Wyatt, M. St. Maurice; Marquette Univ., Milwaukee, WI

Abstract Body:

Pyruvate carboxylase (PC) is a metabolic enzyme that catalyzes the conversion of pyruvate to oxaloacetate (OAA)[1]. In most organisms, this is one of a few anaplerotic reactions that serve to replenish tricarboxylic acid cycle (TCA) intermediates[1]. Due to an incomplete TCA cycle in *Listeria monocytogenes,* PC is the exclusive anaplerotic input for generating OAA and has been shown to be vital for the bacterium's carbon metabolism and pathogenicity[2]. Despite the importance of PC in the central metabolism of most organisms, there are no known *specific* and *potent* small molecule regulators of PC available to study the enzyme[1]. We aim to find, develop, and characterize novel small molecule effectors of PC that will aid in understanding the structure, mechanism, and regulation of PC and that will ultimately lead to new chemical probes to study PC in its cellular context. A novel, fixed-time assay has been developed based on the reaction of OAA with Fast Violet B, which produces a colored complex with an absorbance maximum at 530 nm[3]. Results indicate that the fixed time assay is reproducible, sensitive and responsive to known effectors of *Rhizobium etli* PC, *Staphylococcus aureus* PC, *and L. monocytogenes* PC and has a strong potential to be amenable to high-throughput screening. Assays were optimized in a 96-well format and consist of three basic steps: 1) a reaction of PC with substrates 2) enzyme inactivation with EDTA, and 3) incubation with FVB prior to measuring the absorbance at 530 nm. Preliminary validation demonstrates that the assay is responsive to weak, nonspecific effectors of PC in a dose-dependent manner. Acetyl-CoA, an allosteric activator, increases PC activity and oxalate, a competitive inhibitor, decreases PC activity with excellent signal to background windows. Statistical measures indicate that this is an excellent assay for high-throughput screening with *Z*-factors of 0.85 for the activation assay and 0.87 for the inhibition assay. The assay has been validated with a plate uniformity assessment test and was used in an initial pilot screen to test the assay's response to 1,280 compounds. The pilot screen results indicate that the assay has the strong potential to find novel small molecule effectors of PC that can be developed into valuable research tools to study the enzyme in its cellular context and provide potential novel antimicrobial agents targeted against bacterial PC.

Characterization of Dipeptidyl-Peptidase 4 from *Tannerella forsythia*

Author Block:

M. Nakasato[1], Y. Shimoyama[1], Y. Ohara-Nemoto[2], T. K. Nemoto[2], D. Sasaki[1], T. Yaegashi[1], S. Kimura[1]; [1]Iwate Med. Univ. Sch. Dent., Morioka, Japan, [2]Nagasaki Univ., Nagasaki, Japan

Abstract Body:

Tannerella forsythia is a Gram-negative anaerobic rod, and is a member of 'red complex species' the major causative organisms of chronic periodontitis in human. Since *T. forsythia* as well as *Porphyromonas gingivalis* is asaccharolytic, the proteolytic enzyme(s) including dipeptidyl-peptidases (DPPs) could be crucial for the growth. In this study, we determined the properties of DPP4 hydrolyzing the Pro^2-Xaa^3 bond from *T. forsythia* (TfDPP4) and compared them with those of *P. gingivalis* DPP4 (PgDPP4). The cell suspension of *T. forsythia* as well as *P. gingivalis* markedly hydrolyzed Gly-Pro-4-methylcoumaryl-7-amide (MCA), suggesting that *T. forsythia* possesses cell-associated functional DPP4 as PgDPP4 does. The optimal pH range for the cell-associated TfDPP4 was 7.5 to 8.0. In addition, the cell-associated TfDPP4 activity was decreased with NaCl in a concentration-dependent manner. TfDPP4 was composed of 722 amino acids with molecular masses of 81875 Da with 61.1% amino acid sequence homology to PgDPP4. The enzymatic properties of recombinant TfDPP4 (rTfDPP4) expressed in *Escherichia coli* were also compared to rPgDPP4. The rTfDPP4 preferentially hydrolyzed Gly-Pro-MCA and the DPP4 activity was comparable to that of rPgDPP4. The rTfDPP4 has an isoelectric point of 6.09 that was lower than that of rPgDPP4 by 1 unit, and showed the substrate specificity, and pH- and salt-dependences similar to rPgDPP4. In consequence, the present findings indicated that *T. forsythia* could possess functional DPP4 on the cell surface with very similar enzymatic properties to PgDPP4, which could be involved in the pathogenicity of *T. forsythia*, leading to the onset of human periodontitis.

A Mechanism of Glucose Tolerance of GH1 β-Glucosidases

Author Block:

Y. Xiao[1], X. ZHANG[1], Z. FANG[1], W. YI[2]; [1]Sch. of Life Sci., Anhui Univ., Hefei, China, [2]The First Affiliated Hosp. of Anhui Univ. of Chinese Med., Hefei, China

Abstract Body:

Background: β-Glucosidases are enzymes that hydrolyze β-glycosidic bonds to release non-reducing terminal glucosyl residues from glycosides and oligosaccharides, and thus have significant application potential in industries. However, most β-glucosidases are feedback inhibited by the glucose product, which restricts their application. Remarkably, some β-glucosidases of the glycoside hydrolase (GH) 1 family are tolerant to or even stimulated by glucose. The mechanisms of glucose tolerance and stimulation of the GH1 β-glucosidases is unclear yet. We supposed there might be other glucose binding sites and affecting mechanisms other than the active site and competitive inhibition. **Methods:** In this study, by comparing the primary and tertiary structures of two GH1 beta -glucosidases with distinct glucose dependence, some sites were mutated to investigate their relevance to the glucose effects, and the mutants were biochemically and structurally characterized to reveal the affecting mechanism of the sites. **Results:** Some mutants of a few sites at the entrance and middle of the substrate channel showed altered glucose dependence. Enzymatic kinetics analysis and ligand binding simulation of the wild-type proteins and mutants suggested that the geometry and relative binding affinity/preference of these sites to glucose modulates the glucose dependence. **Conclusions:** A mechanism was therefore proposed to interpret the glucose dependence of GH1 β-glucosidases : (1) Besides binding to the active site, glucose can bind to other sites along the substrate channel with varying affinities. (2) Glucose will inhibit the enzyme activity when it preferentially binds to the active site, while it will be tolerated when it prefers to bind to other sites. (3) Glucose bound to certain sites will enhance substrate cleavage activity through transglycosylation.

***Francisella tularensis* Ybex: Characterization of Homodimerization**

Author Block:

A. M. Hernandez, G. J. Nau; Alpert Sch. of Med. at Brown Univ., Providence, RI

Abstract Body:

Background: *Francisella tularensis*, the pathogen responsible for tularemia, has been classified as a category A biodefense agent by the CDC. *F. tularensis* is a facultative intracellular pathogen that blocks the proinflammatory response after invading macrophages, ultimately preventing the production of cytokines and chemokines. We have previously shown that FTL_0883/FTT_0615c is a *F. tularensis* gene important for virulence and evasion of the host immune response. Little is known about the function of YbeX. A crystal structure for YbeX has been recently generated in which two YbeX molecules are predicted to homodimerize. We investigated this the homodimerization as a means to understand YbeX's function, as well as its role in the pathogenesis of tularemia.**Methods:** The coding sequence of *ybeX* was subcloned into mammalian expression vectors to perform bimolecular fluorescence complementation (BiFC).**Results:** We are the first to show the homodimerization of YbeX using BiFC, confirming the crystal structure prediction. We created constructs expressing full length YbeX fused to fragments of the Venus fluorescent protein, and cotransfected them into 293Tcells. We observed fluorescence when YbeX-VN and YbeX-VC were cotransfected. We have also shown that the position of YbeX relative to the Venus fragment will determine the intensity of the fluorescence, with the most fluorescence signal observed when both subunits were fused to the amino termini of the Venus fragments. We have also shown that deletion of predicted YbeX domains decreases the function of the protein in bacteria, which is predicted to have an effect on YbeX homodimerization.**Conclusion:** YbeX homodimerization occurs within mammalian cells and may function as a molecular sensory of the host cell cytosol.

Consequences of Neocentromere Formation In *Candida albicans* on Chromosome Segregation Accuracy and Drug Sensitivity

Author Block:

L. S. Burrack[1], A. Plemmons[2], A. Saha[2], B. Turman[3], J. Berman[4]; [1]Gustavus Adolphus Coll., Saint Peter, MN, [2]Grinnell Coll., Grinnell, IA, [3]Univ. of Minnesota, Minneapolis, MN, [4]Tel Aviv Univ., Ramat Aviv, Israel

Abstract Body:

Genome stability requires accurate chromosome segregation via assembly of a functional kinetochore at the centromere. Defects in chromosome segregation accuracy can cause DNA damage and chromosome rearrangements as well as aneuploidy, an imbalance in the numbers of individual chromosomes. In cancer cells and fungal pathogens, aneuploidy is linked with the development of drug resistance. However, high levels of genome instability can also sensitize cells to certain drugs and environmental stresses. Here, we used *Candida albicans*, fungi with small, epigenetically-inherited centromeres, as a model system to study how alteration of centromere position affected chromosome segregation accuracy and sensitivity to several classes of chemotherapy drugs and antifungal drugs. We constructed multiple strains where the native centromere was deleted and a neocentromere, or new centromere, assembled at different locus on chromosome 5. We then measured chromosome loss rates using a counter-selectable marker (*URA3*) and SNP-RFLP to confirm homozygosis of the remaining chromosome. All characterized neocentromeres mediated chromosome segregation, but some loci had up to 50-fold higher chromosome loss rates than others. For some stress treatments, there was no difference in the response of strains with native centromeres and neocentromeres. Elevated temperature and treatment with nicotinamide, an inhibitor of histone deacetylase activity, increased chromosome loss rates in all strains tested. Interestingly, treatment with radicicol, an inhibitor of Hsp90, had a greater effect on chromosome loss rates in the tested neocentromere strain compared to the control strain. We are currently expanding these studies to additional neocentromere strains and to additional antifungal and chemotherapy drugs to determine if strains with elevated chromosome loss rates are sensitized to drug treatment and/or if they differ in the frequency of drug resistant isolates.

Two Mitochondrial Matrix Proteases Act Sequentially in the Processing of Mitochondrial Peroxiredoxin Prx1p in *Saccharomyces cerevisiae*

Author Block:

F. Gomes, L. Netto; Univ. of São Paulo, São Paulo, Brazil

Abstract Body:

Mitochondrial peroxiredoxin (Prx1p) from *Saccharomyces cerevisiae* is a thiol-dependent peroxidase that catalyzes the reduction of mitochondrial hydrogen peroxide. Prx1p is synthesized in the cytosol as a precursor with a cleavable N-terminal targeting signal (presequence) and subsequently imported into mitochondrial matrix. The importing process of Prx1p into mitochondrial matrix involves two sequential cleavages catalyzed by mitochondrial processing peptidase (MPP), which removes the presequence, and octapeptidyl aminopeptidase 1 (Oct1p), which removes an octapeptide from the N-terminus of the precursor intermediate generated by MPP. The function of this second cleavage step is still poorly understood, but there is evidence that could be important to the stability protein according to the N-end rule of protein degradation. Thus, this study aimed assesses the role of the Prx1p cleavage by Oct1p toward protein stability and activity. To monitor Prx1p stability, we perform *western blot* analysis using isolated mitochondria from WT and *ΔOCT1* yeast cells incubated over an increasing period of time. We observed a faster degradation of the Prx1p in *ΔOCT1* mitochondria compared with mitochondria from WT strain. The *OCT1* reexpression under its endogenous promoter and terminator in the *ΔOCT1* background recovered the Prx1p degradation rate for levels similar as WT strain, indicating that only absence the Oct1p is responsible for faster degradation of Prx1p. However, the Prx1p cleavage by Oct1p does not significantly alter the peroxidase activity of Prx1p *in vitro*, as assessed by NADPH consumption assays using the recombinant proteins of Prx1p (representing the forms cleaved and not-cleaved by Oct1p). Our results show that processing of Prx1p-intermediate pre-protein by Oct1p leads to a stabilization of Prx1p after import into the mitochondria. This constitutes a protein quality control system that regulates Prx1p homeostasis and probably mitochondrial redox processes.

Structural, Biochemical Characterization, and Evolutionary Origin of Alcohol/Aldehyde Dehydrogenases (Adhe) in *Entamoeba* Varieties

Author Block:

J. Leitao, A. Espinosa; Roger Williams Univ., Bristol, RI

Abstract Body:

Bifunctional alcohol/aldehyde dehydrogenase (ADHE) enzymes are essential for anaerobic respiration in protists and bacteria (i.e. *Entamoeba histolytica*, *Escherichia coli*, group-A-*Streptococcus*, *Pasteurella multocida*, *Clostridium perfingens*, *Clostridium difficile*). Structural and biochemical analysis of ADHE enzymes would contribute to the understanding of their evolution in prokaryotic and eukaryotic lineages. We have previously characterized the bifunctional *Entamoeba histolytica* alcohol/aldehyde dehydrogenase (EhADH2). Since EhADH2 is required for amoebic survival, it is an ideal target for the search of antiamoebic alternatives. Here we report significant features of the ADHE protein structure and function, which was isolated, cloned, and expressed from six *Entamoeba* varieties (*E. dispar*, *E. invadens*-IP-1, *E. invadens* VK, *E. moshkovskii* Snake, *E. moshkovskii* Laredo, and *E. terrapinae*). Alcohol and aldehyde dehydrogenase activities from each ADHE enzyme were analyzed. Six similar molecular weight ADHE proteins (2.7 kDa) were isolated, sequenced to determine the amino acid structure, and demonstrated consistency of evolutionary convergence within ADHE enzymes, which allowed *Entamoeba* varieties to adapt and survive under different environmental conditions. Considering that the evolutionary origin of the family of ADHE enzymes appears to be from diverse lineages, the purpose of this study is to examine the kinetic properties and efficiency of *Entamoeba* ADHE proteins. Concurrently, inhibitory studies using pyrazoline derivatives on *Entamoeba* growth by targeting its EhADH2 enzyme are pursued in our laboratory as a potential anti-amoebic strategy.

Characterization of the Unique Phosphofructokinase in Malaria

Author Block:

A. Y. Gandhi, A. M. Guggisberg, A. R. Odom; Washington Univ. Sch. of Med., Saint Louis, MO

Abstract Body:

The methylerythritol phosphate (MEP) pathway for isoprenoid biosynthesis is a promising drug target for *Plasmodium falciparum*, the causative agent of severe malaria. Through a forward genetics approach, we identified that the enzyme PfHAD2 regulates isoprenoid biosynthesis in malaria by limiting the availability of metabolites to the MEP pathway. Laboratory strains containing a loss-of-function mutation at the *PfHAD2* locus (PfHAD2^{R157X}) demonstrate increased resistance to fosmidomycin (FSM), a specific inhibitor of the MEP pathway, as well as increased steady-state levels of MEP pathway metabolites. Furthermore, FSM sensitivity and MEP pathway metabolite levels are restored in PfHAD2^{R157X} strains possessing hypomorphic alleles of the unique malarial phosphofructokinase *PfPFK9* (PfPFK9^{T1206I}). Sequence similarity analysis groups PfPFK9 in a poorly characterized family of plant-like pyrophosphate-dependent phosphofructokinases (PP_i-PFKs).We hypothesized that PfHAD2 regulates substrate availability to the MEP pathway by controlling the availability of allosteric regulators to phosphofructokinase, the rate-limiting step of glycolysis. In accordance, we identified that purified recombinant PfHAD2 dephosphorylates the purine nucleotides *in vitro*, with highest specificity towards the glycolytic effectors AMP and GMP. To begin evaluating the allosteric regulation of PfPFK9, we used commercially available reagents to implement an assay that links phosphofructokinase activity to the loss of NADH (ε_{340} = 6220 M^{-1} cm^{-1}). We are currently using this assay to measure the specific PfPFK9 activity from wild type, PfHAD2^{R157X}, and PfHAD2^{R157X}/PfPFK9^{T1206I} strains in the presence and absence of AMP and GMP.This approach will identify if a direct regulatory link exists between PfHAD2, glycolysis, and isoprenoid biosynthesis in malaria. Since malaria glycolytic enzymes are distinct from the analogous host enzymes, such a relationship would suggest that the extensive libraries of PP_i-PFK inhibitors already validated in other parasitic protozoa (*Trypanosoma* and *Leishmania*) could be readily repurposed for malaria chemotherapy.

Anaerobic Metabolism of Choline by a Human Gut Bacterium

Author Block:

A. Martinez-del Campo, S. Bodea, C. Chittim, E. P. Balskus; Harvard Univ., Cambridge, MA

Abstract Body:

The human gut microbiota has an extensive set of metabolic capabilities that directly influence human health. These host-microbe metabolic interactions may be beneficial, but can also lead to the development of diseases, such as the case of microbial degradation of choline. Breakdown of this essential nutrient by gut bacteria into trimethylamine (TMA) and further oxidation by liver enzymes into trimethylamine N-oxide (TMAO) has been linked to multiple diseases, including cardiovascular disease, non-alcoholic fatty liver disease, and trimethylaminuria. We recently discovered the first gene cluster (*cut*) responsible for anaerobic choline utilization and also characterized the key enzyme encoded in this cluster that catalyzes choline breakdown to TMA and acetaldehyde, choline trimethylamine-lyase. Having identified these enzymes, we sought to genetically characterize the *cut* cluster from a human gut derived *Escherichia coli* strain. In this study we evaluated the ability of *E. coli* MS 200-1 to grow on choline minimal media either by fermentation or by anaerobic respiration using different terminal electron acceptors. In order to identify the essential genes for choline utilization we constructed knockout mutants of the *cut* cluster genes and analyzed their growth and TMA production phenotypes. Our results demonstrate that fumarate, nitrate, DMSO and TMAO are able to support anaerobic growth on choline, whereas *E. coli* grew poorly under fermentation conditions. Deletion of genes involved in choline transport, choline cleavage, acetaldehyde processing, and encapsulation into a bacterial microcompartment showed impaired growth and lower TMA production when compared to the wild-type strain. Overall, our study confirms the role of the *cut* genes during anaerobic choline metabolism and contributes to establishing a mode for choline metabolism by human gut bacteria.

Characterizing the Fitness Landscape of Bacteriophage MS2 Virus-Like Particles

Author Block:

E. Hartman, M. B. Francis, D. Tullman-Ercek; Univ. of California, Berkeley, Berkeley, CA

Abstract Body:

Background: The bacteriophage MS2 is a well-studied virus that infects *Escherichia coli* and other members of the Enterobacteriaceae. During viral replication, 180 copies of a small Cap protein form an icosahedral capsid, encapsulating its RNA-based genetic information. This process can be mimicked by recombinantly expressing the MS2 coat protein in *E. coli*, such that virus-like particles are spontaneously formed. Researchers are investigating the utility of this highly ordered protein structure in drug delivery, *in vivo* imaging, and water filtration, among other applications. Here, we performed a structure-activity relationship study of the MS2 Cap protein to characterize the genetic landscape of assembly-competent virus-like particles (VLPs).**Methods:** We first generated a library of MS2 Cap protein mutants using error-prone PCR. In recombinant expression, the Cap protein multimerizes and encapsulates available RNA, including Cap protein mRNA. Chromatographic isolation selected for assembly-competent mutants of assembled MS2 VLPs, which were subsequently identified by sequencing the encapsulated RNA. Assembly-competent MS2 Cap protein variants were then individually expressed and characterized by transmission electron microscopy and size-exclusion chromatography.**Results/Conclusions:** These studies have identified multiple residues that can be mutated without disturbing the global structure of MS2 virus-like particles. Indeed, the MS2 Cap protein tolerated a surprising array of mutations—including glycine and proline mutations within regions with conserved secondary structure, a solvent-exposed tryptophan, and charge inversions. Tolerance varied by amino acid chemistry and position. This is the first in-depth biochemical analysis of this virus-like particle, and our study will inform future engineering efforts for all MS2 applications.

Breaking Out: Exploring the Range of Susceptibility to Mycobacteriophage-Encoded Lysterases and Their Potential as Novel Antimicrobials

Author Block:

D. J. Barbeau, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

All double-stranded DNA bacteriophages encode a specialized set of proteins that allows their progeny phages to escape the current host cell at the end of the lytic cycle. At a minimum, this lytic cassette consists of a holin and an endolysin to destabilize the host's plasma membrane and peptidoglycan layer, respectively. This two-enzyme system is sufficient to break open most Gram-positive bacterial hosts, but the phages of bacteria with more complex cell walls often encode additional lysis proteins. For example, the mycobacteria have waxy, mycolic acid-rich cell walls that aid in their antibiotic resistance, and their phages—the mycobacteriophages—encode a lysterase (LysB) in order to efficiently overcome this barrier. These serine esterases have been shown to release mycolic acids from whole mycobacterial cells and purified cell wall components via thin layer chromatography of cells grown in the presence of a ^{14}C-carbon source. Our data also show that exogenous addition of purified lysterases has antimicrobial activity against liquid cultures of several bacteria in the Order Actinomycetales, including bacteria associated with disease and—surprisingly—bacteria that do not contain mycolic acids. These findings highlight our incomplete understanding of lysterase proteins and provide the opportunity to explore their use as antimicrobial agents. In addition to using killing assays to further test the range of LysB-susceptible bacteria, we have been performing preliminary experiments, including testing for human cell cytotoxicity and synergy between LysB and commonly used antibiotics, toward determining the therapeutic potential of LysB in *Propionibacterium* and *Mycobacterium* infections.

Integrative Biology of Mycobacteriophage for Better *Mycobacterium tuberculosis* Control Measures

Author Block:

J. XIE, X. FAN, S. YAN, R. WANG, Q. LI; Southwest Univ., Chongqing, China

Abstract Body:

Background: Tuberculosis, caused by *Mycobacterium tuberculosis*, remains a serious global public health threat largely due to the emergence of antimicrobial resistant strains, shortage of novel antibiotics, and synergy of HIV coinfection. Mycobacteriophage, the virus of Mycobacterium, holds great promise in improving the control of tuberculosis, including diagnostics, and therapeutics.**Methods:** Novel mycobacteriophages were isolated from China, the genome, transcriptome, proteome were determined, together with the transcriptome of the interacting phage and host mycobacteria. Significantly differential expression genes of phage or host were individually characterized by overexpression or deletion to confirm their function.**Results:** Novel mycobacteriophages have been isolated from China soil. Their genomes have been defined. The transcriptome and proteome of interacting Mycobacteriophage SWU1 with *M.smegmatis* were determined. Bioinformatic analysis showed that TCA cycle genes, pentose phosphate pathway, nucleotide metabolism, and metal ions transporter were involved in the interaction.**Conclusions:** The integrative biology of Mycobacteriophage and host is robust and high throughput way to depict the interaction, and pinpoint the weakest point of Mycobacterium for better antibiotics targeting.

The Analysis of Toxicity by *Gene 52* of Mycobacteriophage Fruitloop

Author Block:

C-C. Ko, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

The sequenced genome collection of mycobacteriophages—viruses that infect the genus of *Mycobacterium*—has grown to more than 1000 genomes to date. These genomes are highly diverse, and the majority of the encoded genes' functions are unknown. As a gateway to exploring the unknown, a selection of mycobacteriophage genes were over-expressed in *Mycobacterium smegmatis* mc^2155—a relative of tuberculosis-causing bacteria—to identify those that are detrimental to bacterial growth. Of the 202 genes tested, 21 are toxic to mycobacteria with additional 24 being inhibitory. Using this approach, *gene 52* of mycobacteriophage Fruitloop was identified as a toxic mycobacteriophage gene.To understand how the protein product of Fruitloop *gene 52* (gp52) kills *M. smegmatis*, a co-immunoprecipitation assay was performed followed by mass spectrometry analysis to identify Fruitloop gp52's interacting target(s). As a result, Wag31 of *M. smegmatis*—an essential protein involved in cell shape and cell wall integrity—was identified as a target. Interestingly, over-expression of Fruitloop gp52 results in a change in mycobacterial cell morphology from rod to round, a phenotype similar to that seen when Wag31 is depleted in mycobacteria. Moreover, over-expressing Wag31 allows mycobacteria to survive in the presence of Fruitloop gp52. Further analysis through the isolation of non-toxic Fruitloop gp52 mutants revealed that gp52's V45, I70, and W71 residues are important for its toxicity.Why does mycobacteriophage Fruitloop encode a protein that interacts with the cell wall synthesis machinery of its host? Further elucidating the phage-encoded toxic proteins' mechanisms will advance our knowledge about host-phage interactions. In addition, it also creates opportunities to discover new anti-tuberculosis drug targets at a time when drug-resistant tuberculosis is becoming a severe concern.

Using Rnaseq and Riboseq to Understand Mycobacteriophage L5 Genetics

Author Block:

R. M. DEDRICK, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Few in-depth genome-wide profiles of phage gene expression, translation and protein abundance have been performed, but should provide insights into bacteriophage biology genetics. Although expression patterns are established in a small number of well-characterized *Escherichia coli* phages, little is known within the broad array of highly diverse phages of other hosts. Although 1007 completely sequenced mycobacteriophage genomes have been collected, only two have been characterized by RNAseq to determine gene expression patterns. With the exception of *E. coli* bacteriophage lambda, no other phage has been evaluated using ribosome profiling. Here we describe the transcription, translation and protein profiles for L5, a temperate phage that infects *Mycobacteria smegmatis* and is classified into cluster A (subcluster A2). We have used RNAseq to determine the expression patterns of L5 in early (30min) and late (2.5hrs) lytic growth, as well as the L5 lysogen. Ribosome profiling was completed during late lytic growth using methods previously published by Ingolia *et al*., 2012 and total protein abundance was determined using MS/MS. There are distinct gene expression patterns in L5 with transcription of the right arm of the genome occurring in early infection and the virion structural genes in the left arm of the genome during late infection. The immunity repressor, as expected, characterizes the transcriptional profile of the L5 prophage. Surprisingly, all three expression profiles contain a highly expressed 500bp region at the extreme right end of the genome. Ribosome profiling during late lytic growth reveals that ribosomes are actively translating mRNA from genes transcribed in the RNAseq data and the ribosomes are protecting this highly expressed region. Bioinformatics and MS/MS indicate that this region does not produce a protein product and we predict that it is a ncRNA. Further analysis of this possible ncRNA indicate that it is essential for lytic growth of the phage and is toxic to the host, as well as *E. coli*, unless co-expressed with the L5 immunity repressor. This is just one example of insights derived using "-omics" approaches in mycobacteriophages.

