Iron (Fe) is the fourth most abundant element in the Earth's crust and plays a significant role controlling geochemistry in soils, sediments, and aqueous systems. As part of a study to understand microbially-catalyzed iron and nitrogen biogeochemical cycling in soils, an iron reducing isolate, strain FeAm09, was isolated from Fe-rich soils collected from a tropical forest (Luquillo Experimental Forest, Puerto Rico). Taxonomic analysis of the 16S rRNA gene sequence placed strain FeAm09 in the genus *Geobacter*. Characterization of the optimal growth conditions revealed that strain FeAm09 is a moderate acidophile with an optimal growth pH of 5.0 with little to no growth above a pH of 5.5 and below a pH of 4.5. Strain FeAm09 was isolated under Fe(III) reducing conditions and is capable of growth using soluble Fe(III), Fe(III)-NTA, as well as insoluble Fe(III) oxides (synthetic ferrihydrite) as terminal electron acceptors with H_2 as the electron donor. Strain FeAm09 was capable of coupling growth to the oxidation of solid-phase Fe(II) coupled to the biological reduction of nitrate to ammonium (Fe-DNRA). Dinitrogen (N_2) gas was also formed (denitrification) in equal molar amounts to ammonium. The draft genome sequence of FeAm09 supports the reduction of nitrate to nitrite (*napB*, *napD*) and subsequent nitrite reduction to ammonium (*nrfB*). Genes responsible for reduction of nitrous oxide reductase are absent, thus suggesting production of N_2 was an abiotic nitrite reduction reaction. These results indicate that the Fe-DNRA is microbially catalyzed. Carbon dioxide fixation was verified through assimilation of ^{14}C-labelled CO_2 into biomass under Fe(III) reducing and nitrate-dependent Fe(II) oxidizing conditions. The rTCA cycle was identified (*citB*, *frdB*, *frdC*, *fumB*, *icdI*, *korA*, *korB)* as the only known CO_2 fixation pathway in FeAm09. Together, these data describe the first acidophilic, autotrophic *Geobacter* species capable of nitrate-dependent Fe(II) oxidation. Additionally, the ability of FeAm09 to reduce nitrate to ammonium as the sole nitrate reduction pathway present a model organism that can be used to study the simultaneous biological and abiotic reduction of reactive intermediates such as nitrite.

Iron Oxidation Rates of Diverse Neutrophilic Iron-Oxidizing Bacteria Across a Range of Oxygen Concentrations

Author Block:

J. W. Cohen[1], R. A. Barco[2], J. P. Beam[2], D. Emerson[2], P. Girguis[1]; [1]Harvard Univ., Cambridge, MA, [2]Bigelow Lab. for Ocean Sci., East Boothbay, ME

Abstract Body:

Although neutrophilic microaerobic iron-oxidizing bacteria (FeOB) were some of the first chemolithoautotrophic organisms discovered, their ecophysiology remains poorly understood. Most FeOB require Fe^{2+} as an electron donor to respire O_2, yet the abiotic oxidation of iron proceeds rapidly under atmospheric O_2 concentrations. As such, it has been posited that FeOB predominate in environments with opposing gradients of Fe^{2+} and O_2, where O_2 concentrations are sufficiently low that FeOB out-compete abiotic reactions.[1] While it is apparent that FeOB compete with abiotic oxidations, there are few iron oxidation rate measurements across a range of oxygen concentrations. Here we are studying three marine FeOB in liquid culture across a range of environmentally relevant sub-atmospheric oxygen concentrations using zero-valent iron as a ferrous iron source. We use a non-invasive optical oxygen sensor to monitor headspace oxygen concentration in sealed vials over time. Biological iron oxidation rates derived from oxygen consumption rates were markedly faster than abiotic controls for all strains tested, showing that - at sub-atmospheric oxygen conditions - FeOB likely outcompete abiotic oxidations. Ongoing efforts will examine additional strains to ascertain if this trend remains true across a diversity of FeOB. Differences in iron oxidation rates between strains may reflect adaptations to different environments, as well as diversity in FeOB iron oxidation complexes. These rate measurements expand our knowledge of the biogeochemistry of one of the most common elements in the Earth's crust, and underscore the role of FeOB in global iron cycling.

Oxidation of Cytochrome 583 Is Rate-Limiting When *Acidiplasma aeolicum* Respires Aerobically on Iron

Author Block:

R. Blake, II, K. Hunter, T-F. Li, R. Painter; Xavier Univ. of Louisiana, New Orleans, LA

Abstract Body:

Very little is known about the electron transfer reactions that occur during aerobic respiration on soluble iron by *Acidiplasma aeolicum*, an archaeal member of the Euryarchaeota phylum. We monitored electron transfer reactions among colored cytochromes in intact archaeal cells using an integrating cavity absorption meter (ICAM) that permitted the acquisition of accurate absorbance data in suspensions of intact cells that scatter light. The aerobic iron respiratory chain of *Ap. aeolicum* was dominated by the redox status of an abundant cellular cytochrome that had an absorbance peak at 583 nm in the reduced state. Intracellular cytochrome$_{583}$ was reduced within the time that it took to mix a suspension of the archaea with soluble ferrous iron at pH 1.5 and 45° C. Steady state turnover experiments were conducted where the initial concentrations of ferrous iron were less than or equal to that of the oxygen concentration. Under these conditions, the initial absorbance spectrum of the bacterium observed under air-oxidized conditions was always regenerated from that of the bacterium observed in the presence of Fe(II). The kinetics of aerobic respiration on soluble iron by intact *Ap. aeolicum* conformed to the Michaelis-Menten formalism, with values for V_{max} and K_M of 310 ± 4 nmol/min and 2.0 ± 0.1 × 10^{-4} M, respectively. The reduced intracellular cytochrome$_{583}$ represented the Michaelis complex whose subsequent oxidation appeared to be the rate-limiting step in the overall aerobic respiratory process. The velocity of formation of ferric iron at any time point was directly proportional to the concentration of the reduced cytochrome$_{583}$. Further, the integral over time of the concentration of the reduced cytochrome was directly proportional to the total concentration of ferrous iron in each reaction mixture. These kinetic data obtained using whole cells were consistent with the hypothesis that reduced cytochrome$_{583}$ is an obligatory steady state intermediate in the iron respiratory chain of this bacterium. The ability to conduct direct spectrophotometric studies under noninvasive physiological conditions represents a new and powerful approach to examine the extent and rates of biological events *in situ* without disrupting the complexity of the live cellular environment.

Comparative Microbial Analysis of an Endangered Desert Fish Habitat, Devils Hole, and a Manmade Replica

Author Block:

D. Huerta[1], J. Sackett[2], S. Hamilton-Brehm[2], B. Kruger[2], D. P. Moser[2]; [1]Univ. of Nevada Las Vegas, Las Vegas, NV, [2]Desert Res. Inst., Las Vegas, NV

Abstract Body:

Devils Hole (DH), NV, a water-filled tectonic cavern administered by Death Valley National Park, USA, is the only habitat for the critically endangered Devils Hole pupfish (*Cyprinodon diabolis*). In 2013, the Ash Meadows Fish Conservation Facility (AMFCF) was completed, with the aim of establishing a "backup" population of *C. diabolis*. This facility was painstakingly designed to duplicate the dimensions, microclimate, and water chemistry of DH; however, microbial biogeochemistry has not been compared. We assessed planktonic and sedimentary microbial and microalgal populations, as well as water chemistry, from paralleled locations in DH and the AMFCF to assess how successfully the replica duplicates the natural habitat.Planktonic cells were obtained by filtration (0.2 mm) and sediment was collected by push coring. A total of 21 samples were collected, DNA was extracted, and 16S rRNA gene libraries (V4) prepared on the Illumina platform. Statistical tests included alpha diversity and principal component analysis.While the major ion chemistries of DH and the AMFCF were nearly identical, microbial community compositions between sites were quite distinct. At the AMFCF, major planktonic microbial phyla included *Verrucomicrobia* (~41% of sequences) and *Proteobacteria* (~30%); while DH planktonic communities were dominated by *Planctomycetes* (~30%) and *Cyanobacteria* (~20%).Alpha diversity calculations indicate that DH planktonic communities were more diverse than the AMFCF; with OTU richness in DH being nearly twice that of the AMFCF. Principal component analysis of abundance-weighted UniFrac distances revealed environment-specific clustering of samples. Conversely, the sediment-associated microbial communities clustered together regardless of which location they were collected from (DH or the AMFCF).The findings from this study may be beneficial for the ongoing efforts to reestablish a reserve population of *C. diabolis*. The differences in microbial community composition between the two sites, despite extreme efforts to create identical habitats, could potentially indicate significant differences in the environmental nutrient cycling and primary productivity between the sites.

Patterns of Mutation in Acid-Evolved Strains of *Escherichia coli*

Author Block:

S. Penix, A. S. Gonzales, A. He, K. Creamer, D. Camperchioli, M. W. Clark, P. Basting, J. L. Slonczewski; Kenyon Coll., Gambier, OH

Abstract Body:

In order to colonize the human gut, the bacterium *Escherichia coli* contends with the acidic environment of the stomach. We previously conducted a 2000-generation laboratory evolution experiment of *E. coli* under moderately acidic conditions (buffered at pH 4.6-4.8), which is at the low end of its growth range. Eight isolates, chosen based on increased growth rates compared to the ancestor, were sequenced and analyzed using the breseq computational pipeline. Each isolate acquired several selected mutations, including strains that had insertions in the *cadC* region. Each sequenced isolate also had one mutation in a subunit of the RNA polymerase holoenzyme (*rpoB* or *rpoC*). Replacement of each of these mutant alleles with the ancestral sequence resulted in minimal fitness decreases in acid. The majority of the acid-evolved isolates showed loss of function of lysine and arginine decarboxylases, which was surprising given that these genes are preferentially expressed under acidic conditions. We hypothesize that the buffered system would make it energetically unfavorable to upregulate decarboxylases, because the reaction would fail to neutralize the buffered acid. Similarly, some of the strains showed a loss of GABA production, suggesting that glutamate decarboxylase, an extreme-acid survival system, was selected against during experimental evolution in acid. Consistent with this observation, the isolates in which GABA is not produced were unable to survive in extreme acid (pH 2) under conditions in which the ancestral strain does survive. In contrast, the isolates retaining GABA production have moderate extreme acid survival levels compared to the ancestral strain. We find evidence of varied phenotypes among the acid-evolved strains, suggesting alternative pathways to adaptive success. However, convergence in RNAP mutations and loss of acid-stress mechanisms suggests the potential predictability of evolutionary outcomes under acidic conditions.

Human Immunodeficiency Virus Evolvability is Affected by Synonymous Nucleotide Recoding

Author Block:

M. A. Martinez, A. Jordan-Paiz, S. Franco, M. Nevot; IrsiCaixa, Badalona, Spain

Abstract Body:

Background: Human immunodeficiency virus type 1 (HIV-1) populations, like other RNA viruses, are described as a closely related mutant spectra or mutant clouds termed viral quasispecies. Mutant cloud composition can impact virus evolvability, fitness and virulence. The influence of codon choice in population diversity and evolvability of RNA viruses remains poorly explored.**Methods:** We compared the development of HIV-1 resistance to protease inhibitors (PIs) of wild-type (WT) virus and a synthetic virus (MAX) carrying a codon-pair re-engineered protease sequence with 38 (13%) synonymous mutations. WT and MAX viruses replicated indistinguishably in MT-4 cells or PBMCs. To explore the evolvability of the codon pair re-coded protease, WT and MAX viruses were subjected to serial passages with the selective pressure of PIs [atazanavir (ATV) and darunavir (DRV)].**Results:** After the same number of successive passages in MT-4 cells in the presence of PIs, WT and MAX viruses developed phenotypic resistance to PIs (IC50 14.63±5.39 nM and 21.26±8.67 nM, for ATV; and IC50 5.69±1.01µM and 9.35±1.89 for DRV, respectively). Sequence clonal analysis showed the presence, in both viruses, of previously described resistance mutations to ATV and DRV. However, a different resistance variant repertoire appeared in the MAX virus protease when compared to WT. The G16E substitution was only observed in the WT protease while the L10F, L33F, K45I, G48L and L89I substitutions were only detected in the re-coded MAX protease population. The influence of the G48L mutation, which is extremely rare *in vivo*, on viral fitness was explored and the results obtained will be discussed.**Conclusions:** The differences in the mutation pattern that emerged after PIs treatment suggested that WT and MAX virus proteases occupy different sequence spaces. A particular sequence space can delineates the evolution of its mutant spectra.

Environmental Stress Selects Functional Quorum Sensing System in *Pseudomon asaeruginosa*

Author Block:

R. García Contreras[1], P. Castañeda Tamez[1], M. Saucedo-Mora[1], T. Maeda[2], T. K. Wood[3]; [1]Natl. Autonomous Univ. of Mexico, Mexico City, Mexico, [2]Kyushu Inst. of Technology, Kitakyushu, Japan, [3]Pennsylvania State Univ., State College, PA

Abstract Body:

Background: Quorum sensing (QS) is widespread in bacteria, including *Pseudomonas aeruginosa*, responsible for 10% of nosocomial infections. QS allows the coordination of gene expression for the production of virulence factors like exoproteases, phenazines, and siderophores that are secreted to the environment, therefore these compounds are public goods available for all the individuals of the population. Those individuals that utilize public goods but do not contribute in their production are social cheaters , and they commonly appear in human infections in the form of *lasR* mutants that are unable to sense the main QS autoinducer signal, N-(3-oxo-dodecanoyl) homoserine lactone. Remarkably, the overexploitation of the cooperative individuals by social cheaters has the potential to create a “tragedy of the commons” therefore collapsing growth of the whole population; hence, it is interesting to determine how QS systems are maintained in bacterial populations. In this regard, we previously demonstrated that since QS defective mutants are more susceptible to abiotic stress (oxidative stress by H_2O_2) than wild-type individuals; such common stress provides a means of counter selection against the cheater mutants (3).**Methods:** Here, we explore the role of biotic stress in the form of reactive oxygen species promoting phenazines, competition against other bacterial species and temperate bacteriophages as means of selection for functional QS systems of *P. aeruginosa*. Using competition experiments between mixtures of the wild-type strain and a *lasR rhlR* mutant growing on protein as the sole carbon source as well as phenotypic determination (exoprotease, phenazine, autoinducer production, etc.), **Results:** we were able to show that pyocyanin production selects the wild-type strain and that some bacteriophages that preferentially infect the *lasR rhlR* mutant also select the wild-type, QS-proficient strain. **Conclusions:** Therefore, we speculate these factors maintain the presence of QS systems in bacterial populations in their natural environments, which could be relevant for bacterial ecology as well for the implementation of QS disrupting therapies that are proposed as an alternative to combat bacterial infections .

The Selective Advantage of Synonymous Codon Usage Bias in *Salmonella*

Author Block:

G. Brandis, **D. Hughes**; Uppsala Univ., Uppsala, Sweden

Abstract Body:

Background: The genetic code in mRNA is redundant, with 61 sense codons translated into 20 different amino acids. Individual amino acids are encoded by up to six different codons but within codon families some are used more frequently than others. This phenomenon is referred to as synonymous codon usage bias. The genomes of free-living unicellular organisms such as bacteria have an extreme codon usage bias and the degree of bias differs between genes within the same genome. The strong positive correlation between codon usage bias and gene expression levels in many microorganisms is attributed to selection for translational efficiency. However, this putative selective advantage has never been measured and theoretical estimates vary widely.**Methods & Results:** By systematically exchanging optimal codons for synonymous codons in highly expressed genes we quantified the selective advantage of biased codon usage to range over an order of magnitude, from 0.2 - 4.2 x 10^{-4} per codon per generation.**Conclusions:** These data quantify for the first time the potential for selection on synonymous codon choice to drive genome-wide sequence evolution, and in particular to optimize the sequences of highly expressed genes. This quantification may have predictive applications in the design of synthetic genes and for heterologous gene expression in biotechnology.

Calculating Evolvability of Sialidase and Vlha from Avian Mycoplasmas in a Host Habitat Setting

Author Block:

M. A. MAY[1], N. Mullen[1], K. Pflaum[2], n. Ferguson-Noel[3], E. Tulman[2], D. Brown[4], S. Geary[2]; [1]Univ. of New England, Biddeford, ME, [2]Univ. of Connecticut, Storrs, CT, [3]Univ. of Georgia, Athens, GA, [4]Univ. of Florida, Gainesville, FL

Abstract Body:

The evolvability of a trait is its capacity to permanently change, most notably in response to diversifying natural selection. Naturally occurring evolvability as calculated by comparing selection values between homologous genes whose traits are exposed to different selective pressures. The avian pathogens *Mycoplasma synoviae* and *Mycoplasma gallisepticum* are often found in co-infections, and their genomes show extensive evidence of horizontal gene transfer. Two horizontally transferred virulence-associated traits, sialidase activity and members of the variable adhesin family VlhA, have previously been shown to be under diversifying selection in *M. synoviae* and stabilizing selection *M. gallisepticum* across diverse strains in *in vitro* culture. To test the hypothesis that these traits are significantly evolvable in *M. synoviae* and not *M. gallisepticum*, we examined the phenotypic, genotypic, and evolutionary adaptations in single strains of each species following passage through their host habitat. Isolates from a single point-source introduction of *M. synoviae* into a poultry flock were collected over a period of eighteen months, and isolates showed significant ($P<0.01$) variation in sialidase activity and the sialidase and expressed *vlhA* gene were under significant ($P<0.001$) diversifying selection. In contrast, the siaidase gene of *M. gallisepticum* retained 100% identity and its expression level remained unchanged during experimental infection of white leghorn chickens. Changes in the expressed *vlhA* allele occurred during infection; however, *post vivo* analysis demonstrated immediate reversion to an allele that was under strong stabilizing selection. Selection (ω) values from *M. synoviae* and *M. gallisepticum* were used to calculate Evolvability (E) values for each trait. Similar to *in vitro* analyses with diverse strains, sialidase and VlhA were demonstrated to be significantly ($P<0.05$) evolvable traits when expressed by *M. synoviae* following *in vivo* passage. To our knowledge, this is the first mathematical and functional demonstration of evolvability of bacteria occurring in a natural (non-experimental) habi

Rna Recombination and Mutation Enhance Adaptability During Acute Viral Infection

Author Block:

S. Bianco[1], Y. Xiao[2], I. Rouzine[2], R. Andino[2]; [1]IBM Almaden Res. Ctr., San Jose, CA, [2]Univ. of California San Francisco, San Francisco, CA

Abstract Body:

Background: While a high mutation rate fuels evolution, it also generates deleterious mutations. Recombination may resolve this paradox, alleviating the effect of clonal interference and purging deleterious mutations. **Methods:** We identify a poliovirus recombination determinant and generatea panel of variants with distinct mutation rates and recombination ability.**Results:** We find that recombination is essential to enrich the population in beneficial mutations and purge it from deleterious mutations. Strikingly, the concerted activities of mutation and recombination are key to virus spread and virulence in an infected animal. These experiments inform a mathematical model that shows that the optimal mutation rate in RNA viruses is determined by the trade-off between selection and the accumulation of detrimental mutations in the short evolutionary timeframe of acute infection.**Conclusions:** This work provides experimental proof and a conceptual frameworkto define how the interplay between mutation rates and recombination are tuned to promote evolution and adaptation.

Ctr., Seattle, WA, [5]Howard Hughes Med. Inst., Univ. of Washington, Seattle, WA

Abstract Body:

The human gastrointestinal tract is home to a large, complex and diverse community of microorganisms that can confer numerous benefits to its host. Despite high microbial cell densities in the gut ($>10^{12}$ bacteria per gram), the factors known to shape our microbiomes—vitamins, dietary polysaccharides, metabolites, bacteriocins, host IgA—are diffusible and do not depend on cell-to-cell contact. Human-associated Bacteroidetes, one of two major phyla in the gut, encode functional type VI secretion systems (T6SSs). These macromolecular machines enable donor bacteria to inject antibacterial toxins called effectors into neighbouring recipient bacteria in a contact-dependent manner. However, the role of this weaponry in shaping gut microbial dynamics is unknown. Here we report that prominent human symbionts secure their membership within the microbiome through continuous attack on their immediate neighbours. We use bacterial genetics, gnotobiotic mouse studies and mathematical modeling to measure effector transmission rates exceeding one billion events per minute per gram of gut contents in live animals, and uncover strain-specific effector/immunity repertoires that predict inter-strain dynamics in vitro and in vivo. Moreover, we find that neighbouring species in the gut can partially protect sensitive strains from contact-dependent killing, thereby providing a mechanism for strain coexistence in the face of inter-bacterial warfare. Together, these results define a significant role for contact-mediated antagonism between human gut symbionts and may provide new strategies for precision microbiome manipulation.

Relationships between Ammonia-Oxidizing and Nitrite-Oxidizing Bacteria at Low Substrate Concentrations in Freshwater Enrichments

Author Block:

M. Cai, P. K. H. Lee; City Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Nitrification is a vital oxidation process that links the reduced and oxidized inorganic nitrogen to sustain the global nitrogen cycle. Studies have shown that ammonia-oxidizing bacteria (AOB) and nitrite-oxidizing bacteria (NOB) are fastidious and slow growers, and their interactions are sensitive to sudden environmental changes. Previous research investigating the correlations between AOB and NOB have either conducted the experiments at a high ammonium concentration (2.8 to 60 mM) or using isolates of nitrifiers. In this study, we investigated the ecophysiological characteristics and the relationships between freshwater AOB and NOB by enriching AOB cultures with and without NOB at a relatively low ammonium concentration (0.05 to 1.5 mM).The cultures were enriched from freshwater aquarium biofilters over 1.5 years with ammonium as the sole energy source. Community compositions of the enrichments were determined by 16S rRNA gene amplicon sequencing. A positive correlation was found between nitrification kinetics and the ammonium/nitrite and bicarbonate concentrations. The maximum growth rates (μ_{max}) and half-saturation constant (K_m) indicated that the activity of *Nitrobacter*- and *Nitrospira*-like NOB depended strongly on the presence of the *Nitrosomonas*-like AOB and vice versus. Furthermore, the presence of NOB substantially shortened the lag phase of ammonium consumption, indicating that AOB can adapt to environmental changes more efficiently. Enrichments that had the highest growth rates had a lower abundance of targeted genes (*amoA, norA,* and *Nitrospira* 16S rRNA genes) in the quantitative PCR analysis. The lack of correlation between the abundance of nitrifying bacteria and the activity of nitrification indicates the importance of mutualism between the AOB and NOB guilds in determining the activity of the nitrification process. The metagenomes of the enrichments have been sequenced to further elucidate the metabolism of the nitrifying populations. Overall, this study has provided insights into the relationships between the ammonia-oxidizing and nitrite-oxidizing guilds at low substrate concentrations in the freshwater nitrification process.

Multiple Bacteriocin-Producing *Escherichia coli* Isolated from Coastal Marine Sediment in Hong Kong

Author Block:

L. Teh[1], S. C. K. Lau[2]; [1]The Hong Kong Univ. of Sci. and Technology, Kpwloon, Hong Kong, [2]The Hong Kong Univ. of Sci. and Technology, Kowloon, Hong Kong

Abstract Body:

Escherichia coli can produce bacteriocin, which is a kind of toxin protein that is only active against other closely related bacteria. Bacteriocin production is an anti-competitor strategy of *E. coli* for eliminating neighbouring cells that are competing for nutrients and space. *E. coli* may carry multiple bacteriocin genes to expand the killing range of target bacteria and enhance its competitiveness. The coastal marine sediment environment has been reported as a secondary habitat for *E. coli* and bacterial competition between *E. coli* and indigenous microorganisms is the major biotic factor affecting the survival of *E. coli* in the marine sediments. Bacteriocin has been suggested as a tool for *E. coli* to invade an indigenous bacterial community and establish their own niches. However, the occurrence of multiple bacteriocin-producing *E. coli* in this environment has not been studied. This study aimed to investigate the occurrence of multiple bacteriocin-producing *E. coli* in marine sediment and determine the dominant bacteriocin genes carried by these isolates. Both phenotypic and molecular approaches were utilized to investigate the occurrence of multiple bacteriocin-producing *E. coli* from coastal marine sediment. A collection of 48 isolates of *E. coli* originating from marine sediment in Hong Kong was initially screened for bacteriocin producing phenotype using agar overlay method. Twenty-six isolates were observed to be bacteriocin producers. PCR detection of bacteriocin producing genes followed by DNA sequencing of the PCR amplicons indicated that majority (n=22) of the 26 bacteriocin-producing isolates carry multiple bacteriocin genes. Colicin Ib (n=20) and colicin E7 (n=13) were found to be the most common bacteriocin genes. This is the first study to report that multiple bacteriocin-producing *E. coli* are ubiquitous in the marine sediment and that such environmental matrix may serve as a reservoir for these *E. coli*. Based on the results, we hypothesize that the ability to produce multiple bacteriocin might be beneficial for the survival of *E. coli* in marine sediment. Further studies will be conducted to investigate the relationship between the number of bacteriocin genes carried by *E. coli* and its survivability in the coastal marine sediments.

Evolutionary Enhancement of Social Motility: Insights into Interactions among Soil Bacteria

Author Block:

L. M. McCully, L. M. Smith, M. W. Silby; Univ. of Massachusetts Dartmouth, North Dartmouth, MA

Abstract Body:

The soil bacterium *Pseudomonas fluorescens* Pf0-1 is a model for soil survival, persistence, and biocontrol. When co-cultured with the soil bacterium *Pedobacter* sp. V48, a novel "social motility" phenotype emerges, allowing the co-culture to move on a hard agar surface, an environment where the mono-cultures of both species are immotile. Using experimental evolution, we sought to unveil mechanisms underlying social motility in this model community. Motile co-cultures on 2% agar frequently spawn faster-moving sectors, in which one species has evolved to facilitate faster migration. From over 100 sectors emerged from wild-type interactions, 87% of isolates conferring fast social motility were evolved *Pedobacter*. Evolved Pf0-1 have mostly emerged as a second evolutionary step during co-culture with *Pedobacter* strains which already confer faster social motility. While interaction of wild-type Pf0-1 and evolved *Pedobacter* resulted in social motility two times faster than the wild-type co-culture, interaction of evolved strains of both species resulted in a five-fold increase in social motility. Whole-genome sequencing has shown that most emerged *Pedobacter* strains have mutations in a region of genes related to polysaccharide biosynthesis; repeated selection of such mutants identifies this locus as important for enhancing social motility. Many of these strains have a mucoid phenotype, indicating probable overproduction of extracellular polysaccharides, and implicating EPS as a key driver of social motility. Transcriptomic analysis on mono- and co-cultures of evolved and wild-type strains show a broad range of changes in gene expression in both species. This analysis is beginning to reveal pathways that are altered as a consequence of evolutionary selection. In *Pedobacter*, many genes were upregulated in the polysaccharide biosynthesis locus, reiterating its importance in social motility. In Pf0-1, we observed changes in core aspects of carbon metabolism, as well as changes in flagellar assembly. These studies are revealing novel ways by which these two bacteria communicate and behave, providing new insight into how members of complex soil communities interact. Our research may also lead to development of bacterial communities as biocontrol agents, and approaches to enhance the colonization of biotic surfaces in the rhizosphere.

Redefining 'Core' Microbiome by Evaluating the Functional Role Microorganisms Play in the Assembly and Structure of Their Microbial Community

Author Block:

C. E. Brumlow[1], J. M. Carlson[1], E. Hollister[2], E. Hyde[3], J. Petrosino[2], T. P. Primm[1]; [1]Sam Houston State Univ., Huntsville, TX, [2]Baylor Coll. of Med., Houston, TX, [3]Univ. of California at San Diego, La Jolla, CA

Abstract Body:

Background: Our model vertebrate system for studying the recovery of a mucosal microbiome following a disruption event uses the Western mosquitofish, *Gambusia affinis*. The skin microbiome of *G. affinis*, unlike terrestrial animals, is mucosal and also directly accessible through the water column. This allows for non-invasive disruptions to the external microbiome and rapid sampling. **Methods:** In order to understand what drives microbiome community structure, recovery following two different disruptions was analyzed. A severe point-disruption involved rinsing fish until skin-derived bacterial culturable numbers were greatly reduced. At various time-points after the serial rinse, the skin microbiome of *G. affinis* was sampled and compared to an undisturbed, pre-treatment (PT) control sample. In a separate experiment, a group of fish were exposed to the antibiotic rifampicin in the water column for 3 days and then monitored during recovery. **Results:** After both disruptions culturable numbers drop >99.5% but rapidly recover to exceed the PT density before settling to a level comparable to PT. A profile of 20 community biochemical activities were altered by the disruptions, but returned to patterns similar to PT. In contrast, 16S profile revealed community composition did not return to PT taxa distributions as measured by principal components analysis. During succession of the microbial community after the disruptive events, a single taxa (genus *Myroides* after drug treatment, family *Aeromonadaceae* after physical rinse) dominates early (>80% abundance at 48 hrs), then consecutively declines. **Conclusion:** This data preliminarily supports the hypothesis that the functional roles of organisms within the microbial community may be more important than the taxonomic structure, which agrees with the major finding from the Human Microbiome Project that while community compositions from one body location vary widely between individuals, the biochemical pathways in those communities are remarkably similar.

Impact of Road Salt Runoff on Soil Microbial Communities

Author Block:

K. Baker[1], J. Felker[2], A. Bowers[1], Z. Wummer[1]; [1]Penn State Harrisburg, Middletown, PA, [2]Penn State Berks, Reading, PA

Abstract Body:

Background: Roads are the dominant engineered feature in the US landscape. In most urban and suburban areas, it is unlikely that a individual at any location would be greater than 1 mile from a road surface. And yet, because of their ubiquity and utilitarian purpose, roads are inadequately addressed as sources of runoff impacting the surrounding environment. Many roads are heavily "salted" with deicing substances during the winter months and much of the salt is carried to surrounding areas via runoff and infiltration. Recently, transportation engineers have expressed concern regarding the impact of salt (NaCl) on soils and groundwater. We have investigated the impact of road salt on indigenous soil populations in roadside soils and on the persistence and transport of *E. coli* within these soils. **Methods:** Microcosms were constructed using an engineered sandy-loam soil. The microcosms were watered with artificial storm water (ASW) or with ASW supplemented (ASWS) with road salt. Several of the microcosms watered with ASWS were spiked initially with *E. coli* (10^4 CFU). The applied solutions drained through the microcosms and the resulting leachate was aseptically collected and analyzed for total heterotrophs (viable counts), *E. coli* (MPN), inorganic nutrients (N, P, salinity and trace metals) and hydraulic characteristics (flow).**Results and Conclusions:** Heterotrophic populations remained stable throughout the entire study with no significant differences between systems receiving ASW or ASWS. Although there was no change in the number of microorganisms in the leachate, there were significant changes in the hydraulic characteristics of the soil. Flow was significantly slower in microcosms watered with ASWS possibly reflecting either the development of microbial biofilm, changes in soil structure, or a combination of both of these factors.The presence of added *E. coli* had no effect on the numbers of total heterotrophs in the leachate. *E. coli* persisted in the spiked microcosms watered with ASW throughout the one month study, but declined to non-detectable levels within 2 – 3 weeks in microcosms receiving ASWS.

Factors Affecting Growth of Difficult-to-Culture Oral Bacteria

Author Block:

S. R. Vartoukian[1], F. E. Dewhirst[2], W. G. Wade[1]; [1]Barts and The London Sch. of Med. and Dentistry, Queen Mary Univ. of London, London, United Kingdom, [2]The Forsyth Inst., Cambridge, MA

Abstract Body:

Background: Many oral bacterial species grow poorly on conventional bacteriological media. It has been suggested that growth may be inhibited by hydrogen peroxide in culture media when agar and phosphate are autoclaved together. In addition it is known that acid produced by some bacteria from glucose in culture media may inhibit the growth of other bacteria. The aim of this study was to assess the growth of difficult-to-culture oral bacteria on culture media with and without added glucose and to investigate the substitution of agar in media by gellan gum.**Methods:** *Tannerella forsythia* SP9_20 was cultured on Blood Agar Base No. 2 (BA) and Fastidious Anaerobe Agar (FAA), both supplemented with 5 % horse blood with and without cross-streaks of *Propionibacterium acnes*, and a paper disk soaked with glacial acetic acid for 7 d anaerobically. *T. forsythia* SP9_20, *Anaerolineae* bacterium HOT-439 SP9_5, and *Bacteroidetes* bacterium HOT-365 SP18_29_14 and SP18_29_15 were grown on a BHI-peptone based medium incorporating either 1.0% gellan gum (G) or 1.5% agar (A), and on BA, with *P. acnes* and *Fusobacterium nucleatum* cross-streaks. Growth was graded from - to +++ after 10 and 25 days incubation.**Results:** Independent growth of *T. forsythia* was stronger on FAA (++) than BA (+). In co-culture with *P. acnes* on FAA, a 9-mm zone of inhibition and area of haemolysis was seen around the *P. acnes* streak. A similar zone of inhibition was seen around the acetic acid disk.*T. forsythia* SP9_20, *Anaerolineae* HOT-439 SP9_5, and *Bacteroidetes* HOT-365 SP18_29_14 and SP18_29_15 showed weak growth (+) on BA and no growth (-) on G or A. When cultured with *P. acnes* or *F. nucleatum*, *T. forsythia* SP9_20, *Bacteroidetes* HOT-365 SP18_29_14 & *Anaerolineae* HOT-439 SP9_5 showed stronger growth on G (++, ++ & + respectively) than A (+, - & -), but weaker growth compared to BA (+++).**Conclusions:** Growth of *T. forsythia* is inhibited by acid produced by other bacteria in glucose-containing media. Replacing agar with gellan gum moderately enhances the growth of difficult-to-culture oral bacteria but dependence on helper strains remains a primary growth determinant.

Interspecific Interactions among Meat Spoilage-Related Lactic Acid Bacteria: Insights from the Transcriptome Profiling

Author Block:

M. Andreevskaya, P. Johansson, E. Jääskeläinen, R. Rahkila, T. Nieminen, L. Paulin, J. Björkroth, P. Auvinen; Univ. of Helsinki, Helsinki, Finland

Abstract Body:

Spoilage of modified-atmosphere packaged (MAP) meat is caused by the activity of several bacterial species, mainly lactic acid bacteria (LAB), which form a microbial community. Taking into account the differences in growth rates of spoilage LAB as pure cultures, it is not clear how the LAB with slower growth rates can maintain themselves in actively growing co-cultures in meat. We assume that these LAB, being a part of a common microbial community, might have different metabolism from that in pure culture, which would lead to enhanced growth in co-cultures. However, since most of the studies on bacteria have been done so far in pure culture, little is known about bacterial interspecific interactions in general. In the present study we explore the interactions among three LAB: *Leuconostoc gelidum* subsp. *gasicomitatum* (*Lg*), *Lactococcus piscium* (*Lp*) (both are predominant species in spoiled MAP meat) and *Lactobacillus oligofermentans* (spoilage-associated) using the comparison of RNA-seq based transcriptome profiles of their co-cultures (three pairs and the triplet) and pure cultures at three time points. Preliminary data analysis for the mixed culture of *Lg* and *Lp* revealed that for both species differentially expressed (DE) genes were distributed across multiple functional categories with "carbohydrate and amino acid metabolism" and "transcription" being most affected. Numbers of DE genes determined at the three time points indicate that in co-culture *Lg* adjusted its metabolism earlier than *Lp*. In *Lg*, the growth in mixed culture led to early downregulation of stress protection genes and dramatic shift in glucosamine metabolism from cell wall formation to energetic catabolism. As for *Lp*, the upregulation of several stress-related genes and downregulation of sugar transport were observed. Peculiarly, in both bacteria malolactic enzyme genes exhibited similar expression changes: at first they were upregulated in co-culture and later on downregulated. The metabolic role of malolactic fermentation is still unclear in these LAB genera. To conclude, the findings suggest that coexistence of only two bacterial species already requires global rearrangements in their gene expression. Currently, the transcriptome profiles of other mixed cultures are being analysed.

Cheating Fosters Species Co-Existince in Well-Mixed Bacterial Communities

Author Block:

A. Leinweber[1], F. Inglis[2], R. Kümmerli[1]; [1]Univ. of Zurich, Zurich, Switzerland, [2]Washington Univ., St. Louis, MO

Abstract Body:

Most habitats on earth are populated by diverse bacterial communities. Explaining this high biodiversity is, however, challenging because competition between species occupying the same niche is predicted to lead to the exclusion of inferior community members. Spatial structure has been suggested to stabilize diversity by separating competitors from each other. Alternatively, it has been proposed that the strength of dominant competitors could be weakened through within-species competition, which in turn can relax between-species competition and foster species co-existence. Here, we test these two hypotheses using experimental communities of *Pseudomonas aeruginosa* and *Burkholderia cenocepacia*, two bacterial species naturally co-occurring in soil and human opportunistic infections. First, we manipulated the spatial structure of our communities by growing the bacteria in medium with varying viscosities. Using a mixture of competition assays and experimental evolution, we found that spatial structure did not promote species co-existence: *P. aeruginosa* always eradicated *B. cenocepacia*. Next, we introduced within-species competition by adding a P. *aeruginosa* cheating mutant to co-cultures, which can exploit the iron scavenging siderophores secreted by the wildtype PA under the iron-limited conditions. We found that this form of within-species competition indeed weakened the competitive strength of *P. aeruginosa* towards *B. cenocepacia*, and fostered species co-existence under well-mixed conditions.Taken together, our experiments identify within-species cheating as a novel mechanism, which can promote bacterial biodiversity in habitats with low spatial structuring as for example occurring in marine ecosystems.

Identifying Factors Involved in Interspecies Social Motility

Author Block:

L. M. Smith[1], S. C. Seaton[2], L. M. McCully[1], S. B. Levy[3], M. W. Silby[1]; [1]Univ. of Massachusetts Dartmouth, North Dartmouth, MA, [2]Univ. of North Carolina Asheville, Asheville, NC, [3]Tufts Univ. Sch. of Med., Boston, MA

Abstract Body:

Novel phenotypes emerge upon laboratory co-culturing of the soil bacteria *Pseudomonas fluorescens* Pf0-1 and *Pedobacter* sp. V48, namely 'social motility', the elicitation of movement when strains are in close contact. Identifying genes and pathways involved is key to unraveling mechanisms of this interspecies interaction. Pf0-1 mutants with altered social motility were identified through a transposon screen, highlighting genes related to a secretion system, flagellar assembly, and pili production. Hits in components of a Type 6 Secretion System (T6SS) led to impaired social motility, suggesting that this contact-dependent system, which relies on passing effectors from donor to recipient cell, plays a role in the interaction of these bacteria. Disruption of Pf0-1 flagellar and pilin genes suggests that these structures may not be required for social motility. We sought to decipher the role of T6S, flagella, and pilin in social motility. Strains were engineered with deletions of genes encoding putative VgrG proteins, secreted components of the T6SS. Some exhibit small changes in social motility, indicating that they may be exerting an effect on the interaction. Changes from different effector mutations and the presence of several predicted VgrG may indicate redundancy, possibly requiring multiple deletions to exhibit strong changes in phenotype, or the association of additional effectors to elicit a stronger response. To address the role of flagella in social motility, *fliC* was targeted, as it encodes the main structural component of flagella. Disruption of *fliC* abolishes social motility. Together with our transposon data, this suggests that while swimming motility is not required for social motility, the presence of flagella or flagellin in Pf0-1 is required. Likewise, deletion of *pilM* renders Pf0-1 defective for social motility, indicating that the movement is distinct from Type IV pili-mediated twitching motility. Together, these findings refine important factors involved in this interspecies interaction. Understanding social motility may facilitate the increased effectiveness of colonization of potential biological control agents on plant tissues, as well as providing insight into the mechanisms of interspecies interactions in microbial communities.

Antibiotic Resistance Ecology in a Mutualistic Bacterial Community

Author Block:

B. Adamowicz, W. Harcombe; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Background: Although multispecies bacterial communities are common, our understanding of how species interactions influence microbes' survival and adaptation to stressful environments is limited[1]. Bacteria often obtain essential metabolites from the excretions of other species; in multispecies growth conditions, this dependency should modulate effective sensitivity of cooperating species to stressors such as antibiotics[2]. Specifically, we predict that, in obligate metabolic mutualisms, the effective minimum inhibitory concentration (MIC, the concentration at which no growth is observed) of each species will be lowered to that of the most sensitive species.**Methods**: We have genetically engineered an obligate metabolic mutualism between strains of *Escherichia coli*, *Salmonella enterica*, and *Methylobacterium extorquens* such that, when grown in minimal medium, each species requires a metabolite excreted by a partner to survive[3]. We then determined the MIC for monocultures by OD600 and species-specific fluorescent markers in shaken cultures, and compared this to the MIC observed for the community.**Results:** In tetracycline, community MIC was driven by the most sensitive community member as predicted. *S. enterica* was the most resistant in monoculture growth, with an MIC of >25 µg/mL; this decreased in community growth to 2µg/mL, which matched the monoculture MICs of *E. coli* and *M. extorquens*. In ampicillin, however, the MIC of the most sensitive community member, *S. enterica*, increased from 2µg/mL in monoculture to 5µg/mL in community. This suggests that, in contrast to our hypothesis, community growth protected the most sensitive member rather than being limited by it. However, as predicted, the MIC of *M. extorquens* was decreased in community growth (50µg/mL in monoculture to 5µg/mL in community) due to greater ampicillin sensitivity of its metabolic partners.**Conclusions:** Metabolic cross-feeding altered the effective MIC of bacteria to antibiotic stressors. Further work is needed to determine the mechanisms underlying these effects, particularly in growth in ampicillin, where community growth appears to be protective for sensitive species. Understanding how microbial species interactions influence response to stressors is critical for our understanding of eco-evolutionary dynamics in addition to having significant implications for the treatment of polymicrobial infections.

The Effect of Increased Viscosity on Chemotaxis of *Bacillus* spp. Isolated from Songbird Plumage

Author Block:

M. Vroom, L. Tuhela; Ohio Wesleyan Univ., Delaware, OH

Abstract Body:

The plumage of birds is an ecosystem that harbors a diverse community of microbes including *Bacillus* spp., some of which are known to utilize feathers as the sole source of carbon, nitrogen, and sulfur by secreting keratinase enzymes that degrade β-keratin. *Bacillus* spp. are motile, chemotactic bacteria. Thus, amino acids from damaged parts of feathers could act as chemoattractants for plumage-dwelling *Bacillus* spp. Uropygial oil is used by birds as they preen and is thought to protect plumage from bacteria although not all uropygial oil has antibacterial properties. In this study, the inhibitory effect of increased viscosity on *Bacillus* chemotaxis was quantified to investigate the possibility that uropygial oil functions as a viscous physical barrier to inhibit the chemotaxis of feather-degrading *Bacillus* towards damaged areas on bird feathers, thereby preventing further deterioration. Motility assessments were conducted for over 60 *Bacillus* isolates obtained from songbird plumage via wet mount. Growth curves in coordination with hourly estimates of motility were subsequently performed. From these data, *Bacillus* 4201TV, which exhibited a maximum of 85% motility at 10 hours in the log phase, was chosen for chemotaxis assays. The chemotaxis of *Bacillus* 4201TV was quantified via capillary assays in modified Palleroni chambers. The amino acids of β-keratin tested as chemoattractants were proline, valine, and asparagine at concentrations of either 250 μM and 750 μM. *Bacillus* 4201TV exhibited a positive chemotactic response towards proline, valine, and asparagine at both concentrations with the greatest response ratios at 750 μM. To determine the effect of increased viscosity on chemotaxis, dual quantitative chemotaxis assays were performed using 750 μM proline or asparagine as chemoattractants, and an increase in viscosity was achieved by preparing the amino acids in 0.05% agar. Conditions of increased viscosity reduced the chemotactic response of *Bacillus* 4201TV toward 750 μM proline and asparagine by 41% ($p = 0.31$) and 97% ($p = 0.04$), respectively. The asparagine data suggest that the viscosity of uropygial oil may function as a physical barrier to inhibit the chemotactic movement of feather-degrading *Bacillus* spp. towards areas of feather damage, thus protecting bird plumage.

Interactions between the Human Pathogen *Vibrio parahaemolyticus* and Marine Cyanobacteria

Author Block:

I. B. Gartmon, S. L. Klein, C. R. Lovell; Univ. of South Carolina, Columbia, SC

Abstract Body:

Vibrio parahaemolyticus is an opportunistic human pathogen that occurs naturally in brackish environments. This organism grows fastest in warm waters and with rising surface water temperatures, outbreaks of this organism are increasing in size and frequency. *V. parahaemolyticus* distributions are strongly correlated with blooms of marine phytoplankton, but specific interactions between abundant bloom forming marine cyanobacteria and *V. parahaemolyticus* have not been determined. The Type VI secretion system (T6SS), a *V. parahaemolyticus* virulence feature that permits injection of cytotoxic effector proteins into host cells, is thought to be activated in marine conditions. Studies to date have indicated that T6SS targets bacteria, potentially including cyanobacteria, and this study examined the frequency of the T6SS in environmental *V. parahaemolyticus* strains, using the T6SS marker gene *vipA1*. We also examined the nature of the relationship between *V. parahaemolyticus* and cyanobacteria. Thirty two environmental strains of *V. parahaemolyticus* were screened for *vipA1* and ten (31%) of these strains contained this gene. We infected cultures of two common species of cyanobacteria (*Procholorococcus marinus* and *Synechococcous bacillaris*) with different *V. parahaemolyticus* strains (some lacking T6SS, some with T6SS) and monitored cyanobacterial biomass via chlorophyll *a* fluorescence. We also tested the well known clinical *V. parahaemolyticus* strain por1 (T6SS +) as well as two deletion mutants, por1Δhcp1 (T6SS -) and por1Δhns (T6SS derepressed). *V. parahaemolyticus* stimulated the growth of both cyanobacteria species, regardless of its content of T6SS. *V. parahaemolyticus* is known to cause damage to eukaryotic microalgae, but we did not detect significant damage to the cyanobacteria despite the presence in *V. parahaemolyticus* of mechanisms that could produce damage. Stimulation of blooms of cyanobacteria could result in release of carbon and energy resources that might support elevated *V. parahaemolyticus* cell densities with a correspondingly greater threat to human health.

Microbial Interactions Lead to Rapid Microscale Successions on Model Marine Particles

Author Block:

M. S. Datta[1], E. Sliwerska[2], J. Gore[1], M. F. Polz[1], O. X. Cordero[1]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]ETH Zurich, Zurich, Switzerland

Abstract Body:

Background: Marine particles are nutrient rich microhabitats for dense microbial communities whose collective actions shape the fate of fixed carbon in the ocean. Although particular traits have been identified that allow marine bacteria to exploit particles (for instance, motility and exo-enzyme production), it remains unclear how community dynamics emerge from these traits, particularly in a complex microbial milieu like the ocean. We developed a model system that allowed us to track the dynamics of particle colonization with high spatiotemporal resolution and to explore the underlying drivers of these dynamics via culture-dependent and -independent approaches.**Materials:** We simulated POM with micro-particles made of chitin - a highly abundant biopolymer in the ocean - and incubated them in coastal seawater. Over nearly six days, bacteria from the surrounding seawater self-assembled into communities on the chitin particle microhabitats. At discrete time points, we harvested large pools of particles with which we performed 16S rRNA amplicon sequencing to reconstruct their average community assembly dynamics. Subsequently, we combined metagenomic sequencing with phenotypic assays to characterize the metabolic and behavioral traits underlying these dynamics.**Results:** Particle-associated bacterial communities underwent rapid, highly reproducible community turnover over six days. Although community turnover occurred continuously, we identified three discrete phases of colonization. Following initial stochastic colonization (Phase I), bacterial taxa enriched in chitin metabolism and rapid dispersal ability swept the communities (Phase II). In contrast, Phase III taxa could not metabolize chitin, but instead, consumed carbon sources produced in Phase II, thus marking a community-wide shift in metabolism away from chitin towards other nutrient sources.**Conclusion:** Our results demonstrate that marine bacterial communities assembled on model particles undergo rapid turnover, shifting from a community capable of degrading the particle substrate to one that cannot in a matter of hours. The timescale of this transition could influence the balance between organic matter consumption and biomass buildup, potentially a key factor shaping particle remineralization rates in the ocean.

Biotic Interactions Drive The Rapid Evolution of Penicillium On Cheese

Author Block:

E. A. Landis, I. Bodinaku, B. E. Wolfe; Tufts Univ., Medford, MA

Abstract Body:

Rapid microbial evolution is generally assessed in pure microbial cultures without the influence of neighboring microbes. But in naturally forming communities, microbes contend with competitors as well as fluctuations in resource availability, both of which could influence the rate and direction of evolution. In order to test the influence of biotic interactions, we serially transferred three wild strains of *Penicillium* onto nutrient-rich cheese curd agar both alone (- community) and with three neighboring microbes (+ community). We selected three mutant classes which differed from their ancestor strain in regards to color and spore production, and measured production of the mycotoxin cyclopiazonic acid. We then sought to identify genetic changes underlying differences in phenotype by using comparative genomic sequencing of relevant genes for one ancestral strain and three of its mutants. The effect of adding neighbors in the + community treatment was strain-dependent, with neighbors decreasing the frequency of mutants in two of the three strains we measured. In the three mutant classes we selected, spore production was significantly decreased in all mutants compared to the ancestor. In some mutants, production of cyclopiazonic acid was reduced to below detectable levels (<100 ppm). We were unable to identify any genetic changes underlying these differences, suggesting that phenotypic changes in *Penicillium* mutants may be due to changes in regulatory pathways. Understanding the nature of rapid microbial evolution in novel environments could illuminate the origins of microbial foods and inform how pathogenic microbes adapt to food systems.

Diverse Germination Interactions Among Streptomyctetes

Author Block:

K. Vetsigian, **Y. Xu**; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Bacteria live in crowded and diverse communities and exhibit a wide range of social behaviors mediated by diffusing chemicals. While many types of interactions have been exhaustively studied, little is known about how the germination decisions of individual spores are affected by the activities of their microbial neighbors. In particular, it is currently unknown how widespread or diverse microbial germination interactions are, and there has been no systematic investigation of the spatial and temporal correlations of germinations they cause in communities of spores.Focusing on bacteria from the genus Streptomyces, we developed a high-throughput platform for automated quantification of spore germination on 2D surfaces through time-lapse microscopy. Our platform provides a full picture of germination events and subsequent mycelium growth for many thousands of individuals and allows monitoring of multiple communities in parallel. Fluorescent labeling allows us to investigate single- and two-species communities. By monitoring how the germination probability as a function of time is affected by the spore density and the germination of neighboring spores from same or different species, we quantified the germination interactions among a panel of Streptomyces strains.All species investigated had distinct germination interactions. While germinating spores from some species promoted the germination of their sister spores, other species inhibited their own germination and still others exhibited no interactions. We also discovered strong positive and negative inter-species interactions. These interactions could be reproduced with supernatants from newly germinated spores, which indicated that they are mediated by defusing chemicals. We also discovered that as spores of certain species age they enter a state of deep dormancy that can be fully reversed by chemicals released during germination.This work reveals that, similarly to small molecule interactions at the onset of sporulation, germination interactions among Streptomyces are common and diverse. Thus, bacterial germination is commonly affected by the community context, and different species have adapted different germination strategies. We expect our findings will trigger further activity aiming at determining the nature and diversity of the chemicals mediating the interactions and the ecological contexts favoring different germination strategies.