A Capsular Polysaccharide-Dependent *Campylobacter jejuni* Phage Depends on Intracellular Host O-Glycosylation Biosynthetic Enzymes for Infection

Author Block:

J. C. Sacher, M. A. Javed, C. M. Szymanski; Univ. of Alberta, Edmonton, AB, Canada

Abstract Body:

Background:*Campylobacter jejuni* Pse enzymes encode an O-glycosylation system involved in flagellin modification needed for motility and virulence. Although protein glycosylation systems are increasingly identified in bacteria, interactions between bacteriophages and these systems have scarcely been studied. We have observed that the NCTC 12673 *C. jejuni* phage, although capsular polysaccharide-specific, also depends on intracellular O-glycosylation enzymes.**Methods:**We isolated a spontaneous NCTC 12673 phage variant, "MutC" from a plaque obtained following infection of *pseC* mutant cells by NCTC 12673. We sequenced the genomes of MutC and wild type (WT) phage using Illumina MiSeq. I-TASSER server was used for protein structure and function prediction.**Results:**We found that WT phage was unable to plaque on *C. jejuni pseC* or *pseH* (early gene) mutants, yet plaquing was observed on *pseG, pseI* and *pseF* (late gene) mutants. These results suggest that the phage may require the glycan intermediate produced by PseH, a UDP-linked altropyranose. We identified MutC as a variant able to infect all *pse* mutants. Genomic comparisions of WT and MutC uncovered a frameshift mutation in a polyG tract in the hypothetical gene *gp116*. This resulted in a predicted functional MutC Gp116 product, but a truncated WT product. Previous analysis of an NCTC 12673 phage variant detected Gp116 peptide fragments (22% coverage), suggesting it is a structural protein. BLAST showed that *gp116* is conserved in only 4 other *C. jejuni* phage genomes. Interestingly, I-TASSER showed multiple hits involving glycan-binding proteins.**Conclusion:***C. jejuni* phage NCTC 12673 depends on O-linked protein glycosylation for infection. We have identified a candidate phage protein, Gp116 that could help compensate for the loss of *pse* gene products and restore phage infection. The phage appears to be able to switch Gp116 expression, a mechanism not previously described for *Campylobacter* phages. Future directions will involve purifying $Gp116^{MutC}$ in order to elucidate its function. We also plan to express $gp116^{MutC}$ in *C. jejuni* cells to determine whether it can rescue WT phage infectivity. Understanding the mechanism by which MutC circumvents dependence on *C. jejuni* O-glycosylation could lead to better understanding mechanisms of phage predation.

Photorhabdus Virulence Cassettes (Pvcs) - Novel Phage Tail-Like Mechanisms and Their Role in Streptomyces

Author Block:

M. Vladimirov, S. Mak, J. R. Nodwell, A. R. Davidson; Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

Interactions of bacteria with bacteriophages through evolution has led to the integration of many viral genes into bacterial genomes. In certain cases, incomplete phage genomes can be maintained by bacteria thanks to a novel gain of function. Examples of phage derived mechanisms which contribute to bacterial fitness include the *P. aeruginosa* R-type pyocin and the Type VI secretion system. A new class of contractile phage tail-like genetic elements was recently discovered in *Photorhabdus luminescens* and *Serratia entomophila* and linked to insecticidal activity. These elements were therefore termed PVCs - Photorhabdus Virulence Cassettes. Following extensive annotation of phage-like genes in bacterial genomes we discovered that conserved genetic clusters homologous to PVCs were found in numerous prokaryotes from all phyla, including Gram-negative and Gram-positive bacteria, as well as in several Archaea. Interestingly, PVCs appeared to be highly conserved in *Streptomyces* and some members of the genus contain several PVC clusters in a single genome, however their role remains unknown. The knockout of the tail sheath coding gene, one of the key structural components of the PVC in *S. coelicolor* resulted in a reduction in antibiotic production and negatively affected the ability of *S. coelicolor* to kill other bacterial strains and yeast. We suggest that PVCs could represent the first case of a phage-tail like machinery which constitutes a novel putative secretion system in Gram-positive bacteria.

Characterization and Genome Analysis of Novel Broad Host Range Bacteriophages Infecting Opportunistic Human Pathogens, *Klebsiella* and *Cronobacter sakazakii*

Author Block:

K-J. Yuk[1], E-A. Park[1], S. Ryu[2], J-H. Lee[1]; [1]Inst. of Life Sci. and Resources, KyungHee Univ., Yongin, Korea, Republic of, [2]Res. Inst. of Agriculture and Life Sci., and Ctr. for Food and Bioconvergence, Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Klebsiella is a well-known opportunistic human pathogen infecting primarily immunocompromised individuals underlying diseases including diabetes mellitus or chronic pulmonary obstruction. To control this pathogen, novel phages PKO111 and PKP126 were isolated from various environment. Interestingly, their host range tests showed that these phages infect both *K. oxytoca*, and *K. pneumoniae* as well as even *Cronobacter sakazakii*, suggesting that they are broad host range phages. TEM observation revealed that PKO111 and PKP126 belong to the family *Myoviridae* and *Siphoviridae*, respectively. In addition, these phages showed high stability under various temperature (-20 to 65°C) and pH (3 to 11) conditions. Challenge assay showed that PKO111 and PKP126 inhibit their host strains in 3 log and 2 log reductions, respectively. Their complete genome sequences reveled, PKO111 genome has 168,758-bp DNA length with GC content of 39.39% containing 291 ORFs and 16 tRNA gene, and PKP126 genome has 50,934-bp DNA length with GC content of 50.37% containing 78 ORFs and no tRNA gene. Subsequent phylogenetic analysis of phage major capsid proteins from various *K. oxytoca*, *K. pneumoniae*, and *C. sakazakii* showed the presence of three different phylogenetic clusters. Interestingly, each cluster was associated with phage morphology and genome size (Cluster I including PKO111, *Myoviridae* with ~170-kb; Cluster II including PKP126, *Siphoviridae* with ~50-kb; Cluster III, *Podoviridae* with ~40-kb), suggesting that phages in each cluster may have been evolved from different ancestor. These phages may be good candidates for biocontrol agents against *Klebsiella* and probably for natural food preservatives against *C. sakazakii*.

Characterization and Genomic Study of a Novel Broad Host Range Bacteriophage Hy03 Infecting Both *Escherichia coli* O157:H7 And *Shigella flexneri* Reveal Its Potential as a Biocontrol Agent in Foods

Author Block:

Y-T. Kim[1], E-A. Park[1], S. Ryu[2], J-H. Lee[1]; [1]Inst. of Life Sci. and Resources, Kyung Hee Univ., Yong-in, Korea, Republic of, [2]Res. Inst. of Agriculture and Life Sci., and Ctr. for Food and Bioconvergence, Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Escherichia coli O157:H7 is one of the most severe food-borne pathogen, which infects even at a very low dose. It causes diarrhea, hemolytic uremic syndrome, and hemorrhagic colitis. To control this pathogen, bacteriophage HY03 infecting *E. coli* O157:H7 was isolated from a poultry fecal sample. The morphology was observed with transmission electron microscopy (TEM) and it belongs to the *Myoviridae* family. Interestingly, host range test of HY03 showed that it can inhibit the growth of *E. coli* O157:H7 as well as *Shigella flexneri*, suggesting that it is a broad host range phage. The phage stability test was performed and showed that it is generally stable under various stress condition of pH (3 to 11) and temperature (-20 to 60^{o}C). One-step growth curve analysis showed that eclipse/latent periods are 10 and 20 min and burst size is 10 at a multiplicity of infection (MOI) 0.001. Complete genome sequencing of HY03 by 454-GS FLX revealed that the genome consists of a 170,770 bp-length DNA with GC content of 35.3% containing 292 ORFs. Functional classification of the annotated ORFs showed that three major functional categories including structure and packaging, tails, and host lysis contain 16, 10 and 1 genes, respectively. Food applications of HY03 using fresh edible lettuce were conducted with a clinical isolate of *E. coli* O157:H7 (ATCC 43890) and a food isolate (ATCC 43895), revealing 2 log reduction by the phage HY03 in food environments. In conclusion, the phage HY03 could be useful for development of a novel biocontrol agent or a novel natural food preservative against *E. coli* O157:H7 and even *S. flexneri* in foods.

Rna-Seq Analysis of Enterohemorrhagic *Escherichia coli* O157:H7 Strains Showing Different Levels of Shiga Toxin 2 Production

Author Block:

A. Allué Guardia, B. Rusconi, F. Sanjar, S. S. K. Koenig, M. Eppinger; Univ. of Texas at San Antonio, San Antonio, TX

Abstract Body:

Background: Shiga toxin (Stx) production is the major virulence hallmark of enterohemorrhagic *Escherichia coli* (EHEC) of the O157:H7 serotype. Human disease severity and progression to HUS is a direct result of the mobilization of Stx-converting bacteriophages and coherent toxin production. A high level of heterogeneity in Stx prophage architecture and toxin production capabilities has been observed, however the specific bacterial host and phage loci and pathomechanisms that define and control the strains' individual Shiga toxin virulence state are largely unknown. A substantial number of Stx phage genes are annotated as hypothetical genes of unknown function and it is unknown if these are expressed**.** To investigate pathomechanisms of elevated Stx2 production we used an RNA-Seq approach to characterize the global transcriptomes of different *E. coli* O157:H7 with varying Stx production capabilities, cultivated under basal and Ciprofloxacin inducing conditions. **Methods:** Transcriptomes for eight strain pairs were generated on the Illumina HiSeq platform. Profiled strains produce equal levels of Stx2 and are phylogenetically distant, or vice versa, are closely related strains with varying Stx2 production levels. Sequence reads were comprehensively analyzed using CLC Bio Workbench and visualized with MeV Viewer. **Results:** Our analyses allowed us to test for confounding chromosomal and phage borne factors of increased Stx production. We found significant isolate-specific differences in the global expression profiles, likely associated to the limited yet very important plasticity in these isolates affecting Stx production. We further identified regulatory circuits driven by phage and chromosomal genes that were coordinately expressed along with Stx2 and other virulence factors. **Conclusion:** This study highlights the importance of comparative transcriptomics for identifying loci that are directly or indirectly involved in Stx-phage mediated pathogenesis. Understanding the underlying pathomechanisms and regulatory circuits that define high Stx2 producers through RNA-Seq improves risk assessment and provides targets for the development of alternative anti-stx2 strategies.

Characterization of Proteins in Cbk Phage Lysate

Author Block:

K. Wilson, B. Ely, C. Callahan; Univ. of South Carolina, Columbia, SC

Abstract Body:

Bacteriophage CbK is the best studied representative of the most common type of bacteriophage that infects *Caulobacter crescentus*. The CbK 216 kb genome is estimated to code for 338 proteins. However the function of the majority of these proteins has not been determined. A comparison of the CbK genome to the genomes of 11 closely related phages revealed that only 108 of the protein-coding genes were present in all 12 phages. However the function of the majority of these proteins has not been determined. Therefore, we initiated a study of the proteins contained in the phage particles to identify those genes that code for structural proteins. During CsCl gradient purification of the CbK phage particles, we noticed an additional band of material that had a density that was less than 1.5 g/ml and therefore contained no DNA. Electron microscopy of this material revealed that it contained phage tails, empty phage heads, phage heads containing spiral structures, and globular particles. SDS-PAGE followed by trypsin digestion and MALDI mass spectrometry allowed us to identify the major proteins in this fraction by comparison of the peptide molecular weights to those predicted from the genome sequence. This analysis revealed the presence of homologues to a rIIb-like protein, a transcription termination factor Rho protein, and a nicotinate phosphoribosyl transferase protein in addition to phage head and tail proteins. The presence of these proteins suggested that CbK may form a DNA replication that complex aids in the replication of this virus within the host cell similar to that previously observed for the E. coli bacteriophage T4. Efforts are underway to separate the globular structures from the phage heads and tails so that the proteins involved in each of these structures can be identified.

Cloning and Sequencing of the *Flavobacterium johnsoniae* Bacteriophage Cj1

Author Block:

M. Kempf; Univ. of Tennessee at Martin, Martin, TN

Abstract Body:

Bacteriophage Cj1, which infects motile cells of the gliding bacterium *Flavobacterium johnsoniae*, was one of several bacteriophage isolated from ponds and streams around Madison, WI in the 1970s. There is no published sequence data for bacteriophage that infect *F. johnsoniae*; therefore, a shotgun cloning and sequencing approach was used to obtain bacteriophage genome sequence. A plate lysate method was used to grow bacteriophage Cj1 in *F. johnsoniae*. Bacteriophage genomic DNA was isolated by protease digestion, phenol-chloroform extraction, and ethanol precipitation. Single digests of bacteriophage genomic DNA were performed with *Apo*I, *Dra*I, *Eco*RI, *Nsi*I, *Rsa*I, and *Xba*I, and the resulting DNA fragments were ligated into pBluescript KS+. Cloned DNA was introduced into *E. coli* DH5α by heat-shock. From 39 plasmids, approximately 15 kb of bacteriophage Cj1 DNA has been sequenced, but the genome has not been completely sequenced. Analysis of the bacteriophage Cj1 sequence identified 20 open reading frames that would encode proteins that are greater than 50 amino acids in size. Six of the predicted protein sequences (predicted sizes of 390, 286, 346, 126, 51, and 68 amino acids, respectively) have amino acid identity to other proteins based on standard Protein BLAST searches: Orf1 (34% amino acid identity to RecA); Orf2 (36% amino acid identity over 108 residues to a single-stranded DNA binding protein); Orf4 (33% amino acid identity over 132 residues to a peptidoglycan-binding protein), Orf5 (37% amino acid identity over 82 residues to muramidase); Orf12 (38% amino acid identity over 40 residues to TonB); and Orf 15 (55% amino acid identity over 66 residues to deoxyuridine 5'-triphosphate nucleotidohydrolase). Based on protein database similarity, the proteins Orf4 and Orf5 may be involved in releasing bacteriophage from the host cell and proteins Orf1, Orf2, and Orf15 may be involved in bacteriophage DNA replication. Of the fourteen remaining predicted proteins, nine had amino acid identity to hypothetical proteins in the database while five had no significant similarity to any of the proteins in the database. The predicted proteins of each open reading frame and their identity to proteins in the database will be discussed. Further nucleotide sequencing and analysis will result in a better understanding of the genes and proteins found in bacteriophage Cj1 and potentially how the bacteriophage infects motile bacterial cells.

Function and Evolution of the Cluster A Actinobacteriophage Genetic Circuit

Author Block:

T. N. Mavrich, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Temperate bacteriophages control their lifecycle by employing genetic circuits. These circuits coordinate the temporal expression of genes during infection, lysogeny, and superinfection immunity. Investigation of how phage genetic circuits function and evolve can provide deeper understanding of natural microbial biology as well as help improve the design of artificial circuits for synthetic biology.Over 350 genetically related, temperate phages that infect various hosts of the phylum Actinobacteria have been isolated. These Cluster A phages appear to harness a homologous genetic circuit to control transcription. In contrast to other highly characterized phage regulatory strategies, this circuit utilizes a single transcriptional repressor capable of recognizing a canonical operator site as well as dozens of other potential sites distributed throughout the genome, and *in vitro* it is capable of regulating two stages of transcription - initiation and elongation. However, we do not understand how repression occurs *in vivo*, what degree of selection is imposed on the position, frequency, or sequence of sites, and how this circuit evolves.To investigate how this circuit functions and to identify the evolutionary forces that shape it, we have employed a comparative genomics approach that leverages the natural variation and diversity present among Cluster A phages. Phylogenetic analyses have highlighted that the repressor gene appears to evolve differently than other highly conserved genes. Bioinformatic identification of the repressor's predicted binding sites reveals that while sites co-evolve with the repressor within each genome, they retain a conserved hexameric promoter element. Lastly, superinfection immunity assays have shown that small, incremental changes in the repressor genes and their predicted binding sites may have marked effects on the circuit's regulatory capability. The combination of these approaches has begun to elucidate the dynamics of this evolving circuit.

The Multi-component Antirestriction System of Coliphage P1

Author Block:

D. K. Piya, L. Vara, R. Young, J. J. Gill; Texas A&M Univ., College Station, TX

Abstract Body:

Bacterial type I restriction-modification (R-M) systems present a major barrier to foreign DNA entering the bacterial cell, by cleaving inappropriately modified DNA in a sequence-specific manner. To overcome this defense system, the temperate coliphage P1 encodes proteins that protect its DNA from host type I R-M systems. Previous work has shown that the P1 anti-restriction system was comprised of DarA and DarB (dar for *d*efense *a*gainst *r*estriction), virion-associated proteins that protect DNA against the *Eco*A, *Eco*B, and *Eco*K type I R-M systems. P1*darA*$^-$ has a reduced efficiency of plating (EOP) in *E. coli* strains encoding the *Eco*A, *Eco*B or *Eco*K R-M systems, while P1*darB*$^-$ has a reduced EOP in *E. coli* encoding the *Eco*B or *Eco*K systems. To examine the role of DarA and DarB in the P1 antirestriction system, isogenic P1 deletion mutants were used to reconstitute the restriction phenotypes associated with *darA* and *darB*. While P1(Δ*darA*) and P1(Δ*darB*) produced the expected phenotypes, deletions of adjacent genes *hdf* and *ddrA* also gave a *darA*-like phenotype and deletion of *ulx* produced a *darB*-like phenotype. Interestingly, disruption of *ddrB* caused the phage EOP to become approximately 10-fold higher on *Eco*B or *Eco*K strains, suggesting DdrB acts as a modulator of DarB. All of these restriction phenotypes could be complemented *in trans.* SDS-PAGE and mass spectrometry of CsCl-purified virions revealed that *darA, hdf, ddrA* and *ulx* mutants fail to package DarB in virions and *hdf* mutants fail to package DarA or DarB. Interestingly, virions of P1(Δ*ddrA*), with restriction sensitivity to *Eco*A, still contain DarA, indicating that DarA is necessary but not sufficient for protection of phage DNA against *Eco*A. A combination of isopycnic CsCl gradient centrifugation and transmission electron microscopy showed that *darA* and *hdf* mutants produced high proportions of small-headed virions, suggesting that the antirestriction system is also linked to the process of head morphogenesis. The P1 antirestriction system is more complex than previously realized and is comprised of multiple proteins including DdrA, DdrB, Hdf, and Ulx in addition to the previously described DarA and DarB.

Altering the Speed of the Bacteriophage T4 Dna Packaging Motor

Author Block:

S. Lin, C. J. VanGessel, W. Tang, T. I. Alam, V. B. Rao; The Catholic Univ. of America, Washington, DC

Abstract Body:

Double-stranded DNA packaging in bacteriophage T4 and other viruses is a complex biological process that serves as an excellent model to understand fundamental mechanisms of ATP energy transduction into mechanical work (1). gp17, the packaging motor of bacteriophage T4, translocates T4 genome (171-kbp) into the prohead capsid via an ATP-driven process at a speed of up to 2,000 bp/s, the fastest reported to date (2). The speed of another phage packaging motor, one from phage phi29 that packages ~20-kbp genome, is only 100-bp/s. The speed of the motor may have evolved with the size of the genome, in order to efficiently generate an infectious virus in ~30 min phage life cycle. However, the mechanisms by which the speed of a motor is controlled are unknown in any system. We proposed that the hydrophobic and electrostatic environment in the vicinity of the catalytic glutamate (E256 of gp17) and the gamma-phosphate of the bound ATP might modulate the rate of activation of water molecule, which in turn could control the rate of ATP hydrolysis and the speed of the motor. Guided by structural analyses, we identified two amino acid residues, F259 and M195, in the vicinity of E256 and the gamma-phosphate of the bound ATP in gp17 that might influence the ATP hydrolysis rate. Combinatorial mutagenesis and recombinational rescue were performed at these residues; 138 mutants were screened for each mutant library, and about 130 different phenotypes were sequenced. We found that only aromatic amino acid and leucine substitutions were tolerated at F259 position. At M195 position hydrophobic amino acid substitutions were also tolerated, whereas polar residue substitutions resulted in null or cold-sensitive phenotypes. Interestingly, substitution with serine at M195 resulted in null phenotype, whereas threonine substitution gave cold-sensitive phenotype. Preliminary results showed that gp17 purified from the null and cold-sensitive phenotypes showed greatly reduced ATP hydrolysis and *in vitro* DNA packaging. These results suggest that modulating the hydrophobic environment in the vicinity of catalytic glutamate might be one mechanism to control the speed of the phage T4 DNA packaging motor.

Dissecting the Role of the Partition Factor Parf in TP228 Plasmid Segregation

Author Block:

G. Allison, Dr Daniela Barillà; Univ. of York, York, United Kingdom

Abstract Body:

Antibiotic resistance is one of the most significant health concerns for the public. Bacterial antibiotic resistance can occur for many reasons but the most common is the presence of drug resistant plasmids. Therefore understanding how these drug resistant plasmids are passed from one generation to the next is of high importance and could provide potential drug targets to combat antibiotic resistance. Low copy number plasmids, implicated in antibiotic resistance, utilise partition cassettes in order to ensure faithful segregation at cell division. The multidrug resistance plasmid TP228 is a low copy number plasmid that contains the *parFGH* partition cassette. *parH* is a *cis*-acting centromere-like site, ParG is a DNA binding protein and ParF is a Walker-type ATPase that is able to assemble into higher order structures upon ATP binding. Recent structural data has shown that ParF-ATP dimers interact with each other to form dimer-of-dimer units which create the building blocks of the filaments. This project dissects ParF and its non-specific DNA binding properties as well as looking at how ParF is able to form polymeric structures with the aim of gaining further insights into TP228 plasmid segregation.A range of *in vitro* biochemical assays have been used to study ParF DNA binding and assembly into higher structures. Conventional fluorescence and super resolution microscopy has been used to investigate the *in vivo* localisation of ParF. In this study mutants were constructed to disrupt both DNA binding and ParF self-assembly. Mutants constructed at monomer-monomer and dimer-dimer interfaces affect ParF assembly. Changes in residues in a proline-rich motif positioned at the monomer-monomer interface cause ParF to form stronger monomer-monomer interactions and to self-associate into high order structures in the absence of ATP. This stretch of residues is also important in the interaction between ParF and the binding partner ParG, as the mutants have been shown to have a weaker interaction with ParG. Surface exposed basic residues were identified as potentially being involved in ParF DNA binding and two informative mutants were studied using *in vitro* DNA binding assays. Based on the findings and super resolution microscopy images obtained, a new model for TP228 plasmid segregation is proposed.

Making Vital Connections: Probing Protein-Protein Interactions Underpinning the Segregation of a Multidrug Resistance Plasmid

Author Block:

C. Pennica, M. Barge, A. Leech, D. Barilla'; Univesity of York, York, United Kingdom

Abstract Body:

Bacterial resistance to antibiotics is becoming a global concern. Most of the antibiotics used to treat infections in the past are now obsolete because bacteria developed resistance, hence finding alternative treatments or targets is of fundamental importance. Antibiotic resistance is often encoded by low copy number plasmids, which require an active segregation system to be evenly distributed to the daughter cells at cell division.The segregation system under investigation is that of the TP228 plasmid. The plasmid, first identified in *Salmonella newport*, is responsible for multidrug resistance and has high stability *in vivo*. Segregation stability is conferred by the *parFGH* partition cassette, which encodes a Walker-type ATPase, ParF, a DNA-binding protein, ParG, and contains an upstream centromeric region, *parH*. It has been shown that ParG binds to *parH* in a sequence specific manner and that this interaction recruits ParF to the binding site. This complex, called segrosome, is the fundamental unit for plasmids segregation. Published data suggest that ParF works as a motor protein that drives sister plasmids towards opposite poles of the cell, using the nucleoid as a scaffold.The aim of the project is to probe the molecular interaction between the components of the TP228 segrosome. ParG is a dimeric protein, consisting of a folded C-terminal domain, involved in DNA binding, and two unstructured N-terminal tails. These flexible regions seem to be involved in ParF binding and in improving its ATPase activity. ParG tails are likely to acquire a specific fold upon binding the partner protein ParF. Alanine-scanning mutagenesis of the ParG N-terminal tail has highlighted a number of residues, whose change either abolishes or severely abrogates plasmid partition *in vivo*. Mutant ParG proteins were purified and microscale thermophoresis and surface plasmon resonance were used to quantify the interaction between ParF and ParG N-terminal mutants. These techniques are allowing us to determine which amino acids are directly involved in ParF recognition and which are involved in other steps of the segregation process. The results obtained so far suggest that specific amino acids are essential for ParF binding and mutations at these positions abolish the interaction completely. A model for the ParF-ParG interaction will be proposed and discussed.

Identification and Characterization of the Lipoprotein *N*-Acyl Transferase Gene in *Enterococcus faecalis*

Author Block:

K. M. Armbruster, T. C. Meredith; The Pennsylvania State Univ., State College, PA

Abstract Body:

Approximately 1-5% of all bacterial proteins are lipoproteins, characterized by an N-terminal lipidated cysteine residue anchoring the globular domain to the surface of the cell membrane. Lipoproteins have a wide variety of cellular functions, including nutrient uptake, signal transduction, adhesion, and virulence. They also serve as potent ligands for Toll-like receptor 2 (TLR2), inducing a host innate immune response. Previously, lipoproteins were categorized as either diacyl or triacyl based on the absence or presence of an amide-linked fatty acid. In *E. coli*, addition of this *N*-acyl chain is catalyzed by the integral membrane protein lipoprotein *N*-acyl transferase (Lnt). Despite lacking an *lnt* sequence ortholog, recent structural analyses of lipoproteins from certain Gram-positive *Firmicutes* have demonstrated *N*-acylation [1], suggesting a unique lipoprotein biosynthetic pathway specific to these organisms. To determine the *Enterococcus faecalis* gene responsible for lipoprotein *N*-acylation, a genomic library was constructed and screened for Lnt-type activity. Our results revealed a single candidate protein demonstrating Lnt-type activity encoded by an unannotated sequence harboring a domain of unknown function. Genetic and functional characterization of this candidate protein will be presented.

Elucidating The Role Of A Member Of The MbtH-Like Protein Superfamily In *Myxococcus xanthus*

Author Block:

K. Esquilin-Lebron, M. G. Thomas; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

One way bacteria and fungi produce bioactive natural products such as antibiotics and siderophores is through the use of nonribosomal peptide synthetase (NRPS) multimodular assembly lines. Many NRPSs in bacteria require members of the MbtH-like protein (MLP) superfamily for their solubility and function. Although MLPs are known to interact with adenylation domains of NRPSs, the role MLPs play in NRPS enzymology has yet to be elucidated. MLPs are nearly always encoded within NRPS-encoding gene clusters. To date the only exemption to this rule is found in the Myxococcales order, where genes encoding members of the MLP superfamily are commonly found independently of NRPS-encoding gene clusters. For example, *Myxococcus xanthus* has fourteen NRPS-encoding gene clusters and only one MLP-encoding gene (MXAN_3118), which is not encoded within any of the NRPS-encoding gene clusters. These observations led to these hypotheses that MXAN_3118 may interact with one or more NRPSs, may play some NRPS-independent role, or plays some role in both NRPS enzymology and other physiological processes in *M. xanthus*. To investigate potential NRPS partners for MXAN_3118 I used a comparative genomics approach, leading to the identification of two candidate NRPS-encoding gene clusters. I investigated whether the solubility of any of these NRPSs is influenced by the presence of MXAN_3118 as observed for other MLP-NRPS partners. A cryptic cluster was identified to require MXAN_3118 for solubility of its NRPS components. This finding suggests that MXAN_3118 can functionally interact with NRPSs. Preliminary data suggests that MXAN_3118 is also required for adenylation domains function. We are currently optimizing conditions to identify substrate specificity to further understand the MLP/NRPS interactions in this system. Ongoing efforts to identify the associated metabolite are being pursued. *M. xanthus* NRPS-associated secondary metabolism have been extensively studied, here we identify and characterize the first MLP-dependent NRPS in the Myxococcales order. These findings will allow for the development of a model for the role of MXAN_3118 plays in the physiology of *M. xanthus* and other members of the Myxococcales order and will provide insights into the function of MLPs.

1D and 2D Gel Electrophoresis Analyzing of Recombinant PHB Proteins from New Identified *Bacillus cereus* tsu1 Strain

Author Block:

H. LI; Tennessee State Univ., NASHVILLE, TN

Abstract Body:

One *Bacillus cereus* Strain was isolated from cellulose-agar plate at Tennessee State University, which named as tsu1 strain. The genomic DNA was extracted from the above-mentioned strain and sequenced (Cornell University) and assembled (Pittsburgh Supercomputer Center). Genome sequence of *Bacillus cereus* tsu1 was deposited in NCBI with accession No. JPYN00000000. The assembled DNA contigs were translated into proteins by NCBI Prokaryotic Genome Annotation Pipeline. Five Poly-3-hydroxybutyrate (PHB) synthesis proteins were identified. With Sudan black staining, this bacterium was found producing PHB. The physical properties of the tsu1-PHB were found to be comparable to the standard compounds from Sigma (catalog Number 363502) when analyzed with HPLC and thermal degradation temperature. The five PHA genes (PhaA- beta keto-thiolase, PhaP- Phasin protein, PhaB- acetoacetyl-coA reductase, PhaR PHB synthase subunit, PhaC_N synthase subunit) were cloned and expressed in *E.coli* using Champion pET Directional TOPO Expression Kit (Carlsbad, CA). The recombinant proteins were separated on 1-dimensional and 2-dimensional gels, and analyzed using in-gel trypsin digestion followed by mass spectrometry analysis.

Structural and Biosynthetic Analysis of Fabrubactin, a Siderophore from *Agrobacterium fabrum* c58

Author Block:

V. Vinnik[1], H. Park[2], T. P. Wyche[3], F. Zhang[1], T. S. Bugni[1], M. G. Thomas[1]; [1]Univ. of Wisconsin-Madison, Madison, WI, [2]Massachusetts Inst. of Technology, Cambridge, MA, [3]Harvard Med. Sch., Boston, MA

Abstract Body:

The bioavailability of iron in aerobic environments at neutral pH is low due to the formation of insoluble oxidized iron complexes. To overcome this challenge many bacteria produce siderophores, which are soluble high affinity iron-chelating metabolites. Members of our lab previously identified a siderophore and the associated biosynthetic gene cluster from *Agrobacterium fabrum* strain C58. Here we present conditions for large-scale production and purification of this metabolite that allow for structure determination. Preliminary NMR data suggest the siderophore contains a heterocyclic moiety characteristic of the anachelin family of siderophores. We propose fabrubactin as the name for this siderophore. Our data suggest fabrubactin is made via hybrid polyketide synthase (PKS) and nonribosomal peptide synthetase (NRPS) enzymology. In addition to structural studies, the PKS and NRPS biosynthetic components were purified in order to assess substrate specificity. The enzymology and structure of fabrubactin will provide new insights into the formation of the heterocyclic moiety. These aspects of fabrubactin structure and biosynthesis will be discussed.

Studying Hemagglutinin Protein Interactions in Botulinum Neurotoxin Complex

Author Block:

L. Ab Samad, P. Lwin, W-J. Lin; California Polytechnic Univ. Pomona, Pomona, CA

Abstract Body:

Botulinum neurotoxin (BoNT), produced by *Clostridium botulinum*, is considered one of the most lethal poisons known to humankind. In C. *botulinum* serotype A1 strains, the neurotoxin is non-covalently bonded with several associated non-toxic proteins (ANTPs) such as NTNH and hemagglutinin (HA) proteins; forming a complex up to 900 kD in. The ANTPs in the complex protect the toxin from the acidic and proteolytic environment of the digestive tract as well as facilitate the absorption of BoNT across the intestinal epithelium. The gene organization that harbors the *bont* and *antp* has been well characterized and its association with mobile elements has been reported. However, it is not clear how the neurotoxin complex is formed at the protein level. In this study, we studied protein interactions within the toxin complex using size-exclusion chromatography (SEC), the Yeast Two-Hybrid System, and protein *in-vitro* studies. The SEC of the crude protein extract revealed that the protein complex assembles into two different-sized complexes: the 900kD LL and 500kD L. Further SEC analysis showed that the L complex rearranging itself gradually into the stable LL complex. Interactions of individual proteins were measured by the Yeast Two-Hybrid System. Among several positive interacting pairs, the strongest interaction occurred between HA17 and HA52. Mutation studies of HA52 indicated that the C-terminus was responsible for the binding with HA17. Protein *in-vitro* studies were also performed to provide further confirmation of the interaction between these two proteins. The optimal conditions facilitating the interactions are also investigated. Our data support the hypothesis of HA52 as a bridge between BoNT/NTNH and other HA proteins.Understanding how the neurotoxin complex is assembled will provide information leading to identify ways for preventative and therapeutic treatment of botulism.

Investigation of Protein Synthesis by Mycobacterial Alternative Ribosomes

Author Block:

A. Dow, S. Prisic; Univ. of Hawaii, Honolulu, HI

Abstract Body:

Many bacteria have at least one ribosomal protein with a homologous gene coding for an alternative ribosomal protein (AltRP). The question of whether or not the homologous ribosomal proteins offer distinct functionality to the mycobacterial ribosome was investigated using the bacteria *Mycobacterium tuberculosis* (*Mtb*) and *Mycobacterium smegmatis* (*Msm*), which possess four alternative ribosomal proteins arranged together in an operon. We use genetic manipulation, phenotypic analysis, and proteomics to investigate a role of mycobacterial AltRPs. In culture, mutants devoid of the AltRPs in both *Mtb* and *Msm* have a loss of clumping phenotype and exhibit an altered cell morphology, e.g., bulging of *Mtb* cells. Comparison of the proteomes from *Mtb* and *Msm* with mutants devoid of the AltRPs has identified that the loss of AltRPs causes a perturbation in the proteomic profile of the bacteria during zinc limitation, some of which may be involved in cell wall synthesis and explain the mutant phenotype. It was further observed that the *altRP* mutant of *Msm* has a distinct odor, suggesting overproduction of volatile metabolites. The mutant also has impaired biomass production in the late stationary phase when grown under low zinc conditions, compared to the wild type strain. In conclusion, our data suggest that pathogenic and non-pathogenic mycobacteria share a common mechanism of translational regulation, with zinc as a trigger for switching between two forms of ribosomes.

Rehm[4]; [1]Massey Univ., Palmerston North, New Zealand, [2]Bu-Ali Sina Univ., Hamadan, Iran, Islamic Republic of, [3]Victoria Univ. of Wellington, Lower Hutt, Wellington, New Zealand, [4]MacDiarmid Inst. for Advanced Materials and Nanotechnology, Massey Univ., Palmerston North, New Zealand

Abstract Body:

Alginates display exceptional physicochemical properties appropriate for numerous medical and industrial applications. However, if secreted by the opportunistic human pathogen *Pseudomonas aeruginosa*, it is an important virulence factor, especially during chronic lung infection of cystic fibrosis patients. Alginate is synthesized by a multi-protein complex spanning the inner and outer membranes and periplasm. Components of this apparatus are encoded within the alginate biosynthesis gene cluster which also encodes an alginate degrading enzyme AlgL - the function of which has been highly controversial. Here, we showed that deletion of *algL* gene doubled alginate yield, while enhancing epimerization and impairing O-acetylation of the polymer, without affecting polymer length distribution. However, inactivation of *algL* during planktonic mode completely abolished alginate biosynthesis. Together with our findings from mutual stability and protein-protein interaction experiments, we propose that AlgL is likely to be a free periplasmic protein dispensable for alginate production during growth on solid medium.

Structural and Functional Insights into the ComD Histidine Protein Kinase, a Quorum-sensing Signaling Peptide Receptor of *Streptococcus mutans*

Author Block:

X-L. Tian, Y-H. Li, Oral Biofilm Ecology Group; Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Background: Quorum sensing activation by a signal peptide pheromone (CSP) in *Streptococcus mutans* depends on the membrane-associated histidine protein kinase receptor, ComD, which senses the signal and triggers the signaling cascade for bacteriocin production and other cell density-dependent activities. However, the mechanism of the signal recognition via the ComD receptor in this species is nearly unexplored.**Methods:** In this study, we investigated the membrane topology of the ComD protein using a dual *phoA-lacZ* reporter system. We then determined the roles of the membrane domain of the ComD in CSP recognition and quorum sensing activation.**Results:** We demonstrated that the membrane domain of the ComD receptor protein forms six transmembrane segments with three extracellular loops, loopA, loopB and loopC. By mutational analysis of these extracellular loops combined with luciferase report assays of two CSP-inducible promoters, P*cipB* and P*nlmAB*, we also demonstrated that both loopC and loopB are required for CSP recognition and quorum sensing activation, while loopA plays little role in CSP perception. A deletion or substitution mutation of four residues NVIP in loopC abolishes CSP recognition for quorum sensing activities. Western blotting detected all the mutant proteins in the membrane fractions of the mutant strains, suggesting that a deletion or mutation of these extracellular loops does not affect the insertion of the mutant proteins into the membrane. Consistent with these findings, the loopC and loopB mutants are completely or partially defective in bacteriocin production.**Conclusions:** We conclude that both loopC and loopB are required for forming the receptor and the residues NVIP of loopC are essential for CSP recognition and quorum sensing activation in *S. mutans*.

Structure-Based *In vivo* Functional Analysis of the *E. coli F*tsB-FtsL Cell Division Complex

Author Block:

D. Mahbuba, S. J. Craven, L. M. LaPointe, N. Rangarajan, J. C. Weisshaar, A. Senes; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Background: The FtsB/FtsL complex is a key component of the divisome of *Escherichia coli* and other bacteria. FtsB and FtsL interact with FtsQ and are essential to recruit other downstream proteins to the division site. Despite their importance, the function and the structural arrangement of FtsB/FtsL complex are still poorly understood. Previous evidence from *in vitro* experiments suggests that FtsB and FtsL associate to form a higher-order oligomeric complex. This interaction of FtsB-FtsL complex depends on both the transmembrane and the juxta-membrane coiled-coil regions.**Method:**To address how the structural features of the FtsB/FtsL complex participate in supporting its function, we present the results of a structure-based phenotype analysis of an extensive number of mutations in the transmembrane and coiled coil regions of the complex.**Result:**Despite the fact that the transmembrane domains of FtsB/FtsL form a stable complex *in vitro*, we found that mutations introduced in this region have only a mild effect in cell division. We also found that mutations in the linker region between the transmembrane and coiled coil domain of FtsL impair cell division, whereas similar mutations in FtsB have a milder effect. This is consistent with the hypothesized presence of a flexible linker between the two helical domains in FtsB.**Conclusion:**This work provides a foundation for interpreting the role of protein-protein association in regulating the biological activity of FtsL/FtsB complex and the overall structure-function relationship at the molecular level.

Defining the Regulatory Role of Lipid Raft Micro-Domains in the T Cells Receptor Signaling Pathway

Author Block:

C. C. Osigwe, A. D. Levine; Case Western Reserve Univ., Cleveland, OH

Abstract Body:

We have previously reported that heterogeneity in the lipid composition of the plasma membrane plays a critical role in the T cell receptor (TCR) activation pathway. Our lab has shown that highly-ordered, densely packed lipids in raft-like micro-domains is required for the activation of this receptor complex. In particular, we have shown that the early, enzymatic events associated with TCR activation are dependent on the unique distribution of protein components of the TCR signaling complex with these lipid raft micro-domains. While our results support the importance of these lipid raft micro-domains in TCR signaling, no evidence is available to describe how these rafts are assembled and organized within the plasma membrane. The objective of our study is to define the regulatory role for lipid rafts on the TCR signaling pathway. The following techniques have been employed to investigate this objective. From whole blood, peripheral mononuclear cells (PBMCs) were isolated by Ficol-hypaque density separation. Purified T cells were expanded from PBMC culture by a nine day feeding with interleukin-2. The T cells were activated by cross-linking the TCR with anti-CD3/anti-CD28 co-stimulatory antibodies. Propagation of the signal was analyzed through immunoblot and phospho-flow cytometry analysis for a phospho-ERK response. Lipid raft composition, structure, and assembly will be probed with pre-designed fluorescently labelled phospholipids that selectively associate with distinct regions of the plasma membrane, labeling either a raft-like domain or non-raft domain. Localization of the specific fluorescently labelled phospholipids, balanced against the localization of protein components of the TCR signaling complex using fluorescently-tagged antibodies, is analyzed using confocal and deconvolution microscopy. The biological implications of this study will address how TCR engagement within the context of a lipid raft may lead to an immune response or immune tolerance.

The Transmembrane Domain of the *Staphylococcus aureus* ESAT-6 Secretion System Component EssB Interacts with the Integral Membrane Protein EssF

Author Block:

M. M. Ahmed[1], K. M. Aboshanab[2], Y. M. Ragab[3], K. A. Aly[1]; [1]Sinai Univ., North Sinai, Egypt, [2]Ain Shams Univ., Cairo, Egypt, [3]Cairo Univ., Cairo, Egypt

Abstract Body:

The *Staphylococcus aureus* ESAT-6 Secretion System (Ess) is a specialized machinery encoded by an 11 gene cluster, and dedicated to the secretion of several substrates into mammalian hosts. All 11 proteins coordinate substrate injection into the host cell, resulting in severe health complications. To gain insights into the *S. aureus* Ess pathway, we focused on a pivotal membrane component, termed EssB. EssB is highly conserved in many Gram-positive bacteria, and is a member of the Cluster of Orthologous Groups COG4499. In *S. aureus*, EssB is composed of extended N- and C-terminal stretches that are separated by a 23 amino acid transmembrane (TM) domain. Previous studies have found that EssB is required for toxin secretion into the extracellular environment, but without addressing the molecular events that mediate substrate translocation across the bacterial envelope. Here, a bacterial two-hybrid screen reveals that EssB strongly interacts with EssF, another integral membrane component of the Ess pathway. Further, we created 5 different EssB variants: 1- EssB C-terminal deletion (NTM), 2- EssB TM and C-terminal deletion (N), 3- EssB N-terminal deletion (TMC), 4- EssB N-terminal and TM deletion (C) and 5- EssB N-terminal and C-terminal deletion (TM). Results show that deleting the N- or the C-terminus of EssB, one at a time, did not abrogate EssB-EssF interaction, as long as the TM domain of EssB is present. Interestingly, retaining the TM domain and deleting both, the N- and C-termini of EssB still led to strong interaction with EssF, indicating that the TM domain is indispensable for interaction with EssF. The hydrophobic nature of the TM domain suggests that it may interact with one of the 6 TM domains found in EssF. This hypothesis has been validated by the failure of the only soluble 75 kDa domain of EssF to interact with EssB. Taken together, this study contributes to unveiling the membrane-associated events pursued by the *S. aureus* EssB towards toxin secretion, and will have an important impact on the development of novel treatment options.

Fitness Costs of Disrupting the Glycine Riboswitch in *Bacillus subtilis*

Author Block:

N. E. Lea, A. M. Babina, M. M. Meyer; Boston Coll., Chestnut Hill, MA

Abstract Body:

The glycine riboswitch is a dual aptamer glycine-binding mRNA structure located in the 5' untranslated region of the *gcvT* operon transcript in many bacteria. The mRNA structure acts as a genetic switch that senses cellular levels of glycine. In *Bacillus subtilis,* glycine binds each riboswitch aptamer and allows full-length transcription of the downstream *gcvT* operon via the disruption of a rho-independent transcription terminator. The *gcvT* operon encodes enzymes involved in the glycine cleavage system, and thus the glycine riboswitch is proposed to maintain intracellular glycine levels and facilitate the use of glycine as an energy source. Additionally, the *gcvT* operon is important for glycine detoxification in environments in which high glycine levels can inhibit bacterial growth. The evolutionary conservation, biophysical dynamics, and functional constraints on the glycine riboswitch are particularly interesting. Previous studies propose that the two aptamers demonstrate cooperative binding of glycine, and the vast majority of natural examples of the riboswitch include dual aptamer structures indicating this attribute may be important for cellular fitness. However, recent data suggests that the cooperative binding is an artifact of the constructs used for *in vitro* studies. To examine this question directly, we measured the impact of several riboswitch point mutations on gene expression using a beta-galactosidase reporter assay. Point mutations to the glycine binding sites of each aptamer, the combination of these mutations, and point mutations to the proposed dimerization interface between the aptamers, result in significantly decreased expression of downstream genes in the presence of glycine, suggesting that the regulatory function of the riboswitch is eliminated by these mutations. Furthermore, we find that when integrated into the native locus within the *gcvT* operon, these mutations disrupt biofilm formation, cell motility, and overall cell growth in *B. subtilis* in high glycine environments. These results suggest that a functional dual aptamer glycine riboswitch is necessary for optimal cell fitness under specific environmental conditions.

Two Small Regulatory Rnas, Omra and Omrb, Affect Type 1 Pilus Expression and Survival of *Escherichia coli* Within the Murine Urinary Tract

Author Block:

W. R. Schwan, I. Wu, C. Grosshuesch, D. Baumann; Univ. Wisconsin-La Crosse, La Crosse, WI

Abstract Body:

Background: Uropathogenic *Escherichia coli* (UPEC) is the number one cause of urinary tract infections in humans. The ability to survive in the high osmolality/acidic environment of the urinary tract is an important facet of *E. coli*. In this study, we have examined the roles two small regulatory RNAs (OmrA and OmrB) have on type 1 pilus expression and survival of *E. coli* within the murine urinary tract.**Methods:** Initially, *E. coli* K-12 strains with mutations in *omrA*, *omrB*, and *omrAB* were compared to the wild-type strain using reporter plasmids containing *fim::lacZ* fusions on single copy numbers plasmids. An *omrAB* double mutant was also created in the UPEC strain NU149. The NU149 *omrAB* double mutant was compared to the wild-type strain and the complemented mutant strain by PCR for the orientation of the *fimS* element and hemagglutination titer (HA) when grown in different *in vitro* environments. Furthermore, the NU149 *omrAB* mutant was inoculated into the urinary tracts of female Swiss Webster mice to assess whether the double mutation affected *E. coli* survival in the murine urinary tract.**Results**: Single mutations in *omrA* and *omrB* did not affect *fim* gene transcription in an *E. coli* K-12 strain. However, an *E. coli K-12 omrAB* double mutant demonstrated 1.7-fold greater *fimB* transcription and 3.2-fold greater *fimE* transcription compared to the wild-type strain when the *E. coli* were grown in pH 5.5 Luria broth containing 400 mM NaCl (pH 5.5 LB+). In an *omrAB* UPEC strain, the *fimS* element switched to being more phase OFF and had a lower HA titer compared to wild-type when the *E. coli* were grown in pH 5.5 LB+ medium. The NU149 *omrAB* strain had significantly lower viable counts compared to the wild-type strain within murine kidneys**Conclusion**: Deletion of the individual *omrA* and *omrB* genes had no effect on *fim* gene transcription. However, deletion of both *omrA* and *omrB* had a significant effect on *fimB* and *fimE* transcription, orientation of the *fimS* element, and UPEC survival in murine kidneys.

Hfq Modulates the Locus of Enterocyte Effacement of Enteropathogenic *Escherichia coli* by Means of the Magnesium-Responsive sRNA MgrR

Author Block:

S. Bhatt, T. Buerkert, J. Palmer, E. Storm, J. Ramirez, C. Xander; Saint Joseph's Univ., Philadelphia, PA

Abstract Body:

Enteropathogenic *Escherichia coli* (EPEC) infects host cells by destroying intestinal microvilli and leads to diarrhea. The locus of enterocyte effacement (LEE) is responsible for the observed symptoms. Therefore, regulators of the LEE are critical determinants of the pathogenic state of the bacterium and must be considered for the development of any measures to combat bacterial infections. Recent studies have shown that the LEE-encoded *grlRA* operon, which specifies the LEE repressor, GrlR, and the LEE-activator, GrlA, serves as a hub for multiple regulatory inputs. Whereas transcriptional regulation of the *grlRA* operon has been rigorously investigated, posttranscriptional control remains elusive. We used a reporter *E. coli* strain containing a *grlR'-'lacZ* translational fusion to screen for Hfq-dependent sRNAs regulating *grlR.* One such sRNA that was isolated was MgrR. Overexpression of MgrR reproducibly repressed the *grlR'-'lacZ* fusion. An extensive region of complementarity was evident between MgrR and the cloned region of *grlR,* suggesting that MgrR exerts its effect by direct base pairing. Predictably, a mutation in the base-pairing region of MgrR abolished its ability to repress *grlR.* Intriguingly, though, overexpression of MgrR, activated the cotranscribed downstream gene *grlA,* instead of repressing it. Thus, in summary, our results suggest that the Hfq-dependent sRNA, MgrR, base-pairs to the *grlRA* mRNA and destabilizes *grlR* but stabilizes *grlA.* In the future, we intend to use biochemical approaches including toeprinting assays to corroborate this hypothesis.

The Srna Ryhb Represses the Lee Pathogenicity Island in Enteropathogenic *Escherichia coli* by Base-pairing to the *grlra* Mrna

Author Block:

M. Egan, J. Ramirez, C. Xander, S. Bhatt, Department of Biology, Department of Mathematics; Saint Joseph's Univ., Philadelphia, PA

Abstract Body:

Enteropathogenic *Escherichia coli*, or EPEC, is a diarrheal pathogen that infects infants in developing countries. EPEC belongs to the attaching and effacing (A/E) morphotype, because it directly binds to intestinal epithelial cells and destroys the cellular microvilli. The virulence of EPEC is attributed to its major pathogenicity island: the locus of enterocyte effacement (LEE). Currently, there are no vaccines against EPEC. The problem is only exacerbated by the emergence of multi-drug resistant strains of EPEC. Thus, understanding the regulation of the LEE is critical to develop effective ways to combat EPEC infections. The LEE responds to a host of environmental cues, with the majority of them targeting three LEE-encoded transcription factors: Ler, GrlR, and GrlA. Whereas transcriptional regulation of the LEE has been widely characterized, post-transcriptional regulation, including regulation by trans-encoded regulatory small RNAs (sRNAs), remains understudied. Most sRNAs directly base-pair to their target mRNAs, influencing the translation and/or stability of the mRNA. A subset of these sRNAs requires Hfq, a chaperone protein that assists in the finding and base-pairing of sRNAs to their target mRNAs. One such sRNA is RyhB. Data from beta-galactosidase assays and Western Blots suggest that Hfq and RyhB corepress the *grlRA* mRNA transcript. To better understand how RyhB exerts its effect on *grlRA*, we performed *in silico* analysis. Using IntaRNA, we identified regions of complementarity between RyhB and the ribosomal binding site in the 5' untranslated region (UTR) of the upstream gene *grlR* in *grlRA*. In order to confirm this prediction of direct base-pairing between RyhB and *grlRA*, we constructed a polynucleotide mutation in RyhB's seed region. This mutation completely abolished the ability of the mutant RyhB to base pair to and repress the *grlR'-'lacZ* fusion. Collectively, our results suggest that RyhB represses the LEE by directing base-pairing to the leader segment of the *grlRA* mRNA and preventing the expression of GrlR and GrlA. Consistent with this prediction, overproduction of *ryhB* completely abolished the expression of GrlA and the GrlA-regulated target *ler*. Future studies are aimed at elucidating the precise molecular mechanism of the RyhB-mediated regulation of the LEE.