***pectobacterium Brasiliensis* gains A Competitive Advantage Within The Ecological Niche By The Production Of An Antimicrobial Molecule**

Author Block:

A. Durrant[1], A. Pitman[2], A. Mendoza[1], P. Fineran[3]; [1]Lincoln Univ., Lincoln, New Zealand, [2]Plant and Food Res., Lincoln, New Zealand, [3]Univ. of Otago, Dunedin, New Zealand

Abstract Body:

Background: *Pectobacterium* spp. are important pathogens that influence productivity of the potato industry, causing crop damage both in the field and post-harvest. The predominant pathogen was, until recently *Pectobacterium atrosepticum* (*Pba)*. However, *P. brasiliensis* (*Pbr*), has emerged as a more prevalent and aggressive pathogen [1]. The method by which *Pbr* has displaced *Pba* is unknown. Both bacterial species are routinely isolated together from fields[2], therefore, interactions are likely to occur between the two species. Few studies have focused on competition between two plant pathogens.**Methods:** Competition assays were conducted i*n vitro* and *in planta* between *Pbr* ICMP 19477 and *Pba* SCRI1043. A mutant library was produced for *Pbr* using random transposon mutagenesis and the mutants screened for the inability to out compete *Pba.* The disrupted genes were identified by next generation sequencing. Molecular and microbiology techniques were routinely used to further investigate the role of the identified genes on the competition phenotype of *Pbr* ICMP 19477. **Results:** *Pbr* ICMP 19477 produces a zone of inhibition when grown with *Pba* SCRI1043, indicative of the production of a diffusible antimicrobial molecule. Competition between the bacteria was established *in vitro* and *in planta*, with a greater affect seen in potato tubers. Four *Pbr* ICMP 19477 mutants were identified that did not produce a zone of inhibition. The disrupted genes were identified to be involved in quorum sensing regulation of carbapenem production. These mutants were significantly reduced in competition against *Pba* SCRI1043 in potato tubers. The wild type phenotype was restored by gene complementation.**Conclusions:**In mixed infections, *Pbr* ICMP 19477 out competes *Pba* SCRI1043 by actively inhibiting its growth by the production of a carbapenem molecule. It appears that carbapenem production is an important mechanism by which *Pbr* ICMP 19477 succeeds in its environmental niche. Therefore, this may contribute to the emergence of *Pbr* ICMP 19477 as a pathogen.

Examining Bacterial Coexistence Among Members of the *Arabidopsis thaliana* Root Microbiome

Author Block:

M. J. Powers, J. L. Dangl, E. A. Shank; Univ. of North Carolina, Chapel Hill, Chapel Hill, NC

Abstract Body:

The plant root represents a topologically distinct environment that harbors significant bacterial diversity. These bacteria live in close proximity within the root's endophytic compartment or adhered to the root surface. We predict that bacterial interactions will therefore contribute to how root-associated bacteria colonize and persist in this complex community. To investigate this hypothesis, we explored co-culture interactions between 16 bacteria isolated from *Arabidopsis thaliana* roots, selecting a group of phylogenetically and functionally diverse bacilli, pseudomonads, and actinobacteria. Using combinations of four bacteria, we tested 210 different combinations in a liquid growth competition assay. Strain survival was determined by dilution plating, which was possible based on the distinct colony morphologies of these strains. Interactions were then classified as either coexistence (two or more strains survived) or dominance (one strain dominates). Based on a 16S rRNA gene relatedness metric, we used hierarchical clustering to categorize the 210 combinations into either high diversity combinations or low diversity combinations. In the high diversity group, the percentage of interactions that resulted in coexistence was 88%, whereas in the low diversity group, 58% of the interactions resulted in coexistence. These distributions differ significantly (Two Sample Proportions Test, $p < 0.001$). Thus, bacterial coexistence in liquid cultures appears strongly correlated with higher genetic diversity of the combined strains. In addition, approximately 43% of the combinations in the high diversity group were instances where three or four strains coexisted, compared to only 19% within the low diversity group. This observed trend between bacterial coexistence and increasing genetic diversity could potentially begin to explain the stability and functionality of root microbial communities. We are now determining whether our *in vitro* co-culture results can predict the ability of these bacteria to coexist in an *in planta A. thaliana* root colonization assay. Understanding these bacterial interactions in both an *in vitro* and *in planta* context will allow us to use chemical and genetic approaches to tease apart putative mechanisms for these interactions and their role in microbiome ecology.

Mechanisms Of Microbial Community Assembly Across A Plant-Based Food System

Author Block:

E. R. Miller, B. E. Wolfe; Tufts Univ., Medford, MA

Abstract Body:

Use of molecular techniques in the phyllosphere has begun to shed light on patterns of microbial community composition, however the ecological processes shaping community structure are not well described. For vegetable fermentations, understanding the drivers of microbiome assembly is essential as successful fermentation relies on the presence of a key group of bacteria, the lactic acid bacteria (LAB). In this study, we developed a system to begin to identify ecological drivers of phyllosphere community composition in cabbages used for vegetable fermentation and how differences in the initial phyllosphere community results in changes in the final fermented vegetable product. Using three types of cabbage (Napa Savoy and red) at three sites in the Boston Area we determined the relative roles of host and geography in shaping phyllosphere community abundance and composition. Both site and cabbage variety influenced the overall bacterial abundance for the individual plants, although when looking solely at LAB there was no difference between site and variety. We then fermented the Napa cabbages from each of the three sites using an in vitro fermentation system to determine how phyllosphere community composition impacts fermentation dynamics. The pH of all ferments dropped rapidly suggesting a shift in microbial community composition to favor growth of the LAB. This shift was coupled with a change in the abundance of CFUs. Site differences in abundance were detected with the rural site taking longer for the pH to drop and having an overall lower CFU count at the end of the fermentation process. Ongoing work using amplicon metagenomic sequencing is determining the compositional shifts associated with the observed differences in abundance in the phyllosphere and fermentations. Lactic acid bacteria play the main role in vegetable ferments but are typically not added as a starter culture. Our work shows that reliance on naturally occurring lactic acid bacteria that are variable across space and plant varieties could have implications for the quality and safety of fermented vegetables.

Genome-Wide Identification Of *streptococcus Sanguinis* H_2o_2 Production And Regulation Genes Involved In Community Invasion Resistance

Author Block:

D. Ferrer, X. He, W. Shi; Univ. of California-Los Angeles, Los Angeles, CA

Abstract Body:

Foreign microbes are constantly entering and leaving the oral cavity, yet it remains stable with a relatively constant community of microbes. Using mouse oral flora as a model system, we recently identified a bacterial consortium comprised of three key species with distinct roles: the "sensor", *S. saprophyticus-O103,* the "mediator", *S. infantis-O102,* and the "killer" *S. sanguinis-O101*. They cooperate to detect foreign bacteria, conduct signal relays and regulate "killer's" H_2O_2 production to eliminate invaders. Normally, "mediator" inhibits "killer's" H_2O_2 production, however, "sensor" initiates a signal cascade resulting in the de-repression of H_2O_2 production. This study aimed to identify cellular pathways in "killer" whose activity can be modulated by the "mediator" to affect H_2O_2 production. The *S. sanguinis* SK36 mutant library was grown in 96-well plates. Individual mutants were mixed with *S. infantis*, which inhibits *S. sanguinis* H_2O_2 production, at a 1:1 ratio and spotted with horseradish peroxidase on BHI + leucocrystal violet agar plates. Plates were incubated at 37°C overnight; the H_2O_2 production was monitored as indicated by the development of blue colonies. The library was screened to identify mutants who escaped inhibition by *S. infantis* as well as mutants that had reduced production of H_2O_2 in the absence of *S. infantis.* The parent strain, *S. sanguinis* SK36 was spotted alone and with *S. infantis* on the plate as controls. Several *S. sanguinis* mutants were obtained that consistently escaped H_2O_2 production inhibition by *S. infantis.* These mutants carry deletions in genes that encode proteins with various functions, including a Zn-dependent hydrolase, acetyltransferases, tRNA synthetase, and many uncharacterized proteins. Additionally, a number of mutants were identified that consistently produced less H_2O_2 than the control. These mutants had deletions in ABC-type Mn/Zn transporters, a CMP binding factor, and many uncharacterized proteins. This large-scale mutant screen provided numerous gene candidates for further investigation into the signal relay between *S. infantis* and *S. sanguinis* in modulating H_2O_2 production by *S. sanguinis.* This will provide valuable insight into the communication that occurs between important members of the oral community and into the regulatory mechanism of invasion resistance.

Spatial Proximity Mediates Social Interactions in a Synthetic Two-species System

Author Block:

J. M. Chacón, W. R. Harcombe; Univ. of Minnesota, St. Paul, MN

Abstract Body:

Most microbial growth occurs on surfaces, but we still have little understanding of how spatial proximity influences social interactions. To investigate the influence of spatial structure, we developed a high-throughput method that uses scanners and custom image analysis software to track growth rates and yields of colonies on agar surfaces. As a first application we asked: how does competition vary as a function of colony distance, and is this relationship shaped by resource or competitor identity?We used *Escherichia coli* and *Salmonella enterica* as our model system and provided a variety of carbon sources. Colonies were either precisely placed at distances between 1.25 - 20mm apart or were randomly spread in large numbers on an agar plate. We also compared the strength of competition on an agar plate vs. in a well-mixed flask.We first found that, as expected, increased proximity to another colony significantly reduced colony yield, regardless of species. In general, competition between *E. coli* and *S. enterica* was asymmetric: *E. coli* colonies grew to similar size when near *E. coli* or *S. enterica* colonies, but *S. enterica* colonies grew larger when near *E. coli* colonies. However, the strength of the proximity effect, and the relative strength of intra- vs. interspecific competition, changed with carbon source: providing acetate caused a general decrease in productivity which reduced both the negative effect of close proximity and the difference in intra- vs. interspecific competition. Qualitatively, competition in acetate media was similar on agar and in a well-mixed flask, although *E. coli* grew better on agar. Interestingly, this qualitative similarity between flask and agar was absent when we provided non-overlapping carbon sources. In citrate and lactose media, *E. coli* and *S. enterica* have different carbon niches, and when together in a flask, grew to nearly additive amounts compared to monocultures. However, on a petri dish in close proximity, *S. enterica* and *E. coli* competed for space, and *S. enterica*'*s* faster growth rate on its private resource (citrate) gave it a competitive advantage.We conclude that spatial proximity both tunes competition of species and is an important resource in its own right for surface-living bacteria. In ongoing work, we are exploring whether the effect of spatial proximity scales differently when colonies engage in cooperative vs. competitive social modes.

Green Fluorescent Protein Expression In *pseudogymnoascus Destructans* To Study Bat White Nose Syndrome

Author Block:

T. Zhang, P. Ren, M. DeJesus, V. Chaturvedi, **S. Chaturvedi**; Wadsworth Ctr., Albany, NY

Abstract Body:

Background: *Pseudogymnoascus destructans* (*Pd*) is the fungal etiologic agent of bat white-nose syndrome (WNS). WNS has led to mass die-offs of hibernating bats in many parts of the United States. Several bat species will face extinction if the pandemic spread is not stopped. *Pd* biology and pathogenesis studies are hampered by a lack of molecular toolbox. We describe a successful expression of codon optimized synthetic green fluorescent protein sGFP(S65T) in *Pd*.**Method:** The *sGFP(S65T)* gene was fused in frame with the *Aspergillus nidulans* promoter in the tumor inducing (Ti) plasmid (pRF-HUE) and the resulting plasmid pRFHUE-sGFP(S65T) was transformed into *Pd* by *Agrobacterium tumefaciens*-mediated transformation (ATMT) system with hygromycin B selection. The integration of sGFP(S65T) in *Pd* genome was analyzed by PCR and Southern hybridization. Transformatns were assessed for green fluorescence by confocal microscopy and by flow cytometry.**Results:** The single integration frequency of sGFP(S65T) was approximately 66%. The two randomly selected transformants with single integration event revealed ten-fold higher geometric mean fluorescence compared to the parent strain. Both spores and hyphal structures showed equally high fluorescence expression. Both transformants were mitotically stable after repeated sub-cultures on non-selective medium. The biology of sGFP(S65T) expressing transformants was not altered as judged by psychrophilic growth, sporulation, shape and size of vegetative structure, and urease production. Thus, constitutive expression of sGFP(S65T) is not toxic to *Pd*.**Conclusion:** The sGFP(S65T) transformants are currently under evaluation as reporters in animal experiments and environmental remediation.

Metabolic Profiling of Bat White Nose Syndrome Pathogen *Pseudogymnoascus destructans* and Human Pathogen *Pseudogymnoascus pannorum* Reveals Clues to the Evolution of Pathogenic and Saprobic Lifestyles

Author Block:

H. DeFiglio[1], **S. Chaturvedi**[2], V. Chaturvedi[1]; [1]Wadsworth Ctr., Albany, NY, [2]NY State Dept. of Hlth., Albany, NY

Abstract Body:

Background: *Pseudogymnoascus destructans* (*Pd*) is a novel fungal pathogen of bat white-nose syndrome (WNS) and *Pseudogymnoascus pannorum* (*Pp*) causes humans and animal diseases rarely. Draft genome comparisons revealed *Pp* contained more deduced proteins with ascribed enzymatic functions than *Pd*. We performed metabolic profiling of two pathogens to validate *in silico* predictions.**Methods**: 96-well phenotype microarray plates (Biolog, Hayward CA), were inoculated with fungal spore suspensions OD_{600} = 0.2. The plates were incubated in dark at 15^0C and OD_{600} measured on day 7 (*Pp*) and day 10 (*Pd*). Negative control values were used to normalize recording of growth; each experiment was performed in duplicate on two separate occasions.**Results**: *Pp* exhibited high metabolic activity on a variety of carbohydrates (54% positive rates for analytes tested). Sucrose, sugar alcohols and cyclic oligosaccharides were utilized readily. In contrast, *Pd* grew poorly and on only 23% of carbon-source tested with preference for pyruvic acid, mannose and fucose. *Pd* exhibited robust metabolic activity on a majority of amino acids and peptides (61% positive rates for analytes tested).**Conclusions**: An abundance of carbohydrate degradation pathways provide an explanation for wide distribution of *Pp* in soil enriched with plant materials. A more limited metabolic profile of *Pd* validated *in silico* findings that it contained far fewer proteins and enzymes than Pp. Pd exhibited high preference for utilization of nitrogen sources. This observation provided a functional basis for the colonization and invasion of bat tissues.

Prey Range Of Predatory *bdellovibrio* Strain Isolated From Bioswale Soil

Author Block:

N. Cullen, **S. O'Donnell**, L. E. Williams; Providence Coll., Providence, RI

Abstract Body:

Bdellovibrio are members of the delta-proteobacteria with an obligate predatory lifestyle. *B. bacteriovorus* invades the periplasm of Gram-negative prey bacteria, whereas *B. exovorus* attaches to the outside of prey cells. Both species digest prey bacteria in order to propagate. *Bdellovibrio* are found in a wide range of environments and may attack multiple different prey species, including animal and plant pathogens. This trait makes *Bdellovibrio* an attractive alternative to antibiotics, which are losing effectiveness with the rise in antibiotic resistance.To understand variation in prey range and predation efficiency within *Bdellovibrio*, we aimed to isolate naturally occurring strains of predatory bacteria from soil. Initially, we isolated potential prey bacteria from soil and classified them by 16S rRNA gene sequencing as strains of *Pseudomonas* and *Serratia*. We then used these strains as prey in enrichments of soil samples from a bioswale, which is an artificial landscape feature used to filter rainwater runoff. After purification by plaque formation on double agar overlay plates, we obtained an isolate showing predation on both *Pseudomonas* and *Serratia*. 16S rRNA gene sequencing classified this isolate as a member of *Bdellovibrio*, with ~96% identity to *B. bacteriovorus* 16S rRNA gene sequences and ~92% identity to *B. exovorus* 16S rRNA gene sequences.Based on 1000X phase-contrast microscopy, this soil *Bdellovibrio* isolate appears to invade prey cells, similar to the predatory strategy used by *B. bacteriovorus*. We will perform additional microscopy to determine whether this isolate invades the prey cell periplasm. In addition to *Pseudomonas* and *Serratia*, we will challenge this isolate with other Gram-negative bacteria, including isolates from freshwater environments, to assess prey range and investigate whether this isolate specializes on particular types of prey. This work will contribute to our understanding of predation in bacteria and explore the potential for therapeutic applications of predatory bacteria in the control of pathogens.

Isolation And Characterization Of Predatory Bacteria From An Estuary

Author Block:

B. Enos, L. E. Williams; Providence Coll., Providence, RI

Abstract Body:

Predatory bacteria are bacteria that attack and digest other bacteria in order to propagate. Predatory bacteria have been isolated from soil, marine and freshwater environments. The most well-studied predatory bacteria belong to four proposed families within the delta-proteobacteria. Certain species within these families, such as *Bdellovibrio bacteriovorus*, are found in a wide range of environments, whereas other species, such as *Halobacteriovorax marinus*, are restricted to marine environments. Both of these species are obligate predators that attack Gram-negative prey bacteria, including animal and plant pathogens. Because of this, predatory bacteria may serve as biocontrol agents and alternatives to antibiotics.To understand the diversity of predatory bacteria adapted to saltwater environments, we aimed to isolate predators from an estuary site in coastal Rhode Island. As a first step, we isolated seven strains of potential prey bacteria from the estuary site and classified these by 16S rRNA gene sequencing as *Vibrio* and *Enterovibrio*. We then used these strains as prey in enrichments of estuary water samples. An enrichment using a *Vibrio* strain as prey showed very small predatory bacteria by 1000X phase-contrast microscopy. We obtained a pure isolate of the predatory bacteria in this enrichment by plaque formation on double agar overlay plates.The predatory isolate appears to invade prey cells based on 1000X phase-contrast microscopy. Genus-specific PCR suggests that this isolate is not a member of *Bdellovibrio*. Moving forward, we will classify this isolate using 16S rRNA gene sequencing. We will also test prey range by challenging the isolate with the other potential prey bacteria isolated from the estuary. This work will broaden our understanding of diversity in predatory bacteria adapted to saltwater environments and contribute to efforts to develop predatory bacteria as biocontrol agents against bacterial pathogens.

A Highly Divergent Bioluminescent Isolate Suggests a Previously Undiscovered *Aliivibrio* Species

Author Block:

M. Whyte, C. F. Wimpee; Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract Body:

Bioluminescence is widely scattered across the tree of life with representatives in more than 700 genera, distributed among various microorganisms as well as fungi, plants, and animals. In bacteria, bioluminescence is confined to the Gammaproteobacteria, almost entirely in three genera of the family Vibrionaceae: *Vibrio*, *Photobacterium*, and *Aliivibrio*. This laboratory has been carrying out a long-term study of bacterial bioluminescence as a model system for bacterial molecular evolution. Methods used include PCR amplification of *lux* genes as well as other genes, followed by restriction enzyme fingerprinting, sequencing, and phylogenetic analysis. In a recent screening of seawater from St. Petersburg, Florida, we isolated 80 strains with an identical unusual *luxA* fingerprint pattern. One isolate, designated SP1, was chosen for further analysis. It was found that the *luxA* sequence of SP1 is significantly divergent from all other known bioluminescent bacterial species, sharing only 80% nucleotide sequence identity with the closest known relative, *Aliivibrio salmonicida*. Such a surprising evolutionary distance led us to hypothesize that SP1 represents an undescribed species. To test this hypothesis, we isolated and sequenced additional genes. Analysis of other *lux* genes shows that the SP1 *lux* operon shares the gene arrangement of *A. logei* and *A. salmonicida*. Besides *lux* genes, several housekeeping genes also place SP1 in the genus *Aliivibrio*. However, the very low sequence identity of several genes (*luxC*, 50%; *luxA*, 80%; *luxE*, 79%; *luxR*, 75%; *toxR*, 75%, *gyrB*, 88%; *mreB*, 89%) show that SP1, while sharing most similarity with the genus *Aliivibrio*, is significantly divergent from the other known species of that genus. These data suggest that SP1 represents a previously undiscovered species of *Aliivibrio*.

Impact of Biochar Addition and Co-Inoculation with *Bradyrhizobium a*nd *Pseudomonas* Strains on Growth of Soybean

Author Block:

D. Jabborova; Inst. of Genetics and Plant Experimental Biology, Tashkent, 111226, Uzbekistan, Tashkent, Uzbekistan

Abstract Body:

Background: Plant growth promoting rhizobacteria (PGPR) provide an alternative to chemical fertilizers as they contribute to increased plant growth and development. Therefore, PGPR have been extensively documented for their positive impact on plants, but if added with biochar, enhancement of crop yield, also help in preventing fertilizer run-off and helping plants. We studied the effect of biochar application co-inoculated with *Bradyrhizobium japonicum* USDA 110 and *Pseudomonas putida* NUU8 strains on growth of soybean (*Glycine max* L. (Merr.).**Methods:** Plants were grown in loamy sandy soil taken from ZALF experimental field station, Müncheberg, Germany. We was used Pyrolysis char from wood (Pyreg-char) as a soil amendment at concentrations of 0.5 and 5%. A pot experiment was performed with seven different treatments, i.e., loamy sandy soil (control), soil + biochar 0.5 %, soil + biochar 0.5 % + *B. japonicum* USDA 110, soil + biochar 0.5 % + *B. japonicum* USDA 110+ *P. putida* strain NUU8, soil + biochar 5 %, soil + biochar 5 % + *B. japonicum* USDA 110, soil + biochar 5 % + *B. japonicum* USDA 110+ *P. putida* strain NUU8. The length and biomass of roots and shoots, as well nutrient uptake were measured soybean.**Results:**Generally, all treatments showed an increase in growth as compared to plants grown in untreated soil. The treatment - soil + biochar 0.5 % + *B. japonicum* USDA 110 + *P. putida* strain NUU8 provided the most benefits in nodulation, plant growth and nutrient uptake of soybean compared to all other treatments. It was observed that addition of biochar to soil influenced the overall growth of plants positively but co-inoculation of with B. *japonicum* USDA 110 and *Pseudomonas P. putida* NUU8 strains even enhanced this effect further. The treatment - "soil + biochar 0,5 % + *B. japonicum* USDA 110+ *P. putida* strain NUU8" also showed a significant increase in nutrient contents of soybean and soil.**Conclusions:**Hence, it can be concluded that both biochar and co-inoculation of with B. *japonicum* USDA 110 and *Pseudomonas P. putida* NUU8 strains are effective treatments for a sustainable soybean production on sandy soils.

Phosphate Solubilising Bacteria (PSB) with Multifarious Growth Promoting Traits from Tropical Forests of India Can Enhance Growth of Crop Plants

Author Block:

H. Chakdar, P. L. Kashyap, P. Saxena, A. K. Srivastava; ICAR-Natl. Bureau of Agriculturally Important Microorganisms, Maunath Bhanjan, India

Abstract Body:

Phosphorus (P), currently believed to be the most limiting nutrient in tropical regions. In India, about 46% of soil is classified as P-deficient. Utilization of mineral phosphate resources like rock phosphate for crop production is a big challenge as "P" becomes immobilized rapidly and become unavailable to the plants. Phosphate solubilising bacteria (PSB) with phosphate mineralizing activity and other growth promoting traits will be very useful for utilization of rock phosphates for growth enhancement of crop plants. Forest soils are rich source of organic "P" compounds and can harbour PSB with P mineralizing activity. Under this background, surveys were conducted in the tropical forests of West Bengal and Meghalaya, India. A total 83 candidate PSB were isolated using NBRIP agar. Upon further screening on agar plates containing URP, fifteen colonies showing halo zones were selected for quantification of P solubilisation. Among them 7 isolates could solubilise ≥200 mg URP/lt and were identified based on 16S rDNA homology as *Serratia nematodiphila* NGNB2, *Bacillus megaterium* NGNB17, *Burkholderia cepacia* PSKP1, *B. cepacia* JUNP1, *B. vietnamiensis* PSKP2, *Bacillus gingsensoli* JB1 and *Klyuvera cryocrescens* JBP1. Due to reported pathogenic nature of *Burkholderia*, only four isolates viz. NGNB2, NGNB17, JB1 and JBP1 were screened for phosphatase activities and other growth promoting traits like phytohormone production, HCN & siderophore production, K & Zn solubilization following standard methodologies.

Isolates	IAA production (mg/lt)	Acid phosphatase (U/lt)	Alkaline phosphatase (U/lt)	Solubilization of	Production of		
K	Zn	HCN	Siderophore				
NGNB17	0.7	94.5	13.0	-	-	-	-
NGNB2	ND	4.4	24.0	+	-	-	+
JB1	ND	3.3	18.0	-	-	-	+
JBP1	1.0	8.2	18.0	+	-	-	+

ND: Not detectedThese isolates were subjected to pot trial for growth promotion in maize, wheat and chickpea. It was observed that all the isolates could significantly enhance the biometric parameters like fresh and dry weight of root and shoot, length of root and shoot. The isolates despite their distinctly different ecological origin hold promise as bioinoculants for enhancing crop productivity due to their multifarious growth enhancing attributes.

A "Trojan Horse" Strategy to Block Transmission of a Plant Pathogen - *Xylella fastidiosa*

Author Block:

A. K. Arora[1], T. A. Miller[2], R. Durvasula[3]; [1]Texas A&M Univ., College Station, TX, [2]Univ. of California, Riverside, CA, [3]Univ. of New Mexico, Albuquerque, NM

Abstract Body:

Background: Arthropod borne diseases are a big burden to global agriculture. The economic damage caused by these diseases runs into billions of dollars. Chemical insecticides are the main weapon against vector borne diseases, which control vector population. However, insecticide application is associated with environmental contamination and resistance development. Other methods including transgenic and paratransgenic insects are being developed to control these diseases. Paratransgenesis, which is a "Trojan Horse" strategy relies on a symbiont to deliver anti-pathogen molecules within the vector-gut. These molecules make the vector-gut hostile to pathogen survival, thereby decreasing vector competence. Here, we report a paratransgenic strategy to block transmission of *Xylella fastidiosa*, a global plant pathogen, by its vector, the glassy-winged sharpshooter (GWSS, *Homalodisca vitripennis*), using a commensal bacterium *Pantoea agglomerans*.**Methods:** Using the *E. coli* hemolysin secretion system we genetically engineered *P. agglomerans* to express two antimicrobial peptides (AMPs) - melittin and scorpine like molecule (SLM). These AMPs were selected based on their higher toxicity towards *Xylella* as compared to *Pantoea*.**Results:** Only 15.8% of the paratransgenic GWSS, which harbored melittin or SLM expressing *Pantoea*, acquired *Xylella.* This was significantly lower than the control group, in which 85.6% GWSS acquired *Xylella* ($p<0.0001$). These paratransgenic GWSS when allowed to feed on naive grape plants failed to transmit *Xylella*.**Conclusions:** We were able to block transmission of *Xylella*, which infects more than 150 plant species, by its most important vector, GWSS, using a transgenic bacterium. This is the first report of blocking transmission of a plant pathogen using a paratransgenic strategy. This will open the door of development paratransgenic strategies to control other vector borne plant diseases.