The Catabolite-Responsive sRNA Spot42 Represses Indole Production by Directly Base-Pairing to the *tnaC-tnaA* Intergenic Region of enteropathogenic *Escherichia coli* (EPEC)

Author Block:

S. Bhatt, V. Jenkins, E. Mason, J. Ramirez; Saint Joseph's Univ., Philadelphia, PA

Abstract Body:

Enteropathogenic *Escherichia coli* bacteria (EPEC) is a major cause of diarrheal disease in developing countries. EPEC causes disease due to the presence of the pathogenicity island locus of enterocyte effacement (LEE). A number of non-LEE encoded regulators control the LEE. One such regulatory element is the *tnaCAB* operon. The *tnaCAB* operon specifies the genes *tnaC*, *tnaA*, and *tnaB*. *tnaA* encodes the enzyme tryptophanase which converts tryptophan to indole, ammonia, and pyruvate. Indole is a bifunctional molecule, which induces the LEE and also functions as a secreted exotoxin that kills the worm *C.elegans*. Thus, any regulator of the *tnaCAB* operon would contribute to the ability of EPEC to cause disease in the mammalian and worm model systems. We screened for sRNA regulators of the *tnaCAB* operon by overexpressing sRNAs in EPEC and measuring indole production. One sRNA, Spot42, completely abolished indole production. Computational analysis revealed a region of complementarity between Spot42 and the intergenic region of *tnaC* and *tnaA*. The predicted *tnaC-tnaA* intergenic base pairing region was fused to a reporter *lacZ* gene lacking its 5' UTR and some of the N terminal codons to generate a hybrid *tnaA'-'lacZ* translational fusion. Overproduction of Spot42 repressed this minimal *tnaA'-'lacZ* translational fusion. Presently, we have introduced mutations in the base-pairing region of Spot42 and compensatory mutations in *tnaC-tnaA* intergenic region to provide genetic evidence for direct interaction between the Spot42 and *tnaC-tnaA* intergenic region. Additionally, we we are exploring how overexpression of Spot42 affects EPEC pathogenesis in the *C. elegans* and mammalian models of infection.

Discovery and Validation of a Conserved S6:S18-Interacting RNA *cis*-Regulator That Inhibits Translation of *E. coli rpsF*

Author Block:

A. M. Babina, Y. Fu, M. W. Soo, K. Deiorio-Haggar, M. M. Meyer; Boston Coll., Chestnut Hill, MA

Abstract Body:

More than half of the ribosomal protein operons in *Escherichia coli* are regulated by structures within the mRNA transcripts that interact with specific ribosomal proteins to inhibit further protein expression. These RNA structures exhibit a great deal of variation in size and complexity and utilize different mechanisms to regulate gene expression, including inhibition of translation initiation or elongation and premature transcription termination. The majority of these RNA regulatory structures are specific to Gammaproteobacteria. However, we and others have recently identified a widely distributed putative mRNA structure preceding the operons encoding small subunit ribosomal proteins S6 (*rpsF*) and S18 (*rpsR*) via comparative genomic approaches. Examples of this RNA from both *E. coli* and *Bacillus subtilis* are shown to interact *in vitro* with an S6:S18 complex. Structural probing and nuclease protection assays verify the predicted RNA secondary structure, identify the protein-binding site, and reveal that the proposed binding site bears a strong resemblance to the S18-binding site within the 16S rRNA. We also demonstrate that in *E. coli*, this RNA structure regulates gene expression in response to the S6:S18 complex. β-galactosidase activity from a *lacZ* reporter translationally fused to the 5'UTR and first nine codons of *E. coli rpsF* is reduced fourfold when both S6 and S18 are overexpressed together, but not individually. Measurement of transcript levels shows that although reporter levels do not change upon protein overexpression, levels of the native transcript are reduced fourfold, suggesting that this mRNA regulator prevents translation and this effect is amplified on the native transcript by other mechanisms. This work emphasizes how experimental verification can translate computational results into concrete knowledge of biological systems. The S6:S18-interacting mRNA structure is a relatively unique example of RNA *cis*-regulators of ribosomal protein synthesis found in bacteria, as it is highly conserved throughout the bacterial world and interacts with a complex of secondary rRNA-binding proteins.

Anaerobic Induction of FrsA Expression by the Oxygen-FNR-sRNA Regulatory Pathway

Author Block:

B-R. Jang, K-J. Lee, K-H. Lee; Sogang Univ., Seoul, Korea, Republic of

Abstract Body:

Fermentation respiration switch (FrsA) is an enzyme catalyzing a conversion of pyruvate to acetaldehyde and carbon dioxide. FrsA protein level was not detectable in *Vibrio vulnificus* cells grown under oxygen-rich condition, and thus the *in vivo* activity of pyruvate decarboxylation derived from FrsA was observed in the cells grown under oxygen-limited condition. To investigate the regulatory mechanism(s) for the anaerobic induction of FrsA expression and activity, its transcription was monitored using both *frsA*-transcription reporter and quantitative RT-PCR assays. However, no significant difference was observed in its transcription and the resultant transcripts in the cells grown under aerobic or anaerobic conditions. This result lead us to consider the specific regulation at the post-transcription level and to examine the involvement of sRNA in FrsA expression. A candidate regulatory sRNA for FrsA expression (Rsf), including the sequences complementary to the 5'-UTR of *frsA* mRNA, was identified in *V. vulnificus* genome. A northern blot revealed the presence of 350 nucleotide-long sRNA. Its regulatory role was examined via monitoring FrsA levels in the *rsf*-deleted mutant *V. vulnificus*. In the absence of *rsf* gene, the negative effect of oxygen on the cellular level of FrsA was abolished, and thus the *rsf* mutant exhibited high activity of pyruvate decarboxylation even under the aerobic condition. It was further determined the regulatory dependency of Rsf on oxygen in repressing FrsA expression. Expression of the *rsf* gene was repressed by a transcription factor FNR under anaerobic condition, whereas repression of *rsf* transcription by FNR was relieved in the presence of oxygen. Thus, this study demonstrates that the cellular content of FrsA is minimized during aerobic growth via repression of its expression by Rsf. This repression, however, is relieved under anaerobic condition via repression of the *rsf* transcription by FNR, resulting in higher levels of the cellular FrsA and the mixed-acid fermentative metabolisms.

***Neisseria meningitidis* Utilizes Twin Small Rnas (Twin Nmsrs) to Switch from Cataplerotic to Anaplerotic Metabolism**

Author Block:

Y. Pannekoek[1], R. A. G. Huis in 't Veld[1], K. Schipper[1], S. Bovenkerk[1], G. Kramer[2], M. Brouwer[1], D. van de Beek[1], D. Speijer[1], A. van der Ende[1]; [1]Academic Med. Ctr., Amsterdam, Netherlands, [2]EMBL, Heidelberg, Germany

Abstract Body:

Neisseria meningitidis is primarily a commensal of the human oropharynx that sporadically causes septicemia and meningitis. Meningococci adapt to diverse local host conditions, differing in nutrient supply, like blood and cerebrospinal fluid (CSF), by changing their metabolism and protein repertoire. We investigated whether small RNAs are used by the meningococcus to regulate gene expression leading to adaptation to nutrient variation. By whole transcriptome analyses two structurally nearly identical small RNAs (designated Neisseria metabolic switch regulators NmsR-A and NmsR-B) with 70% nt identity (twin NmsRs) were identified. Functionality of twin NmsRs was investigated using growth assays with a wild type strain (wt) a deletion strain (Δ*twin*), by complementation of Δ*twin* and by comparative proteomics of these variants. Overexpression of twin NmsRs impaired growth in nutrient poor medium and cerebrospinal fluid but not in nutrient rich medium and blood, suggesting a connection between the twin NmsR regulon and the stringent response. Ten proteins, functionally involved in the tricarboxylic acid cycle, with increased expression in Δ*twin,* were identified. By using a *gfp*-reporter system in *E. coli*, direct antisense interaction between 6 out of 10 of these potential mRNA targets and NmsR-A was confirmed. Regulation of target mRNA by twin NmRs was assessed by RT-qPCR in the variant meningococcal strains and confirmed for 4 targets (*prpB, prpC, gltA* and *sucC*). These results suggest that twin NmsRs are involved in regulating switches between cataplerotic and anaplerotic metabolism in this pathogen. The connection with the stringent response was further indicated by the differential expression of twin NmRs in a *relA* deletion versus wt strain (RT-qPCR). In conclusion: The identification of small regulatory RNAs of meningococci as regulators of general metabolic switches, adds an interesting twist to their versatile repertoire in bacterial pathogens.

Non-Canonical Translational Regulation of *E. coli manXYZ* Operon by Small RNASgrS

Author Block:

S. Azam, C. K. Vanderpool; Univ. of Illinois, Urbana, IL

Abstract Body:

The canonical model of small regulatory RNA (sRNA) mediated translation regulation assigns different roles for the sRNA and the chaperone partner Hfq. According to this model, the sRNA forms a duplex near the mRNA Shine-Dalgarno (SD) region and directly competes with the incoming ribosome. Here, the sRNA is the primary regulator; it shields the SD region from the ribosome while the chaperone Hfq facilitates duplex formation between the sRNA and the target. Contrary to this well-studied model, there are examples where an sRNA base pairs with a non-SD region, *e.g.,* the coding region, and inhibits translation by a mechanism independent of mRNA degradation. Although several studies have reported examples of non-traditional base pairing mediated regulation, mechanistically, these are the least understood aspects of sRNA biology. The secondary glucose transporter *manXYZ*, is the only known polycistronic target of SgrS targetome and the mRNA possesses two binding sites for the sRNA SgrS. One site is located in the *manX* coding region and the second is in the *manX-manY* intergenic region. Preliminary findings based on a set of in vivo and in vitro studies suggest that *manX* translation is repressed in a 'role-reversal' fashion where the chaperone Hfq acts to directly to occlude ribosome binding. We anticipate that the outcome of this study will reveal the mechanistic details of the interplay among Hfq, sRNA and the translation initiation complex.

Alba4'S Stage-specific Roles in Translational Repression and Active Translation in the Malaria Parasite

Author Block:

E. E. Munoz, M. F. Kennedy, M. M. Shipley, S. E. Lindner; Pennsylvania State Univ., University Park, PA

Abstract Body:

Translational repression, the blocking of mRNA translation by stabilization or degradation of mRNA, has been identified as a critical mechanism for the transmission and successful establishment of malarial infections. Interestingly, ALBA domain (acetylation lowers binding affinity)-containing proteins functionally bind RNA, and in Plasmodium, ALBA proteins associate with known translational repressors (e.g., DOZI/CITH). Thus, ALBA4 may also play a role in translational repression. To understand its role, we used reverse genetics to knock out ALBA4 and to append a C-terminal GFP-tag to determine its importance. We observe two major phenotypes at transmission points in the ALBA4KO parasite: 1) an increase in the number of exflagellating male gametes, and 2) a significant decrease in salivary gland sporozoite load due to a defect in sporozoite development. To determine ALBA4's mechanism-of-action we conducted immunoprecipitation/mass spectrometry (IP/MS) experiments and total RNA-seq to identify protein binding partners and transcripts that may be regulated by ALBA4. In gametocytes, we found that ALBA4 associates with translational repression machinery. However, in asexual stages ALBA4 associates with active translational machinery (e.g. elongation factors, ribosomal proteins). Excitingly, we also performed the first successful IP/MS of a protein complex from sporozoite stages. In oocyst-sporozoites, ALBA4 associates with yet another complex comprised of other ALBA proteins and putative RNA-binding proteins. Our RNA-seq data indicates that ALBA4 is involved in the regulation of transcripts of other RBPs (including Puf1), and transcripts important in gametocytes and early mosquito stage (e.g., MDV1, PSOP2, PSOP17, CelTOS, PLP2, p47, p48/p45). In the absence of ALBA4, we believe the exflagellation phenotype is a result of the deregulation of transcripts encoding kinases and cytoskeletal elements that are important for male gamete activation. Taken together, we propose that ALBA4 is an important player in RNA homeostasis through translational repression and translational efficiency, depending upon stage and complex composition. These data also suggest RBPs can be involved in multiple molecular mechanisms, highlighting that RNA homeostasis is a dynamic and intricate process.

RNA Anti-Sense Expression System to Test Targets for Genetically Specific Therapy against Pathogenic Bacteria

Author Block:

V. Casas, S. R. Maloy; San Diego State Univ., San Diego, CA

Abstract Body:

Traditional broad-spectrum antibiotics suffer from high levels of resistance, and disruption of the host microbiome that can result in chronic secondary sequelae. New diagnostic methods allow rapid, precise identification of pathogens responsible for an infection, allowing the rationale use of narrow-spectrum antimicrobials. It is possible to design genome based antisense nucleotides that disrupt a critical genetic target present in a particular pathogen, but lacking in the microbiome. In addition, antisense nucleotides can be rapidly redesigned for new target specificity in response to development of resistance. The focus of our research was to lay the foundation for this new strategy, by first developing a system to test the concept of using antisense RNA to knock down expression of essential genes leading to inhibition of bacterial growth. The system could then be used to screen bacterial genes identified via bioinformatics as targets for use in antisense RNA therapy. The system needed to be inducible and tightly regulatable and produce a short transcript more likely to bind to its target RNA. We used a vector previously optimized for high expression of toxic proteins, carrying an *rrnB* terminator, and under control of the *Escherichia coli rhaTRS* promoter and regulatory genes (pVX128). Into pVX128, we cloned an antisense oligo for the RNA polymerase alpha subunit (*rpoA*) and transformed it into *E. coli*. Expression of the *rpoA* antisense construct was tightly regulated by growth in D-glucose or L-rhamnose. Upon induction, growth was consistently inhibited by 10x when compared to controls. Expecting to see greater growth inhibition, we hypothesized that the antisense transcript was being degraded by the bacteria's RNAse III enzyme responsible for degrading RNA/RNA duplexes. To test this hypothesis, we made an rnc-14::ΔTn10d deletion in the *E. coli* strain using P1 transduction and tested this strain with the antisense construct. The deletion of the RNAseIII function increased growth inhibition by 100-1000x, as compared to the controls and RNAseIII wild type strain. The RNAseIII mutant results suggest a multiplex approach to targeting essential genes as well as genes that degrade antisense RNA duplexes would yield greater growth inhibition. These results lay the groundwork for building an arsenal of adaptable antisense therapies that can stay ahead of a quickly evolving pathogen.

Rpos Independent, Growth Phase Dependent Gene Expression in *Escherichia coli*

Author Block:

D. Sharma, S. Chiang, H. Schellhorn; McMaster Univ., Hamilton, ON, Canada

Abstract Body:

Global changes in gene expression in response to environmental cues is hallmark of bacterial adaptation. In Escherichia coli, the alternative sigma factor RpoS is important for adaptation to nutrient deprivation. While RpoS controls many genes in early stationary phase it is not clear if RpoS has an important physiological role during extended stationary phase or during periods of senescence. We found that levels of RpoS dependent transcripts are maximal during early stationary phase (OD600 = 1.5 - 2.0) and subsequently decline, suggesting that additional regulators may be important following early stationary phase adaptation. Other genes such as tryptophanase, which controls indole signalling, is induced in a growth phase dependent manner in both WT and rpoS backgrounds. We examined global changes in gene expression during extended incubation, up to 2 days, to examine expression profiles during post stationary phase in planktonic cells. Data indicates that mRNA levels of RpoS and its regulon members decrease to low levels after 48 h. Gene transcripts that are abundant during prolonged starvation are RpoS-independent and include those important in biofilm formation and those of cryptic prophage. These data are consistent with the idea that RpoS acts as a transient regulator important during initial stages of stress adaptation but less important during prolonged starvation or senescence and that the post stationary phase gene expression during extended incubation is characterized by a set of regulators/survival genes that are independent of RpoS.

Influence of Natural Products and Heat Shock on Swarming and Gene Expression of Shiga-Toxin Producing *Escherichia coli*

Author Block:

C. Caballero, **J. Merino**, N. L. Heredia, S. Garcia; Univ. Autonoma de Nuevo León, San Nicolás, N.L., Mexico

Abstract Body:

Background: Shiga-toxin producing *Escherichia coli* (STEC) strains are pathogenic for humans and capable to causing severe illnesses such as bloody diarrhea, hemorrhagic colitis, and hemolytic uremic syndrome. Heat and natural antimicrobials are being used to control STEC. This study analyzed the effect of heat and natural products on swarming and expression of virulence genes in strains of STEC (serotype O103, O26 and O111).**Methods:** Control strains were non-pathogenic *E. coli* and EHEC O157:H7. Citral, eugenol and hexanal were used alone or in combination with heat stress (HS, cultures from 37°C subjected to 46°C for 1h and then to 55 °C for 1h). Minimum bactericidal concentration and sub-inhibitory concentrations were determined. Swarming was determined in plates with 0.3% agar. Total RNA was extracted from O26 serotype and the cDNA synthetized for analysis of gene expression by qPCR, using GAPDH as housekeeping gene.**Results:** MBC against the five strains ranged from 0.9 to 1.3 mg/mL for citral, 0.58 to 0.73 mg/mL for eugenol and 2.2 to 2.5 mg / mL for hexanal. Natural products and heat sock significantly reduced cell viability. Eugenol and hexanal reduced swarming of O26 STEC by 16% and 14% respectively and O26 swarming was equal or greater than EHEC O157:H7. Eugenol w/wo HS decreased (0.5 to 0.4-fold) *flhC* gene (flagella) expression of STEC O26 compared to control without treatment. In a similar way, hexanal plus heat decreased 0.5 fold *flhC* expression. This decrement in *flhC* expression could explain reduction of swarming observed. Eugenol treatment decreased 0.2 fold expression of *rpoH* and *rpoE*; and hexanal plus HS reduced (0.6 fold) *rpoS*. Hovever, Citral w/wo HS, eugenol with HS and hexanal without HS overexpressed (1.8, 1.4, 1.2, 0.6 fold) *rpoS* gene. stx1 gene expression was reduced 0.4 and 0.2 fold after HS and citral plus HS respectively. Citral showed the higher decrease (42% of reduction compared with untreated control) in swarming mobility of STEC O26, followed by citral plus HS (30% of reduction).**Conclusions:** This study indicates that combined use of natural products and heat stress affects the growth and swarming motility and expression of genes involved in virulence.

UV and Temperature Resistance in Phyllosphere Microbial Isolates

Author Block:

L. Posada, I. C. Acosta, C. A. Ruiz, C. Garcia, M. M. Zambrano; Corporacion Corpogen, Bogota, Colombia

Abstract Body:

Background The Paramo ecosystem in the Colombian Andes is exposed to environmental conditions that can be considered harsh for microorganisms, such as high UV exposure and daily shifts in temperature. We hypothesized that microbial isolates obtained from the phyllosphere of endemic *Espeletia sp.* plants could harbor unique adaptations that could be potentially useful in industrial, environmental or clinical settings.**Methods** We isolated 50 strains from the *Espeletia* sp. phyllosphere and characterized them morphologically and by sequencing the 16S rRNA gene for bacteria and the ITS region for fungi. Strains were screened for survival under high doses of UVC radiation, from 50 to 800 J/m^2, and tested for their capacity to survive at different temperatures (-20, 4, 45, 55°C). Selected strains were analyzed for their capacity to withstand temperature shifts between 37C° and -20°C. One strain resistant to high doses of UV radiation was selected for transcriptomic analysis using Illumina HiSeq.**Results** The isolates included 10 fungi, 26 Gram negative and 14 Gram positive bacteria. The majority of the strains survived poorly (<90%) when exposed to 50 J/m^2 radiation. Two S*phingomonas sp.* strains were able to resist 100 J/m^2, one *Pseudomonas sp.* strain resisted 50 J/m^2, and the yeast *Cryptococcus flavescens* survived 95% with 200J/m^2. The most resistant strain, *Deinoccocus swuensis*, showed >95% survival at 800 J/m^2; transcriptomic analysis of this strain is underway. Three *Bacillus sp.* strains were capable of resisting high temperatures (45 and 55C°), while 13 strains were able to resist freezing (-20ºC, >99% viability). Two of these strains, the yeast *Hannaella oryzae* and the bacterium *Burkholderia glathei*, were further analyzed and found to have > 94% survival when subjected to shifts of temperature between -20 and 37ºC.**Conclusions** The Paramo environment imposes selective pressure on plants and their associated microbiota, resulting in microorganisms capable of resisting high doses of UV radiation and rapid changes of temperature, conditions characteristic of this ecosystem. Both bacteria and fungi were identified in this study, some of which are promising in terms of understanding the mechanisms involved and their possible biotechnological potential.

Abstract Body:

Background: Psychrophilic Antarctic *Psychrobacter* sp. PAMC 21119 was isolated from permafrost in Antarctica, and it grows and divides at -5°C. In this study, we investigated the transcriptomic and proteomic responses of this species to cold temperature by comparison approach of -5°C with 20°C to understand how extreme microorganisms survive under subzero condition. **Methods:** For transcriptome analysis was subjected to next-generation sequencing using an Illumina Hiseq. Proteome analysis employed two-dimensional electrophoresis (2-DE) and a 4800 MALDI TOF/TOF instrument (ABSCIEX). We subjected the differentially expressed transcripts and proteins to GO analysis and were classified into different categories using COG databases. Molecular pathways of differentially abundant proteins were analyzed using KEGG online resource. Some cellular metabolic activities were measured, including succinate dehydrogenase activity, intracellular ATP concentration, and proton concentration.**Results:** We found 2,906 transcript expression in all replicates from both temperature treatments, and 611 differentially expressed genes ($\geq$ 2 fold, $p < 0.005$) by RNA-seq. A total of 60 spots ($\geq$ 1.8 fold, $p<0.005$) showed differential expression on 2-DE and the proteins were identified by MS/MS. The most prominent up-regulated genes encoded proteins involved in metabolite transport, protein folding, and membrane fluidity. Proteins involved in energy production and conversion, and heme protein synthesis were down-regulated.**Conclusion:** This study has highlighted some of the strategies and different physiological states that *Psychrobacter* sp. PAMC 21119 has developed to adapt to the cold environment of Antarctica and has revealed strong candidate molecules involved in cold adaptation.

Characterization of *dnaK* Mutation in Persistence of *Staphylococcus aureus*

Author Block:

A. Loveland, V. K. Singh, N. R. Chamberlain; A. T. Still Univ. - Kirksville Coll. of Osteopathic Med., Kirksville, MO

Abstract Body:

Background: Persistence is a non-heritable bacterial characteristic that results in bacteria surviving toxic events via the alteration of gene expression. Numerous genes for stress response proteins have been studied and indicate the importance of these proteins in bacterial survival. The *dnaK* gene codes for a stress response protein called a heat-shock chaperone that can also prevent denaturation of vital proteins following exposure to other types of stress. The purpose of this study was to characterize the effects that a knockout *dnaK* mutation has on persister cell numbers in *Staphylococcus aureus* SH1000 (wild type, WT) when treated with antibiotics at several growth stages.**Methods:** Previous studies using multiple bacterial strains have suggested that cell size plays an important role in determining optical density, quantifying colony forming units per milliliter (CFU/ml), and treating cells with an appropriate amount of antibiotic. The optimal optical densities (OD_{600}) were determined for WT (0.25, 0.50, 0.75, 1.0, 1.5) and *dnaK* mutant (0.22, 0.37, 0.48, 0.70, 1.25). Two samples were obtained at the optimal OD_{600}: one sample was taken to determine the pre-treatment CFU/ml and another sample was taken to determine the post-treatment CFU/ml after being treated with either oxacillin (30 µg/ml) or erythromycin (30 µg/ml). Survival percentages were calculated and statistical analysis was completed using a Student's T-test.**Results:** In this study, we have determined that the *dnaK* mutant was smaller in size than the WT strain ($P < 0.0001$). When treated with oxacillin, the *dnaK* mutant exhibited similar survival to the WT strain at each optical density except at OD_{600} 0.75 (0.48 *dnaK* mutant equivalent). At OD_{600} 0.75 the *dnaK* mutant displayed a significantly lower percent survival (*P = 0.024*). When erythromycin was utilized as the antibiotic treatment, the *dnaK* mutant exhibited decreased survival relative to the WT at OD_{600} 0.75/0.48 (*P = 0.022*), 1.0/0.70 (*P = 0.006*), and 1.5/1.25 (*P = 0.043*).**Conclusions:** These findings suggest the importance of DnaK in bacterial persistence. However, its role in persistence is dependent on the antibiotic that is used for treatment as well as the optical density at which samples are harvested and treated. Further studies will focus on the effects seen with other classes of antibiotics.

Reexamining Persister Formation in *Escherichia coli*

Author Block:

Y. Shan, K. Lewis; Northeastern Univ., Boston, MA

Abstract Body:

Persisters are dormant variants that form a subpopulation of drug tolerant cells largely responsible for recalcitrance of chronic infections. Toxin/antitoxin modules have been linked to persister formation in *Escherichia coli*. The current standard model holds that nutrient stress causes stringent response, upregulation of ppGpp synthesis by RelA/SpoT, which causes activation of the Lon protease to degrade antitoxins; active toxins then inhibit translation, resulting in dormant, drug-tolerant persisters. We examined several stresses including stringent response and found that they all upregulate at least some of the interferase toxins. Two of the stresses, high salt and stringent response, induced persister formation, but unexpectedly, the upregulated toxins were not responsible for increased persister formation under these conditions. While a *relA/spoT* mutant formed less persisters, we trace this to primarily the lower cell density in a population of this strain. We similarly did not see an effect of deletion of the other components of the proposed model on persister formation, Lon and PPK/PPX. This suggested the need to reexamine the mechanism of persister formation. Sorting dim cells carrying a ribosomal promoter linked to degradable GFP (*rrnB* P1-GFP) enriches in persisters. *rrnB* P1 is repressed by ppGpp and activated by ATP. Enrichment of persisters is observed in the background of a *relA/spoT* mutation, suggesting that *rrnB* P1-GFP is a persister marker responding to ATP levels rather than ppGpp. Decreasing the level of ATP by treatment with arsenate causes drug tolerance, apparently due to inactivity of targets. We conclude that persisters are cells that stochastically lose ATP, possibly due to random errors.