Lysinibacillus Sphaericus* Plant Growth Promoter and Phytoremediation Enhancer in *Canavalia ensiformis

Author Block:

S. A. Martínez, J. Dussán, Microbiological Research Center(CIMIC); Univ. de los Andes, Bogotá, Colombia

Abstract Body:

The recent genome sequencing of OT4b31, CBAM5 and III(3)7 strains revealed that *L.sphaericus* has nitrogen metabolism genes and multiple copies of metal resistance genes. Due to these insights, the aim of this study was to determine its role in the nitrogen cycle and lead phytoremediation process in contaminated soils with toxic metals.These strains of *L.sphaericus* and other four (OT4b26, OT4b32, OT4b49 and 2362) were tested for nitrogen metabolism (nitrogen fixation and nitrification) and indole acetic acid (IAA) production; the results were analyzed with a Kruskal-Wallis test.In the greenhouse study were used 100 seedlings per treatment: contaminated soil with lead (600ppm) with *L.sphaericus* consortium and respective control. The plant-growth parameters measured were: height, leaf number, dry weight, dry weight percentage, root length, shoot length, root:shoot, root mass, and foliar area; also were quantified nitrate and ammonia concentration in soil and lead concentration in root and soil as well. These measurements were performed every month for three months; the results were analyzed with a Student´s t-test.All *L.sphaericus* strains fixed molecular nitrogen (0,61-1,47mg/L) and oxidized ammonia to nitrate (0,26-0,7mg/L); III(3)7 and 2362 strains were the best nitrogen fixers, meanwhile OT4b31 and OT4b49 were the best ammonia oxidizer strains. All strains produced IAA in L-tryptophan supplemented media (3,3-5,0µg/mL); the best producers were the OT4b49, III(3)7, CBAM5 and 2362 strains.The green house study showed that in *L.sphaericus* consortium treatment height, foliar area, leaf number, root length and shoot length of *C.ensoformis* were statistically higher. According to nutrient content in soil, nitrate and ammonium decreased through time in both treatments. On the other hand, the bioaccumulation of lead in roots were higher in bacteria treatment; especially in the second sample where the lead concentration was almost two fold in contrast to the control.Finally we found a wide participation of *L.sphaericus* in the nitrogen cycle in soil and in lead phytoremediation. Then we consider that this microorganism can be a plant growth promoter bacteria (PGPB).

Preparation of Culture Media from Natural Ingredients as an Alternative to Produce *Bacillus sphaericus* Biomass for Use in Biological Pest Control Larvae in Commercially Important Crops

Author Block:

L. C. Sanchez, L. C. Corrales, L. L. Gonzalez, M. A. Calderon, N. G. Parra, D. P. Correa, M. A. Rodriguez; Univ. Colegio Mayor de Cundinamarca, Bogotá, Colombia

Abstract Body:

Background: One of the most important tools to verify the feasibility of a microorganism is the culture media. It´s use meant the way to visualize these microscopic particles and check their viability. Later, it was the way to get large amounts of biomass and find the most convenient substrate to activate any metabolic pathway. In this research, the objective went evaluate some culture media, to produce biomass and *Bacillus sphaericus* spore, which it gives an entomopathogen action. **Methods:** We selected seven substrates between grains, legumes and seeds. They were evaluated individually and in admixture. It was analized the production by direct and indirect viable cells recount. Solid media were tested with chickpeas, wheat and peas alone and in combination (GTA, by its initials in Spanish). Finally, *Bacillus sphaericus* entomopathogenic effect was evaluated on larvae of *Plutella xylostella* and *Tuta absoluta.* **Results:** The sporulation was 92% and the spores were terminals; just one, the treatment with chickpeas presented complete sporulation of 91% at 48 hours. About culture media with legumes and seeds, the culture media which contained sunflower presented the best performance and sporulation. The two best culture media, with more than 80% of sporulation were carried to scale of 1 L. After 7 hours of fermentation, GTA broth presented 3,20 x 10^9 cel/mL while G broth presented a recount of 3 x 10^{13}cel/ML after 10 hours. The native strain UCMCB3, presented the best entomopathogen effect in culture media, GTA with 90,91% mortality, at a concentration of 1, 6 x 10^8 spores/mL. This result is statistically significant when other doses ($p = 2.364^{e-07}$) **Conclusions:** It was concluded that the development of culture media with natural components meets the nutritional requirements for growth and are an alternative in terms of biomass production and obtaining primary or secondary bacterial metabolites

Characterization of the R-Pyocin Gene Cluster of *Pseudomonas chlororaphis* 30-84

Author Block:

R. Dorosky, L. S. Pierson, III, E. A. Pierson; Texas A&M Univ., college station, TX

Abstract Body:

Pseudomonas produces R-type pyocins, high molecular mass bacteriophage-derived bacteriocins that resemble phage tails. R-pyocin structural genes are encoded within the bacterial chromosome along with genes encoding a lysis cassette containing a holin and a lytic enzyme (1). Holins are small transmembrane proteins that facilitate cell lysis by accumulating and permeabilizing the cytoplasmic membrane thereby allowing the lytic enzyme into the periplasmic space and ultimately cell lysis (2). A previous study of the rhizosphere-colonizing bacterium *Pseudomonas chlororaphis* 30-84 revealed that production of the phenazine 2-OH-PCA was correlated with eDNA production as well as expression of an R2-type pyocin gene cluster (3). The present study demonstrates the functionality of *P. chlororaphis* pyocin lysis cassette, characterizes the pyocin particle, and shows the importance of cell lysis and pyocin release for competition among bacteria and the persistence of rhizosphere populations. To demonstrate the functionality of the lysis cassette, the holin and lytic genes were cloned separately or together into an expression vector behind an arabinose-inducible promoter. Co-expression of both genes resulted in cell lysis, whereas no cell lysis was observed when the genes were expressed separately. Moreover, cells of a *P. chlororaphis* holin-deletion mutant do not lyse when induced by UV radiation and do not accumulate as much eDNA as the wild type, consistent with an autolysis-deficient phenotype. Observations using transmission electron microscopy of the lysates of wild type following UV induction revealed rigid, rod-shaped, phage-like particles characteristic of R-type pyocins. This lysate inhibited the growth of some *Pseudomonas* species, but did not affect the growth of other bacterial genera tested. Mutation of the holin also affected the ability of *P. chlororaphis* to compete with pyocin-sensitive bacteria in biofilms and survive in the wheat rhizosphere. These results demonstrate that *P. chlororaphis* 30-84 possesses a fully functional lysis cassette and R-pyocin particle, and provides evidence for their ecological role in microbial interactions and rhizosphere dynamics.

Isolation and Identification of Causative Agent of Potato Common Scab and Potential Use of Antagonistic Bacteria as a Biological Control of Disease

Author Block:

A. Sarwar[1], C. R. Osorio, Male[2], C. Cabaleiro[2], Z. Latif[1]; [1]Univ. of the Punjab, Lahore, Pakistan, [2]Univ. of Santiago de Compostela, Santiago de Compostela, Spain

Abstract Body:

Background: Potato is considered as a cheaper nutritional source to eradicate hunger problem of the world. Common scab (CS) is a foremost bacterial disease of potato causing potato damage all around the world.**Methods:** The current study was designed to check the prevalence of CS in potato growing provinces like Punjab, Pakistan and Galicia, Spain. Samples of potato with tuber lesions collected from 25 different localities, were processed to find the causative agent of this disease. 124 bacterial strains were isolated and identified as *Streptomyces* spp. on the basis of morphological and physiological characteristics. Species specific 16S rRNA primers were used to confirm *Streptomyces* strains at species level. The antagonistic bacterial strain *Streptomyces hygroscopicus* AS-1 was isolated from soil and identified by 16S rRNA gene sequencing.**Results:** Out of 124 *Streptomyces* strains, 34 strains were confirmed as pathogenic due to the presence of *txtAB* gene. Among pathogenic *Streptomyces* strains, 56% strains were confirmed as *Streptomyces europaeiscabiei*, 25% *S. bottropensis*, 12% *S. turgidiscabiei* and 7% as *S. stelliscabiei* whereas 40% pathogenic *Streptomyces* strains were also positive for *nec1* and 23% for *tomA* genes. Isolated pathogenic *Streptomyces* strains were screened for CS disease symptoms while antagonistic *S. hygroscopicus* strain was evaluated to inhibit the CS disease production in pot assay. Disease severity index was established in tubers from 0-500. *S. turgidiscabiei* and *S. europaeiscabiei* showed highest disease severity index as 146 and 70 respectively. Antagonistic *S. hygroscopicus* reduced the disease severity index up to 18 and 7 for *S. turgidiscabiei* and *S. europaeiscabiei* strains respectively.**Conclusions:** This study provides an alternative strategy to control the spread of common scab in potato and other tuber related daily consumable foods for controlling hunger problem of the world.

Detection of Cccvd Variants in Palms by One Step Rt Late Pcr

Author Block:

R. K. Finol-Urdaneta[1], K. E. Pierce[1], R. Sambanthamurthi[2], M. Ong-Abdullah[2], L. Wangh[1]; [1]Brandeis Univ., Waltham, MA, [2]Malaysian Palm Oil Board, Selangor, Malaysia

Abstract Body:

Background: Palm tree products constitute major nutritional and economical resources in many tropical countries. Coconut *Cadang cadang* Viroid (CCCVd) infection results in slow but catastrophic productivity loss. A CCCVd variant causes orange spotting in oil palm. Disease symptoms are common to many other palm pathologies, making precise detection of the causative agent critical to field management and germplasm exchange procedures. But, association of viroid titers and viroid variants to disease progression remains unknown.**Method:** RT-LATE-PCR efficiently generates single-stranded amplicons improving assay sensitivity as compared to conventional RT-PCR. End-point detection with low temperature fluorescent probes is exquisitely specific and distinguishes sequence variations as shifts in melting temperature (T_M) of probe/target hybrids. Thus, these technologies allow for rapid, quantitative detection of palm viroids in a closed-tube One-Step reaction.**Results:** Several sets of LATE-PCR primers were designed and used to amplify cDNA from synthetic CCCVd RNA and infected palm isolates. CCCVd probes hybridized to synthetic DNA targets of reported CCCVd variants, at end point of PCR, and end point of RT-LATE-PCR of viroid RNA. Strong fluorescent signal showed T_M consistent with specific CCCVd variant sequences. An internal control was implemented which amplifies mitochondrial nad5 mRNA across "trans-splicing" junctions in a region encompassing exons 2 and 4, separated by >33,000 nucleotides. The lack of probe signal from samples without reverse transcriptase demonstrated the absence of DNA contamination in palm RNA samples, and/or the inability to generate the long product under our PCR conditions. This control allowed for sample quality control, and provided the means for relative quantification of CCCVd, by comparison of specific probe signals from control and pathogen LATE-PCR products.**Conclusions:** We have constructed a fast and reliable assay that detects, distinguishes and quantifies CCCVd variants in coconut and oil palms. Validation and implementation of the assay in the field will enable accurate diagnosis of infected palms and derived germplasm. Analyses of experimentally infected palms will contribute to the understanding of CCCVd patho-physiology in these economically important crops.

Nematicidal Potential of Extracellular Metabolites of *Bacillus pumilus* and *Bacillus thuringiensis* Against *Meloidogyne javanica*

Author Block:

S. N. Mukry[1], S. A. Khan[2]; [1]Natl. Inst. of Blood Diseases & Bone Marrow Transplantation, Karachi, Pakistan, [2]Univ. of Karachi, Karachi, Pakistan

Abstract Body:

Background: Nematodes are a group of pests detrimental to economically important plants. Most of the effective chemical nematicides are non-biodegradable, toxic and non-specific. Biological nematicides from microbes are generallyenvironmental friendly. In the present study a large pool (130) of *Bacillus* sp was screened for their nematicidal potential against root-knot nematode *Meloidogyne javanica.* **Method:**The eggs and larvae of *M. javanica* were isolated from infected roots of egg plant, after treatment with 1% bleach followed by sequential sieving 100, 250 and 400 mesh size. For hatching test 20-60eggs /ml were exposed to 1ml of cell free culture supernatant (CFCS) of each Bacillus species in sterile glass cavity block *(in triplicate).* The cavity-blocks were incubated in a moist chamber at 25°C and observations were made by counting number of hatched eggs after 24, 48 and 72h microscopically. The larvicidal activity was also observed similarly for three days by adding 25-40 larvae/ml instead of egg suspension. Partially purified and chemically characterized metabolites of *Bacillus pumilus* S108(a), *Bacillus pumilus* S113 and *Bacillus thuringiensis* S128 were selected for green house experiment on tomato seedlings by root dip and soil drench methods. Factorial ANOVA and Duncan's multiple-range test were performed using CoStat, 4. The mean %, standard deviation and probability were also determined by SPSS.**Result:** Only 7% of the test strains exhibited anti- hatching activity. *The* CFCS from few caused stimulation of hatching and the juveniles were immediately killed after hatching. Considerable larvicidal (> 50%) activity was exhibited by 115 *Bacillus* strains. ***The exposure-time and*** larvicidal potential was proportional to each other.The nematicidal metabolite of strains S108(a), S113 and S128 were heat-labile and protease-sensitive proteins. There was >50% reduction in knot/gall-formation in all the cases. The % reduction in nematode population/g root was 53%, 54% and 46% for strains S108(a), S113 and S144, respectively. **Conclusion:** The hatching stimulatory strains can be used to control nematode infection at an early stage of their life-cycle. The extracellular metabolites of strains S108(a), S113 and S128 can be used to control root-knot infection of *M. javanica.*

Evaluation of Genotoxic Potential of Pesticides (Lufenuron and Emamectin) Using the *Allium cepa* Assay

Author Block:

M. Khawer, S. Sultan; Univ. of the Punjab, Lahore, Lahore, Pakistan

Abstract Body:

Background: Over the past few decades, the use of pesticides has been increased enormously in agriculture. These pesticides help in combating pests (insects, weeds etc), but at the same time, have potential threats for the plant itself and its consumers.**Methods:** In this, study two pesticides, lufenuron and emamectin were evaluated for genotoxicity and mutagenicity using *Allium cepa* chromosomal aberration test and Ames test, respectively. For genotoxicity evaluation, 7 concentrations (D1= 0.05%, D2= 0.1%, D3= 0.15%, D4= 0.2%, D5= 0.4%, D6= 0.6%and D7= 0.8%) of both pesticides were used.**Results:** Both pesticides were involved in decreased germination rates for onion seeds, inhibition of root length and decreased mitotic indices when compared to negative control (autoclaved water) in dose dependant manner. While the chromosomal aberrations (micro nuclei, vacuolated nuclei, chromosomal breakage, sticky chromosomes, vagrant chromosomes and chromosomal bridges) increased as the pesticide concentration increased. For mutagenicity detection, Ames test was performed using two *Salmonella typhimurium* strains i.e. TA98 and TA97a to detect frame shift mutations. For lufenuron doses used were LD1= 50 %, LD2= 75 % and LD3= 100 %. For emamectin doses used were ED1= 0.05 %, ED2= 0.1 % and ED3= 0.5 %. For both pesticides at least one concentration showed high mutagenicity.**Conclusions:** So, it was confirmed by that both pesticides have genotoxic and mutagenic effects. Additional mutagenicity tests should be conducted for further validation of these results which will confirm the predictions for pesticide's effect in an organism.

Microbiomes of Potato-Cyst-Nematodes Isolates Kept in Laboratory Conditions

Author Block:

D. N. Proenca[1], I. L. Conceicao[2], P. V. Morais[1]; [1]CEMUC, Univ. of Coimbra, Coimbra, Portugal, [2]CFE, Univ. of Coimbra, Coimbra, Portugal

Abstract Body:

Background: Potato is an important staple crop worldwide with an estimated production of 375 million tons every year. Portugal has a lower potato yield average comparatively to the average in European Union and may be attributed to the presence of plant-parasitic nematodes as, for example, potato-cyst nematodes (PCN), *Globodera* spp. Recently, in some European collections, PCN isolates kept in lab cultures started to die and were not able to multiply after the first generation obtained in potato cultures in pots. This is a problem shared by the Portuguese collections. This work is aimed to assess the microbiome of wild PCN and PCN maintained in laboratory collections.**Methods:** Cysts from *Globodera* spp. were extracted from soil infested with PCN. DNA was extracted from wild cysts (W-PCN), immediately after their isolation from the soil, and from cysts maintained in laboratory (L-PCN) in closed glass tubes, at room temperature, during 6 months. Molecular methods (DGGE and Illumina MiSeq) were used to assess the microbiomes (Bacteria, Archaea and Fungi) present in cysts. Sequence data were processed using MR DNA analysis pipeline (MR DNA, Shallowater, TX, USA).**Results:** DGGE profiles showed that the microbial community was different between wild and laboratory cysts. When comparing W-PCN with L-PCN, by the analysis of Illumina Miseq, it was possible to verify in L-PCN the increase of classes *Gammaproteobacteria* (30% to 60%, namely *Acinetobacter*) and *Bacilli* (8% to 20%, namely *Bacillus* and *Staphylococcus*) and a decrease in the percentage of microorganisms of the classes *Actinobacteria* (18% to 8%), *Sphingobacteriia* (7% to 1%), *Betaproteobacteria* (13% to 1%) and *Alphaproteobacteria* (20% to 7%). The number of bacteria and archaea involved in nitrification pathways in L-PCN was lower than in W-PCN. Moreover, we found the yeast *Saccharomyces* (30%) in L-PCN microbiome.**Conclusions:** The microbiomes of L-PCN and W-PCN are different and these differences might be involved in the loss of viability of the isolates in lab cultures. Saccharomyces was previously shown to kill nematodes and its presence in the L-PCN microbiome could also be related to the death of PCN maintained in lab conditions.

The Cucumber Microbiome Shifts in Response to Rainfall

Author Block:

S. M. Allard[1], A. Ottesen[2], S. A. Micallef[1]; [1]Univ. of Maryland, College Park, MD, [2]US Food and Drug Admin. (Ctr. for Food Safety and Applied Nutrition), College Park, MD

Abstract Body:

Cucumber (*Cucumis sativus*) is a vining crop cultivated on the ground and commonly consumed raw. It has been implicated in multiple foodborne disease outbreaks in recent years. Research indicates that the levels of fecal indicator bacteria on crops spike immediately following a rainstorm, potentially representing an increased food safety risk. In this study, we profiled the surface bacterial communities of cucumber fruit in the days surrounding a rainstorm. Cucumber fruit samples (n=24) were collected from a Maryland organic farm 4 days before, and 1 and 4 days after a rain event (precipitation=12.45 mm). DNA was extracted from washes of fruit surfaces and used for microbial community profiling using Illumina sequencing. A 508 base pair fragment spanning the V1-V3 hypervariable regions of the 16S rRNA gene was amplified and sequenced using MiSeq v3. Resulting sequencing data was quality filtered and analyzed using QIIME v. 1.8. After quality filtering, 1.1 million reads were retained for alpha and beta diversity analysis. At a sampling depth of 29,287 sequences per sample, approximately 1,618 OTUs (97% similarity) were identified for each sample. Cucumber samples collected 4 days before, 1 day after, and 4 days after a rain event clustered separately, showing a significant influence of collection date on microbial community composition (R^2=0.225, p=0.002). The 4 day pre- and 1 day post-rain samples hosted significantly different communities (p=0.002), however the 4 day post-rain samples were not significantly different from either treatment. Rain resulted in a temporarily elevated relative abundance of Xanthamonadaceae (p=0.04), a group containing several plant pathogens; relative abundance returned to pre-rain levels by day 4 post-rain. Rain also resulted in an increase in Paenibacillaceae (p=0.01), a family comprising several beneficial and biocontrol species, which had only slightly decreased 4 days post-rain. This study demonstrated a shift in the structure of cucumber fruit surface-associated bacterial communities following a rain event on a Maryland organic farm that had only partially reversed within 4 days. The susceptibility of plant hosts to pathogen colonization could be enhanced by these weather-induced shifts in microbial species dominance.

Bacterial Populations on the Surfaces of Organic and Conventionally Grown Almond Drupes

Author Block:

J. A. McGarvey; USDA ARS FTDP, Albany, CA

Abstract Body:

Aims: To compare the bacterial populations on organically and conventionally grown almond drupes before and after hull split. **Methods and Results**: We constructed 16S rRNA gene libraries containing approximately 3,000 sequences each from the bacteria from organically and conventionally grown drupes before and after hull split. We observed that before hull split both conventionally and organically grown drupes were colonized by relatively few types of bacteria that were mostly common phyllosphere-associated *Proteobacteria*. However, the organically grown drupes contained significantly more *Alphaproteobacteria* and the conventionally grown drupes contained significantly more *Gammaproteobacteria.* The conventionally grown drupes also contained significantly more sequences associated with the phylum *Actinobacteria.* After hull split, we observed a significant increase in bacterial diversity, with many newly appearing sequences that were not normally associated with the phyllosphere. **Conclusions:** Organic and conventional growing methodologies influence the types of bacteria on the pyllosphere and hull split results in a burst of microbial diversification. **Significance and Impact of the Study**: Production of organic produce is increasing due to consumer preferences, but it was unknown how this methodology affects the bacterial populations on the phyllosphere. This is the first study to compare the bacterial populations of organically and conventionally grown almond drupes.

Antagonistic Activity of Bacteria Against Root Rot Fungal Pathogens of Ginseng

Author Block:

A. Sundararaman[1], J. Young[2], C. Sung[3], S. S. Lee[1]; [1]Kyonggi Univ., Suwon, Korea, Republic of, [2]Agricultural research and Extension services, Suwon, Korea, Republic of, [3]Gyeonggido Agricultural Res. and Extension services, Suwon, Korea, Republic of

Abstract Body:

Korean *Panax ginseng* C.A. Meyer with thousand years of history, has been traditionally known as medicinal plant with mysterious powers in the orient. The efficacy of ginseng has been recognized based on oriental medical science theory and determined that ginseng roots and its extracts revitalize the body. Ginseng crop cultivation is highly vernacular to phytopathogenic fungi such as *Rhizoctonia solani, Cylindrocarpon destructans, Collectotrichium* and *Botrytis cinera.* The phytopathogen outbreak leads to replant disease in which the crop cannot be cultivated for consecutive years in the same soil. Our studies focuses on the biocontrol ability of bacterial species against fungal pathogens of ginseng. The bacterial strains were isolated from the rhizosphere of ginseng and in vitro tests were performed to check the efficiency of antagonism. Two effective strains were subjected to 16S rRNA partial gene sequencing and found belonging to the genus *Bacillus* and *Paenibacillus*. In vivo analysis was performed in pots under shade at green house conditions. The results of pot experiment showed the efficiency up to 67% reduction in root lesions. Bacterial inoculum was prepared in bulk and the culture filtrate was analyzed for the active metabolites responsible for the antagonistic properties. The culture filtrate analysis showed that the compounds belong to the surfactant group of lipopeptides such as Iturin and Plipastatin. The crude metabolites were purified and analyzed by LC-MS to confirm the mass of the metabolite and identify the molecular structure. Further work focuses on the identification of the gene corresponding to antifungal property.

Changes in the Rhizosphere Bacterial Community Composition in Cotton Plants

Author Block:

R. Alcántara-Hernández[1], A. Ponce-Mendoza[2], A. Wegier[3]; [1]Inst. of Geology, Mexico City, Mexico, [2]Comisión Natl. para el Conocimiento y Uso de la Biodiversidad, Mexico City, Mexico, [3]Jardin Botanico del Inst. de Biologia, Mexico City, Mexico

Abstract Body:

The understanding of plant root-microbe associations has had an increasing interest during the last decades, as these interactions result in a dynamic microenvironment where bacteria play an important role in nutrient uptake and plant growth. The use of metagenomic methods has improved our understanding of the non-culturable component of the rhizosphere community. However, there are still gaps in the comprehension of this community, specially in field studies. Samples from bulk soil and soil up to 10 mm from the roots of *Gossypium hirsutum,* were taken from crops in experimental plots located in two sites under similar irrigation systems. Then, a 16S rRNA gene high-throughput sequencing method was used to explore the diversity and affiliation of the bacterial component (obtaining composite samples from 10 plants per treatment, amplified and analyzed by triplicate). Our aims were i) to observe the differences in the bacterial community structure between bulk soil samples and the rhizosphere of cotton plants in a long-term cultivated regosol, ii) to compare the rhizosphere communities in two soils with different characteristics, and iii) to observe if there are differences in the rhizosphere community under two different farming systems, i.e. organic and conventional. Our results showed that the structure of the bacterial community in bulk soil samples was different from that of the rhizosphere in *Gossypium hirsutum.* The bacterial phyla in the rhizosphere included Proteobacteria, Actinobacteria, Acidobacteria, Planctomycetes, among others. However, plants in the regosol, showed a higher proportion of bacteria belonging to the candidate phylum TM7. The conventional and organic farming system showed slightly differences in the composition of the bacterial community, although further studies most be done to clarify the modifications in the bacterial structure at higher taxonomic levels.

***Bacteroidales* as Indicator of Fecal Contamination Source Tracking on Artificially Contaminated Tomato and Strawberry**

Author Block:

S. Garcia Alvarado, L. G. Hernandez, 66455, **J. A. Merino, 66455**, N. Heredia; Univ. Autonoma de Nuevo Leon, San Nicolas NL, Mexico

Abstract Body:

Background: Fecal contamination associated with the consumption of vegetables is a health issue worldwide. Current methods used to investigate the possible presence of pathogens, such as *Salmonella* spp. and *E. coli* O157: H7 in vegetables, are based in searching fecal indicator organisms; however, these are time-consuming and do not indicate the origin of contamination. It has been reported that the order *Bacteroidales* can be used as an alternative indicator and for tracking the source of contamination, due to host-specific sequences conserved in its genome. The objective of this work was to determine the association between fecal contamination, *Bacteroidales* and traditional bacteria indicators.**Methods:** Fecal sources from human and animal were used and applied on tomato and strawberry. Validation of oligonucleotides of host-specific (human, bovine and canine) markers of the 16S rRNA gene of *Bacteroidales* was performed using PCR. Tomato and strawberry samples were contaminated with diluted stool with an initial charge of *Bacteroidales* (between 6 and 8 log CFU/g) and 3 to 6 log CFU/g of traditional indicators of the various hosts. Traditional indicators (*E. coli*, total coliform and *Enterococcus)* were enumerated and the universal marker AllBac was quantified by qPCR. Host source was identified by PCR.**Results:** The limit of detection of PCR was 1.35 to 10.35 logarithmic gene copies, corresponding to an LOQ up to 2 cells. No correlation between levels of *Bacteroidales* and traditional bacterial indicators was observed. In all samples of contaminated vegetables, levels of *Bacteroidales* was 2 log CFU higher than traditional indicators; however, traditional indicators showed high variation and *E. coli* from bovine source was not detected in tomato samples. Identification of host specific markers in vegetables samples was 100% in almost all cases when the samples were contaminated with a 1:1000 dilution of feces. Contamination with dog feces was detected by PCR even at 1:100,000 dilution of feces, in 60% of cases.**Conclusions:** Based on these results, the use of Bacteroidales provide valuable information to identify the source of fecal contamination, and could help to reduce the risks of contamination of produce.

Metagenomic Analysis of the Rhizobiomes of the Invasive Plant *Schinus terrebinthifolius* (Brazilian Pepper Tree) Suggest Active Alteration of Soil Microbiota Compared to Natives in Southeastern Florida

Author Block:

K. K. Dawkins, N. Esiobu; Florida Atlantic Univ., Boca Raton, FL

Abstract Body:

Background: The Brazilian peppertree (BP) is a category 1 invasive plant, displacing disturbed sites, mangroves and pinelands. BP is responsible for the loss of up to 3000 km^2 of terrestrial ecosystems in Central and Southern Florida. A 24.4 hectare plot previously invaded by dense BP vegetation could not be restored with natives until the top-soil itself was removed; which prompted our quest to determine the possible impact of BP and soil microorganisms. This report contrasts the rhizobiome (metagenomic) diversity and richness of BP and two adjacent non-invasive native plants across Southeastern Florida with the goal of identifying trends that could support allelopathy and or enemy recruitment strategies.**Methods:** Six sample sites spanning three counties across Southeastern Florida were sampled for rhizospheric soil of BP, Shepherd's needles (*Bidens alba)*, Firebush (*Hamelia* patens) and bare soil. Metagenomic DNA from rhizobacteria and fungi were extracted using a modified MoBio Powersoil DNA kit procedure. Bacterial 16S rDNA was sequenced and analyzed with the Illumina Mi-Seq system and QIIME software respectively. Arbuscular Mycorrhiza (AM) counts were done microscopically and the internal transcribed spacer (ITS) of extracted fungal DNA is being sequenced employing the Sanger sequencing method after cloning.**Results & Conclusion:**The average AM spore count of 221 +/- 38.4 spores/g of soil was significantly higher under BP compared to *Bidens alba* (151 +/- 28.4 spores/g), *Hamelia* patens (108 +/- 23.2 spores/g) and bare soil (83 +/- 14.4 spores/g) with a p value of <0.001. The presumptive Genus *Funneliformis* (32%) and *Septoglomus* (23%)were most abundant under BP. Over 5 million bacterial sequences were obtained producing 100,574 operational taxonomic units (OTU) where BP had the lowest average OTUs (9593). The most abundant phylum found throughout all samples were the *Proteobacteria* averaging 56.3%. Remarkably, BP soil had a 2 fold increase in prevalence of the phylum *Verrucomicrobia* (ANOVA, $F_{3,18} = 6.5$, $p = 0.004$). There was a drastic decrease in the order *Enterobacteriales* (16.4%) under BP with $p<0.001$ compared to bare soil (42.37%). These findings suggest BP may be recruiting specific microbes and eliminating others through allelopathy.

Investigation of an Antibiotic Biosurfactant Produced by a Plant-growth Promoting Strain of *Pseudomonas koreensis* Isolated from Connecticut

Author Block:

L. Iboki, E. Lewis Roberts, J. Thurber; Southern Connecticut State Univ., New Haven, CT

Abstract Body:

Fluorescent pseudomonads are of particular interest due to their biological control potential. The production of cyclic lipopeptide biosurfactants (CLPS) has been observed in some fluorescent pseudomonads and these CLPs have been linked to controlling growth of pathogenic microbes. While *Pseudomonas koreensis* has been isolated in both Korea and Mexico, only Mexican strains produce CLPs. The Mexican strains have also been shown to support plant health in tomato plants. In addition to a phylogenetic analysis, we examined biosurfactant production, antibiotic activity, and plant growth promotion activity of a new strain of *Pseudomonas koreensis* isolated in Connecticut, U.S.A.The 16s rRNA sequence of a fluorescent bacterium isolated from the rhizosphere of a Japanese Maple tree (*Acer japonica*) shared 97% identity with *Pseudomonas koreensis*. Evolutionary history of the Connecticut soil isolate was inferred by Maximum Parsimony analysis of the 16s sequence compared to other Pseudomonas strains including three *Pseudomonas koreensis* strains isolated in Mexico and two strains from Korea. The Connecticut isolate clustered with *P. koreensis* strains from Korea (95% bootstrap support). An atomized oil droplet assay detected a putative CLP biosurfactant produced by the new *P. koreensis* isolate grown on tryptic soy agar (TSA). A total of 0.3 µg (in 30µl methanol) of the biosurfactant spotted onto TSA plates showed marked antibiotic activity identified through clear zones of inhibition against *Staphylococcus aureus, Pseudomonas pudita,* and *Bacillus subtillis* overlaid on the plates. Addition of the bacterium to soils of twenty individual heirloom tomato (*Solanum lycopersicum*) plants resulted in significantly increased biomass (38% increase) over control plants. Furthermore, only 4 out of 48 individual tomato plants inoculated with the bacterium exhibited leaf rolling after being subjected to 3 days with no water at 40 °C, in contrast to 100% leaf rolling observed on un-inoculated controls.The ability to produce a biosurfactant differentiates our strain from the Korean isolates. In addition, our findings indicate that the Connecticut *P. koreensis* isolate could be used as a biological control agent, or to improve the health of tomato plants exposed to abiotic stresses.

Bio-Augmentation Potentials of Indigenous *Azospirillum* Isolates in Drought Conditions

Author Block:

R. Anandan, D. Lakshmipriya, V. Nithyakalyani, L. Aswini, S. Rajkumar, P. Rajendran; Dr MGR Janaki Coll. of Arts and Sci. for, Chennai, India

Abstract Body:

Background: Indian sub-continent is facing a serious agricultural crisis in terms of fast shrinking cultivable lands. Genetically manipulated crops and farm chemicals have enhanced the farm production. But indiscriminate and unbalanced use of farm chemicals had led to a decline in the soil fertility. Urbanization has channelized water resources to domestic use inducing drought condition that has complicated the agro climate. South India, the 'cradle of paddy' is now largely embalmed with non-cultivable land mostly due to drought conditions. Soil microbes are actively investigated for their soil reclamation potential in drought conditions. In this background, this study was taken up to characterize *Azospirillum* spp. soil isolates and assess their *in situ* potentials to support plant growth and yield in drought conditions.**Methods:** Paddy field soil samples from 3 agronomic zones in Tamilnadu, India were screened for *Azopirillum* spp. using standard techniques. They were further confirmed with 16S rRNA PCR and evolutionary relationship established with MEGA6. *Azospirillum* soil isolates were screened for specific plant growth promoting traits that includes, IAA production, mineral solubilisation, extracellular enzymes, exopolysaccharide production (EPS), N2 fixation, siderophore and ammonia production. Isolates were tested for desiccation tolerance. *In situ* experiments were conducted with *Orzya sativa* (paddy) enforcing specific drought conditions with plant growth and yield as the end point.**Results:** A total of thirty two bacterial isolates were confirmed as *Azosipirillum* spp and their genotypic relationship established with 16S rRNA PCR. Their IAA production ranged from 9 - 25 μg/mL; Nase activity, 113-429 nmol C_2H_4/H/mg; and EPS, 32-214 mg/L. Two isolates exhibited remarkable desiccation tolerance and were proceeded to *in situ* studies. Both the isolates had a positive impact on the plant growth and yield with ASP9 having superior outcome especially when combined with an organic carrier, Panchakavya at drought conditions. Field trials in drought hit crop fields are underway to test their commercial application potentials.**Conclusions:** This study categorically demonstrates the bio-reclamation and plant growth promoting potentials of *Azospirillum* spp. especially under harsh field conditions

Molecular Mechanisms for Virulence and Host Colonization of the Xylem Restricted Plant Pathogen Erwinia Tracheiphila

Author Block:

J. Rocha, L. Shapiro, R. Kolter; Harvard Med. Sch., Boston, MA

Abstract Body:

Erwinia tracheiphila (Enterobacteriaceae) is a Gram (-) plant pathogen that causes a fatal bacterial wilt in some cucurbit cultivars. *E. tracheiphila* is obligately insect-transmitted via the frass of striped or spotted cucumber beetles, which it is able to persistently colonize. Despite being one of the first bacterial phytopathogens described in the early 20th century, the molecular basis of plant pathogenicity and colonization capabilities for either plants or insect vectors are still unknown. The study of this model system is relevant both because of the economic losses due to bacterial wilt infection, and because whole genome sequencing data suggests *E. tracheiphila* may have recently emerged into its current niche, making it an important model for understanding the evolution and rapid emergence of plant pathogens.In this study, comparative genomic analyses were performed to identify candidate virulence genes and host colonization factors. Our *in silico* analyses revealed one *hrp* and one *inv/spa* Type III Secretion System (T3SS), and flagellar synthesis operons in the *E. tracheiphila* genome. The presence of these secretion systems is puzzling, as *E. tracheiphila* is xylem limited, which is an ecological niche where few microbes utilize T3SS or flagella. To investigate the functional importance of these operons, we developed the first molecular genetic tools for this bacterium. We generated *gfp*-transcriptional fusions for assessing gene expression *in vitro* and *in vivo* and constructed deletion mutants for determining factors essential for the colonization of both plant and insect hosts. Our results show that the T3SS *hrp* operon is up-regulated in the xylem during the early and middle stages of infection, relative to expression levels in pure culture. Inoculation experiments using clean deletion mutants showed that the *hrp* T3SS is essential for pathogenesis. We also showed that while flagellar motility increases the speed of movement through xylem and the rate of symptom appearance it is not absolutely essential for pathogenicity.These results provide the first insight into virulence mechanisms in this model. Continuing work will use the tools developed to examine additional virulence genes in order to understand this recently evolved plant pathogen.

Microbial Risk Assessment of Treated Wastewater Used for Urban Farming

Author Block:

T. A. Bayleyegn; St. Paul's Hosp. Millennium Med. Coll., Addis Ababa, Ethiopia

Abstract Body:

In Ethiopia, following urbanization especially in Addis Ababa, populations living around the suburbs have been using treated wastewater by stabilization pond for urban agriculture and produce different vegetables for their daily consumption and also outlet to the urban population. However, the suitability of the treated wastewater for irrigation purpose has never been studied before, so that this suitability assessment has crucial concern of the health of communities that live around the irrigation and also to the whole population of the city who consume the products. 500 ml of wastewater samples were taken from the inlet and outlet points of stabilization pond of Addis Ababa Water & Sewerage Authority and another 500 ml of water sample from the irrigation area of the urban farming with sterile bottles and transported to Ethiopian Public Health Institute (EPHI) water quality laboratory with icebox and analyzed for microbial tests such as: Total coliform count, Fecal coliform count and E.coli counts.The following table presents the Microbial level of the three water samples taken from different sites which indicates there is a significant decrement in the Microbial load before and after treatment of the wastewater:

Microbial tests	**Sample source**		
	Inlet of sewages	**Outlet of sewages**	**Irrigation site**
Total coliform counts	1.5 x10^6CFU/ml	3x10^4CFU/ml	3x10^4CFU/ml
Fecal coliform counts	5x10^5CFU/ml	1x10^3CFU/ml	1.1x10^3CFU/ml
E-coli counts	4x10^5CFU/ml	6x10^2CFU/ml	6.2x10^2CFU/ml

Generally, although the results show a significant change of Microbial load by the treatment pond (about 2 logs), the result revealed that the treated water still insufficient to use for irrigation purpose as it is recommended by WHO; the level of fecal coliform for irrigation should be less than 1000/100ml (WHO, 2006).

Impact of Different Temperatures on Biology and Time Concentration Mortality of *Plutella xylostella* L. (Lepidoptera; Plutellidae) Larvae against *Bacillus thuringiensis* (Bt) and Deltamethrin

Author Block:

W. Jaleel[1], S. Saeed[2], H. Yurong[1], Q. Saeed[2], M. N. Naqqash[3]; [1]South China Agricultural Univ., Guangdong, Guangzhou, China, Guangzhou, China, [2]Bahauddin Zakariya Univ., Multan, Multan, Pakistan, [3]Dept. of plant production and technologies, Faculty of Agricultural Sci. and Technology, Niğde Univ.,, Nidge, Turkey

Abstract Body:

Background: *Plutella xylostella* L.is a most damaging pest of brassicae crops in most countries of world i.e. Pakistan, China e. t. c. with preferred hosts cabbage (*Brassica oleracea* var. capitata) and cauliflower (*B.oleracea* var. botrytis). So cost of control of *P. xylostella* is around 4.5 billion dollars annually on world-wide basis primarily with chemical control.Effective management of this pest is essential due to the fact that these vegetables are economically very important crops with high cosmetic value.**Methods:** Evaluation of suitable temperature for its development and second testing was performed by bioassay with leaf dip method on unselected population of *P. xylostella* 3rd instar larvae against deltamethrin and *Bt Cry1Ac* at different temperatures i.e. 15°C, 20°C, 25°C and 30°C.**Results:** Total larval duration was significantly longer at 15°C temperature. Fecundity was 288.09±4.65 eggs per female in its life at 20°C that was significantly higher than other temperatures. The *P. xylostella* mortality was higher (87.50%) against deltamethrin at 30°C after 24 hours. So, same trend was depicted against *Bt Cry1Ac.* Results concluded that with the increase in temperature, mortality of *P. xylostella* was increasedagainst deltamethrin and *Bt Cry1Ac*.**Conclusions:** According to result that was life duration of *P. xylostella* was inversely proportional to temperature but mortality was directly proportional to temperature. Base on the ecological assumption temperaturestrategies is the best tool for Integrated Pest Management against *P. xylostella* at farmer level.

Elucidating Molecular Underpinnings of Extracellular Electron Transfer in Metal Breathing Microbes Using Evolutionary Genomics Approaches

Author Block:

S. Phadke, K. Carpenter, O. Bretschger; J. Craig Venter Inst., La Jolla, CA

Abstract Body:

Extracellular electron transfer (EET) is a process through which microbes shuttle electrons from donor substrates to solid phase electron acceptors such as various metal oxides. Microbial EET is ubiquitous in natural ecosystems and directly determines microbial fitness in some environments; however, we largely lack the knowledge of how selection on rates of EET shapes microbial genome composition as well as genetic networks involved in EET. We combined the power of experimental evolution and next generation sequencing to identify the rates as well as patterns of single nucleotide polymorphisms (SNPs) and Indels in pure cultures of EET-active bacteria grown under controlled laboratory conditions in the presence of electrochemical stimuli. We compared SNP and Indel patterns in biofilms vs. suspension communities to understand if cellular phenotype affects the genome-wide mutational landscape. Our analysis reveals that the genetic makeup of cells in biofilm vs. suspension communities diverges during evolution. Our approach also allows us to reveal previously hidden players in the genetic networks underlying the EET activity. Because EET-active microbes have been held as promising biocatalysts in technologies such as wastewater treatment and biosensing that integrate bioelectrochemical stimuli, our results emphasize the need to characterize evolutionary trajectories of these important biocatalysts for developing robust biotechnological applications as well as understanding the evolutionary context of dissimilatory metal reducing bacteria.

Control of Nanofiltration Membranes Biofouling by Using a New Anti-Fouling Coating

Author Block:

Y. LI[1], H. R. ZHANG[1], K. L. YEUNG[1], **N. Zhan**[2]; [1]The Hong Kong Univ. of Sci. and Technology, Hong Kong, Hong Kong, [2]The Hong Kong Univ. of Sci. and Technology, Hong Kong City, Hong Kong

Abstract Body:

Background: Membrane biofouling is a major impediment limiting a more widespread use of membrane technologies. The formation of biofilm on the membrane surface can cause considerable technical problems and economical losses, especially in reverse osmosis (RO) and nanofiltration processes. **Methods and Results:** This work describes a new multi-functional formulation that permits either reversible or irreversible coating of membrane during normal operation. The formulation consists of antimicrobial micelles which was formed by natural and synthetic materials, these include functionalized chitosan, phosphatidylcholine, primary, secondary and tertiary amine as well as zwitterionic compounds. Tests show that the coating exhibit both contact-killing and anti-adhesion properties that are effective in retarding biofilm formation on the membrane surface. The treated membranes can maintain better than 2 log reduction (99 %) of *E. coli* and effectively prevent surface colonization even in the presence of soiling agents. Comparisons made with uncoated membrane showed no reduction in water permeation and dye rejection rate, indicating minimal impact of the treatment on the original membrane filtration property. Moreover, stability tests showed that the membrane retained better than 85% of the filtered anti-biofoulant after normal cross-flow operation.**Conclusions:** This new coating material can be applied in filtration membrane systems in order to prevent fouling problems, and improve the industrial efficiency.

Role of Nutritional Richness, Hypoxia, Bioactive Cell-Wall Glycopeptidolipid on Biofilm Formation in *Mycobacterium avium* subsp. *hominissuis*

Author Block:

Y. Tateishi[1], S. Matsumoto[1], Y. Nishiuchi[2]; [1]Niigata Univ., Niigata, Japan, [2]Osaka City Univ., Osaka, Japan

Abstract Body:

Background: *Mycobacterium avium* subsp. *hominissuis* (MAH) is the major causative agent of non-tuberculous mycobacteriosis, the representative case of zoonotic and environment-related infectious disease in the industrialized countries. Although glycopeptidolipid (GPL), a MAH-specific bioactive surface molecule, has been suggested to confer colony morphology and swarming in previously, the precise mechanism of biofilm formation in MAH is yet to be know. In this study, we investigated the atmospheric and nutritional condition and the role of glycopeptidolipid (GPL) on biofilm formation in MAH. **Methods:** Seventeen environmental isolates were obtained from bathrooms of MAH lung disease patients' residence. Biofilm formation assay was performed in glass tubes and in polystyrene plates, in normal eutrophic media (7H9/ADC) or oligotrophic media (only containing less than one-tenth amount of albumin and glycerol), under hypoxic (5% O_2), hypercapnic (5% CO_2), or ambient condition, respectively at 37 ^oC. The ultrastructure of biofilm was analyzed by surface electron microcopy. Experiment of exogenous supplementation of GPL was performed to obtain a final concentration of GPL as 100, 500, and 1,000 μg ml^{-1} when mixed with growing rough mutant cells. **Results:** MAH reference strain 104 formed biofilm as surface pellicle in glass tubes only in eutrophy under hypoxic condition, neither in eutrophy under atmospheric condition nor in oligotrophy. Thirteen strains (76 %) formed biofilm in polystyrene plates under hypoxic condition, and 16 strains (94 %) formed thick biofilm under hypoxia as equal to or greater than under hypercapnia in glass tubes. GPL-producing wild type strains developed much thicker biofilm than GPL-deficient rough mutants. The biofilm of wild type strains had robust membranous structure and possessed a plenty of bacteria compared with that of rough mutants. Exogenous supplementation of GPL in rough mutants developed the same phenotype of biofilm as wild type strains. **Conclusions:** Both hypoxia and nutritional richness are necessary factors for biofilm formation in MAH. Furthermore, GPL plays a major role on biofilm development in MAH. This study provides a new insight into the molecular pathogenesis and efficacious prevention of biofilm infectious disease.

Synergistic Activity in Biofilm Formation and Biocontrol Between *Bacillus subtitlis* and *Bacillus cereus*

Author Block:

Y-y. Yu[1], F. Yan[1], J-h. Guo[2], Y. Chai[1]; [1]Northeastern Univ., Boston, MA, [2]Nanjing Agricultural Univ., Nanjihn, China

Abstract Body:

Rhizosphere bacteria *Bacillus subtilis* and *Bacillus cereus* are widely used biological control agents (BCAs). Our previous studies show that *B. subtilis* SM21 and *B. cereus* AR156, when applied together, were more efficient in controlling tomato wilt disease caused by *Ralstonia solanacearum*. This suggests a synergistic activity in biocontrol between these two species. *B. subtilis* is able to form structurally complex multicellular communities, known as biofilms. Biofilm plays a key role in process of biological control of tomato wilt disease by *B. subtilis*. We thus hypothesize that the promoted biocontrol efficacy upon co-application of *B. subtilis* and *B. cereus* was due to enhanced biofilm formation by *B. subtilis* during bacterial interaction. In this study, we found that *B. cereus* AR156 was able to enhance biofilm formation by *B. subtilis* SM21 upon co-culture. In addition, matrix gene expression was upregulated and pellicle biomass increased upon co-culture. We separated the biofilm-inducing active compound from AR156 pellicle by sonication and filtration of the supernatant. This active compound is able to stimulate *B. subtilis* biofilm formation in a non-biofilm-inducing medium (LB medium) in a dose-dependent manner. In search of potential sensor(s) for the active compound, we noticed that biofilm of a SM21 derivative bearing Δ *kinC* mutation was not induced by the compound, suggesting the histidine kinase KinC might be involved in sensing the active compound. In conclusion, our preliminary data showed that *B. cereus* AR156 enhanced *B. subtilis* SM21 biofilm and the stimulation is possibly mediated by activating *B. subtilis* KinC. This study provided molecular evidence for the synergistic biocontrol activity.

Prevalence of Antibiotic Resistance among Biofilm Forming Bacteria Isolated from Domestic Environments in Dubai

Author Block:

S. Balaji, K. A. Vasudev, P. Srinivasan, S. Singh, **N. Sood**, T. S. Gokhale, R. Subramanian; Birla Inst. of Technology & Sci., Dubai, United Arab Emirates

Abstract Body:

Background: Biofilm forming bacteria in domestic environments are potential source of pathogenic microbes and food spoilage. Comprehensive studies on biofilm bacterial communities in household environments and antibiotic resistance remain unexplored in UAE. The present study was to isolate, characterize and to screen for antibiotic resistance in bacteria isolated from biofilms.**Methods:** Samples from households comprising of kitchen sinks, household drain systems and shower curtains were obtained and grown on nutrient, selective and differential media. A total of 27 different colonies were isolated from 12 samples. Bacterial isolates were identified based on colony morphology, Gram's staining and biochemical characterization.**Results:** Several genera were found that include *Pseudomonas, Shigella, Bacillus, Salmonella, Vibrio, Enterobacter*, *Campylobacter* and *Proteus* species. Nearly two third of the isolates were *Enterobacter* and *Proteus* species. The selected 27 isolates were subjected to antibiotic resistance test on nutrient medium using the standard antibiotics disks. Most of the bacterial isolates were resistant to tested antibiotics. Further studies on 16s rRNA based identification and phylogenetic profiling in progress.**Conclusions:** The preliminary study on biofilm in household environments is significant to catalogue in this region due to sparse work conducted so far. The data could be useful to correlate certain infectious diseases and the role of biofilm forming bacteria in domestic environments.

Synergistic Virulence Generation by *Pseudomonas aeruginosa* Strains, Implications for Application in Bioelectrochemical Systems

Author Block:

E. M. Bosire, L. M. Blank, M. Rosenbaum; RWTH Aachen Univ., Aachen, Germany

Abstract Body:

Pseudomonas aeruginosa virulence factors, especially phenazines, have gained attention for application as redox mediators in bioelectrochemical systems (BES). Other pathogenicity factors like rhamnolipids and siderophores might play an important role in enabling biofilm formation on the electrodes. In bacterial-based BES, bacteria metabolise substrates and liberated electrons are shuttled to an external electron acceptor (anode) *via* soluble redox mediators among other modes of electron transfer. One of the promising applications of these technologies is electricity generation from wastewater. Like in natural communities, microorganisms often build synergistically interacting microbial consortia in wastewater BES. In these interactions, consumption of fermentation products by *P. aeruginosa* leads to increased phenazine production and consequently increased electroactivity of the whole community. This natural phenomenon can be a basis to design synergistically interacting co-cultures, where *P. aeruginosa* is the redox mediator producer. However, the physiological roles of these secondary metabolites, how they are employed under varying ecological conditions across the *P. aeruginosa* strains, and the capacity of the phenazines as redox mediators in BES is yet to be fully understood. To investigate the performance of *P. aeruginosa* strains (PA14, PA01 and a BES isolate KRP1), we cultured them in media containing different substrates including fermentation products, assessed their virulence factor production and electroactivity. Our study reveals remarkable differences among the three strains in the production of phenazines, rhamnolipids and the tendency to form biofilms under the BES conditions and different substrates. Further, the strains exhibit different electroactivity capacities due to differences in phenazine spectra. The virulence factor generation and the electrochemical behaviour of the phenazines observed will not only be useful in improving BES performance but also in understanding the usage of phenazines in the different redox-controlled ecological niches of *P. aeruginosa*.