Characterizing the Role That the Translational GTPase BipA Plays in Adaptation in *E. coli* MG1655

Author Block:

R. A. Bova, V. L. Robinson, D. R. Benson; Univ. of Connecticut, Storrs, CT

Abstract Body:

BipA, also known as TypA, is a conserved translational GTPase. It has been proposed to be involved in translation, ribosome biogenesis and assembly, tRNA modification, translocation, cell polarity, cell division and signaling events in a cell. BipA interacts with the 70S ribosome in a GTP-dependent manner and has been shown to have an altered association in the presence of (p)ppGpp and associate with the 30S subunit under certain conditions. Mutations in *bipA* seem not to affect normal balanced growth but do confer a variety of other phenotypes including loss of virulence or symbiotic competence, enhanced motility, growth at low temperatures and cell surface alterations. Nevertheless, few unified explanations for the observed phenotypes of *bipA* mutants are available. We tested the effect that various nutritional and physical transitions have on the balanced growth of *Escherichia coli MG1655* and its Δ*bipA* derivative. Conditions tested included sudden shifts in carbon and nitrogen sources, aerobic-anaerobic transition, temperature, detergents, salinity and oxidizing agents. Under the experimental conditions used, a lag in the adaptation to the new growth condition was consistently observed for *bipA* null mutants. After the lag, the specific growth rate of the two strains was the same. The lag could be complemented with a full-length *bipA* gene. We conclude that BipA is needed foradaptation to new conditions but is not necessary during normal cellular growth. We hypothesize that BipA can be considered an adaptational GTPase that interacts with the ribosome during environmental change.

Opsins Inhibit Lycopene Elongase Enzymes in Halophilic Archaea

Author Block:

R. F. Peck; Colby Coll., Waterville, ME

Abstract Body:

Halophilic Archaea live in dynamic environments that undergo dramatic changes in osmolarity and nutrient availability. These organisms must rapidly change resource allocation to respond to current conditions. In *Halobacterium salinarum*, the light-driven proton pump bacteriorhodopsin is produced under low-oxygen conditions and catalyzes the conversion of light energy to usable cellular energy. Bacteriorhodopsin consists of an integral membrane protein, bacterio-opsin, and a covalently-bound retinal cofactor. The retinal cofactor is synthesized *de novo* in *H. salinarum* from carotenoid precursors including the 40-carbon lycopene. In the biosynthetic pathway of membrane-protective compounds called bacterioruberins, lycopene elongase (Lye) converts lycopene into a 50-carbon compound. Thus, Lye activity reduces lycopene available for retinal production. We previously identified a regulatory mechanism in which bacterioopsin inhibits Lye to promote retinal synthesis.To examine if this mechanism is found in organisms besides *H. salinarum*, we expressed homologs of bacterioopsin and Lye in *Haloferax volcanii*, a halophilic Archaea that lacks native opsins. Three archaeal and two bacterial opsins tested demonstrated no ability to inhibit *H. salinarum* Lye. However, our preliminary results indicated that expression of the *Haloarcula vallismortis* cruxopsin-3 inhibits the activity of Lye from the same organism. Correspondingly, *H. salinarum* bacterioopsin does not inhibit the *H. vallismortis* Lye. These results suggest that opsins specifically inhibit Lye from the same organism. Together, our findings raise the possibility that opsins and Lye co-evolved to allow efficient production of retinal when required for functional opsin-retinal complexes.

Induction of Gene Expression under Respiration-Inhibitory Conditions by the AldR Transcriptional Regulator in *Mycobacterium smegmatis*

Author Block:

J-A. Jeong, J-I. Oh; Pusan Natl. Univ., Busan, Korea, Republic of

Abstract Body:

Although *Mycobacterium* species are obligate aerobes, a gradual depletion of oxygen from their culture is known to lead to dramatic changes in gene expression. Expression of the *ald* gene encoding alanine dehydrogenase (Ald) was induced under oxygen-limiting conditions and in the presence of alanine, and the induction of *ald* expression was mediated by the AldR transcriptional regulator in response to alanine availability. It was also proposed that Ald is required for both utilization of alanine as a nitrogen source and growth under hypoxic conditions by maintaining the redox state of NADH/NAD^+. We have previously shown that hypoxic induction of *ald* results from increased intracellular levels of alanine in *Mycobacterium smegmatis* under hypoxic conditions. *M. smegmatis* contains two terminal oxidases, an aa_3-type cytochrome *c* oxidase and a cyanide-insensitive *bd*-type quinol oxidase. Using aa_3 cytochrome *c* oxidase (Δ*ctaC*) and *bd* quinol oxidase (Δ*cydA*) mutant strains grown aerobically, we demonstrated that the blocking of electron flux through the cytochrome *c* pathway of the respiratory electron transport chain led to induction of *ald* expression. Under respiration-inhibitory conditions such as the presence of cyanide, expression of the *ald* gene in the Δ*cydA* mutant was more strongly induced compared to that in the wild-type (WT) over the same concentration range of cyanide, implying that the extent of electron flow through the electron transport chain is inversely related to *ald* expression. The lower intracellular alanine levels in the Δ*ald* mutant than in the WT during hypoxic growth indicate that Ald catalyzes the reductive amination of pyruvate to L-alanine to recycle NADH to NAD^+ when oxygen becomes limiting. Consistent with the results, Δ*ctaC* mutant strain grown aerobically displayed an increase in both the ratio of NADH to NAD^+ and the cellular level of alanine compared to the WT. When *M. smegmatis* encounters respiration-inhibitory conditions, the reductive amination reaction by Ald is a way the bacterium recycles NADH to NAD^+, thereby increasing the intracellular level of alanine. These findings suggest that AldR senses not only alanine directly but also respiration-inhibitory signals indirectly to induce *ald* expression under respiration-inhibitory conditions.

J. Wu, C. Xi; Univ. of Michigan Sch. of Publ. Hlth., Ann Arbor, MI

Abstract Body:

Background: Extracellular adenosine-5'- triphosphate (eATP) is now well known a signaling molecule in animals and plants. Recent study show it promotes biofilm formation in bacteria on biotic and abiotic surfaces (Xi, C., et. al., 2010). Here we investigated how E. coli cells respond to the treatment of eATP. **Methods:** A whole-transcriptome analysis was conducted to reveal the differential gene expression induced by eATP. qPCR was used to confirm the results of the microarray assay. Traditional biochemical assays were used for detecting and quantifying the key intermediates identified by both assays. **Results:** Results showed that extracellular ATP impeded *Escherichia coli* swimming and swarming motility, promoted its production of enterobactin, and rendered its ability to resistant acid. The whole-transcriptome analysis and qPCR data demonstrated that eATP induced the expression of an array of genes involved in the above mentioned responses. The whole-transcriptome analysis also revealed that eATP promoted *E. coli* TCA and glyoxylate cycles by transporting and using exogenous amino acids, di-peptides as carbon resources, and produced critical biochemical intermediates (i.e. chorismate and indole) as important precursor and internal signaling molecule, respectively. **Conclusion:** These data suggest that extracellular ATP can alter metabolism pathways in bacteria by affecting cellular processes both at transcriptional level and metabolomics level, potentially playing a physiological role in transducing stress and pathogenicity.Keywords: extracellular adenosine-5'-triphosphate (eATP), signaling molecule, *Escherichia coli*, metabolism, TCA and glyoxylate cyclesReferences:Chuanwu Xi, Jianfeng Wu. 2010. dATP/ATP, a multifunctional nucleotide, stimulates bacterial cell lysis, extracellular DNA release and biofilm development. Regulation of Cellular Level of Fermentation Respiration Switch (FRSA) by IIA^{Glc} and DegQ

Author Block:

K-J. Lee, H-W. Yang, K-H. Lee; Sogang Univ., Seoul, Korea, Republic of

Abstract Body:

Enzymatic activity of FrsA catalyzing a conversion of pyruvate to acetaldehyde and carbon dioxide is required for the complete mixed-acid fermentation of glucose by *Vibrio vulnificus* under oxygen-limited conditions. Its activity is highly enhanced by a direct interaction with the dephospho-form of IIA^{Glc} (d-IIA^{Glc}). The cellular level of FrsA has been shown to be increased in cells grown in glucose-rich medium under anaerobic condition. Screening of *V. vulnificus* mutants by western analysis using anti-FrsA antibodies revealed that a mutant deficient in a gene encoding the protease homologous to the *Escherichia coli* DegQ contained higher FrsA than the wild type. Complementation of the mutant with the intact *degQ* gene resulted in decrease of FrsA in cells grown glucose-limited medium. To investigate whether FrsA is a substrate for DegQ, *in vitro* proteolysis reaction was reconstituted using recombinant proteins of FrsA and DegQ. SDS-PAGE analysis of the reaction mixtures showed that FrsA proteolysis by DegQ was apparent in a dose-dependent manner of added protease. Since the *in vivo* level of the cellular FrsA was influenced by glucose and FrsA exhibited a strong affinity to d-IIA^{Glc}, recombinant IIA^{Glc} was included in the *in vitro* proteolysis reaction. FrsA proteolysis by DegQ was inhibited by d-IIA^{Glc} in a concentration-dependent manner. The reaction mixture including the phospho-form of IIA^{Glc}, however, did not show any inhibitory effect on DegQ proteolysis. Therefore, this study demonstrates that the stability of FrsA protein is highly increased in cells growing in glucose-rich condition via evading the proteolytic attack by DegQ by binding with d-IIA^{Glc}. It further suggests that the increased levels of cellular content and enzymatic activity of FrsA under this condition would guarantee enhanced mixed-acid fermentation of glucose.

Molecular Engagements for Hyper Glucose-Tolerance of Acetic Acid Bacteria, *Tanticharoenia sakaeratensis* and *Asaia bogorensis*

Author Block:

H. Hadano[1], N. Okamoto[1], S. Takebe[1], K. Matsushita[2], **Y. Azuma**[1]; [1]Kindai Univ., Kinokawa, Japan, [2]Yamaguchi Univ., Yamaguchi, Japan

Abstract Body:

Acetic acid bacteria (AAB) form a divergent phylogenetic group, and two phylogenetically closed AAB, *Tanticharoenia sakaeratensis* and *Asaia bogorensis*, show a distinctive ability to grow in media containing 30% glucose. To clarify mechanisms for the hyper glucose-tolerance, comparative omics analyses, including genome DNA sequencing, transcriptome and proteome analyses, were performed. The results illustrated that the two AAB altered expressions of similar genes and systems under different conditions with low and high glucose concentrations. In both AAB gene expressions for glycolysis and pentose phosphate pathways decreased, and ones for antioxidant enzymes (such as superoxide dismutase (SOD) and peroxidase) and cytochrome o ubiquinol oxidase increased. On the contrary, the omics analyses indicated a variety uniqueness of each bacterium. For instance, under high glucose conditions, *T. sakaeratensis* repressed a main energy metabolism including NADH dehydrogenase (complex I) and induced gene expression of pyruvate decarboxylase, whereas *A. bogorensis* promoted expressions of more stress responsible genes involved in anti-oxidation, such as DNA starvation/stationary phase protection protein (Dps) and osmotically inducible peroxiredoxin OsmC. Because the complex I is a main superoxide producer, *T. sakaeratensis* deems to need less antioxidant enzymes than *A. bogorensis*. We herein propose that enzymes managing oxidative stresses are engaged in overcoming the high glucose stress, and the acquisitions of the glucose tolerance systems in the two AAB were evolutionally independent.

The Role of the Srna-encoded Small Protein Sgrt in the *Escherichia coli* Glucose-phosphate Stress Response

Author Block:

C. Lloyd, C. Vanderpool; Univ. of Illinois Urbana-Champaign, Urbana, IL

Abstract Body:

* SgrT is a 43-amino acid protein encoded within the small regulatory RNA (sRNA) SgrS; both counterparts are expressed in *Escherichia coli* under glucose-phosphate stress - a condition in which the accumulation of non-metabolizable phosphosugars (such as αMG) is bacteriostatic. SgrT and SgrS base pairing can independently mitigate glucose-phosphate stress but act through separate mechanisms; SgrS base pairing destabilizes the mRNA of the major glucose transporter PtsG and inhibits its synthesis, while SgrT inhibits its transport activity. Using the radiolabeled glucose analog αMG in transport assays, we found that SgrT exhibits a strong and speedy inhibition of stable preexisting PtsG transporters while SgrS base pairing only modestly inhibits tranport as an indirect result of PtsG translational repression. To compare SgrT and SgrS target specificities, we used induction of the stress response as a measure of transport via a transcriptional P_{sgrS}-*lacZ* fusion and found that while SgrT was able to inhibit uptake of the PtsG substrate αMG, it was unable to inhibit uptake of the analog 2DG, which is solely transported through ManXYZ - another mRNA target of SgrS riboregulation. The specific targeting of PtsG by SgrT was thought to be because the activator of PtsG, $EIIA^{Glc}$, performs inducer exclusion. Indeed, when SgrT-producing cells were grown in both lactose and αMG, SgrT overrode inducer exclusion and allowed the utilization of lactose as a carbon source, recovering faster than cells without lactose. In this way direct inhibition of PtsG activity indirectly allows cells to replenish depleted glycolytic intermediates expended by the glucose PTS to import non-metabolizable analogs, which is believed to be the root of the stress. We used an SgrT-regulated hybrid PtsG and SgrT-resistant PtsG V12F mutant to determine the membrane domain of PtsG is physiologically important for SgrT regulation, however further structure-function studies must be performed to understand the extent and mechanism of this interaction.

The Effects Of Cell Density And Biofilm Formation On Melanin Production In A Novel *pseudomonas* Species

Author Block:

P. L. Lawrence, L. R. Aaronson; Utica Coll., Utica, NY

Abstract Body:

Pseudomonas sp. UC17F4 is a novel bacterial species that was isolated from the cutaneous flora of red-backed salamanders on the basis of its antifungal activity. One of the most interesting characteristics of this species is its ability to produce two different forms of the brown pigment, melanin. Eumelanin is a high MW molecule that is contained within the cytoplasm of the bacterial cell, while pyomelanin is a low MW secreted form. Studies in our lab have shown that melanin production in this bacterium is regulated by light exposure, and by the availability of iron and suitable carbon sources. We have recently observed that melanogenesis is dependent on high cell density and the development of biofilms. Cultures of UC17F4 were grown in either tryptic soy-yeast extract (TSYE) broth or in citrate-enriched Lawrence Minimal Medium (LMM). Eumelanin content was assayed by spectrophotometric analysis of cell lysates in 1% SDS. As culture densities increased, so did cellular melanin content, increasing 6-fold from the onset of stationary phase. Cultures inoculated at higher cell density also exhibited higher melanin content. Biofilm-forming cultures produced 5-fold higher levels of eumelanin than did planktonic broth cultures. Biofilm cultures were grown in 35 mm plates in both TSYE and LMM broth, and exhibited density-dependent melanin content. Similar results were observed in biofilms formed on nitrocellulose filters placed on LMM and TSYE agar plates. To further study the dependence of UC17F4 biofilm formation of melanogenesis, NaCl was added to cultures to inhibit the development of biofilms. Bacterial eumelanin content in the biofilm mass declined by 90% as NaCl concentration increased to 1% (w/v) compared to untreated controls. Treatment of cultures with Furanone 56, an inhibitor of quorum signaling in Pseudomonads, resulted in a 30% reduction in eumelanin content. The quorum signaling compound C12-homoserine lactone stimulates only a modest increase in melanogenesis. Supplementation of early exponential-phase cultures with cleared supernatants from 48 hr biofilm cultures resulted in up to a 2-fold increase in cellular melanin content. These data suggest that melanogenesis in *Pseudomonas* sp. UC17F4 is under the control of one or more signaling compounds. Ongoing studies are being conducted to isolate and characterize melanogenic signal compounds, and regulatory pathways in the bacterium.

Characterization of the Global Regulatory Network of *Trans*-Translation in *Pseudomonas aeruginosa*

Author Block:

B. Li[1], L. Silo-Suh[2], S-J. Suh[1]; [1]Auburn Univ., Auburn University, AL, [2]Mercer Univ. Sch. of Med., Macon, GA

Abstract Body:

Trans-translation, catalyzed by tmRNA, is a uniquely bacterial process for recycling ribosomes stalled on mRNA. To understand the regulation of tmRNA in *P. aeruginosa,* we previously isolated 18 transposon insertion mutants with altered expression of *ssrA,* the gene encoding for tmRNA. The site of transposon insertion in these mutants suggested that LPS modification and c-di-GMP metabolism may affect ribosome recycling. We also took a predictive approach based on the mutant phenotype and identified putative regulatory circuits between *trans*-translation and various global regulators of gene expression in *P. aeruginosa*. Our data indicated that tmRNA is required for expression of *rpoS, lasR, rhlR,* and *vfr*. Interestingly, RpoS, LasR, and RhlR were all required for full expression of *ssrA,* suggesting a complex regulatory circuit between *trans*-translation and these global regulators. In contrast, although Vfr was required for full expression of *ssrA, trans*-translation appeared to repress *vfr* expression. Since the nutritional alarmone (p)ppGpp mediates expression of *rpoS* and other genes which are coordinately controlled by LasR and RhlR in *P. aeruginosa*, we also assessed *ssrA* expression in both the *relA* mutant and *relA spoT* double mutant, which is severely impaired for accumulation of (p)ppGpp during nutritional stress. Surprisingly, we found that even though *ssrA* expression decreased by approximately 80% in the *relA* mutant, it only decreased by 30% in the *relA spoT* double mutant, suggesting that the level of cellular (p)ppGpp is a crucial factor for *ssrA* expression in *P. aeruginosa*. Moreover, our data from static biofilm assays with wild-type PAO1 and the *ssrA* mutant showed that the mutant forms approximately 40% more biofilm than the parent, indicating a role for tmRNA in *P. aeruginosa* biofilm formation. Finally, in order to study the overall effect of ribosome recycling in *P. aeruginosa,* we constructed a derivative of the *ΔssrA* mutant in which we can control the expression of *PA3990,* a putative ArfA encoding gene, to maintain the viability of the bacterium. Our previous attempts to construct *ΔssrA ΔPA3990* double mutants had been unsuccessful although the *ΔPA3990* mutant behaved similarly to the wildtype. These data support our hypothesis that PA3990 is a ArfA homologue.

Identification of Clpxp Substrates during Carbon Starvation

Author Block:

C. N. Peterson[1], N. Maragos[1], P. Ngo[2], T. Von Rosen[3]; [1]Suffolk Univ., Boston, MA, [2]Suffolk Univ.y, Boston, MA, [3]Max Planck Marine Microbiol. Inst., Bremen, Germany

Abstract Body:

Cellular protein concentrations reflect a balance between synthesis, degradation, and dilution by cell growth. Synthesis is routinely analyzed in high-throughput experiments, but fewer studies consider degradation, particularly under non-optimal growth conditions such as starvation. ClpXP is a central and conserved protease that degrades numerous proteins. Here, we modified the ClpXP protease trap assay to identify which proteins are degraded under glucose and no glucose conditions. Substrates involved in replication, cAMP hydrolysis, protein synthesis, pyrimidine synthesis and carbohydrate transport and metabolism were found to be associated with ClpXP during starvation. Conversely, substrates involved in the stress response, glycogen synthesis and pyrimidine metabolism were more likely to be degraded in glucose conditions. Almost all of these proteins had a canonical C or N terminal ClpX tag on them. Thus, the Clpx protease markedly remodels its substrate profile during starvation.

Isolation of Suppressors That Recover Cold-Sensitive Growth Defect Caused by *bipA* Deletion in *Escherichia coli*

Author Block:

E. Choi, J. Hwang, H-h. Lee, J. Park, Y-S. Seo; Pusan Natl. Univ., Busan, Korea, Republic of

Abstract Body:

Background: BipA (BPI-inducible protein A) protein is translational GTPase conserved in a large variety of bacterial species and structurally similar to other translational GTPases, including EF-Tu, EF-G, and EF4. In addition, *bipA* deletion mutant shows various phenotypes, indicating that it has global regulatory properties. These results have given rise to conjecture that BipA may play a role as regulatory protein controlling translation of target genes through interaction with the ribosome. Furthermore, recent structural studies show that BipA interacts with 50S ribosomal subunit and A-site tRNA. However, precise molecular mechanism of BipA in translation regulation is not completely understood.**Methods:** To investigate whether overexpression of other *E. coli* genes can recover the cold-sensitive growth defect observed in *bipA* deletion mutant, we constructed genomic library from *bipA* deletion strain and screened suppressors for the cold-sensitive growth phenotype of Δ*bipA* strain.**Results:** We isolated and identified two suppressors that were capable of restoring the Δ*bipA* mutant phenotype; RplT and YebC. RplT, ribosomal protein L20, is a component of 50S ribosomal subunit and it is assumed that L20 might be required for maintaining the 50S ribosomal subunit in the correct conformation for binding of aminoacyl-tRNA. YebC is putative transcriptional factor, but its precise role has not yet been addressed. Their overexpression also restore ribosome assembly defect at low temperature and sensitivity to antibiotics. In contrast, capsule formation at low temperature of Δ*bipA* strain didn't decrease, when each suppressor was overexpressed, indicating that rescues of growth defects of Δ*bipA* strain at low temperature have no correlation with capsule formation.**Conclusions:** Our findings suggest that BipA may regulate translation efficiency through stabilization of binding of aminoacyl-tRNA to ribosome binding and raise the possibility that YebC participates in translation via regulating transcription of component of ribosome or ribosome assembly factor.

Testing the Composition of the *Bacillus subtilis* Stressosome Complex Using Co-Immunoprecipitation *In Vivo*

Author Block:

K. Lopez-Damian, C. Y. Bonilla; Gonzaga Univ., Spokane, WA

Abstract Body:

A bacterium's ability to cope with environmental stresses such as, pH, temperature and reactive oxygen species, determines its chances of survival. The stress response mechanisms used by pathogens such as *Staphylococcus aureus* and *Listeria monocytogenes*, are well conserved in non-pathogenic bacteria like *Bacillus subtilis*. Therefore, examining the stress response mechanism in *B. subtilis* will aid in understanding how bacteria, including pathogens, adapt and survive exposure to environmental stress. In *B. subtilis*, the stressosome is composed of RsbS, RsbT, and four RsbR homolog proteins, and acts as a signaling hub that integrates different environmental signals. We know that the kinase RsbT is inhibited by RsbS and RsbR proteins in the absence of stress. Releasing RsbT activates the SigB cascade leading to the up regulation of multiple genes to respond to the stress. Yet the reason for the four homologs and how they transduce the signal is not fully understood. The purpose of my project is to determine the composition of the *B. subtilis* stressosome *in vivo* in the presence of environmental stress in order to elucidate the mechanism of action of each RsbR homolog. When exposed to different stresses, the stressosome could respond by (1) changing the RsbR protein-protein interactions revealing the role of each homolog or (2) affirming their redundancy by requiring all RsbR proteins in order to multiply the signal and effectively respond. My approach was to tag the canonical RsbR gene, RsbRA, using a Myc tag at the endogenous locus. I verified insertion of the tag by sequencing and western blot; and analyzed the viability of the strain using a survival assay, which exposed growing the cells to Hydrogen Peroxide (5mM) before plating to allow recovery. The results indicated that the presence of the Myc tag impacted the function of the protein rendering the cells more sensitive than wild type cells. I plan to test the effect of smaller tags on RsbRA protein function using the survival assay. Once a tagged strain is found to be functional, stressosome composition will be analyzed by western blot and immune-precipitation to identify the protein-protein interactions or the ratio of each RsbR protein present in the complex.

Bacterioferritin Comigratory Protein (BCP) Plays a Protective Role against Thermal Stress in the Fission Yeast

Author Block:

S. H. Lee[1], **I. W. Ryu**[1], H. W. Lim[2], K. Kim[1], C. J. Lim[1]; [1]Kangwon Natl. Univ., Chuncheon, Korea, Republic of, [2]Shebah Biotech Co., Chuncheon, Korea, Republic of

Abstract Body:

The *Schizosaccharomyces pombe* structural gene encoding bacterioferritin comigratory protein (BCP) was previously cloned using the shuttle vector pRS316, and the recombinant plasmid was named pBCPlO. The *BCP*$^{+}$ mRNA level in the pBCPlO-containing yeast cells was significantly higher than that in the control yeast cells, indicating that the cloned gene is functioning. In this work, we tried to evaluate the protective role of BCP against high incubation temperatures using the BCP-overexpressing recombinant plasmid pBCP10. When the incubation temperature was shifted from 30°C to 37°C or 42°C, the *S. pombe* cells harboring the plasmid pBCPIO exhibited better growth at both 37°C and 42°C than the vector control yeast cells. They were identified to contain the lower reactive oxygen species (ROS) and nitrite content, an index of nitric oxide (NO), after the shifts to higher incubation temperatures, than the vector control cells. After the temperature shifts, changes in glutathione content, superoxide dismutase and glutathione peroxidase activities were also compared. In brief, the *S. pombe* BCP plays a protective role in the defensive response to thermal stress.

Analysis of Orf19.7296p in the *Candida albicans* Osmotic Stress Response

Author Block:

R. Rodriguez, K. A. Conrad, E. C. Salcedo, J. M. Rauceo; John Jay Coll. of The City Univ. of New York, New York, NY

Abstract Body:

Fungal signaling pathways coordinate morphogenesis, biofilm formation, and stress adaptation. These processes are essential to the pathogenicity of *Candida albicans*, the most common human fungal pathogen. Here, we explore the role of plasma membrane protein Orf19.7296p in the osmotic stress response. We previously showed that *ORF19.*7296 transcription is significantly increased following acute cationic (1M NaCl) stress; however, Orf19.7296p function and localization following osmotic stress is unknown. We used fluorescence microscopy to examine the cellular localization of an Orf19.7296p-YFP fusion protein following exposure to 1M NaCl in yeast cells and hyphae. Surprisingly, our microscopic images revealed that Orf19.7296p-YFP formed punctate foci around the cell periphery. Also, Orf19.7296p was present in the vacuole; although we cannot rule out the possibility this observation may be a consequence of protein recycling. Quantitative analysis using flow cytometry revealed that the Median Fluorescence Intensity (MFI) of log phase cells treated with salt was statistically greater than untreated samples (*p*-value = 0.0008). Moreover, the MFI was higher in early and late stationary phase samples compared to log phase cells for salt-treated and untreated cells. Strikingly, we did not observe fluorescence in hyphae. We phenotypically characterized a homozygous *orf19.7296*Δ/Δ null mutant strain. We did not identify a growth defect when cells were exposed to various pH levels, hyperosmotic stress, cell wall stress, and plasma membrane stress. Also, we did not observe any defects in germ tube morphology or endocytosis. Collectively, our results show for the first time that Orf19.7296p forms stable puncta in the PM, is maximally expressed during stationary phase, and specifically localizes to yeast cells. Our future studies will investigate the extent that Orf19.7296p may associate with eisosomes, plasma membrane microdomains that form punctate foci. In fission yeasts, eisosomes were shown to mediate osmotic stress signaling.

Microwave Facilitation of Cryo-substitution

Author Block:

D. W. DORWARD; NIH, NIAID, Hamilton, MT

Abstract Body:

Cryo-substitution of vitrified biological samples is a premier process for preserving near-native morphology for electron microscopy. Typically frozen samples are immersed in fixatives and organic solvent below -80 °C, then warmed for hours to days to dissolve the ice and crosslink structures for embedding, sectioning, and examining. Although agitation can hasten processing, it involves enclosing samples and fixatives in vials at -195 °C, inserting the vials into pre-cooled aluminum blocks, and allowing the blocks to reach 20-23 °C on a shaker. Potential issues include vial rupture or leakage, uneven sample warming, unmeasured pressure changes and effects, and variable temperature ramping rates. To assess if microwave energy could facilitate the process, a commercial cryo-thermal platform was adapted for use in a microwave processor. The platform was configured to hold vented microwave sample vessels, and to use a controller, feedback sensors, liquid nitrogen, and heaters to regulate sample temperature between +/-100 °C for desired time periods. During processing, samples were moved to fresh reagents at desired time points and temperatures. Using the platform and 80 W of microwave power, frozen samples such as *Bacillus subtilis* or yeast were substituted, crosslinked, and dehydrated in 1 to 1.5 hr. Infiltration with low-temperature embedding resin added about 1 hr. ImageJ line profiles showed that contrast between adjacent structures in *B. subtilis* and yeast was roughly two-fold greater in cryo-substituted cells than in samples processed conventionally. Multiple processing runs showed less than +/- 1.5% deviation from mean temperatures (°K) at 33 two-minute time points from sample introduction to completion. Samples processed successfully with this system include Archaea, Eubacteria, protozoans, algae, ticks, and mammalian cells and tissues. Post-section immune labeling of *Borrelia burgdorferi* for NapA was plentiful and specific. Furthermore, 250 nm sections of cryo-substituted samples were ideal for light microscopy and electron tomography. Thus, cryo-substitution in microwave processors can dramatically increase fixation rate and throughput, providing stability and reproducibility, with considerable flexibility in types of samples, reagents, parameters, and applications.

Alteration of Substrate Binding Site of Cel12a by Site-Directed Mutagenesis & Its Comparison with Wild-type Enzyme

Author Block:

A. S. Prajapati[1], V. A. Pawar[1], K. J. Panchal[1], B. R. Dave[1], D. H. Patel[2], R. B. Subramanian[1]; [1]Sardar Patel Univ., Anand, India, [2]P.D. Patel Inst. of Applied Sci., Anand, India

Abstract Body:

Global demand for energy has grown with the development of new industries, requiring constant improvement and search for new sources of energy. One of the challenges today is releasing the energy of glucose that nature has cleverly locked into lignocellulosic biomass. Lignocellulose can provide ample raw materials for biofuel production, via its hydrolysis and the fermentation of the released sugars. Currently, cellulolytic enzymes are often used to catalyse this step, particularly cellulases, which hydrolyse the β-1, 4 glycosidic linkages in cellulose. Even though many cellulases are being isolated, the efficiency of hydrolysis is very poor. Thus, there is a need to modify and improve this enzyme to make it potent, efficient and suitable for our own purposes. This could be done by altering the substrate specificity of enzyme which help to accommodate various substrates. Approaches like enzyme engineering, reconstitution of enzyme and bioprospecting for superior enzymes are gaining importance. Using Site-Directed Mutagenesis, the role of different amino acids within the catalytic domain of an enzyme can be studied. Mostly the aromatic residues of cellulase limit the size range of substrate accepted in the binding site. Five different aromatic residues of the substrate binding pocket of Cel12A were investigated by Homology modelling. These residues are highly conserved and play an important role in steric hindrances to substrate binding. The alteration of these residues may allow the enzyme to accommodate various substrates. All five residues substituted with alanine (A) through Polymerase Chain Reaction. Wild-type Cel12A and its mutated genes were cloned and overexpressed in BL21 and the proteins were analyzed by SDS-PAGE. A band with molecular weight of ~29 kDa was observed. Results of the site-specific mutation led to an alteration in substrate specificity from CMC to xylan. This indicates the effect of aromatic residue on substrate binding, catalytic process and overall catalytic efficiency, making it an interesting candidate for further studies.

Mutations in the Ribosome: A Story of Treatment, Resistance and Physiological Shifts

Author Block:

A. Jimenez-Fernandez[1], M. Brauer[1], E. Juskewitz[1], H. K. Johansen[2], S. Molin[1]; [1]Danmarks Tekniske Univ., Hørsholm, Denmark, [2]RigsHosp.et, Copenhagen, Denmark

Abstract Body:

RNA polymerase and ribosomes, composing the macromolecular synthesis machinery (MMSM), carry out the central processes of transcription and translation, but are usually seen as mechanical elements with no regulatory function. Extensive investigations of gene regulation and the high degree of evolutionary conservation of the cellular MMSM tend to support this view. However, under certain selective conditions the machinery itself may be targeted by adaptive mutations, which result in fitness increasing phenotypic changes. Here we investigate and characterize the role of ribosomal mutations in adaptive evolution.Several mutations in ribosomal genes have been identified in the genome analysis of nearly 700 *Pseudomonas aeruginosa* isolates from the airways of infected cystic fibrosis patients. Among these mutations we have repeatedly identified insertions, deletions and substitutions in specific ribosomal genes. Our goal is to elucidate the consequences of these mutations.Here we show the phenotypic characterization of mutations in three ribosomal proteins: L4, L6 and S1. Strains with mutations in L6 and S1 have reduced growth rate and an altered antibiotic resistance pattern, while none of these phenotypes are observed in L4 mutant strains. The selection for mutations in ribosomal protein genes is partly explainable by the antibiotic treatment of the patient as observed in the L6 case. But other mutations cannot be directly associated with antibiotic resistance.Clarification of the potential pleiotropic consequences of the specific mutations in ribosomal proteins is important for our understanding of biological evolution, and will have impacts on the design of new treatment strategies to combat microbial infections.

Structural Analysis of Proteome Vulnerability to Oxidative Damage in *Deinococcus radiodurans*

Author Block:

R. L. Chang[1], J. W. Sher[2], D. A. Stork[1], P. A. Silver[1]; [1]Harvard Med. Sch., Boston, MA, [2]Yale Univ., New Haven, CT

Abstract Body:

Protein damage by reactive oxygen species (ROS) affects molecular function and cellular phenotype. The most critical protein damage by ROS is irreparable carbonylation of arginine, lysine, proline, and threonine sidechains (RKPT), leading to misfolding, aggregation, and proteolysis. Empirical data suggests intrinsic vulnerability to ROS varies with tertiary structure, but previous studies have been only in sequence space. This study investigates whether distribution of RKPT in 3D structures determines vulnerability of RKPT. Understanding properties underlying ROS sensitivity also enables study of protein oxidation phenotypes. We analyzed the structural proteome of the radioresistant bacterium *D. radiodurans* in comparison to a non-resistant bacterium. *D. radiodurans* is especially robust to ROS exposure from irradiation; this may be due in part to evolved intrinsic protection of key proteins.Structures were obtained for all encoded proteins in *D. radiodurans*, *E. coli*, and for a training set with experimentally measured carbonylated sites (CS). PDB structures were supplemented by homology modeling using I-TASSER and ProtMod. The CS data paired with structures includes 419 unique proteins and 840 CS. RKPT content, relative reactivity, depth, solvent exposure, and interatomic distances were analyzed as potential determinants of carbonylation. Pairwise comparison of *D. radiodurans* and *E. coli* structural proteomes was enabled by mapping orthologs by sequence and functional annotation.Our findings show site depth strongly correlates with CS. Solvent exposure is not a strong determinant. Structure-derived reactivity of RKPT agrees with sequence-based, except that threonine is more reactive than previously thought. Proximity of CS may owe to progressive unfolding of proteins exposing natively buried sites. Proteome-wide comparisons of RKPT distributions in *D. radiodurans* and *E. coli* only showed a slightly more buried trend in *radiodurans*; however, certain *radiodurans* proteins exhibit far less surface RKPT than their *E. coli* orthologs, most notably 30S ribosomal protein S13 and 50S ribosomal protein L4. This finding supports that proteins involved in translation, required for recovery from widespread ROS damage, are intrinsically protected from ROS in *radiodurans* and may be key to radioresistance.

Differences in Heat Susceptibility of Human Norovirus Strains is Predicted by Docking and Molecular Dynamics Simulations

Author Block:

M. Moore, B. Mertens, B. Bobay, L-A. Jaykus; North Carolina State Univ., Raleigh, NC

Abstract Body:

Background: Environmental stresses, chemical disinfectants and physical processes impact human norovirus infectivity, frequently by destroying capsid integrity. Recent data suggest variability in the resistance of different noroviruses to these treatments, but the molecular basis for such differences has not been well investigated. Ligand binding assays combined with ligand docking and molecular dynamics (MD) simulations have potential to be used to explain the nature of differential norovirus capsid stability. The purpose of this study was to apply docking and MD approaches to select norovirus strains to facilitate prediction of strain-specific differences in heat susceptibility.**Methods:** The major capsid proteins (VP1) of GII.4 Houston (HOV), GII.4 Sydney (SYV), and GII.2 Snow Mountain (SMV) were constructed using MODELLER v10.1 based upon previously reported crystal structures. MD simulations of the VP1 were performed using the GROMACS 4.4.5 package with a 100 ns simulation. A 3D structure of aptamer M6-2 was generated using the MC-Fold/MC-Sym webserver and docked to each of the VP1 proteins using HADDOCK to compare to aptamer M6-2 binding to the VLPs. Predicted strain-based differences were evaluated using aptamer and receptor binding assays in addition to dynamic light scattering (DLS) and transmission electron microscopy (TEM).**Results:** MD simulations predicted HOV to be much more heat labile than SMV or SYV as it had a lower number of P-to-P-domain hydrogen bonds and higher total solvent accessible surface area. Further, the degree of secondary structure change in the receptor/aptamer binding area of the VP1 was more dynamic for HOV compared to SMV and SYV. Docking analysis revealed similar residues for M6-2 binding to HOV, SMV, and SYV. Binding assays confirmed MD simulation predictions, as HOV had a significantly ($p < 0.05$) lower melting temperature ($68.9 \pm 1.1^{o}C$) than SMV ($75.0 \pm 0.8^{o}C$) and SYV ($73.1 \pm 0.4^{o}C$) using M6-2. Receptor binding, DLS, and TEM also confirmed this prediction.**Conclusions:** This is the first report describing norovirus GII.4 strain-based heat susceptibility differences and the molecular basis for such differences. Combinations of the reported receptor binding and *in silico* methods can be useful in predicting and identifying differences in norovirus strain-based resistance to inactivation strategies.

Molecular Basis for Pyranopyridine Inhibition of Gram-Negative Antibiotic Efflux Pumps

Author Block:

H. Sjuts[1], A. V. Vargiu[2], S. M. Kwasny[3], S. T. Nguyen[3], H-S. Kim[4], X. Ding[3], A. R. Ornik[1], P. Ruggerone[2], T. L. Bowlin[3], H. Nikaido[4], **K. M. Pos**[1], T. J. Opperman[3]; [1]Goethe-Univ. Frankfurt am Main, Frankfurt am Main, Germany, [2]Univ. of Cagliari, Cagliari, Italy, [3]Microbiotix, Inc., Worcester, MA, [4]Univ. of California Berkeley, Berkeley, CA

Abstract Body:

Background: The *Escherichia coli* AcrAB-TolC efflux pump is the archetype of the Resistance-Nodulation-cell Division (RND) exporters from Gram-negative bacteria. Overexpression of RND-type efflux pumps is a major factor in multidrug resistance (MDR), which makes these pumps important antibacterial drug discovery targets. However, the development of potent efflux pump inhibitors has been hindered by the lack of structural information for rational drug design.**Methods:** Because the AcrB efflux pump is an integral membrane protein with a polyspecific binding behavior, co-crystallization with drugs has been challenging. To overcome this obstacle, we have engineered and produced a soluble version of AcrB (AcrBper), highly congruent in structure with the periplasmic part of the full-length protein, and that is capable of binding substrates and potent inhibitors. Here, we describe the molecular basis for pyranopyridine-based inhibition of AcrB using a combination of cellular, X-ray crystallographic, and molecular dynamics (MD) simulations studies.**Results:** The pyranopyridines bind within a phenylalanine-rich cage that branches from the deep binding pocket of AcrB, where they form extensive hydrophobic interactions. Moreover, the increasing potency of improved inhibitors correlates with the formation of a delicate protein- and water-mediated hydrogen bond network.**Conclusions:**These detailed insights provide a molecular platform for the development of novel combinational therapies using efflux pump inhibitors for combating multidrug resistant Gram-negative pathogens.

Inc., Tokyo, Japan, [5]Japan Aerospace Exploration Agency, Tsukuba, Japan, [6]Showa Univ., Tokyo, Japan

Abstract Body:

Background: Opportunistic infections caused by antimicrobial resistant bacteria are becoming serious threats in many countries. Many opportunistic pathogens are Non-Fermenting Gram-Negative Rods (NFGNR). Some of these pathogens utilize protein or peptide as carbon or energy source. Especially, Dipeptide production is an important in the peptide metabolism, because of an inner membrane preferentially transports "dipeptide" rather than an "amino acid". Dipeptidyl peptidases (DPPs) have a key role in the dipeptide production in periplasm. Moreover, Growth retardation was observed in DPPs gene disruptant of *Porphyromonas gingivalis* (Pg) (Nemoto *et al., JBC* 2011). Major DPPs in periplasm are consists of DPP4, POP (Proryl Oligo Peptidase), DPP7 and DPP11. These DPPs liberate a dipeptide from N-terminus of peptides according to their specificity in the P1 position (Explanation of their specificity: DPP4 (Pro or Ala), POP (Pro or Ala), DPP7 (Hydrophobic or Basic), DPP11 (Acidic)). DPP7, DPP11 belong to Clan SC S46, and others belong to Clan SC S9. Whereas The S9 peptidases are widely distributed from prokaryotes to eukaryotes, The S46 peptidases are peculiar to some anaerobic gram-negative bacteria. **Methods:** Crystallizations of PgDPP11 and *Psedoxanthomonas mexicana* WO24 DAP BII (PmDAP BII : bacterial DPP7) were performed with the hanging drop vapor diffusion method and counter-diffusion method under a micro-gravity environment in ISS "kibo". Initial phases of the PmDAP BII and PgDPP11 were determined by Single-wavelength Anomalous Diffraction (SAD) method and Multi-wavelength Anomalous Diffraction (MAD) method, respectively. **Results**: We determined the structures of PgDPP11 and PmDAP BII, but with different substrate specificity. These structures describe the peptide digestion and substrate recognition mechanisms in S46 peptidases. **Conclusions:** These structure-function studies could be useful for the Structure Based Drug Design of novel antibiotics for NFGNR which have S46 peptidases. **References:** Sakamoto *et al., Sci. Rep.* 4977 (2014), *Sci. Rep.* 11151 (2015).

Inhibition of the Central Quorum-Sensing Transcription Factor LuxO

Author Block:

A. Hurley, H. Boyaci Selcuk, F. M. Hughson, B. L. Bassler; Princeton Univ., Princeton, NJ

Abstract Body:

Quorum sensing (QS) is a mechanism of bacterial cell-cell communication that enables bacteria to assess cell population density and control collective behaviors. QS relies on the production, release, accumulation, and detection of signal molecules called autoinducers. In pathogenic vibrios, including *Vibrio cholerae*, the accumulation of autoinducers at high cell density triggers repression virulence factor production and biofilm formation. At low cell density, in the absence of autoinducers, transmembrane receptors phosphorylate the AAA+ ATPase transcriptional regulator LuxO. LuxO~P activates expression of genes required for virulence and biofilm formation. At high cell density, autoinducer binding inhibits the kinase activity of the receptors leading to de-phosphorylation and subsequent inactivation of LuxO. This event terminates QS-controlled transcription of biofilm and virulence genes. Xray crystallography has revealed the structure of LuxO and, therefore, the native mechanism of regulation in the central protein of the QS circuit. Natural negative regulation occurs through competitive inhibition of the ATPase activity via the linker domain that connects the regulatory receiver and the catalytic central domain. Mutational analysis of key interacting residues in both domains of LuxO have constitutively activated the protein in support of this structure-based mechanism. Interestingly, crystals of the central domain bound to a specific LuxO-inhibitor, AzaU, revealed a similarly competitive mechanism, mirroring the natural regulation.

Non-Canonical Mode of De-Repression by Phage Antirepressor

Author Block:

M. Kim[1], H. Kim[2], S. Son[2], H-J. Yoon[1], Y. Lim[1], J. Lee[1], J. Chun[1], H. Na[1], Y-J. Seok[1], K. Jin[3], Y. Yu[2], S. Kim[1], S. Ryu[1], H. Lee[1]; [1]Seoul Natl. Univ., Seoul, Korea, Republic of, [2]Kookmin Univ., Seoul, Korea, Republic of, [3]Pohang Univ. of Sci. and Technology, Pohang, Korea, Republic of

Abstract Body:

DNA-binding repressors negatively regulate a transcription of many genes, and de-repression is necessary for the desired gene expressions. Thus, several mechanisms for a dissociation of repressor from the operator have been studied. Previously, we identified an antirepressor-mediated de-repression system from a *Salmonella* temperate phage SPC32H. Here, we present a non-canonical mode of de-repression, as revealed by the crystal structure of homo-tetramer of truncated repressor (Rep) and hetero-octameric complex of the Rep and cognate antirepressor (Ant). Instead of competing with the Rep for the DNA-binding site, Ant binds in a tetrameric form to the C-terminal domains of two Rep dimers, then bind to N-terminal domains of Rep dimers as well. This resulted in a release of two Rep dimers from the operators. Mutational analysis with size-exclusion chromatography and gel retardation assay suggested that Rep Phe187 plays an important role in the DNA binding via Rep tetramerization and Asp36, Arg40, and Lys46 are critical for the DNA binding. Inability of Rep mutants in the gene repression was also revealed in an *in vivo* bioluminescence reporter assay. Intriguingly, Rep F187A mutant, which existed as the dimer form only, hardly bound to DNA even at high concentration, suggesting that the dimer pairs for DNA-binding are contributed by different dimers of the Rep tetramer. Ant residues (Arg37, Asn58, and Tyr76) that positioned at the interfaces between Rep and Ant in the Rep-Ant complex were also assessed in their function both *in vitro* and *in vivo*; Ant mutants showed reduced binding (K_d > 100 μM) to the Rep, and consequently, exhibited a decreased prophage induction from host *Salmonella* in the presence of an induction agent. Based on these results, we propose a non-canonical mode of de-repression where the DNA-binding Rep was reversibly inactivated by the binding of cognate Ant that collapsing the Rep tetramer.

Structural Studies of the Bile Salt Hydrolase from *Lactobacillus salivarius*

Author Block:

F. Xu[1], **W. Geng**[2], X. Hu[3], J. Lin[2]; [1]Beijing Academy of Agriculture and Forestry Sci., Beijing, China, [2]The Univ. of Tennessee, Knoxville, TN, [3]Sch. of Life Sci., Fudan Univ., Shanghai, China

Abstract Body:

Background: The bile salt hydrolase (**BSH**) is a gut bacterial enzyme that negatively influences host fat digestion and energy harvest. BSH enzyme activity functions as a gateway reaction in the small intestine by deconjugation of conjugated bile acids. Extensive gut microbiota studies have suggested that BSH is a key mechanistic microbiome target for developing novel non-antibiotic feed additives to improve food animal production and for designing new measures to control obesity in humans. However, research on BSH is still in its infancy, particularly in terms of structural basis of BSH function, which has hampered development of BSH-based strategies for improving human and animal health.**Methods:** The C-terminal His-tagged BSH from *Lactobacillus salivarius* NRRL B-30514 was purified for protein crystallization and structural analysis. The predicted functionally important residues were subjected to site-directed mutagenesis; the activity and substrate specificity of the mutated BSH enzymes were evaluated.**Results:** The crystal structure of the *L. salivarius* BSH was obtained at a resolution of 1.90 Å, which revealed this BSH as a member of the N-terminal nucleophile hydrolase superfamily. Two BSH molecules packed perfectly as a dimer in one asymmetric unit. Comparative structural analysis of *L. salivarius* BSH identified residues critical for catalysis and substrate specificity. Replacement of the residue Cys 2 with Ser abolished activity of the *L. salivarius* BSH, confirming that Cys 2 plays an essential role in BSH catalysis. In addition, the Tyr-24-Phe amino acid substitution dramatically changed substrate specificity for the *L. salivarius* BSH.**Conclusions:** This study revealed the first crystal structure of the BSH from lactobacillus species, the major BSH producer in the intestine. Our findings also provided insights into structural basis of BSH activity, which is important for future translational research by modulating *in situ* BSH activity.

Studies on the Unfolding of a Global Staphylococcal Virulence Regulator with a Flexible C-Terminal End

Author Block:

K. Sau[1], A. Mahapa[1], S. Mandal[2], S. Sau[2]; [1]Haldia Inst. of Technology, Haldia/Purba Medinipur, India, [2]Bose Inst., Kolkata, India

Abstract Body:

Background: SarA, a dimeric protein, acts as a global virulence regulator in *Staphylococcus aureus*. The single-domain structure or the folding-unfolding mechanism of this regulator has not been verified or demonstrated.**Method:** To determine the folding-unfolding mechanism and the domain structure of SarA, a recombinant SarA (rSarA) has been studied using various *in vitro* tools.**Results:** Our limited proteolysis data indicate that rSarA is a single-domain protein with a flexible C-terminal end. rSarA appears to unfold by different mechanism in the presence of different denaturant. While guanidine hydrochloride (GdnCl)-induced unfolding of this protein occurred via the generation of two dimeric intermediates, urea-induced unfolding of rSarA proceeded sequentially through the production of a dimeric and a monomeric intermediate. The structures and the surface hydrophobicity of the intermediates differed and also varied notably from those of native rSarA. Of the intermediates, the GdnCl-generated intermediates possessed a molten globule-like structure. In comparison with the native rSarA, the intermediate generated at low GdnCl concentration carries a compressed shape, whereas, other intermediates acquire an enlarged shape. The thermal unfolding of rSarA, unlike chemical-induced unfolding, was completely irreversible in nature.**Conclusion:** We have confirmed the single-domain structure of SarA and shown that its C-terminal end is relatively flexible in nature. In addition, we have provided clues about the folding-unfolding mechanism of this global virulence regulator.

The Domain-Connecting Helix of a Mip-Like Peptidyl-Prolyl *cis-trans* Isomerase is Critical for Its Structure, Function, Stability and Shape

Author Block:

S. Sau, S. Polley; Bose Inst., Kolkata, India

Abstract Body:

Background: FKBP22, an *Escherichia coli*-encoded peptidyl-prolyl *cis-trans* isomerase, shares substantial identity with the Mip-like virulence factors. Two domains of the Mip-like proteins are joined by a protease-sensitive α-helix. While their N-terminal domains are involved in dimerization, their C-terminal domains carry catalytic site and bind inhibitors like rapamycin and FK506. Very little is known about the roles of the domain-connecting helix on the structure, function, stability and shape of any Mip-like protein.**Method:** To describe the roles of the domain-connecting helix in Mip-like proteins, a recombinant FKBP22 (rFKBP22) and its three point mutants I65P, V72P and A82P have been studied using multiple probes. Each mutant carries a Pro substitution mutation at a specific location in the helix.**Result:** We have demonstrated that the three mutants differ not only from each other but also vary from rFKBP22 in structure and activity. Urea-induced equilibrium unfolding of mutants occurred via the formation of at least one intermediate. Conversely, rFKBP22 was unfolded by a two state mechanism in the presence of urea. Besides, the stabilities of the mutants, particularly I65P and V72P, were considerably different from that of rFKBP22. However, mutations little affected the rapamycin binding affinity of rFKBP22. Of the mutants, I65P was not only associated with the maximum levels of structural/functional loss but also dissociated partially in solution. Our computational studies have indicated that there is a severe collapse of the shape in I65P due to the abnormal movement of its C-terminal domains.**Conclusion:** Our data have demonstrated that the domain-connecting α-helix is vital for the Mip-like proteins.