Optimization of ALI Assay for Model Archaeon and Isolation of Novel Adhesion Mutants

Author Block:

G. Legerme, M. Pohlschroder, R. Esquivel; Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Biofilm formation is a fundamental adaptation to environmental stress that is found throughout the prokaryotic domains. The Air-liquid interface (Ali) assay is a method used to quantify cell surface adhesion, the first step in biofilm formation. Although this assay has been successfully used to screen transposon insertion libraries for several bacterial species, an analogous assay had not been optimized for any archaeal species. In the model archaeon *H. volcanii*, we have now adapted the Ali assay for use in 96-well plates, allowing us to rapidly screen a transposon insertion library for adhesion mutants. Using this protocol, we identified 19 genetically diverse adhesion mutants. One of these mutants contains an insertion between genes encoding CheB and CheW, chemotaxis machinery components primarily known for their effect on motility in bacteria. In a second mutant, we identified an insertion in *pilB1*, a gene that encodes a paralog of the *H. volcanii* ATPase PilB3, which plays an essential role in surface adhesion by aiding in the biosynthesis of adhesion pili, suggesting the efficacy of this approach for identifying proteins that play roles in pilus biosynthesis and function, as well as in adhesion. Moreover, considering that PilB1 is not essential for *H. volcanii* surface adhesion like PilB3 is, as seen in using the 12-well Ali assays, this suggests the possibility of differential supplemental expression of specific adhesion pili in different conditions. In fact, in using the 12-well assay, of the five *H. volcanii* PilB paralogs and of its 42 predicted pilins, only PilB3 and six pilins appeared to be required for adhesion. Since *pilB1* is co-regulated with genes encoding additional predicted pilins, these pilins may be subunits of pili that mediate surface adhesion under certain conditions. We are currently determining the specific differences between conditions used for the 12-well assay compared to the 96-well assay that affect the surface adhesion of the *pilB1* mutant. Additional adhesion mutants contained insertions in genes that encode transcriptional regulators as well as in genes encoding componentsof metabolic pathways. Further characterization of these mutants should advance our understanding of the mechanisms underlying archaeal biofilm formation..

Adhesion of Bacteria to Microplastics in Freshwater

Author Block:

M. Hossain, M. Jiang, Q-H. Wei, L. Leff; Kent State Univ., Kent, OH

Abstract Body:

Microplastics (plastic debris less than 5mm in diameter) are of particular concern to the environment. Previous research has shown that microplastics provide a substratum for bacterial adhesion in the oceans. However, there is a paucity of information on the adhesion of freshwater bacteria to plastics, especially microplastics. We examined the following microplastics: polypropylene (PP), polystyrene (PS), high-density polyethylene (HDPE), and low-density polyethylene (LDPE). Each type of plastic possesses specific surface morphologies and characteristics which influence adhesion of the bacterial species: *E.coli*, *A.calcoaceticus*, *B.cepacia*, *S.paucimobilis*, *P.aeruginosa*, *Synecococchus* spp.Scanning Electron Microscopy (SEM) was used to visualize and quantify the colonization of recently discarded "new" microplastics at weeks 0, 4, and 8 composed of PP, PS and PE (representing both HDPE and LDPE) and "eroded" microplastics sampled from the beaches adjacent to Cleveland, OH. The bacteria were allowed to colonize microplastics in water from Lake Erie. Fluorescent microscopy was also used to quantify bacterial colonization. Quantification of EPS was performed to determine how plastic surface characteristics affect bacterial adhesion properties.Imaging showed a gradual increase in attachment of bacteria on all forms of microplastics. PS exhibited high microbial attachment through the entirety of the study, while HDPE, LDPE and PP had relatively minimal microbial attachment at week 4 and had biofilm matrices by week 8. Eroded microplastics had higher bacterial attachment than new microplastics.Imaging indicated that presence of bacterial flagella affects bacterial attachment and EPS production, with peritrichous *E.coli* displaying highest bacterial abundance on microplastics while producing the least amount of EPS. Meanwhile, non-flagellated *A.calcoaceticus* had lowest abundance and highest amount of EPS production.Our findings indicate that bacterial attachment to microplastics in freshwater is influenced by the unique properties of different classes of microplastics. As the plastic ages in the environment, its surface becomes eroded causing higher bacterial attachment. In addition, bacteria adopt varying strategies to attach to the plastic surfaces based on their physiological properties.

Biofilm Formation on 304 Stainless Steel in Marine Water Studied by Optical and Scanning Electron Microscopy

Author Block:

B. S. Neves, A. M. N. Korres; Inst. Federal de Educação, Ciência e Tecnologia do Espírito Santo, Vitória, Brazil

Abstract Body:

Biofilms are complex communities of microorganisms attached to surfaces or associated with interfaces. Adherence of bacteria to metal surfaces can initiate the biofilm formation within which the metabolic processes can significantly affect of the corrosion surface. This study reports microbial biofilm formation on 304 stainless steel surface in marine water by the counting (CFU/cm^2) and image by optical and scanning electronic microscopy. Experiments were performed in laboratory. Steel coupons were immersed in marine water collected from Ilha do Boi Beach (Vitória, ES, Brazil) during four weeks. CFU/cm^2 and images were determined for each time using optical stereomicroscope (Leica EZ4 HD) and scanning electron microscope (Zeiss 900, Germany). Samples were sputtered (Super Cool Sputtering System, Bal-Tec®, SCD 050, Germany) and images were obtained in SEM. Results showed biofilm was formed in all situations, except on the first week. CFU/cm^2 indicated biofilm formation on second, third and fourth week, respectively $5{,}15 \times 10^4$, $9{,}15 \times 10^5$ e $8{,}74 \times 10^5$. First week showed number of CFU/cm^2 of $2{,}50 \times 10^2$, indicating biofilm was not formed considering a value of 10^3 and 10^5 cells per cm^2 to biofilm formation. Images from stereomicroscope in fresh samples showed the steel surface with microbial adhesion offering a real dimension of the preview image, with the zoom facilitated look the details of the agglomeration, texture and color microbial growth. The results of the test EDS associated with scanning electron microscope images validated the data indicating the existence of iron oxides because the surface of the coupon, sodium chloride because to sea water, and also organic substances due to the formation of biofilms. The high-resolution images show the biofilm growth during the period of the study. Morphological characterization by optical microscope showed the presence of elliptical yeast like organisms. The study of biofilms becomes important in marine environment because its adhesion to surfaces may cause biofouling and deterioration of structures, leading losses for various sectors.

***Deinococcus aquaticus,* Life or Death in a Biofilm Driven by Desiccation**

Author Block:

A. Zarling, F. Mayer, K. Laux, S. Mitchell, N. Weiss, R. Krueger, A. Limbach, A. Dorner, J. Draven, G. Dungar, C. Schmitz, R. Koll, Z. Stuebs, S. Mueller-Spitz, A. Horkman; Univ. of Wisconsin Oshkosh, Oshkosh, WI

Abstract Body:

Desiccation is a state where cells are exposed to extremely dry conditions, which results in numerous physiological changes and may lead to cell death upon rehydration. The extremophile *Deinococcus radiodurans* is resistant to long-term desiccation related to its ability to repair DNA damage. Desiccation tolerance is assumed to be a common trait for all members of this genera. However, whether this trait provides an ecological advantage for deinococci inhabiting biofilm environments that are prone to extreme variation in water potential is a question of interest. *D. aquaticus* are common members of shallow freshwater biofilms, yet it is unknown what controls their dominance and survival under these harsh conditions. To address this question, the survival and morphological changes of four *D. aquaticus* strains was explored following desiccation and rehydration over a six week period. All cultures were grown to mid-exponential phase prior to desiccation to ensure the cells possessed the machinery essential for DNA repair. Regardless of the biofilm habitat, the four isolates survived six weeks of desiccation; however, each strain showed different patterns of regrowth after rehydration. Strain P17 had doubled cell counts after week one and two showing the potential for reductive division post-rehydration. However, between 60-88% of the starting culture for the other three strains (P34, P43, and P71) died following one week of desiccation. Two strains (P34 and P71) were particular sensitive to long-term desiccation with less than 5% of the starting culture remaining viable. Even though two strains (P34 and P43) were isolated from the same biofilm habitat and share genome-wide similarity, survival was significantly different. The variation in the long-term desiccation survival was attributed to an extracellular matrix excreted by the individual strains. Based upon scanning electron micrographs of desiccated cells, both P17 and P34 were heavily encased in a protective matrix. This thick matrix was not seen for strains P71 or P43. We hypothesize that resistance to desiccation stress in *D. aquaticus* relates to strain viability in expression of an extracellular matrix when grown in a pure culture and predict these strains may protect other ecotypes present in a mixed community.

Growth-Phase Dependent Attachment of *Acidithiobacillus ferrooxidans* to Metal Sulfide Ores

Author Block:

J. Iordanou, S. Popko, **S. E. Blumer-Schuette**; Oakland Univ., Rochester, MI

Abstract Body:

Initial contact between *Acidithiobacillus ferrooxidans* and surfaces is important for the development of a monolayer biofilm that facilitates direct dissolution of metal sulfides. Typical extracellular structures used to mediate cell-surface attachment include flagella and pilus systems. While the genome sequence for *A. ferrooxidans* ATCC 23270 does not encode for flagella, both type IV and tight adherence pilus systems have been identified from the available genome sequence. Using the Integrated Microbial Genomes database to query for additional pilus systems, we also identified genes encoding for chaperone/ usher pili in the genome of *A. ferrooxidans* that may also be used for attachment to surfaces. Here, we propose that the pilus systems used in surface attachment are expressed in a growth phase dependent manner, and are crucial for attachment to hydrophobic surfaces. Initially to determine if there are growth phase-dependent effects on attachment, we measured biofilm deposition by *A. ferrooxidans* grown on soluble iron(II). Crystal violet staining of the biofilm formed on hydrophilic (borosilicate glass) and hydrophobic (polystyrene) surfaces were used to quantify biofilm formation over time. Polystyrene supported cell attachment, with over twice as much biofilm being deposited. Increases in biofilm also correlated with active growth of the planktonic cells, as determined by enumeration using microscopy. Aside from inert surfaces, we also monitored the ability of cells grown on soluble iron to attach to pyrite, an insoluble iron sulfide. Comparing the number of planktonic cells left after incubation with pyrite at various growth time points, we observed a 58% reduction in *A. ferrooxidan*s attachment during the transition to stationary phase. This result was reproduced in three independent cultures. In order to determine which pilus systems are being expressed prior to entry into stationary phase, we designed primer sets for quantitative RT-PCR to monitor expression of key genes in the three distinct pilus gene clusters. Our results so far indicate a role for attachment mechanisms that are hydrophobic in nature and are expressed during active growth of the planktonic culture. Data on the expression of the three pilus systems will add to our mechanistic understanding of how A. ferrooxidans initiates attachment to metal sulfides.

Quorum Sensing in *Paracoccus denitrificans* PD1222 Inhibit Cell Aggregation

Author Block:

K. Morinaga, M. Toyofuku, N. Nomura; Univ. of Tsukuba, Tsukuba, Japan

Abstract Body:

Various bacteria communicate with each other via signal molecules to control their behavior. Especially, cell density dependent cell to cell communication is called quorum sensing. While most quorum sensing studies are based on pathogenic bacteria, numerous bacteria in the environment possess' quorum sensing systems, which functions are not fully understood (Churchill MEA, *et al.*, 2011). To investigate the role of quorum sensing in a non-pathogenic bacteria, we used *Paracoccus denitrificans*, which is frequently isolated from activated sludge or soils. *P. denitrificans* synthesizes N-hexadecanoyl-AHL (C16-HSL) (Schaefer AL, *et al.*, 2002). To examine the phenotypes regulated by C16-HSL, we constructed a non-AHL-producing mutant (*luxI* mutant) of *P. denitrificans* Pd1222. The *luxI* mutant strongly aggregated while the wild-type did not. The aggregation of the *luxI* mutant was not observed when C16-HSL was added to the culture. This result suggests that quorum sensing in *P. denitrificans* inhibits cell aggregation. SEM analysis showed that the *luxI* mutant produced fiber-like extracellular matrix that was not observed in the wild-type. To identify the genes involved in this quorum sensing-inhibited aggregation, we screened transposon mutants of the *luxI* mutant. Several transposon mutants of the *luxI* mutant that did not aggregate were obtained and the positions where the transposon was inserted were identified. Most transposons were inserted in putative polysaccharide synthesis genes, suggesting that quorum sensing in *P. denitrificans* Pd1222 regulates aggregation through the production of extracellular polysaccharides. Our results imply that *P. denitrificans* Pd1222 avoids forming cell aggregates when the cell density is high.

***In Vitro* Response to Guanidine Desinfectant Cleaner (GDC) on Multidrug Resistant Gram Negative Bacteria**

Author Block:

M. G. Quinteros[1], P. Rigou[1], R. D. Marino[2], A. Farinati[1]; [1]SALVADOR Univ., MARTINEZ, BUENOS AIRES, Argentina, [2]Hosp. FJ Muñiz, BUENOS AIRES, Argentina

Abstract Body:

Background: The multidrug resistant bacteria are a concern in the hospital-acquired infections. The bacterial cells are in planktonic or within biofilm (BF). This have intrinsic resistance to conventional antimicrobial substances, including disinfectants. This event has motivated new approaches to eliminate or disrupt BF after it has already been formed. **Aim:** to study the response of a chemical derivative of guanidine (poli hexametilen guanidine clorhidrate-PHG) (GDC) on planktonic (PL) and biofilm (BF) multidrug-resistant bacteria (MDR).**Methods:** bacteria species used were: IMP13; KPC and VIM producer *Pseudomonas aeruginosa* (Pae) n=3; CMY-2 and CTX-M-2 *Escherichia coli* (Eco) n=2; CTX-M-15 and KPC-2 *Klebsiella pneumoniae* (Kpn) n=2; *Acinetobacter baumannii* (Aba) n=1. The minimal inhibition dilution (MID) for all those planktonic bacteria was 1/100 of GDC. **Biofilm:** A dilution of 100 microliters overnight from each bacteria was inoculated in 6 TS Broth (TSB) recipient and a glass coupon (GC) is put in as a biofilm support. All isolates were incubated at 37^0C with an without GDC in a recommended dose (1/100) and were observed at 24 hours (previously we determined the BF formation at different hours). Everything was read by optical microscopy previous crystal violet tinction.**Results:** we observed that the MID was 1/500 and 1/400 for planktonic MDR. Over MDR BF the 1/100 dose was not effective; except for Eco: bacterial growth was zero for the dose and time recommended by the manufacturer. Some BF exposed to disinfectant at recommended dose should be interacting longer; *Acinetobacter baumannii* biofilms should be tested at higher doses of disinfectant in order to evaluate the dose at which it is eradicated.**Conclusions:** GDC is useful to clean contaminated surfaces with MDR planktonic bacteria but not for BF at recomended doses.

Anti-Bacterial and Anti-Biofouling Effects of Self-Assembly Cationic Polymers Coated on Multiple Substrates

Author Block:

H. ZHANG[1], K. L. YEUNG[2]; [1]The Hong Kong Univ. of Sci. and Technology, Hong Kong, Hong Kong, [2]Hong Kong Univ. of Sci. and Technology, Hong Kong, Hong Kong

Abstract Body:

Background: Water related Industrial applications including cooling tower systems, water reservoir tanks and membrane filtration processes are susceptible to microbial contamination. Various kinds of chemical biocides are used to remove the bacteria. However, many microorganisms in aquatic environment tend to colonize on surface of substrates by encapsulating themselves into slimy matrix, which is known as biofilm. Once biofilms are formed, their resistance to biocides is greatly improved, and result in huge loss in industrial processes. **Method and Result**: This work studied the effect of cationic self-assembly polymers on biofouling reduction. Single polymer and combination of different polymers were formulated into micelles and applied onto different substrates including PVC, stainless steel and glass. Contact killing tests were carried out on *E.coli*, *P. aeruginosa*, *S. aureus and B. subtilis*. 4 log (99.99%) reduction was achieved on all tested bacteria strains. The formulation was coated onto different substrates using dopamine as adhesive by layer-by-layer method. The stability of coating was measured by immersing samples for over 2 weeks. X-ray photoelectron spectroscopy was applied for the quantification of functional moieties on the coated substrates surface. The anti-biofouling test was analyzed by scanning electron microscope. The quantification of bacteria attached onto the coated surface was measured by Direct Enumeration technique. In the anti-adhesion test, the coating can achieve 2 log (99%) reduction of *E.coli* attachment onto PVC and 85% reduction of E.coli attachment onto stainless steel. **Conclusion:** The study showed both high bactericidal and high anti-adhesion efficacy of formulated cationic polymer coating. The coating can be stably attached onto multiple substrates using layer by layer methods, which can be used in academic research and industrial applications.

Fungal Isolates Form Biofilms in Hemodialysis Fluids

Author Block:

R. H. Pires[1], L. Teodoro[1], L. G. Lopes[1], C. H. G. Martins[1], M. C. Jamur[2]; [1]Univ.e de Franca, Franca, Brazil, [2]Univ.e de São Paulo, Ribeirao Preto, Brazil

Abstract Body:

Background: In hemodialysis procedure, the dialysate is constituted by hemodialysis machines mixing treated water (by reverse osmosis), acid and bicarbonate concentrates. Appropriate water purity has been standardized by a variety of organizations, professional societies and pharmacopoeias. The absence of any type of antimicrobial in the water makes it susceptible to microbial contamination downstream of the water treatment, which contributes to the development of biofilms in the dialysate pathway of the proportionating system of hemodialysis machines. This study aimed to evaluate the ability of biofim formation by fungal isolates in the dialysate and its constituent solutions, comparing to the RPMI culture medium.**Methods:** *Aspergillus, Fusarium* and *Penicillium* isolates were recovered from the water circuit of a hemodialysis facility. The biomass of the biofilms were determined by the crystal violet method and its ultrastructures were visualized by scanning electron microscopy (SEM).**Results:** *Fusarium* strains (10 isolates) were the most homogeneous group in biofilm-forming ability on both dialyate and other solutions. *Aspergillus* (18 isolates) showed high variability in biofilm formation. *Aspergillus* isolate 186 formed biomass in the dialysate equal to the biomass formed in RPMI, while 33.3% and 44.4% of the isolates formed more biomass in base or acid concentrates than in the dialysate. The biomass formed in the dialysate, for all strains of *Penicillium* (7 isolates), was greater than that formed in the concentrated acidic or basic. SEM analysis of *Aspergillus* biofilms formed on RPMI medium showed dense aggregation of hyphae, presence of conidial structures and matrix. **Conclusions:** The demonstration that fungal biofilm can be formed in dialysis fluids strengthens the need for the inclusion of fungi and, in particular, biofilms, in quality of dialysis fluid for haemodialysis therapy.

***Agrobacterium*-Mediated Transient Expression Using Modified Geminiviral Replicons Provides Rapid High-Yield Production of Vaccine Antigens and Monoclonal Antibodies in Plants**

Author Block:

A. Diamos, T. Anderson, J. M. Crawford, H. S. Mason; Arizona State Univ., Tempe, AZ

Abstract Body:

Agrobacterium-mediated expression systems have been investigated as alternatives to traditional fermentation-based systems for the production of recombinant proteins. We have developed a system that uses *Agrobacterium* to deliver modified bean yellow dwarf virus replicons to plant cells, which, unlike many other plant expression systems, is capable of producing heteromultimeric proteins with more than 2 heterosubunits (Huang et al., 2010). However, the system had not been optimized to maximize yield and reduce plant cell death.To address these concerns, we evaluated *Agrobacterium* strains LBA4301, LBA4404, GV3101, and EHA105 harboring geminiviral replicons by syringe infiltration to leaves of *Nicotiana benthamiana*. We found that strain EHA105 reduced tissue cell death, enhanced reporter GFP expression, and provided a >2-fold increase in monoclonal antibody production measured by ELISA. To determine whether viral replication components also played a role in cell death, we created modified vectors that varied the wildtype expression of Rep and RepA. We found that a modest reduction of both Rep and RepA reduced cell death, and despite also reducing the accumulation of replicon DNA as measured by semi-quantitative PCR, resulted in a ~50% increase in production of Norwalk virus capsid protein measured by ELISA. We evaluated diverse genetic elements for their capacity to improve mRNA stability and efficient utilization by the plant cell. Using protein gel quantification and ELISA, we found that the 5' untranslated from *Nicotiana benthamiana* homologs of the photosystem K subunit gene enhanced GFP production by as much as 40% more than the widely used omega leader from tobacco mosaic virus. We also found that the tobacco Rb7 matrix attachment region positioned 3' of the gene terminator enhanced monoclonal antibody production by up to 3-fold using ELISA. Together, we used these modifications to produce Norwalk virus capsid protein at 1.8mg per gram leaf fresh weight, more than twice the highest level ever reported in a plant-based system, and the monoclonal antibody rituximab at 1 mg per gram leaf fresh weight.

Analysis of UV Protective Compounds from Cyanobacterial Isolates

Author Block:

s. nosheen; Univ. of the Punjab, Lahore, Pakistan

Abstract Body:

Ozone layer is continuously decreasing due to increasing atmospheric pollutants as a result UV radiations reaching on the surface of Earth are increasing day by day. Living organisms have different mechanisms to cope up with hazardous UV radiations, even some organisms produce UV protective compounds. In cyanobacteria, production of UV protective compounds is a very competent defense mechanism. In this study cyanobacterial isolates were analyzed for the production of UV protective compounds by using quite efficient extraction method to analyze how common and diverse these substances are present among them. UV absorption spectrum of extracted compounds was analyzed by UV spectrophotometer. Hyper UV protective compounds producing isolates (three filamentous and two unicellular isolates) were selected and their compounds were analyzed for UV and Nitrate stress. Various peaks of absorbance were observed, in all three regions of UV. Strains showed variations in the distribution of UV protective compounds. Overall trend that was observed according to number of peaks is UV-C > UV-B > UV-A. UV stress induces the production of UV protective compounds and nitrate stress also affects its production. There was not only increase in the number of peaks but absorbance values were also increased and trend shifts toward the production of more UV-B and UV-A compounds as compare to control. These multipurpose UV protective compounds can find applications in various fields and industries including pharmaceutical, paint, sunglasses and most important skin care and cosmetics industry.

Genetically Inducible Recovery of Cyanobacterial Biomass by Autoaggregation

Author Block:

M. Fisher[1], **C. Keal**[1], V. Patil[2], D. Nielsen[2], R. Curtiss, III[3]; [1]Southern Connecticut State Univ., New Haven, CT, [2]Arizona State Univ., Tempe, AZ, [3]Arizona State Unversity, Tempe, AZ

Abstract Body:

One attractive method to produce renewable energy is the development of biofuels made by cyanobacteria, which can be engineered to produce biofuels, biofuel precursors or bioproducts from CO_2, sunlight and water. A major obstacle to economical production of such bioproducts is harvesting cyanobacteria from their liquid media. Centrifugation, for instance, is energy intensive and increases production cost. Therefore, low energy mechanisms for biomass harvest are necessary. Herein we describe a novel process for biomass harvest in which cyanobacteria were engineered to express genes encoding type V secreted adhesins. In their native organisms, type V secreted proteins are necessary for adhesion of the bacterium to their target host cells. Additionally, when over produced, they elicit autoaggregation and subsequent precipitation from the culture medium. We wished to determine whether expression of such adhesins would have a similar effect in cyanobacteria. Therefore, *Synechocystis* PCC 6803 was engineered to express either aipA, *taaP*, *tibA* or *yadA* under control of the promoter $P_{nrsB,}$ which can be induced by the presence of Nickel. These strains were named SD1011, SD1012, SD1013 and SD1014, respectively. In addition, the *tibA* gene was placed under control of the promoter P_{cmpA}, which can be induced by CO_2 limitation. This strain was named SD1022. Following construction of these strains, we tested them for their ability to precipitate out of solution. SD1011, SD1012, SD1013 and SD1014 were grown in 125 ml of BG-11 to an OD_{730} of 1.0. After a 24-hour induction with 6 μM Ni^{++}, 25 ml of the induced culture was aliquoted into a sterile, 125 ml Erlenmeyer flask. The adhesion producing strains SD1011, SD1012, SD1013 and SD1014 precipitated out of solution within 8 hours. We observed similar results with SD1022 by CO_2 limitation. Importantly, we noted that volume and the shape of the culture flask influenced the outcomes of agglutination. SD1022 grown in 800 ml of BG-11 in a septation flask failed to show dramatically different autoagglutination from the wild-type strain. These data indicate: *Synechocystsis* is capable of producing functional type V secreted proteins, that these proteins properly translocate to the outer membrane and they are able to function as autoagglutinating adhesins.

Synthetic Ecology for Quantitative Prediction of Anti-Contamination Strategies in Biofuel-Producing Cultures of *Synechocystis* PCC 6803

Author Block:

R. Allen[1], A. Zevin[2], R. Curtiss, III[3], R. Krajmalnik-Brown[1]; [1]Arizona State Univ., Tempe, AZ, [2]Univ. of Washington, Seattle, WA, [3]Univ. of Florida, Gainsville, FL

Abstract Body:

We previously engineered *Synechocystis* to secrete fatty acids such as laurate, a jet fuel precursor. An outdoor 4,000-liter photobioreactor (PBR) of *Synechocystis* culture that became contaminated by heterotrophic bacteria had reduced yield of laurate. We hypothesized that chemical additives such as salt, alkalinity and/or antibiotic will inhibit growth of these heterotrophs while allowing *Synechocystis* to flourish, improving laurate yields.To test this hypothesis, we used factorial analysis to model heterotroph growth response to three factors: NaCl concentration, pH, and kanamycin concentration. Growth was tested in rich media (LB broth), and also in laurate-producing *Synechocystis* cultures. Forty contaminant isolates were combined to create a single Defined Consortium, which was then used as inoculum for each of 19 growth conditions generated by central composite design. ANOVA of heterotroph growth measured a statistically significant response surface regression ($p < 0.05$). We tested the model using two different Defined Consortia (a total of 80 isolates), and also two different Undefined Consortia derived from lake water. Growth of both Defined and Undefined Consortia matched model predictions, supporting our hypothesis that these additives inhibit heterotroph growth. Furthermore, these data support that levels of these additives can quantitatively predict heterotroph growth independent of the species present.Attempts to generate a surface response regression in *Synechocystis* cultures were unsuccessful, indicating the presence of additional factors contributing to growth. However, a time-course assay showed that laurate is protected for over 72 hours in the presence of additives (as measured by FID GC), compared to less than 24 hrs without additives.We conclude that this study is a proof-of-principle for further investigation of using a Defined Consortium to quantitatively model "generalized" PBR contamination under controlled conditions. We propose this is possible due to the widely conserved mechanisms of resistance to salt, alkalinity, and antibiotics across diverse bacterial phyla, which we will investigate using deep sequencing of 16s rDNA followed by metabolic prediction with PICRUSt.