Assessment of Knowledge and Practice of Laboratory Personnel Regarding General Safety Rules in Microbiology Department of Private Laboratories in Karachi-Pakistan

Author Block:

U. Khattak, **Z. Fatima**, J. Zaheer, Z. Zahid, N. H. Ali; Dow Univ. of Hlth.Sci., Karachi, Pakistan

Abstract Body:

Background: Safety is an essential component of working of any laboratory. The infections caused by micro organisms can be prevented by using general safety rules in microbiology laboratory. This study was conducted to determine the knowledge and practice of laboratory personnel regarding general safety rules in microbiology laboratories and to identify the safety measures taken by them to prevent the spread of infection.**Method:**This was a comparative study which used a standardized questionnaire to survey knowledge, attitude and practice of laboratory personnel regarding general safety rules working in microbiology departments of different private laboratories in Karachi-Pakistan. Approximately 100 laboratory personnel were assessed on the basis of 14 questions.**Results:**Regarding knowledge, approximately 70% of laboratory personnel knew the very important issues related with laboratory safety like discarding of tested samples, importance of safety cabinets and protective devices etc. On the other hand the attitude towards practice, only 50% to 60% of the laboratory personnel follow safety rules i.e. wearing gloves and lab coats, washing hands properly, decontaminating their working bench before and after the work. Reporting of any spill or accident to laboratory supervisor was not practiced by any of them except only few. Avoidance of eating and drinking in laboratory is only practiced by 20%.**Conclusion:**Our research showed the deficit in the awareness of safety precautions amongst laboratory personnel and demonstrates that knowledge and practice of safety rules is unsatisfactory. The importance of training regarding practice of general safety rules needs emphasis. Efforts should be made to increase knowledge of laboratory personnel regarding spread of infection and its cure because if the laboratory personnel is not be safe from the infection than how can the quality is maintained.

Implementation of Biosafety Program Audit for Infectious Diseases in Laboratories of Clevb at 2015

Author Block:

S. -. -. -. El Mahdy, 1983; Central Lab for Evaluation of Vet Biologics, Cairo, Egypt

Abstract Body:

On an annual basis , laboratory staff should be asked to rate the four primary controls of biosafety and justify each rating, so at the two last months in 2015, the biosafety committee of CLEVB has carried biosafety program audit to the four primary controls of biosafety programs in laboraties for persons that dealing with infectious agent. These four primary controls include Engineering , standard operating procedures (sops), personal protective equipment (PPE) and administration. The objective of this surveillance is monitore the professionality and technical capacity of the employees towards the biosafety programs. According to biosafety scoring system used to provide a grading scale for each primary control of biosafety, approximately 65%, 30%, 4%, 1% and 0% of the participants studied were given excellent , good, fair , poor and unacceptable scale. It was significantly that the workers in the different department promising in the implementation of biosafety measures through the programmed plan. Close analysis also indicated that there were significant differences participants in justify between the grade provided for each primary control of biosafety.

Validation of Autoclave Parameters for Sterilization of Medical Waste on a Bio-Containment Unit

Author Block:

B. C. Ellis, K. Dionne, B. Garibaldi, M. Reimers, N. Parrish; The Johns Hopkins Hosp., Baltimore, MD

Abstract Body:

Background: Successful autoclave-based decontamination of medical waste depends on a number of parameters including sterilization temp, cycle type/time, and load configuration. The type of material, size of the load, and the way it is packed relative to the chamber size has a direct effect on adequate sterilization.**Methods:** Manufacturer default parameters were tested by running simulated loads with assessment of sterility. Loads consisted of items expected from a patient room such as saturated linens, protective personal equipment/dry trash, and liquids (0.1L to 1L). Both rapid (3 hr) and standard (48 hr) biological indicators (*Geobacillus stearothermophilus*) were placed in the center of each load to assess sterility. Various cycle types were tested: liquid, gravity and vacuum along with varied ancillary settings including purge, run, and dry times, and temp. Additional variables were tested including the type/number of bags, bag closure, and the use of a solidifying agent to absorb excess liquids. In total, 19 different load-run configurations were tested including unique cycle programs developed as a result of this study.**Results:** 84% (16/19) of the runs performed using factory default settings failed. The most difficult loads to sterilize were those containing saturated linens which required a vacuum cycle to achieve adequate sterilization. Liquids and other trash required different cycles/settings. Optimized cycle parameters required separation of load types into standard waste, saturated linens, and liquids. For linens and standard waste, vacuum cycle parameters were modified from factory default settings by maximizing the pre-vac steps, decreasing the psi differential, and increasing the time to 60 min (linens) or 30 min (standard waste). Liquids (0.1L to 1L) were sterilized using a 120 min cycle at 253°F on a liquid setting.**Conclusions:** This study demonstrates that use of factory default settings for sterilization of medical waste in the absence of validation using simulated loads risks release of infectious waste. Since every load differs in composition and density, it is critically important to simulate expected waste with concomitant assessment of sterility using the proper biological indicators. This is especially important in high-level, bio-containment facilities where BSL-3 or 4 level pathogens may be encountered.

Cell-Based Reference Material for Qpcr: Stability Study

Author Block:

S. Da Silva, N. Lin; NIST, Gaithersburg, MD

Abstract Body:

Microbial quantification and detection face a series of practical and technological challenges including those related to the nature of the samples involved in the analysis (e.g., matrix from clinical and environmental samples). Despite efforts to improve methods, confidence in the measurements is lacking, especially for measurements made at the point of need or point of care where results are used to inform critical decision-making (e.g. biothreat detection). To address the need for measurement confidence, we are developing a reference material based on whole cells as a low-risk surrogate to challenge nucleic acid-based detection technology workflows, including sampling, DNA extraction, and detection. We stably inserted DNA sequence External RNA Control Consortium-00095 (ERCC-00095 from NIST SRM 2374) into a *Saccharomyces cerevisiae* strain to convey specificity. Feasibility as a reference material for quantitative polymerase chain reaction (qPCR) was demonstrated previously via interlaboratory study. Currently, we report the on-going stability study of a dry-format of the material by measuring cell number, cell viability, and DNA integrity as a function of time (up to 4 months) and temperature in Celsius (-20, 4, 20, 50). These conditions represent deviations that might occur during shipping or storage and help establish shelf-life. Preliminary results suggest acceptable cell number stability, with no statistically significant change in cell number at any temperature over time. In contrast, ~90 % loss in cell viability was observed at 50 °C after just 30 days, while other temperatures had no viability change, indicating 50 °C should be avoided to maintain viability. DNA integrity is currently being assessed by qPCR and pulsed field gel electrophoresis. Overall, this engineered yeast holds promise to support measurement assurance for the analytical process of nucleic acid-based detection technologies, encompassing the method, equipment, and operator, to increase confidence in microbial detection results.

Improvement of Biosafety Measures in Evaluation of *Fowl Pox & Newcastle* Vaccines Using Challenge Test

Author Block:

A. Hussein, A. Ali; Central Lab for Evaluation of Vet Biologics, Cairo, Egypt

Abstract Body:

Pox is a common viral disease of domestic birds(chickens, turkeys, pigeons and canaries) caused by a group of avian *pox* viruses which are members of the genus *Avipox* viruses of the *poxivirdae*-It is a slow spreading disease characterized by the development proliferative of discrete nodular proliferative skin lesions o the non-feathered parts of the body (cutaneous form) or fibrino-necroric proliferative lesions in the mucous membranes of the upper respiratory tract, mouth and esophagus (diphtheritic form).-In contaminated environments, aerosols transmission occurs by feathers and dried scabs containing *pox* virus particles causing both cutaneous and respiratory infection.-Control of fowl and pigeon pox is carried out vaccination with modified live *pox* virus vaccines.-Challenge 3 weeks later after vaccination of chickens by scarification of the opposite wing with the local Egyptian virulent strain of fowl pox viruses in dose 10^3 EID_{50}/dose, the birds should be observed for 14 days.-Newcastle Disease is an infectious of domestic poultry and other bird species with virulent ND virus. It is world-wide problem that presents primarily as an acute respiratory disease, but depression, nervous manifestations, or diarrhea, may be the predominant clinical form.-A suitable challenge strain for assessment has been stressed. For live vaccines of *Newcastle* virus, the method recommended involves the vaccination of 10 or more SPF or other fully susceptible birds.After 14-25 days, each vaccinated bird and ten control birds are challenged intramusculary with at least 10^4 EID50 (50% egg infectious dose) of *ND* challenge virus, challenge birds are observed for 14 days, at least 90% of the control birds must develop clinical signs and die within 6 days of Newcastle disease.-Evaluation of *Fowl.Pox and Newcastle Vaccines* were done in an ordinary chicken cages, but now improvement in the quality control of the challenge virus is done at chicken isolators to improve and protect the environment from the challenge virus and chickens from the complication by poor environment and other infections.

Bio-Risk Assessment Of Salmonella Food Poisoning As Public Health Threat In The Egyptian Hatcheries And Table Eggs

Author Block:

S. S. -. -. Salama, 1993; Central Lab for Evaluation of Vet Biologics, Cairo, Egypt

Abstract Body:

Introduction: Salmonellosis is one of the most important food poisoning organisms. There are many different kinds of these Salmonellae but *Salmonella typhimurium* and *Salmonella enteritidis* are the most common types. The CDC estimates that 1.4 million cases of salmonellosis occur annually. Because many milder cases are not diagnosed or reported, the actual number of infections may be 30 or more times greater. The situation of this problem not clearly known in Egypt specially source of contamination because the food poisoning may be noticed in children, adult and people with impaired immune systems are the most likely to have severe infections.So, It is important to map and assess salmonella bio-risk hazard along the poultry value chain in Egypt. This study focuses on investigation of salmonella infection in hatcheries as an intermediate node along the production chain and table egg farms.**Methods:** A total of 910 swap samples were taken from different places in different 5 hatcheries including storage room, fertile eggs, Setters, hatcheries, chicks and from workers. Another 420 table egg samples were collected from 5 different farms before distribution. Samples subjected to bacteriological isolation, biochemical identification and molecular confirmation.**Results:** Generally isolation rate of salmonellae was 41% but between workers and in table eggs were 32% 37% respectively. The isolated serotypes varied between S. enteritidis, S. typhimurium, S. Gallinarum , S. paratyphi, S. pullorum and S. Montevideo indicating a horrible situation from the public health hazardous point of view.**Conclusion:** Assessment of current situation based on isolation rate and the type of isolated salmonellae reflect a scary situation of salmonellosis in hatcheries node and table egg farms especially among workers and in table eggs. This requires awareness, development and application of biosecurity and bio-risk management campaigns to get rid of this problem to avoid public health hazards.

Update on Influenza Rapid Testing Course and Pandemic Preparedness Course for Clinicians and Utilization of Course E-Resources

Author Block:

L. O. Williams[1], S. Chitavi[2], B. Longo[2]; [1]CDC, Atlanta, GA, [2]The Joint Commission, Oakbrook Terrace, IL

Abstract Body:

Background: An online influenza rapid testing course for clinicians, "Strategies for Improving Rapid Influenza Testing in Ambulatory Settings (SIRAS)" was developed and launched in 2012 by The Joint Commission (TJC) and the CDC. The course was restructured in 2013 to four 30-minute modules. (http://www.jointcommission.org/siras.aspx). In response to SIRAS participants' feedback on training needs, an influenza pandemic preparedness course was developed and launched in Apr. 2015 and restructured in Oct. 2015 into two shorter segments: 1) pandemic planning and response, and 2) laboratory testing and patient management/treatment. Specimen collection videos https://www.youtube.com/playlist?list=PLNQfL_CJ36fK08KEPjxu1ZKJn7GuFtn-N. , and other e-resources are offered. Recent utilization data are presented. SIRAS is being translated into Spanish.**Methods**: Courses were developed and restructured into shorter modules based on participants' feedback. E-resources were offered, and unique webpages for easy access were designed. Courses are updated annually and relaunched in Oct. Social media and TJC communication channels are used for marketing. Course utilization data are compiled annually and e-resource utilization is tracked cumulatively.**Results**: There were 5,864 visitors to the SIRAS webpage and 1,615 enrollments from Oct. 2014 - Sept. 2015. There were 1,722 visitors to the pandemic course webpage and 608 course enrollments since it was launched in Apr. 2015 - Sept. 2015. Since updating and relaunch in Oct. 2015, there have been 477 enrollments in SIRAS and 571 enrollments in the pandemic course, representing upward trends. The SIRAS course CE issuance rate increased to 82% (Oct. - Dec. 2015) compared with 34% during the first year and 48% last year. There were 2,345 downloads of Infographics; 10,325 views of the RIDT post on TJC's "AmBuzz" blog, and 133,291 views of specimen collection videos through Dec. 2015. Satisfaction rates were 98% for SIRAS and 94% for the pandemic course.**Conclusions:** Clinicians have welcomed the ongoing opportunity for continued education in influenza testing and preparedness. Annual updating of courses before the onset of influenza season attracts increased usage of e-resources and enrollments. Specimen collection videos, and other course tools are increasingly popular.

Ecological Niche Modeling of *Dermacentor marginatus* in Georgia

Author Block:

I. Burjanadze[1], J. Blackburn[2], I. Kracalik[3], S. Chubinidze[4], P. Imnadze[1], N. Tsertsvadze[1], G. G. Chanturia[1]; [1]Natl. Ctr. for Disease Control and Publ. Hlth.(NCDC), Tbilisi, Georgia, [2]Spatial Epidemiology and Ecology Res. Lab, Dept. of Geography, Univ. of Florida, Gainesville,, FL, [3]Spatial Epidemiology and Ecology Res. Lab, Dept. of Geography, Univ. of Florida, Gainesville, FL, [4]Richard G. Lugar Ctr. of the Natl. Ctr. for Disease Control and Publ. Hlth.(NCDC), Tbilisi, Georgia

Abstract Body:

Dermacentor marginatus, also known as the ornate sheep tick, is the principal arthropod vector of many pathogens which are a major cause of diseases as in humans and animals. Transmission of many tick-borne diseases, including tularemia, are highly associated with this *Ixodidae* tick in Georgia. The purpose of this study was to describe spatial and epidemiological characteristics of *D.marginatus* helping lead to identification of its ecological niche in Georgia.The fieldwork data obtained from multiple projects was used to predict respective distributions of *D.marginatus* using the ecological niche modeling system Genetic Algorithm for Rule-Set Production (GARP). We used five variables to construct models at both resolutions: annual mean temperature, annual temperature annual range, annual precipitation, precipitation of wettest month, and precipitation of driest month. The accuracy of the current distribution was then quantified through the use of accuracy metrics, which utilized the 25% testing data that was withheld from the modeling experiment.The BioClim current scenario received an area under curve (AUC) score of 0.749, SE=0.063; Z=7.36. The model had a total omission of 20.0% and average omission of 23.0% meaning that 100.0% of the independent (testing) locality data were predicted correctly by at least one model and 77.0% of the independent locality data were predicted correctly by all models in ten best subsets. An average commission was 27.94% and total commission 18.62%.The 102 spatially unique points of *D. marginatus* were randomly divided into 75% (n=76) training set used for modeling and 25% (n=26) testing set for model prediction.Using ecological niche modeling strategies in conjunction with spatial clustering techniques could help in identifies areas of concern. The results of the study will help to guide the sampling efforts of future studies of tick-borne diseases focusing with the dissemination of *D. marginatus* in Georgia.

Protective Capabilities of Bacterial Outer Membrane Vesicles to Improve Encapsulated Enzyme Stability

Author Block:

N. J. Alves, K. B. Turner, S. A. Walper; Naval Res. Lab., Washington, DC

Abstract Body:

Background: Utilizing common molecular biology techniques, researchers have been able to manipulate bacteria to produce enzymes for use in diverse industries. However, maintaining enzyme stability for many real world applications remains a long standing problem requiring the use of chemical additives as well as strict storage and transportation protocols. By programming the bacteria to both produce and package enzymes within outer membrane vesicles (OMV) we sought to improve enzyme stability for use in difficult enzyme applications. **Methods:** *E. coli* was utilized to develop a phosphotriesterase (PTE) packaging scheme in which a synthetic SpyTag/SpyCatcher (ST/SC) linkage was incorporated into the PTE-SC and a ST modified membrane anchoring protein (OmpA-ST) to facilitate packaging of PTE within OMV. OMV were isolated by ultra-centrifugation and enzyme stability was assessed utilizing paraoxon as a substrate post prolonged storage at elevated temperatures, iterative freeze-thaw cycles, and lyophilization. Enzyme activity was also assayed across a range of environmentally collected water samples. **Results:** Under all storage conditions the OMV encapsulated PTE demonstrated improved stability when compared to free PTE. The stability enhancement was particularly notable at elevated temperatures after 14 days of storage at 37C retaining 34.5% activity compared to 0.3%, post lyophilization 64.2% compared to 1.8%, and post four freeze-thaw cycles 92.7% compared to 27.7% for OMV packaged PTE compared to free PTE, respectively. Lyophilized samples were also utilized in long term remediation assays as well as in paraoxon contaminated environmental samples collected from: pond, building downspout, pavement puddle, and dirt puddle sources. **Conclusions:** Our findings demonstrate that packaging PTE within bacterial OMV provides for a supportive micro-environment that maintains enzyme activity across all storage conditions tested. This technique can be adapted for use with alternate enzymes and proteins for environmental remediation, pharmaceutical delivery, and industrial applications.

A Simple Pipeline to Assess Genetic Diversity Between Bacterial Genomes

Author Block:

J-F. Pombert, I. Veseli, Y. Sun, R. R. Butler, III; Illinois Inst. of Technology, Chicago, IL

Abstract Body:

Calculating the number of single nucleotide polymorphisms (SNPs) and insertions/deletions (indels) between distinct genomes is an important component of the assessment of their genetic diversity. The gold standard approach used to generate this information consists of mapping short accurate high-throughput sequencing reads from one or more species against a reference genome, from which variants are called. This approach works well when short sequencing read data are available, however sequenced genomes deposited in public repositories do not always include the reads that were used to generate consensuses. Moreover, the newest long read technologies from Pacific Biosciences and Oxford Nanopore, both increasingly used to sequence bacterial genomes, produce fragments that often exceed 20 kb. While one can align genomes and/or long reads against each other, the results are often suboptimal when the investigated samples feature a large amount of syntenic differences, as the presence of chromosomal reorganization can cause the mapping to fail. An elegant solution to this problem is to deconstruct the complete genomes or long reads into shorter fragments, a shotgun approach, and to use these smaller synthetic reads as input for mapping. We have implemented this approach as an easy-to-use portable Perl script named SSRG.pl (available on the lab's GitHub page), and have integrated it with BWA and VarScan, well-known read mapping and SNP/indel calling tools. Test cases indicate that the results obtained with the synthetic reads are similar in every way to those obtained from genuine illumina reads, with the same advantages and caveats, and can therefore be reliably used as substitute when analyzing haploid genomes. Using this pipeline, we are able to compare SNPs and indels between any two bacterial genomes available in GenBank.

Intein-based Evolutionary Insights Into the Mycobacterial Phenotypic Network (Mpn) in the Genus Mycobacterium

Author Block:

O. Kweon, S-J. Kim, D. Bae, J. Chon, J. Sutherland, C. Cerniglia; NCTR, Jefferson, AR

Abstract Body:

Background: The bacterial genus *Mycobacterium* is of great interest in the medical and biotechnological fields. We previously generated a practical mycobacterial compendium using phylogenetic, genomic, pan-genomic, and phenotypic information and then reconstructed a mycobacterial phenotypic network (MPN). The systematic mycobacterial information allowed a new approach called Network Based Functional Pan-Genomics (NBFPG) to build connections between genomic dynamics and phenotypic evolution. In this study, we update the mycobacterial compendium and the MPN with newly genome-sequenced mycobacteria and use inteins (protein splicing elements), as indicators of gene flow to identify possible evolutionary trajectories in the genus *Mycobacterium*.**Methods**: Pan-genomic analysis using EDGAR; sequence alignment, clustering, and phylogeny using T-Coffee; mycobacterial genomes and intein from JGI/IMG and InBase.**Results**: Initially, we updated the mycobacterial compendium and the MPN with 50 newly completed genome-sequenced mycobacteria, giving a total of 77 strains of mycobacteria. The updated compendium and MPN provide the enhanced pleiotropic and epistatic evolutionary resolution of nine representative mycobacterial phenotypes according to the genomic dynamics. No noticeable alterations in the scale-freeness and connection strength were observed in the updated MPN. A bottom-up survey identified several types of intein from the proteins (RecA, GyrA, DnaB, and SufB), existing sporadically in the phylogeny. Integration of the distribution and phylogenetic signals of the inteins into the MPN revealed possible trajectories of gene transfer. The strong connection, from the PAH-degrading strains in the free-living mycobacterial group to obligately intracellular *M. leprae* strains via the nontuberculous mycobacteria (NTM) in the facultatively host-associated mycobacterial group, suggests a plausible evolutionary trajectory in the genus *Mycobacterium*.**Conclusion**: MPN-based integration of the intein-centric evolutionary signals enhances evolutionary resolution at the network level, which allows the more powerful NBFPG to fill the knowledge gaps between genome and phenome in the genus *Mycobacterium.*

Gene-by-Gene Diversity in Across Bacterial Genomes of Various Species, Including *M. tuberculosis* and *Neisseria*

Author Block:

S. Hauck; Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Background: With the rise of high throughput whole genome sequencing, thousands of genomes for epidemiologically important bacterial species have become available. While these genomes are on occasion of poor quality, in combination they are a useful resource for exploring the diversity and selective pressures acting on a species at a gene-by-gene level.**Materials & Methods:** Whole genomes from public archives such as the Sequence Read Archive (SRA) were added to the PubMLST database, following assembly via a Velvet optimiser pipeline. This database runs the BIGSdb (Bacterial Isolate Genome Sequence database) software, which allows for genome annotation based on a set of reference sequences that defines genes, and an iterative scanning and definition process for new alleles of those genes. Measures of diversity were then calculated from the length, count of unique alleles, and ratio of variable sites in each defined locus, using the mean for the genome as the point of comparison.**Results:** This method was first applied to a data set of 7681 *Mycobacterium tuberculosis* genomes, using the nearly four thousand genes in the H37Rv annotation as the reference. This identified both conserved and diverse genes, which were respectively often coding for the information pathway and for surface-bound products. Genes in the ESAT-6 family appeared to be genetically diverse but functionally conserved, suggesting perhaps two stages of evolution with different pressures. The distribution of synonymous mutations indicated that the vast majority of the *M. tuberculosis* genes are under purifying selection, while genes in *Neisseria meningitidis* showed an evenly distributed level of selection, and *N. gonorrhoeae* showed many positively selected genes in a background on mild purifying selection.**Conclusion:**The availability of thousands of genomes and fully annotated reference genomes, together with population annotation software, allows for genes to be explored as "gene pools" that can be compared in order to reveal the evolutionary forces which act of them. This method allows to simple and rapid evaluation of gene targets across an entire genome using a large number of isolates to avoid sampling bias. This method also allows for a more rigorous choice of molecular markers to be made, as it can take into account the diversity or lack thereof of the potential target.

Comparative Transcriptomics of Enterotoxigenic *Escherichia coli* Isolates in Response to Bile

Author Block:

J. R. Sistrunk[1], J. Sahl[2], F. Qadri[3], J. Fleckenstein[4], D. Rasko[1]; [1]Univ. of Maryland, Baltimore, Baltimore, MD, [2]Translational Genomics Res. Inst., Flagstaff, AZ, [3]Intl. Ctr. for Diarrhoeal Disease Res., Mohakhali, Bangladesh, [4]Washington Univ. in St. Louis, St. Louis, MO

Abstract Body:

Background: Enterotoxigenic *Escherichia coli* (ETEC) is a non-invasive, diarrheagenic pathovar of *E. coli* that causes 40 million cases of Travelers' Diarrhea every year and results in an annual 500,000 deaths worldwide. ETEC virulence is characterized by the production of plasmid-encoded enterotoxins that typically lead to a profuse watery diarrheal illness. However, ETEC has been isolated from study participants exhibiting a range of clinical presentations including severe and mild diarrhea, and even asymptomatic colonization. Host products, such as bile salts, that the bacterium encounters along the human gastrointestinal tract are thought to induce expression of ETEC virulence genes that facilitate colonization and disease. **Methods:** RNA-Seq was used to elucidate the transcriptional responses of five clinically diverse ETEC isolates in response to bile salts. Two severe ETEC isolates, including prototype H10407, a mild, and an asymptomatic isolate were grown in LB and DMEM media supplemented with 3% sodium choleate prior to total RNA extraction. The transcripts were sequenced and mapped to each isolates' genome qRT-PCR validation on 25 additional ETEC isolates was used for validation. **Results:** RNA-Seq revealed differential expression of both isolate-specific and shared genes in response to bile salts. Interestingly, colonization factor genes encoding CFA/I fimbriae were only up regulated in the non-prototype severe ETEC isolate, while significantly down regulated in all other isolates. However, motility genes were up regulated in the isolates that saw colonization genes down regulation. qRT-PCR screening in 25 additional ETEC isolates demonstrated that neither clinical presentation nor *E. coli* phylogroup were predictors of the transcriptomic response to bile. **Conclusions:** All four ETEC isolates exhibited variable transcriptomes in response to bile. The transcriptional regulation of ETEC colonization and motility genes suggest presence of diverse regulatory networks in ETEC. Continued investigation of global transcriptional responses may further reveal differences in the pathogenic potential within the ETEC pathovar.

Comparative Transcriptomics of *Acinetobacter* Species Exposed to Multiple Classes of Antimicrobials

Author Block:

T. H. Hazen[1], S. C. Daugherty[1], A. C. Shetty[1], K. Abolude[1], J. K. Johnson[2], A. Harris[2], D. A. Rasko[1]; [1]Inst. for Genome Sci., Baltimore, MD, [2]Univ. of Maryland, Baltimore, MD

Abstract Body:

Acinetobacter baumannii and other disease-associated *Acinetobacter* species have become increasingly linked with hospital-acquired infections over recent decades making them a pathogen of increasing concern. In recent years, high-throughput sequencing has been used to characterize the genomic and transcriptomic diversity of *Acinetobacter* isolates associated with healthcare facilities. However, much remains unknown regarding the number and different types of transcriptional pathways involved in the development of antimicrobial resistance. In the current study, we used RNA sequencing (RNA-Seq) to characterize the global transcriptional responses of nine genomically-diverse *Acinetobacter* isolates upon exposure to four different classes of antimicrobials (carbapenem, aminoglycoside, polymyxin, fluroquinolone), and a general stress inducing agent (NaCl). Phylogenomic analysis of the nine *Acinetobacter* isolates analyzed in this study demonstrated that four were *A. baumannii* and belonged to the global clone 2, three others were part of the *A. calcoaceticus-A. baumannii* (ACB) complex, and the remaining two isolates were an *A. radioresistans* and an unidentified *Acinetobacter* species. These nine *Acinetobacter* isolates were obtained from a cohort study that investigated the distribution of antimicrobial resistant bacteria among patients receiving treatment at one of the intensive care units (ICUs) of the University of Maryland Medical Center. RNA-Seq analysis demonstrated there was diversity in the number and types of protein-encoding genes that were transcriptionally-altered in each *Acinetobacter* isolate following exposure to antimicrobials or to NaCl. The total number of genes that exhibited significant differential expression (DE) following exposure to an antimicrobial compared to growth without the antimicrobial ranged from 0-916 depending on the isolate and species. Among the genes that exhibited increased expression following exposure to antimicrobials were hypothetical proteins, transcriptional regulators, and translocators. These findings provide insight into the genes that are part of the global transcriptional responses of *Acinetobacter* to different antimicrobial agents.

Comparative Genomic Analysis of Genetic Exchange among Bacteria Species

Author Block:

M. J. Soto-Giron, L. M. Rodriguez-R, K. T. Konstantinidis; Georgia Inst. of Technology, Atlanta, GA

Abstract Body:

Horizontal gene transfer, mediated by homologous recombination (gene replacement or conversion), contributes to diversification, genomic evolution, and ecological adaptation of bacterial species, including pathogens. Some bacteria are thought to follow a clonal structure model while others present a recombining mixture of diverse genotypes. The increased number of sequenced genomes makes the robust investigation of population diversification and recombination rates now possible. In this study, we propose an alternative method to estimate the rates of genetic exchange using the number of observed shared genes relative to the number of identical genes expected by chance based on the average amino acid identity (AAI) between genome pairs. We applied this method to several bacterial species with distinct ecologies and found that the expected level of recombination was robust and agreed with previous reports detecting close to zero recombination rates for obligatory and intracellular bacteria such as *Buchnera aphidicola*. However, the contribution of recombination to bacterial diversification was more similar than previously thought in generalist organisms such as *Neisseria meningitidis* and *Campylobacter jejuni*. We analyzed the population dynamics and recombination signatures of *C. jejuni*, a pathogen associated with foodborne infections, using isolates from distinct hosts and regions of the world (n >200). Our results suggested a cosmopolitan population clustered mainly in four clades with pervasive recombination among the clades (e.g., recombination to mutation ratio was 3.6). Among the 133 core genes with recombination signals, we identified genes related to resistance to bacitracin, erythromycin, and amikacin antibiotics as well as virulence factors associated with serum resistance, invasion of epithelial cells, and adhesion. The transmission of antibiotic-resistant genes requires more attention to control the emergence of multi-resistance genotypes and the exchange of virulence factors may increase the virulence of recipient strains.

Automatic Text Mining of Prokaryotic Phenotypic Characters Using Micropie

Author Block:

L. R. MOORE[1], J. Mao[2], C. Blank[3], M. Ackerman[1], H. Cui[2]; [1]Univ. of Southern Maine, PORTLAND, ME, [2]Univ. of Arizona, Tucson, AZ, [3]Univ. of Montana, Missoula, MT

Abstract Body:

The study of the evolution of microbial traits requires both phylogenetic as well as phenotypic trait information (also called phenomics). Next generation sequencing has enabled high throughput (meta)genomic analyses, but collecting phenotypic information, either *de novo* or from published taxonomic literature, to create large taxon-character matrices is still tedious and time-consuming. We are creating a natural language processing (NLP) tool, Microbial Phenomics Information Extractor, or MicroPIE, that enables faster collection of microbial phenomic information from published literature. MicroPIE takes taxonomic descriptions in XML files as input and extracts more than 50 types of qualitative and quantitative microbial characters, such as Cell Shape, Organic Substrates Utilized, and Temperature Optimum. The main extraction steps are: 1) splitting paragraphs into sentences; 2) predicting the characters described in the sentences by using automated classifiers; and 3) extracting character values from the sentences by applying a variety of NLP methods. We provided MicroPIE with a library of microbial-specific terms derived from ~1000 taxonomic descriptions from the Archaea, Bacteroidetes, Cyanobacteria, and Mollicutes as a starting point, but have also developed an ontology (MicrO) of prokaryotic phenotypic and metabolic characters. MicrO is organized using a formal logical framework and will be incorporated into a future version of MicroPIE to assist with character identification and extraction, to facilitate identification of trait synonyms used in prokaryotic taxonomic descriptions, and to populate character matrices with higher-level character states. Matrices generated by the MicroPIE prototype are being compared automatically and manually to a hand-generated, gold standard matrix of 111 taxa with >4000 character values, and preliminary results of precision and recall are very promising (>80% for 38% of characters so far). MicroPIE will be open-source once it is released. The matrices extracted using MicroPIE are in a format that can be combined with phylogenomic trees for conducting phylogenetic comparative analyses to test evolutionary hypotheses.

The Effect of History on Evolution of *Desulfovibrio vulgaris* Hildenborough Under Elevated Temperature

Author Block:

M. L. Kempher[1], R. Song[1], A. Zhou[1], G. M. Zane[2], S. M. Kosina[3], T. R. Northern[3], J. D. Wall[2], A. P. Arkin[3], J. Zhou[1]; [1]Univ. of Oklahoma, Norman, OK, [2]Univ. of Missouri, Columbia, MO, [3]Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

The contributions of history, adaptation, and chance to evolution have long been debated. Adaptation and natural selection have been regarded as the most important influences on evolution. However, prior historical events may place constraints on or promote the appearance of certain mutations. In order to further investigate the influences of history on evolution, three groups of *Desulfovibrio vulgaris* Hildenborough (*Dv*H) with varying evolutionary histories were propagated in the laboratory under elevated temperature (41°C) for 1,000 generations. The three groups included six populations that were started from the Ancestor (An) with no prior evolution and named An-T 1 – 6, six populations that had been previously propagated for 1,200 generations under control conditions (LS4D medium, 37°C) and named EC-T 1 – 6 (EC: Evolved Control), and six populations that had been previously propagated for 1,200 generations under elevated salt conditions (LS4D medium, 37°C, +100 mM NaCl) and named ES-T 1 – 6 (ES: Evolved Salt). All 18 populations were then propagated in LS4D without additional salt but at an elevated temperature (41°C). Phenotypic changes and relative fitness of each population were then assessed using growth analysis (growth rate, lag phase time, and maximum OD). Each population was re-sequenced to map the mutations that had accumulated. Prior evolution under high NaCl provided some cross-protection to heat stress. The ES population had a slight advantage at 41°C compared to the EC and An population. However, after 1,000 generations at 41°C the advantage was minimized. Additionally, the EC-T populations had increased growth at elevated salt compared to the EC population, providing further evidence that an adaptation to either heat or salt provided cross-protection for the other. At 46°C, a temperature previously determined to be lethal to the ancestor, the populations with evolutionary history had slightly increased growth rate and final OD_{600} compared to the An populations. Direct head-to-head competitions between the evolved populations and the wild-type ancestor are currently ongoing. A direct measurement of fitness will be important in determining the role of chance, adaptation, and history on evolution.

Genomic Characterization of the *mutS-rpoS* region of *Cronobacter* Species

Author Block:

E. E. Jackson, S. J. Forsythe; Nottingham Trent Univ., Nottingham, United Kingdom

Abstract Body:

Background: The *mutS-rpoS* genomic region has been identified as a highly variable and evolving via horizontal gene transfer. Genes in this region may contribute to virulence and within the *Cronobacter* genus, 3 of the 7 species have been linked to human illnesses. This work was undertaken to examine the *mutS-rpoS* region in *Cronobacter* to determine its role in the virulence of certain species. **Methods:** The genomes of 136 strains, covering six *Cronobacter* species were examined and sequences were extracted using Artemis. All genomes are available at http://www.pubmlst.org/Cronobacter. Phylogenetic networks of the region were constructed using SplitsTree to visualize possible recombination events.**Results:** All *Cronobacter* species and strains contained the same seven genes between *mutS* and *rpoS* (Figure 1). These genes include phenolic and aromatic acid decarboxylases (*bsdC, bsdC, pad1*), possibly related to the association of *Cronobacter* with plants. The region also includes genes encoding a drug efflux pump and two transcriptional regulators. Phylogenetic networks showed recombination events prior to the divergence of the *Cronobacter* spp. No recombination events were observed between strains of different species after divergence and limited recombination was observed between strains of the same species.Figure 1. Gene organization of the *mutS-rpoS* genomic region of *Cronobacter*

Conclusions: The *mutS-rpoS* genomic region of *Cronobacter* spp. is consistent among the species, despite that only 3 species have been linked to human illnesses. The *mutS-rpoS* region does not contain genes directly related to virulence, but some may be related to environmental survival. Very little recombination has occurred in this region, likely due the clonal nature of the *Cronobacter* genus.

Phylogenetic Analysis of Electrically Conductive Pili of *Geobacter* Species

Author Block:

D. E. Holmes[1], Y. Dang[2], D. R. Lovley[2]; [1]Western New England Univ., Springfield, MA, [2]Univ. of Massachusetts Amherst, Amherst, MA

Abstract Body:

Studies have shown that electrically conductive pili (e-pili) can enable long-range electron transfer to insoluble minerals, to other cells, and through electrically conductive biofilms. Most studies of e-pili have focused on Fe(III)-respiring bacteria from the genus *Geobacter*, *G. sulfurreducens* and *G. metallireducens*. The e-pilin gene from both of these organisms is significantly shorter (60-90 aa) than type IV pilA from other organisms (>120 aa), and is accompanied by a gene (pilA-C) located directly downstream that codes for a small protein composed of beta sheets and a transmembrane domain. In order to evaluate the phylogenetic conservation of e-pilin and pilA-C genes among the order Desulfuromondales and other Fe(III) respiring bacteria, 96 different genomes were analyzed. Most (79%) of the bacteria in the order Desulfuromondales possess e-pilin genes, however, this gene was present in only 2 out of 72 Fe(III)-respiring bacteria from other taxonomic orders suggesting that most Fe(III)-reducing bacteria rely on mechanisms other than e-pili for electron transport to Fe(III). Further sequence analysis suggested that both the e-pilin and pilA-C gene is undergoing positive selection among the genus *Geobacter*. It has been speculated that the shorter pilus monomer permits tighter packing of aromatic amino acids, and possibly other amino acids, in a manner that promotes electron conduction along the length of the pili. It has been shown that e-pili are required for direct interspecies electron transfer (DIET) in defined co-cultures. Therefore, further studies were done on metagenomic and metatranscriptomic libraries assembled from environments where DIET is likely to occur: anaerobic digesters, ANME-dominated subsurface sediments, and rice paddy subsurface sediments. While the majority of e-pilin sequences from the bioreactor and rice paddy samples were most similar to *G. sulfurreducens*, e-pilin sequences from another metal respiring bacterium (*Desulfobacterium autotrophicum*) were predominant in ANME-1 dominated sediments. This study provided insight into the evolution of this unique electron transfer mechanism and identified molecular signatures that are diagnostic for DIET that can greatly aid the study of this process *in situ*.

The Evolution Of The Amoa, Pmoa And Bmoa Genes Measured By Ka/Ks Ratios

Author Block:

E. LAU, D. P. Lukich, T. Le; West Liberty Univ., West Liberty, WV

Abstract Body:

Background: The copper-containing membrane-bound monooxygenase (CuMMOs) enzyme family consists of enzymes that facilitate the oxidation of methane (CH4) (catalyzed by particulate methane monooxygenase, pMMO) and ammonia (NH3/NH4) (catalyzed by ammonia monooxygenase, AMO), in both aerobic and anaerobic methanotrophs and nitrifiers, respectively, and the oxidation of C2-10 alkanes (catalyzed by particulate butane monooxygenase, pBMO). Despite catalyzing different substrates, pMMO, AMO and pBMO form catabolic enzymes related structurally and evolutionarily to each other, and they are encoded by the genes pmoA, amoA and bmoA, respectively. It has been suggested that oxygen-dependent methane and ammonia monooxygenases evolved from a substrate-promiscuous ancestor after horizontal transfer(s) into new hosts, which eventually became methanotrophs and nitrifiers. However, no extensive studies have been conducted on molecular selection and adaptation of the beta-peptide structure of pmoA, amoA and bmoA gene products, which form transmembrane polypeptides, and on selective pressures acting on them and their evolutionary history. **Methods:** In this study, over 80 near-complete pmoA, amoA and sequences of known methanotrophs and ammonia oxidizers and single bmoA gene from Nocardioides sp. CF8 from database were downloaded and analyzed to assess whether the combined amoA, pmoA and bmoA gene tree is congruent to the 16S rRNA gene tree for methanotrophs and ammonia oxidizers. The coding gene was separated into 15 segments and pairwise Ka/Ks values were calculated to assess the evolutionary and selection pressure exerted on these taxa in each segment, based on the hypothesis that they evolved from a methanotrophic ancestor, as well as calculate Ka/Ks values between members of each family. **Results:** Our analyses indicated a high level of negative (or purifying) selection between and amongst all taxa. Ka/Ks values were highest between methanotroph pmoA and the anammox or Ammonia oxidizing Archaea (AOA). **Conclusions:** Overall, these analyses demonstrate that the pmoA and amoA genes are under purifying selection within the pmoA and amoA clusters, and supports the hypothesis that one of these genes likely arose from the other via horizontal gene transfer.

Bacteria Form Distinct Ecological Groups That May Impact Nutrient Cycling and Dead Zone Formation in the Chesapeake Bay

Author Block:

E. Sakowski, S. Abraham, G. Kim, S. Preheim; Johns Hopkins Univ., Baltimore, MD

Abstract Body:

The Chesapeake Bay is vital habitat for numerous fish and invertebrate species but is subject to anoxic conditions and dead zone formation during the summer that can result in mass mortalities of these organisms. The development of these dead zones is intimately tied to bacterial metabolism and nutrient cycling, fueled largely by nitrogen and phosphorous pollution. However, high-resolution characterizations of the spatiotemporal distributions of bacterial groups and their role in nutrient cycling and dead zone formation in the Bay are lacking. In this study, bacterial communities were characterized by 16S rRNA amplification and sequencing at a single site in the Chesapeake Bay known to experience anoxia in the summer. Water samples were collected at 1m intervals from surface to bottom in June, July, and August 2015 to capture bacterial communities before and during anoxia formation. Overall, water sample bacterial communities segregated by sample month and depth and formed 11 clusters by hierarchical clustering (4 June clusters, 3 July clusters, 4 August clusters). The most abundant OTUs were present in all 11 clusters at varying relative abundances but belonged to one of four groups defined by OTUs with correlated relative abundance profiles, suggesting these OTUs may be interacting. Groups were specifically associated with one or more of the 11 month- and depth-specific clusters. One group consisted of OTUs that were associated with all four June clusters where dissolved oxygen remained above 2 mg L^{-1} (hypoxia). Two groups were associated with the oxygenated waters in the upper two July and August clusters, respectively, while one group was most abundant in July and August anoxic water clusters. Surprisingly, these OTU groups were composed of similar taxonomic lineages, as 17 taxonomic families representing on average 57% of the cluster communities were present in all four groups. This indicates that related OTUs may have different ecological impacts as a result of specific ecological interactions, and inferences of metabolism and distribution based on taxonomic lineage may be misleading. Ultimately, understanding the impact of specific OTU interactions on community distribution, metabolism, and dead zone development will be crucial to developing better models of dead zone formation and strategies to mitigate their impact in the Chesapeake Bay.

Abundance and Diversity of Nitrifying Microbes in Sediments Impacted by Acid Mine Drainage

Author Block:

B. Ramanathan, J. D. Sackett, T. Roane, A. C. Mosier; Univ. of Colorado Denver, Denver, CO

Abstract Body:

Background: Extremely acidic and metal-rich acid mine drainage (AMD) waters can have severe toxicological effects on aquatic ecosystems. AMD was shown to completely halt nitrification, which plays an important role in transferring nitrogen to higher organisms and in mitigating nitrogen pollution. **Methods:** We evaluated whether AMD differentially impacts three groups of microorganisms involved in nitrification: ammonia-oxidizing archaea (AOA), ammonia-oxidizing bacteria (AOB), and nitrite-oxidizing bacteria (NOB). Sediment and water were collected from AMD-impacted aquatic sites during June and August/September 2013 and 2014 in the Iron Springs Mining District (Ophir, Colorado). Many of the sites were characterized by low pH (<5), low dissolved oxygen concentrations (<6 mg/L), and high metal concentrations. Community sequencing based on the 16S rRNA gene revealed the presence of AOA (*Nitrososphaera* and *Nitrosopumilus*), AOB (*Nitrosomonas*), and NOB (*Nitrospira*) at multiple AMD-impacted sites. The overall abundance of AOA, AOB and NOB were examined using quantitative PCR (qPCR) amplification of the *amoA* and *nxrB* functional genes and 16s rRNA genes. **Results:** The total gene copy numbers across the 2013 and 2014 samples ranged from $2x10^3$-$4.9x10^7$ archaeal *amoA* copies/µg DNA, $7.3x10^5$-$7.7x10^7$ *Nitrospira nxrB* copies/µg DNA and $1.5x10^3$-$5.3x10^5$ AOB 16s rRNA copies/µg DNA. Overall, AOA were found to be more abundant than AOB and NOB in most of the sample sites across 2013 and 2014. Archaeal *amoA* genes were detected in sediments with pH as low as 3.2. Preliminary analyses showed no significant correlation between gene abundance and the measured environmental parameters (pH, temperature, DO and heavy metal levels). **Conclusion:** These findings extend our understanding of the relationship between AMD and freshwater nitrifying microbes and provide a platform for further research.

Ecology Of Ammonium Oxidizing And Nitrite Oxidizing Microorganisms In Namibian Coastal Upwelling Zone At Different Depths

Author Block:

E. LAU[1], C. H. Frame[2], E. J. Nolan, IV[1], Z. W. Dillard[1], M. A. Kinker[1], D. P. Lukich[1], N. E. Mihalik[1], K. E. Yauch[1], S. Waychoff[1]; [1]West Liberty Univ., West Liberty, WV, [2]Univ. of Basel, Basel, Switzerland

Abstract Body:

Background: The upwelling of nutrient-rich South Atlantic waters (as part of the Benguela current) along the Namibian coast sustains some of the highest rates of primary production in oceans, which involves important steps in the Nitrogen cycle. However, the ecology of nitrifying microbes in this ecosystem is not well-studied. **Methods:** Using deep multiplex sequencing of (~450bp) 16S rRNA amplicons, complemented by salinity, temperature, dissolved oxygen, Photosynthetically Active Radiation (PAR), fluorescence and N2O isotope concentration measurements, we profiled the microbiota at 10m, 25m, 100m, 130m, and 250m depths. We assessed the diversity and abundance of Ammonia oxidizing Archaea (AOA), Ammonia oxidizing Bacteria (AOB), and nitrite oxidizing Bacteria (NOB), which oxidize ammonium (NH4+) or ammonia (NH3) to nitrite (NO2−), and nitrite to nitrate (NO3−).**Results:** Our data indicate that the AOA or anammox (anaerobic oxidation of ammonium by Archaeal ammonia oxidizing microbes) are the dominant nitrifying microbes at 25m and below, where dissolved oxygen levels in the upwelling seawater becomes depleted. Their abundances and diversity far exceed that of other nitrifying bacteria.**Conclusions:** This study supports previous reports on the abundance of anammox cells, and biomarker lipids that indicate that anammox bacteria are responsible for significant losses of fixed nitrogen in this ecosystem, as well as other oxygen-depleted upwelling seawaters.

Physiological Study of Ammonia-Oxidizing and Nitrite-Oxidizing Enrichment Cultures from a Freshwater System

Author Block:

A. Boddicker, N. Deevers, A. C. Mosier; Univ. of Colorado Denver, Denver, CO

Abstract Body:

The oxidation of ammonia into nitrite and nitrate (i.e., nitrification) is thought to be a critical, rate-limiting step in the removal of nitrogen pollution from freshwater systems. Nitrification is thought to be performed by four major groups of microorganisms: ammonia-oxidizing archaea (AOA) and bacteria (AOB), nitrite-oxidizing bacteria (NOB), and the newly discovered comammox bacteria that completely oxidize ammonia to nitrate. Very few representatives of these microorganisms have been cultured in the lab and even fewer have been completely isolated. The organisms are difficult to isolate due to their slow growth and competition with heterotrophic contaminants, but more cultivation will lead to a more in-depth understanding of nitrification biochemistry and capability. Here, we describe seven enrichment cultures from the South Platte River basin in Colorado. Functional gene PCR and Illumina MiSeq sequence analyses showed all seven cultures contain an NOB belonging to the *Nitrobacter* genus. Three of the cultures also contain an AOB belonging to the betaproteobacteria phylum, creating co-cultures capable of oxidizing ammonia all the way to nitrate. Nitrite production and consumption in the enrichment cultures has been monitored for more than one year. A growth curve was calculated for one of the AOB/NOB co-cultures showing the production and subsequent consumption of the intermediate nitrite. Several of the enrichment cultures were grown at different nutrient levels to determine optimal growth conditions and response to nutrient pollution. Future work will include in depth physiological and genomic characterization. These findings will aide in the understanding of the diversity and abilities of freshwater nitrifying organisms.

Nitrogen Cycle Evaluation (Nice) Chip to Quantify and Sequence All Functional Genes for the N Cycle Simultaneously

Author Block:

M. Oshiki[1], T. Segawa[2], **S. Ishii**[3]; [1]Natl. Inst. of Technology, Nagaoka Coll., Nagaoka, Japan, [2]Natl. Inst. of Polar Res., Tokyo, Japan, [3]Univ. of Minnesota, St. Paul, MN

Abstract Body:

Background: Various microorganisms play key roles in the Nitrogen (N) cycle. Quantitative PCR and PCR-amplicon sequencing of the N cycle functional genes allows us to analyze the abundance and diversity of these microbes in various environmental samples. However, analysis of multiple target genes can be cumbersome and expensive. Large sequence variations present in some of the target genes require the use of multiple primer sets, which further increases the time, labor, and cost required for the analysis. PCR-independent analysis such as metagenomics and metatranscriptomics is useful to identify the key players for the N cycle; however, it becomes expensive when we analyze multiple samples and try to detect N cycle functional genes present at relatively low abundance. Here, we present the application of microfluidic chip technology to quantify and prepare sequencing libraries targeting all functional genes for the N cycle (i.e., nitrification [*amoA*, *hao*], denitrification [*napA*, *narG*, *nirK*, *nirS*, *norB*, *nosZ*], dissimilatory nitrate reduction to ammonium [*nrfA*], anaerobic ammonia oxidation [*hzs*], nitrogen fixation [*nifH*]) as well as taxon-specific 16S rRNA gene markers.**Methods:** In the N cycle evaluation (NiCE) chip, 48 qPCR assays could be run for 48 samples each (a total of 2304 reactions) per run. The resulting amplicons were recovered from the chip and used for MiSeq sequencing. The DNA samples from pure and artificially mixed bacterial cultures and environmental samples were used as the test samples along with the standard plasmid DNA mixtures.**Results:** Similar results were obtained by NiCE chip and conventional PCR assays. We could obtain the quantitative information of each gene by monitoring the amplification curve in real time. In addition, results obtained by NiCE chip followed by MiSeq sequencing were similar to those obtained by MiSeq done without using NiCE chip.**Conclusions:** The NiCE chip can provide high-throughput format to quantify and prepare sequencing libraries for all functional genes in the N cycle. This tool should advance our ability to explore N cycling in various environments.

Bacterial Siderophores in the Underworld: Siderophore Production by Cave Bacteria in Carlsbad Caverns National Park

Author Block:

T. R. Duncan, D. E. Northup, M. Werner-Washburne; Univ. of New Mexico, Albuquerque, NM

Abstract Body:

Determining how iron is acquired by subsurface bacteria remains an unanswered question that would shed important light on how bacteria live in caves. Surface bacteria use iron acquisition molecules, such as siderophores, to acquire iron. Siderophores have been found in many oligotrophic (low nutrient) environments, which include the open ocean, deep subsurface soil, lakes, and polar ice, and give clues to the nature of siderophores in caves. Microbes in oligotrophic caves have to rely on highly efficient mechanisms to collect essential nutrients, including iron. We hypothesize that cave bacteria synthesize and use siderophores to acquire critical iron needed for cellular processes. We investigated potential siderophore production in Lechuguilla and Spider Caves in Carlsbad Caverns National Park. We subcultured media inoculated with cave secondary minerals in Spider and Lechuguilla Caves, obtaining 170 bacterial isolates. These isolates were tested with chrome azurol sulfate (CAS) assay for siderophore production, with Arnow's and $FeCl_3$ assay for siderophore-type, and a subset of 18 pure isolates were identified by 16S rRNA gene sequencing. The majority (60/170) of cave isolates tested Cas-positive and Cas-slightly positive at 11-25 days. The siderophore-type assays revealed that the majority of siderophores made were hydroxamate-positive and potential hydroxamate-positive and catechol-negative. 16S rRNA gene sequencing of 15 siderophore-positive isolates revealed members of α-, β-, γ-*Proteobacteria*, *Bacteroidetes*/*Chlorobi* group, *Actinobacteria*, and *Firmicutes*. The presence of isolates that produce siderophores supports our hypothesis that cave bacteria are using siderophores to acquire iron. These studies will shed light on the production of siderophores in oligotrophic subsurface environments.