Characterization of Plant Cell Wall-Acting Esterases: The Effect of Ionic Liquids on Ferulic Acid Release from Corn Stover

Author Block:

P. Palacios; INRA Inst. Natl. de la Recherche Agronomique, Marseille, France

Abstract Body:

Plant cell wall-acting esterases play an important role in facilitating the microbial degradation of lignocellulosic biomass through the cleavage of ester bonds on the substituted polymers. Recombinant feruloyl and acetyl esterases from *Pycnoporus cinnabarinus*, *Volvariella volvacea*, *Penicillium funiculosum*, and *Penicillium purpurogenum* were heterologously produced in *Pichia pastoris*, biochemical characterized and their activity tested in ionic liquids (ILs) as solvent on model and natural substrates. This is the first detailed investigation concerning the effect of ionic liquids on acetyl and feruloyl esterases. Heterologous production of the acetyl esterases from *V. volvacea* and *P. purpogenum* and a type-B feruloyl esterase from *P. funiculosum* was successfully achieved. In addition, the gene coding for CE1 from *Pycnoporus cinnabarinus* was cloned, expressed and the corresponding protein biochemically characterized for the first time and shown to be an acetyl esterase. The use of 1-Ethyl-3-methylimidazolium acetate ionic liquid resulted in a 2 to 5.5-fold increase in the activity of all the esterases on model substrates such as *p*-nitrophenyl acetate and methyl caffeate, and approximately 3-fold on the release of ferulic acid from corn stover by PfFaeB. Two other previously characterized feruloyl esterases (AnFaeA and TsFaeC), an L-arabinofuranosidase (TxAbf) and three xylanases from *Trichoderma viride*, *Neocallimastix patriciarum* and *Podospora anserina*) were also tested with ionic liquids. The ILs induced positive and negative effects depending on the enzyme and the substrate used. The tolerance of the enzymes to ILs was also dependent on the temperature of incubation. The obtained results suggested that the effect of ILs on enzymes activities is thermo-substrate dependent and that the stability and kinetic constants are modified by the presence of ILs. Depending on the enzyme, the hydrolytic activity on lignocellulosic biomass can be improved or reduced in the presence of these solvents. Further work is needed to discover and evaluate the factors that affect the interactions between ILs, enzymes and substrates in order to contribute to the optimization of enzymatic lignocellulose degradation process.

Phosphorus Limitation Enhances Biodiesel Production in Dark-Grown Algae Fed Grain or Lignocellulosic Hydrolysates

Author Block:

N. Shrestha, **M. A. Schneegurt**; Wichita State Univ., Wichita, KS

Abstract Body:

Algae grown in the dark on pure sugars or plant biomass hydrolysates accumulate lipids suitable for biodiesel. We have previously reported on the growth of *Chlorella kessleri* on grain and lignocellulosic hydrolysates. Nitrogen limitation has been shown previously to increase the accumulation of lipids by algae. While this scheme works well with media supplemented with pure sugars, biomass hydrolysates are complex mixtures that contain a variety of nitrogen sources. It is difficult to reduce their bioavailable nitrogen content. We have investigated the potential of phosphorus limitation to enhance the accumulation of algal lipids, since it may be straightforward to remove phosphorus compounds using physicochemical means such as functionalized beads. *Chlorella* was grown in a series of media creating a range of nitrogen or phosphorus limitations, either autotrophically in the light or heterotrophically in the dark on sucrose or a lignocellulosic hydrolysate of big bluestem (*Andropogon gerardii*). Algal growth was measured by direct microscopic cell count and by chlorophyll content, while lipid accumulation was estimated using a Nile red assay. Nutrient limitation led to lower growth rates and stationary-phase culture densities, as expected. Nitrogen starvation led to increased lipid content when *Chlorella* was grown on sucrose, as previously reported. Similarly, phosphorus starvation led to increases in lipid accumulation of 5- to 7-fold on a dry weight basis. Iron starvation did not elicit an increase in lipid content. When big bluestem hydrolysates were used to support heterotrophic growth, lipid accumulation also was enhanced 3- to 7-fold by nitrogen or phosphorus limitation. There were differences in the composition of the lipids by FAME analysis. While the lipid content of cells increased, the biomass yields from starved cultures were concomitantly lower, such that the total lipid content by volume of culture was not substantially increased. A two-stage reactor system may work, where algae are grown in nutrient-replete medium to high density and then moved to nutrient-limited conditions to increase lipid yields. The sharing of technologies (fermenters) and feedstocks (grain and grass hydrolysates) between bioethanol and biodiesel production may provide new opportunities for flexible production of renewable liquid fuels using existing infrastructure.

Abstract Body:

Corn fibre is the fibrous matter remaining after the wet-milled corn has been sieved. The potential of using these corn fibres for the production of cellulolytic enzyme was assessed. Microorganisms capable of utilizing corn fibre as the sole carbon source were evaluated. Corn fibres were pre-treated with 25% ammonia and then added to the compounded medium (MM1). Appropriate dilutions of soil sample obtained from Science village, Nnamdi Azikiwe University, Awka, Anambra State, were used to inoculate the medium. The isolates obtained were assessed for the production of cellulase enzyme by flooding with congo red. The isolates include *Aspergillus flavus*, *Aspergillus niger*, *Geotrichum* sp.and *Penicillium* sp. *A. flavus* showed the highest zone of hydrolysis while none was observed on *A. niger.* This study has shown that *A. flavus* producing the highest zone of inhibition could be used for cellulase production using pretreated corn fibre as substrate.

One-Pot Enzymatic Pretreatment of Lignocellulosic Biomass for Bioenergy Production

Author Block:

J. L. Tran, T. Nadelson, B. Wang, K-H. Chu; Texas A&M Univ., College Station, TX

Abstract Body:

Background: Lignocellulosic biomass is abundant, available, and rich in organic material, making it a potential source for sustainable bioenergy production. Available lignocellulosic biomass includes wood, agricultural and forest residues, and some urban waste like yard trimming, paper waste, and saw dust. As the biomass are complex biopolymers composed of mainly cellulose, hemicelluloses, and lignin, it is necessary to pretreat the lignocellulosic biomass to produce fermenting sugars. Current practice of pretreating lignocellulosic biomass, commonly using chemical methods followed by enzymatic hydrolysis for depolymerization, is costly and not sustainable.**Methods, Results and Conclusions:**In this study, we explore the possibility to pretreat lignocellulosic biomass with direct application of enzymes for effective depolymerization. Specific objective of this study is to investigate potential for using engineered-enzymatic producing *E.coli* to pretreat lignocellulosic biomass to release sugars and monomers for producing triacylglycerol (TAG) by TAG-accumulating bacteria. TAG, a major component in fats, oils and lipids derived from plants, animals, fungi, and bacteria, is the material for the production of biodiesel, a clean and renewable liquid form of bioenergy. Cellulose-degrading gene, *Egls*, and Xylose-(most common hemicellulose) degrading gene, *XynA*, from Bacillus subtilis strain 168, and lignin-degrading genes, *DypB*, from *Rhodococcus jostii* RHA1 have been cloned into plasmid vectors and separately transformed into *E.coli* cells. The *E.coli* cells are currently lignocellulosic degrading gene expressions at low levels.On-going research efforts improve gene expression and test for activity of enzyme producted to optimize the pretreatment of lignocellulosic biomass for higher TAG production. The results of this study are expected to minimize environmental impacts of lignocellulosic biomass disposal while generating value TAG feedstock for biodiesel production.

Lignocellulose-Derived Byproducts Inhibition on the Activity of Halotolerant Xylose Reductase from *Debaryomyces nepalensis*

Author Block:

B. Paidimuddala[1], S. Gummadi[1], R. Ashish[2]; [1]Indian Inst. of Technology Madras, Chennai, India, [2]Indian Inst. of Technology, Madras, Chennai, India

Abstract Body:

Background: Xylitol is a multi-beneficial natural sugar substitute that can be produced from lignocellulose derived xylose. Xylose reductase (XR) that converts xylose to xylitol could be exploited for the development of enzyme based bioprocess to surpass the shortcomings associated with current chemical and microbial processes. But the lack of knowledge on the effect of major lignocellulose derived byproducts (LDBs) that generated while preparation of hydrolysates, on enzyme, leading to end up with failures. To study this, we used previously cloned novel halotolerant XR from *Debaryomyces nepalensis* (*Dn*XR).**Methods:** In this study, for the first time, we investigated the effect of phenol, furfural and acetate on the activity of *Dn*XR. In the presence of LDBs, enzyme activity was determined by spectrophotometric monitoring of the change in A_{340} with NADPH as a cofactor and stability of *Dn*XR was assessed at 30°C. The kinetic parameters were determined by non- linear regression and half-life of the enzyme was calculated by considering first order deactivation kinetics. The given values are mean of triplicate measurements.**Results:** The IC_{50} (half maximal inhibitory concentration) of phenol, furfural and acetate were found to be 20, 50 and 55 mM respectively. At their IC_{50}, the enzyme showed catalytic efficiency of 0.55 ± 0.03 mM^{-1} s^{-1} when compared to control. All LDBs showed competitive inhibition on enzyme activity as evident from increased K_M and decreased catalytic efficiency (k_{cat}/K_M) in the presence of inhibitor. Phenol which originates from lignin of lignocellulose, was exhibited maximum inhibition with IC_{50} 20 mM on the activity of enzyme among three. Nevertheless, half- life of enzyme at 10 mM phenol was reduced to 1 h from 14 h (control). Whereas, at 50 mM acetate and 30 mM furfural the half-life of enzyme was found to be 5 h and 2 h respectively.**Conclusions:** We found that phenol acting as a potent inhibitor of *Dn*XR. The hydrolysates with low concentration of LDBs should be used in enzyme based approach. The results of this study would give more insights to develoep an enzymatic bioprocess for the production of xylitol at industrial grounds.

Interactions And Metabolic Output Of Acetoclasitc Hydrogenotrophic Archaea Grown In Co-Culture With Cellulose Degrading Bacteria

Author Block:

F. S. Mayer; Univ. of Wisconsin Oshkosh, Oshkosh, WI

Abstract Body:

The biodigester on the University of Wisconsin Oshkosh campus is the first of its kind in North America; the energy produced by this dry digester is utilized by the university. The feedstock material consists of organic waste including food waste from the University of Wisconsin Oshkosh, as well as food and yard waste collected from the city of Oshkosh and agricultural waste from nearby farms. The feedstock is degraded by microbes via a dissimilatory food web resulting in methane and CO_2 production. This gas mixture is then combusted to harness electrical and thermal energy. Two main types of microbes that make this process possible are cellulose degrading bacteria and methanogenic archaea. These microbes work as part of a nutritional symbiosis; cellulose degrading bacteria digest the feedstock and produce acetate, hydrogen and CO_2 while methanogenic archaea are able to utilize these products to produce methane. Strains of acetoclastic, methanogenic archaea were isolated from the biodigester and cultured using media designed to mimic the digester environment. In addition, a strategy to isolate a cellulose degrading bacterium was undertaken using cellulose filter disks inoculated with digetate from the biodigester. The digester bay itself was used as the incubator for the duration of the 28-day cycle. This approach allowed for cultivation and subsequent isolation of cellulose degrading bacteria. Finally, co-culture studies were conducted involving two microbial species already growing in pure culture: *Methobacterium formicicum* (an hydrogenotrophic, methanogenic archaea) and *Clostridium thermocellum* (a cellulose degrading bacterium). The cultures were maintained under anaerobic conditions and headspace pressures were monitored to detect gas production and consumption. The results of these preliminary studies suggest that cellulose degrading bacteria are capable of supporting the growth of methanogenic archaea.

Abstract Body:

Protein is one of the most abundant biomolecules found on the Earth. Keratin is an example of such a non-food protein found in nature. Keratin hydrolysate are used in feedstock as supplements. However, recent developments in metabolic engineering direct the possibility of using such feedstock for biofuel production. The amino acids could be converted into 2-keto acids or tricarboxylic acid intermediates by deamination. The present work aims at characterization of keratin hydrolysate for use as a feedstock for biofuel production**.** In the present study, the gene encoding keratinase from *Bacillus altitudinis RBDV1* was cloned in *Escherichia coli*. The amino acid sequence inferred from the 1130-bp nucleotide sequence revealed that the protein is 376 amino acids long & has an estimated molecular weight of ~41,433 Da. Sequence analysis of Keratinase gene revealed sequence similarities with members of the Subtilisin family of proteases. The recombinant keratinase was purified by affinity chromatography. Its molecular weight was found out to be ~44,000 Da. For further characterization, effect of temperature & IPTG concentrations was studied on the expression of recombinant proteases & solubilization of the expressed enzymes. The recombinant keratinase was characterized for various catalytic properties. The property of the hydrolysate was evaluated by HP-TLC. The amino acid profile of this keratin hydrolysate will then be used for biofuel production using the genetically modified *E.coli.*

Mixed Cultures of Freshwater Microalgae and Bacteria for High Lipid Productivity

Author Block:

D. E. Berthold, 33199, **K. G. Shetty**, K. Jayachandran, 33199, M. Gantar, 33199; Florida Intl. Univ., Miami, FL

Abstract Body:

Incorporating biofuels derived from microalgae biomass into energy production is becoming a realistic choice for achieving goals of reducing the fossil fuel dependency. Microalgae biofuel is a feasible technology since microalgae have high growth rates and lipid levels and can be processed using infertile land and wastewater. The microalgae biofuel industry is however facing productivity issues that hinder the development of large-scale projects. Microalgae success is largely dependent on lipid accumulation that usually occurs under depleted nutrient conditions. Nutrient-deficient conditions that stimulate lipid storage, in turn, inhibit biomass production.Manipulating the conditions that allow for both high lipid and cell growth rates during cultivation is desired. In order to overcome cell and lipid productivity issues, we propose the use of mixed cultures of oleaginous freshwater microalgae and bacteria. Ten samples from the South Florida region were used for isolation of microalgae and bacteria. Three species of freshwater microalgae and forty strains of bacteria were isolated and cultured on BG-11 and nutrient agar respectively. For mix culturing, bacteria cultures were incubated separately in 10ml of nutrient broth medium for 1 week, harvested, and then combinations of individual strains of algae and bacteria were inoculated and incubated in 24-well plates at 25 °C under continuous fluorescent lighting (50 μmol photons $m^{-2}s^{-1}$). Growth and lipid content were assessed for 15 days by recording the *in vivo* chlorophyll-a fluorescence and Nile Red fluorescence, respectively. Results indicate that one strain of microalgae, *Coelastrum sp.* 46-4, when grown in mixed culture with one particular strain of bacteria *sp.* 121-1-1 resulted in 63% and 31% increase of biomass and lipid content respectively. Analysis of microalgae growth on bacteria-free supernatant revealed biomass increase from 0.089 to 0.26 g L^{-1} day^{-1} and lipid productivity increase from 21 to 68 mg l^{-1} day^{-1}. Additional analysis of the mix culturing of *Coelastrum sp.*46-4 and bacteria *sp.* 121-1-1 is required in for identifying the factor responsible for observed growth and lipid increase. Our goal is to identify prospective bacterial growth-promoters that improve the productivity of microalgae biofuel technology.

Boosting Power Output of Microbial Fuel Cells by Chemically Activating the Graphite Cathode

Author Block:

P. Song[1], L. Zhang[2], Z. Lu[2], D. Li[2], Y. Liu[2], G. Huang[2], J. Ma[3], L. Cai[2]; [1]Thomas Nelson Community Coll., Hampton, VA, [2]East China Univ. of Sci. and Technology, Shanghai, China, [3]Univ. Libre de Bruxelles, Brussels, Belgium

Abstract Body:

The broad application of microbial fuel cells (MFCs) has been hindered by its low power output and high cost of the cathode material, which is often made of precious metals. In this study we chemically treated graphite with H_3PO_4 and used it as the catalyst-free MFC cathode. We observed a dramatic improvement of the oxygen reduction reactions (ORR) near the cathode when the graphite was treated with 14.62 M H_3PO_4 for 12h between 30 and 50 ºC. The resulting power density was 7.9 W/m^2, 2.4 times higher than that of the untreated control. Fourier Transformation Infrared (FTIR) spectra and Methylene Blue Analysis revealed that H_3PO_4 treatment increased specific areas of the graphite and allowed more oxygen-containing functional groups to bind to the surface, which facilitated ORRs. Since the chemical activation process involves mainly one simple immersion step, with no requirement for heating, electrochemical processing or the use of expensive chemicals, it is a highly cost-effective approach to improve the performance of MFCs. We recommend *in situ* chemical treatment of graphite cathodes in scale-up MFCs to optimize their various industrial operations.

Behavior of Cu2+ in Anode of Microbial Fuel Cells

Author Block:

P. Song[1], D. Chang[2], L. Zhang[2]; [1]Thomas Nelson Community Coll., Hampton, VA, [2]East China Univ. of Sci. and Technology, Shanghai, China

Abstract Body:

Abstract:We investigated the behavior of copper ions in the anodic chamber of microbial fuel cells (MFCs) by gradually increasing the concentration of Cu^{2+} from 2.78 to 111.11 mg/L. The transformation, distribution, and removal of Cu^{2+}, as well as its effect on voltage output were analyzed. Results showed that at low levels ($[Cu^{2+}]$ < 19.44 mg/L initially and ended at 0.36 mg/L after batch operation), Cu^{2+} could improve the voltage output of MFCs; while when $[Cu^{2+}]$ exceeded 22.22 mg/L, it would inhibit MFC performance. At low $[Cu^{2+}]$, the average Cu^{2+} removal efficiency was over 95% with the maximal efficiency reaching 99.99%. XPS analysis revealed that 21% of Cu^{2+} was reduced to Cu^{0}, which may have acted as nanoparticles to enhance the MFC performance of MFC. The columbic efficiency was decreased, mainly due to the chemical oxygen demand (COD) from the Sulfate Reducing Bacteria. To our knowledge, this is the first report to show that Cu^{2+} gets reduced to its metallic form on the MFC anode, and its addition improves the voltage output of MFCs. We also show that reduction and precipitation were the major mechanisms for the removal of Cu^{2+} in MFCs.

Synthesis of Fluorescent Cus Nanoparticles by a Highly Metal-Resistant Antarctic Bacterium. Potential Application as Photosensitizer in Solar Cells

Author Block:

L. Saona[1], N. Órdenes-Aenishanslins[2], N. Bruna[3], C. Norris[2], **J. Pérez-Donoso**[3]; [1]UCHILE, Santiago, Chile, [2]UChile, Santiago, Chile, [3]UNAB, Santiago, Chile

Abstract Body:

Background: Fluorescent nanoparticles or quantum dots (QDs) are semiconductor nanoestructures used in biotechnological and industrial applications (biomedicine, renewable energies and optoelectronics). Their interesting properties are consequence of composition, structure and nanometric size. Most QDs are chemically produced and constituted by elements such as Cd, Te, Se, In and Zn. In this context, very few has been reported regarding the production of Cu-based fluorescent nanoparticles, constituting an opportunity to give added value to the principal exportation product of Chile.During the last years, biological methods for QDs biosynthesis have gained interest because they are cheap, eco-friendly, non-toxic and in most cases generate QDs with new properties. The molecular bases of bacterial biosynthesis of NPs are still unknown, however the participation of cellular peptides, proteins, polymers and thiols has been reported.**Methods and Results:** Based on this, our laboratory has recently developed a method for the biosynthesis of fluorescent Cu-nanoparticles using a highly Cu-resistant strain isolated from Antarctica (MIC 20 mg/mL). Due to its Cu resistance and uptake, probably consequence of improved catalase activity, this bacterium represents a unique candidate to evaluate biosynthesis of NPs at high Cu concentrations.In this work we report the intracellular aerobic biosynthesis of fluorescent CuS nanoparticles during exponential growth phase at 28ºC. Biosynthesized NPs are aqueous-soluble (indicative of an organic capping), with a monodisperse size distribution below 10 nm (HR-TEM), constituted by CuS (EDX) and display a unique emission peak between 500 and 700 nm when excited with UV light (Synergy Fluorescence reader H1M).**Conclusion:** Because of their semiconductor and spectroscopic properties these NPs represent a potential candidate for developing biological solar cells. We are testing purified CuS NPs produced by this novel Antarctic strain as sensitizers on “quantum dots sensitized solar cells”.

Biosolubilization of Coal in Pakistan

Author Block:

M. Ali; Univ. of the Punjab, Lahore, Pakistan

Abstract Body:

Background: Pakistan with about 185 billion tons is known to contain sixth largest reservoir in the world. Coal fired power plant, Thermo catalysis and Pyrolysis are common practices across the world, but as they are not economical and ecofriendly, compelling the modern world towards a better approach of coal solubilization. Therefore, recently coal biosolubilization is considered as promising technology for coal conversion into value added products i.e. humic acid, fulvic acid, methane and other aromatic compounds. The present study is specifically undertaken to investigate the solubilization of coal by aerobic microorganisms.**Methods:** Efficient coal solubilizing microorganisms were isolated from samples of water, soil and coal taken from Salt range, Chakwal. After screening by agar plate assay, bacterial strains AY2, AY3 and fungal strains AY5, AY6 were shown to have effective coal solubilization activity. UV-Vis spectroscopy, infrared spectroscopy and SEM were performed to characterize the solubilization residues. Intensity of biosolubilization was determined by measuring the net weight loss of the coal pieces.**Results:** Coal solubilization was observed to be about 25.93% by AY2, 36.36% by AY3 and 50% by AY6 while AY5 showed maximum coal solubilization (66.67%). UV spectrum showed an increase pattern of absorbance while IR spectrum indicated alterations in comparison to the original coal. Aromatic acids and other organic functional groups of hydroxyl, cyclane, carbonyl, ether linkage and aromatic rings were conceived in graph. Evidence for the presence of microorganisms and surface erosion of coal residues in contrast to control coal samples were obtained through SEM.**Conclusions:** the microorganisms isolated from coal mines have enough potential of coal solubilization and conversion into valuable products suggested various applications in different fields.

High Culturability of the Microbial Community from Hydrogen Producing Reactors

Author Block:

L. Fuentes[1], L. Braga[1], E. Castelló[2], **C. Etchebehere**[1]; [1]Biological Res. Inst. Clemente Estable, Montevideo, Uruguay, [2]BioProA Lab, Montevideo, Uruguay

Abstract Body:

Background: Production of hydrogen by dark fermentation is an alternative to produce a clean fuel using agro-industrial wastes. To improve the process it is necessary to understand the microbiology of the system. Several studies have been conducted analyzing the microbial communities from hydrogen producing bioreactors using molecular tools, but only in few cases a partial culturing strategy were included. The aim of this work was design strategies to isolate the microorganisms predominant in hydrogen producing reactors.**Methods:** Based on previous work and revision of the literature, it was possible to conclude that the microbial communities from hydrogen producing reactors are mainly composed by four different physiological guilds: 1-spore forming strict anaerobic fermenters, 2-non-spore forming strict anaerobic fermenters, 3-facultative fermenters 4-lactic acid bacteria. According to the growth characteristics of these microorganisms we designed strategies to isolate them from samples taken from hydrogen producing reactors. The isolation strategies were tested in two samples taken from different hydrogen producing reactors fed with raw cheese whey. The isolates were characterized according to the 16S rRNA gene sequence analysis and the production of hydrogen and other metabolites were determined in the pure cultures. To determine the coverage of our isolation strategies from the total community we analyze the samples used for the isolation by 16S rRNA gene pyrosequencing.**Results:** The results showed that the four strategies were successful for the isolation of the predominant organisms reaching coverage of more than 90% of the OTUs present in the community. 43 strains were isolated and characterized as belonging from the genera *Acetobacter, Micrococcus, Chryseobacterium, Rahnella, Lactobacillus, Pseudoclavibacter, Propionibacterium, Megasphaera, Bifidobacterium* and *Clostridium.* From those, the strains characterized as *Clostridium, Rahnella* and *Megasphaera* produced hydrogen by fermentation. The phylogenetic analysis showed a close relationship between the isolates 16S rRNA gene sequences and the sequences retrieved in the pyrosequencing analysis.**Conclusions:** It was demonstrated for first time the high culturability of the hydrogen producing bioreactors biomass.

Anaerobic Digestion of Algae: Microbes, Gas and Temporal Changes

Author Block:

A. Doloman[1], Y. Soboh[2], C. Miller[1], R. Sims[1]; [1]Utah State Univ., Logan, UT, [2]Palestine Technical Coll.s - Arroub, Arroub, Palestinian Territory

Abstract Body:

Background: Anaerobic digestion (AD) is a microbiologically coordinated process with dynamic relationships between bacterial players. Although key bacterial players carrying out AD of various substrates have been identified in the literature, a comprehensive understanding of dynamic changes in the bacterial composition during the AD process is currently incomplete. The objective of this research was to assess changes in bacterial community composition that coordinates with anaerobic co-digestion of algal biomass cultivated on municipal wastewater treated in facultative lagoons. **Methods:** Duplicates of a high-rate continuous-flow reactor with up-flow anaerobic sludge blanket (UASB) were used to achieve high rates of algae decomposition and biogas production. Sodium hydroxide was added to the algal feed to balance the carbon-to-nitrogen ratio of the feedstock, with final C/N ratio of 21/1. Samples of the sludge blanket were collected throughout AD and extracted DNA was subjected to next-generation sequencing (MiSeq platform) using methanogen *mcrA* gene specific and universal bacterial primers (338F and 785R). Resulting sequences were quality filtered and analyzed in the MOTHUR software. Statistical analysis of significant differences between samples at various time points was performed within the MOTHUR pipeline. **Results:** Analysis of the data revealed that samples taken at different stages of AD had varying bacterial composition, with initially low abundance of key phyla in the seeding inoculum from the wastewater lagoons sludge. A group consisting of *Bacteroidales, Pseudomonadales* and *Enterobacteriales* was proposed to be responsible for the hydrolysis of algal biomass. The methanogenesis phase was dominated by *Methanosarcina mazei,* which contributed to the production of biogas with up to 90% of methane composition. **Conclusion:**. Results of observed changes in the composition of microbial communities during AD can be used as a roadmap to stimulate identified key bacterial species of each phase of AD in order to increase yield of biogas and rate of biomass decomposition. Waste grown algae have a high biogas potential and this research demonstrates a successful exploitation of methane production from algae without any biomass pre-treatment.

Assessing the Potential of Different Tropical Biomasses as Feedstock for Biogas Production Through Anaerobic Digestion

Author Block:

W. R. Morales-Medina, L. A. Ríos-Hernández; Univ. of Puerto Rico at Mayaguez, Mayaguez, Puerto Rico

Abstract Body:

Second generation biofuels are considered a potential alternative to face the peak oil crisis. The challenge in the development of these non contaminant fuels is the finding of a viable biomass. Puerto Rico, a sub-tropical island, is rich in flora and other potential biomasses. In this island, climbing vines compose the 20% of the flora population, meanwhile marine algae and seagrasses are highly abundant in the littoral zone. This fact lead us to study the potential of these biomasses as feedstock for biogas production through anaerobic digestion. We used 10 species of biomasses and submitted them to a aqueous extraction pretreatment through blending, in which we separated the water-soluble and non-soluble fractions. Both fractions were anaerobically digested and compared with untreated biomass. Reactors were prepared using 160 mL serum bottles and inoculated with effluent from anaerobic reactors previously enriched with similar biomasses. Methane production and biodegradation were measure by GC and HPLC. Results showed that climbing vines yielded more methane than seagrasses and most algae. The effect of the pretreatment varies with every biomass, but liquid fraction yielded less methane than untreated biomass in all cases. Up to 78.16 L/Kg of methane was obtained from the solid fraction of *Epipremnum spp.*, potentially producing up to 720 W/hr per Kg of biomass, meanwhile untreated *Dioscorea spp.* and *Acanthophora spp.* yielded almost 60 L/Kg (~560 W/hr per Kg). These three feedstocks showed a net methane production greater than the woody biomass production average of 50 L/kg, what makes them excellent candidates for industrialization.

K. Navarro[1], D. Derilus[2], F. Godoy-Vitorino[1], C. Louime[2]; [1]Inter American Univ. of Puerto Rico, San Juan, PR, [2]Univ. of Puerto Rico, San Juan, PR

Abstract Body:

Background: We have evaluated the feasibility of the conversion of marine algae into biogas through bench-scale anaerobic digestors inoculated with different sea water samples and designed to overcome sodium and sulfur inhibition through manipulation of the salinity and pH levels. The present study aimed at characterizing the microbiome of salt water anaerobic digester samples collected along the coast of Puerto Rico in different salinity and pH regimes. We hypothesize that the populations that evolve in each chamber will have different composition according to the salinity levels of the system the geographical origin of the samples. **Methods:** Higher salinity was experimentally induced through daily introduction of dried ground sargassum to the anaerobic digestors with microalgae. Genomic DNA extraction was done from the 30ml filtered seawater and sequenced with the miseq Illumina platform. Sequence analyses was performed with QIIME using the RDP database as reference. **Results:** A total of 1,751,790 sequences were binned into 122,668 OTUs.Alpha rarefaction plots indicate that richness is higher in samples acquired from the Caribbean sea compared to those obtained from Atlantic coastal areas, as is significantly richer in high salinity and high pH. A total of 74 phyla were found with a dominance of Proteobacteria across all samples followed by Bacteroidetes and Planctomycetes. A total 1,224 genus were found across all samples with a dominance of 1,176 bacterial genus (with dominance of *Vibrio* and Pirellulacea) and 48 from Archaea with dominance of Desulfobacteraceae. Phyla distribution of Archaea shows that Parvarchaeota (dominate in most samples followed by Crenarchaeota (*Nitrospumilus*) and Euyarchaeota. We found that *Desulfococcus* was significantly associated with moderate pH while *Desulfoccus* dominated at higher pH values and higher salinity. Methanogenic taxa were distributed across salinity and pH. **Conclusion:** We found that microbial communities can be partitioned according to the salinity and pH regimes with an increase in sulfate reduction at high salinity and moderate pH.

Bacterial Degradation of Reactive Textile Dyes

Author Block:

A. Azad, Islam K, Alam MJ, Hossen MZ, Islam MM, Chowdhury TA and Bhuiya EH; Shahjalal Univ. of Sci. and Technology, Sylhet, Bangladesh

Abstract Body:

Most of the textile industries in Bangladesh dispose reactive dyes in the environment without any treatment and pollute the environment severely. To obtain bacteria having remarkable ability to decolorize and degrade reactive textile dyes, 30 bacterial isolates were isolated from the effluents collected from two textile industries and two leather industries. Screening of these isolates for dye decolorization and degradation capability was performed in nutrient broth medium by using eight structurally different reactive textile dyes. Among these bacterial isolates, 12 isolates showing one or more dye decolorizing ability within 48 h of incubation were identified based on morphological, cultural and biochemical characteristics. Decolorization and degradation capabilities of *Aeromonas, Pseudomonas* and *Bacillus* was optimized under different physicochemical conditions by using Novacron Super Black G (NSB-G), one of the eight reactive dyes. These bacteria decolorized and grew well up to 500 mgl^{-1} of NSB-G. *Aeromonas sp., Bacillus sp.* and *Pseudomonas sp*. showed significant decolorization by 93, 92 and 91%, respectively at 200 mg/l of NSB-G after 96 h of incubation under optimum conditions. Biodegradation and decolorization of reactive dye was confirmed using UV-VIS Spectrophotometry and Fourier Transform Infrared Spectroscopy (FTIR). Peaks at 600 nm during the course of decolorization were observed and the peak of the parent dye compound was completely disappeared after 96 h of incubation. Analysis by thin layer chromatography indicated that the dyes were degraded into many parts. These results clearly indicated that the dye had been catabolized and utilized by these bacterial isolates. Finally azo-reductase activities have been characterized in the biodecolorized supernatant. High decolorization extent supports the notion that these bacterial isolates might be potential in the biological treatment of dyeing mill effluents.

Marine Microbial Consortium Applied to Rbbr Textile Dye Detoxification and Discoloration

Author Block:

G. A. L. Vieira[1], V. M. Oliveira[2], L. D. Sette[1]; [1]São Paulo State Univ., Rio Claro - SP, Brazil, [2]Campinas State Univ., Paulínia - SP, Brazil

Abstract Body:

Background: Marine environments are susceptible to contamination by industrial wastes, and also may represent a target niche for microbial prospecting for bioremediation. Marine microorganisms are adapted to saline conditions and have potential for being used in many biotechnological processes, as bioremediation, a promising approach for the degradation of environmental pollutants using metabolic potential. The aim of this study was to evaluate the potential of marine microbial consortium in detoxify and discolor RBBR textile dye applying experimental design.**Methods:** Microbial consortium were structured using two ligninolytic fungi isolated from marine invertebrates of Brazilian coast, and two bacteria from oil reservoir (off-shore), previously selected based on their capacity to produce enzymes and to degrade hydrocarbons. Experimental design (Plackett & Burman - matrix 20, with four central points) was used to evaluate 13 independent factors in the RBBR textile dye detoxification and discoloration. Erlenmeyer flasks containing 50 ml of medium, the microbial consortium and RBBR were kept in incubators for 7 days at 140 rpm and 28 °C. Toxicity assay was applied using *Artemia* sp. as bioindicator (n=30) in triplicate and discoloration percentage was calculated by the ratio between initial and final spectrophotometric absorbance ($\lambda_{594\ nm}$).**Results:** This first experimental design (P&B 20) was successfully applied. Four assays showed high rates of detoxification (89 - 98% *Artemia* sp. survivors) and 59 - 82% of discoloration. Assay 11 showed high levels of detoxification and discoloration, 94% and 82%, respectively. It is important to highlight that this assay contained the maximum dye concentration (750 ppm RBBR) and 100% of salinity (artificial sea water), revealing the power of marine microbial consortium for environmental pollutants bioremediation. Moreover, the absent of glucose and other independent variables in assay 11 characterize low cost to the process.**Conclusions:** Experimental design was a useful tool in this work, since statistical analyses of independent factors allow the evaluation of its influence and effects in the process. Some variables were eliminated and other fixed for future experiment in order to get the optimization of bioremediation process.

Decolorization of Synthetic Textile Dyes Using Yeasts Isolated from Fruit Peels and Leaves

Author Block:

A. NGO, G. Dedeles, M. Devanadera; Univ. OF SANTO TOMAS, Manila, Philippines

Abstract Body:

Background: Discharge of synthetic dyes poses a big threat as they are poorly biodegradable and toxic due to their complex nature. In search for alternatives to physical and chemical treatments, decolorization of dyes by different microbes is now being considered as a promising approach **Objectives:** Delorization of synthetic dyes by yeast co-cultures and consortia from leaves and fruit peels was assessed with 50 ppm (parts per million) dye concentration. **Methods:** Yeasts from leaves and fruit peels were screened for potential decolorization at 25-50 ppm. Decolorization parameters were optimized for the synergistic property and development of yeasts co-cultures and consortium. Possible decolorization reaction was initially assessed by cell immobilization, SDS-PAGE, and FTIR analysis. **Results:** A total of 16 organisms were isolated from rose, mango, and pineapple leaves and pineapple fruit peels. Only 4 organisms showed highest decolorization of four synthetic dyes namely- Direct Pink B (DPB), Disperse Yellow 5G (DY5G), Direct Fast Orange S (DFOS), and Reactive Turquoise Blue G (RTBG). The optimum condition for best decolorizers of selected dyes at 50 µg/mL were *Candida guilliermondii* Y011 for DPB at pH 9, 37^{o}C; *C. dubliniensis* Y014 for DY5G at pH 4, 25^{o}C; *C. guilliermondii* Y004 for DFOS at pH 7, 25^{o}C, and *C. famata* Y003 for RTBG at pH 4, 35^{o}C. All of the 4 yeast isolates did not show any antagonistic activity when subjected to lawn-spotting method for the formation of co-cultures and consortium. The best co-cultures obtained 61% decolorization of DPB, 65% decolorization of DY5G, 41% decolorization of DFOS and 50-51% decolorization of RTBG. Immobilized yeast cells were active in decolorizing the dyes and SDS-PAGE analysis confirmed the presence of an extracellular protein. FTIR results also showed that there are changes in the functional group of Direct Pink B while minimal changes in the functional groups of the Reactive Turquoise Blue G implying that there was a different pathway of decolorization. **Conclusion:** Yeasts in co-cultures and consortia can decolorize toxic synthetic dyes with different possible decolorization pathway like enzyme degradation and bioaccumulation. This could be used for possible treatment in wastewater systems.

Stirred Tank Bioreactor with Immobilized *Aspergillus terreus* Qms-1: Textile Effluent Treatment Approach

Author Block:

Q. Laraib[1], M. Shafique[2], M. Sohail[1]; [1]Univ. of karachi, karachi, Pakistan, [2]federal urdu Univ., karachi, karachi, Pakistan

Abstract Body:

Background: Textile sector is one of the greatest generator of liquid effluent pollutants all over the world, contributing to serious health hazards. Biodegradation and biodecolorization of Congo red (a direct di-azo dye) by a fungal strain *Aspergillus terreus* QMS-1 was studied in a self-designed lab scale stirred tank bioreactor (STR).**Method:** The strain QMS-1 was isolated from effluent of a local textile industry and was immobilized on pieces of natural loofah sponge for biodegradation of dye in a stirred tank bioreactor (STR). The reactor operation was carried out under aerobic condition with working volume 1L at room temperature and pH 5.0 in continuous flow mode with dye concentration of 100 ppm in simulated textile effluent. The reactor was run on fill with hydraulic retention time (HRT) of 24 hr.**Result:** Overall, the color was removed by 97% with 100 ppm and HRT of 12 hr.**Conclusions:** The STR system was found a cost-effective, stable and easily maintained system for the in-situ treatment of textile waste water by *Aspergillus terreus* QMS-1. It also represents an inexpensive and readily available process for the development of biomass that has a significant potential of dye decolorization.

Microbial Ecology and Pharmaceutical Removal in an Ecological Wastewater Treatment Plant

Author Block:

I. N. Balcom; Lyndon State Coll., Lyndonville, VT

Abstract Body:

Background: The environmental effects of pharmaceutical and personal care products (PPCP) from wastewater treatment plants (WWTP) is an area of emerging concern due to widespread contamination and PPCPs' potential to cause adverse effects at relatively low concentrations. However, very little is known about the treatment of PPCP by ecological WWTP. **Methods:** To assess role of plants in the treatment PPCP by an ecological WWTP at a highway rest stop facility, we characterized the microbial communities residing on plant roots immersed in wastewater. Microbial genomic DNA from aqueous wastewater, plant root biofilm samples and single pharmaceutical compound enrichment cultures was sequenced by massively parallel sequencing. The phylogenetic structure of the microbial communities was analyzed with the lowest common ancestor algorithm. The system's microbial xenobiotic metabolism was examined by comparing the location, identity, and relative abundance of known xenobiotic gene sequences. **Results:** The concentrations of PPCP in the system were in many cases much greater than typical values reported for conventional WWTP. Whole metagenome shotgun sequencing of twelve WWTP and eight enrichment culture samples generated more than 388 million and 177 million paired-end reads, respectively. **Conclusions:** Recalcitrant PPCP (such as carbamazepine) detected at relatively high concentrations may accumulate as the wastewater is reused in the toilets and urinals. Two distinct communities were found in the aqueous and plant root biofilm samples. The initial treatment tanks were dominated by microbial taxa of fecal origin (Bacilli), while the latter tanks had higher microbial species richness. These patterns highlight the importance of providing sufficient physical heterogeneity to allow the development of diverse microbial biofilm communities. We propose that the presence of plants in the WWTP protect the system from disturbances as PPCP inputs change with the changing population of Interstate rest stop visitors. This is achieved by promoting microbial functional richness, thereby increasing metabolic resilience as plant root exudates impart structurally diverse carbon sources.

Anaerobic Toxicity of Eight Aromatic Pharmaceutical and Personal Care Products

Author Block:

A. W. Porter, S. Wolfson, J. Campbell, L. Y. Young; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Pharmaceutical and personal care products are emerging contaminants that are found in the environment as the result of incomplete removal over the course of the wastewater treatment process. We hypothesize that biodegradation of these chemicals during the anaerobic digestion step could be limited due to toxic effects on the microbial community. Eight aromatic compounds (atenolol, bisphenol-A, diphenhydramine, ibuprofen, naproxen, nonylphenol, octylphenol, and triclosan) commonly found in municipal waste treatment were tested to determine if the presence of each individually would have a negative effect on the microorganisms in anaerobic digestate by measuring methane production as a proxy for anaerobic microbial activity. Methane production was quantified by GC and was slightly reduced in cultures amended with pharmaceutical compounds, however, it was almost completely repressed in the presence of the antimicrobial product triclosan. Surfactant by-products octylphenol and nonylphenol also showed moderately decreased methane production. HPLC analysis of naproxen amended cultures showed evidence of biotransformation within the 34 day sampling period, although there was little change in concentration of the other substrates tested. The microbial community within the anaerobic digester is very complex, but there were noticeable differences in the denaturing gradient gel electrophoresis fingerprints that corresponded to the cultures with decreased methane production. These data indicate that some substrates had little effect on anaerobic microbial activity, but were not biodegraded within the timeframe of this study. Further investigations into bioavailability of these substrates may be necessary to understand the anaerobic biodegradation potential of pharmaceutical and personal care products, as any that are not transformed during wastewater treatment will be released with treated effluents and may ultimately accumulate in anoxic sediments.

Anaerobic Transformation of Naproxen by Methanogenic and Sulfidogenic Consortia

Author Block:

S. J. Wolfson, A. W. Porter, L. Y. Young; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Pharmaceutical compounds, now recognized as environmental contaminants, are potential carbon sources for microbes. Naproxen, a common nonsteroidal anti-inflammatory drug, has been detected in wastewater treatment influent, treated effluent, and environmental waters. The biodegradation potential of naproxen in environmental sediments and the mechanism of naproxen transformation under two anaerobic conditions was investigated. To determine microbial degradation of naproxen in anaerobic wastewater digestion, methanogenic enrichment cultures were established with wastewater digestate as inoculum. The microbial degradation potential of naproxen in the environment was determined using anoxic estuarine sediment inoculum under sulfate reducing conditions. Enrichment cultures were fed 1mM naproxen as the sole carbon source. Substrate loss was monitored with HPLC, and GC/MS was used to identify intermediate metabolites. Both methanogenic and sulfate reducing primary enrichment cultures transformed 1mM naproxen to 6-o-desmethylnaproxen (DMN) in 23 and 59 days, respectively. Continual enrichment, naproxen addition, and culture transfer resulted in consistent stoichiometric transformation of naproxen into DMN with no loss of the transformation product observed over one year. Methane production and sulfate loss confirm the loss of one carbon and not complete mineralization of the 14-carbon naproxen compound, indicating demethoxylation. Community 16S rRNA fingerprinting revealed differences in organisms present in naproxen transforming cultures and unamended cultures. The enrichment of two robust consortia specialized in demethoxylating naproxen and provides insight into the transformation of methoxyaromatic contaminants in anaerobic systems.

Biotransformation of Sulfadiazine by a Mixed Microbial Culture

Author Block:

X. Li[1], R. Levine[1], Y. Zhang[1], D. Snow[1], L. Durso[2], Y. Leng[1]; [1]Univ. of Nebraska-Lincoln, Lincoln, NE, [2]USDA, Lincoln, NE

Abstract Body:

Background: Certain microbes can transform antibiotics in the environment. However, little is known about the identity of these microbes and their antibiotic biotransformation processes. The objectives of this study were to (1) isolate bacterial strains capable of transforming antibiotics, (2) determine the biotransformation kinetics of antibiotics, (3) characterize the effects of background carbons on the biotransformation kinetics, and (4) identify biotransformation products under various environmental conditions.**Methods:** Sulfadiazine (SDZ) was used as the model antibiotic in this study due to its frequent occurrence in livestock wastes. Surface soil from a cattle feedlot was collected to enrich potential SDZ degrading bacteria. A mixed culture was obtained after several cycles of enrichment in a mineral solution containing 10 mg/L SDZ as the sole carbon and energy source.**Results:** Despite repeated efforts, no single SDZ degrading strain could be isolated from the mixed culture. 16S rRNA gene sequence analysis showed that the culture consisted primarily of two major bacterial species, *Brevibacterium epidermidis* and *Castellaniella denitrificans*. The degradation kinetics of SDZ by the mixed culture could be described using a mirrored logistic function, with a biotransformation rate measured to be at 4.86 $mg \cdot L^{-1} \cdot d^{-1}$. Three types of background carbons were tested: diluted R2A medium, glucose, and humic acid. The mixed culture had the fastest and slowest SDZ biotransformation rates when diluted R2A and humic aicd were used as the background carbon, respectively, at concentrations equivalent to SDZ on a carbon basis. The mixed culture could also degrade other sulfonamide compounds such as sulfamethazine and sulfamerazine, at transformation rates slower than that of SDZ, but could not degrade sulfathiazole. Using liquid chromatography tandem mass spectrometry, we identified 2-aminopyrimidine (2-AP) as a major biotransformation product of SDZ in the absence and presence of the background carbons tested. Another biotransformation product detected was confirmed to not be 4-aminobenzenesulfonate, the remaining structure after the cleavage of 2-AP from SDZ.**Conclusions:** This work presents a comprehensive study of microbial biotransformation of SDZ under various environmental conditions.

Isolation and Characterization of Alachlor-degrading Bacterium *Acinetobacter* sp. Gc-A6

Author Block:

H. Lee, H. Kim, J. Yun, J-O. Ka; Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Alachlor is a widely used herbicide for preemergence control of annual grass and broadleaf weeds. Owing to its frequent detection in environments, toxicity and mutagenicity, it is important to elucidate degradation mechanism of alachlor and eliminate alachlor and its metabolites from the environments. However, there is limited information on degradation of alachlor and the degradation rate of alachlor is relatively low. In this study, we isolated an alachlor-degrading bacterium, and investigated its ability to degrade alachlor. Also, metabolites produced during degradation of alachlor were identified and novel alachlor degradation pathway was proposed.**Methods:** An alachlor-degrading bacterium was isolated through enrichment processes from agricultural soils. The degradation pathway of alachlor was studied by GC-MS analysis.**Results:** An alachlor-degrading bacterial strain, GC-A6, was isolated and identified as *Acinetobacter* sp. by 16S rRNA gene sequence analysis. The isolate was able to utilize alachlor as a sole source of carbon and energy for its growth in mineral medium. The strain GC-A6 completely degraded 200 mg L^{-1} of alachlor within 72 hours, showing rapid alachlor degradation. The isolate degraded alachlor through two pathways. Alachlor was initially degraded to 2-chloro-*N*-(2,6-diethylphenyl)acetamide which was subsequently degraded through two pathways, 2,6-diethylaniline pathway and 7-ethylindoline pathway. 2,6-diethylaniline was transformed to *N*-(2,6-diethylphenyl)formamide, which was then completely mineralized. 7-ethylindoline also was completely mineralized.**Conclusions:** *Acinetobacter* sp. GC-A6 could utilize and completely mineralize alachlor with high degradation rates. Moreover, the strain could degrade alachlor simultaneously through two pathways, without accumulating any intermediates. Therefore, the *Acinetobacter* sp. GC-A6 may be useful for removal of alachlor and its metabolites from the contaminated environments.

Molecular and Ecological Characteristics of Carbamate Pesticide-Degrading Bacteria

Author Block:

D-U. Kim, H. Lee, J-O. Ka; Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Several studies have focused on the isolation and characterization of carbamate insecticide-degrading microorganisms. In spite of these studies, little information on degradative pathways and genes of carbamate insecticides is available. In this study, novel carbamate insecticide-degradative pathways of *Sphingobium* sp. was characterized, nucleotide sequence of carbofuran degradative plasmid pJE1 was analyzed, and a carbofuran degradation-related gene of pJE1 was identified.**Methods:** Intermediate metabolites was determined by GC-MS analysis. Library construction for plasmid sequencing was performed using the shotgun method. After complete nucleotide sequencing, open reading frames (ORFs) were predicted by the RAST server. For the comparison of plasmid nucleotide sequences, the Artemis Comparison Tool was used. Determined the level of expression of the examined genes using the standard curves. Ct values and normalized them based on 16S rRNA expression and relative gene expression was quantified using the $2^{-\Delta\Delta Ct}$ method. **Results:** *Sphingobium* sp. JE1 was observed to degrade carbofuran through a new pathway, via carbofuran-phenol and 5-hydroxycarbofuran. Another significant character of JE1 was that it had carbofuran hydrolase gene dissimilar to the previously reported *mcd* gene. *Sphingobium* sp. JE1 has a carbofuran-degradative 220kb-sized plasmid pJE1 and pJE1 observed to have novel catabolic genes. First of all, according to the phylogenetic analysis, ParA from pJE1 was classified as a novel clade. In particular, the type IV secretion-like system was present in the same order as in other aromatic compound degrading bacteria even they had low sequence similarity. Relative mRNA expression analysis showed that VirB4, one of the type IV secretion-like system-related gene, is involved in carbofuran degradation. The result shows that, in association with carbofuran degradation, pJE1 has an unique macromolecular translocation system similar to the type IV secretion system.**Conclusions:** *Sphingomonas* sp. JE1 was shown to be capable of degrading carbofuran, using it as a sole source of carbon and energy, through a novel pathway producing an unknown red compound. pJE1 had type IV secretion system-like clade, and relative mRNA expression analysis showed that VirB4 was related to carbofuran degradation.

Nanoremediation of Microbial Contaminants Screened from Algal-Wastewater Systems

Author Block:

A. Limayem[1], A. Micciche[1], E. Haller[1], B. Nayak[2], F. Gonzalez[1], S. S. Mohapatra[1]; [1]Univ. of South Florida, Tampa, FL, [2]Pinellas County Utilities, Largo, FL

Abstract Body:

Background: Algal biofuels have regained interest as environmentally attractive sources of renewable energy. The life cycle assessment (LCA) indicates that algal biofuel production is not sustainable if wastewaters are not used for algae cultivation. However, microbial contaminants inhabiting wastewaters give yield loss of up to 95%. Our preliminary molecular screening from local wastewater systems evidenced the prevalence of lytic bacteria detrimental to algae growth. The objective of this study was to test the efficacy of a scalable nanoremediation on lytic bacteria and prove its mechanistic effect through Transmission Electron Microscopy (TEM).**Methods:** Previously screened strains of *Pseudomonas, Micrococcus,* and *Bacillus* through 16S rRNA DNA sequencing from anaerobically digested wastewaters received from local algae bioreactors were tested against polymeric chitosan-based nanoparticles, 3 kDA, combined with Zinc oxide (CZNPs). The minimal inhibitory concentration (MIC) test conforming to NCCLS Standards was performed using 96 well plates loaded with CZNPs at a 2 fold dilution prior to the addition of 50 µL of ~5×10^5 CFU/mL of bacteria in tryptic soy broth media. Plates were mixed, incubated for 24h at 37°C, and observed visually for the last clear well containing the minimum concentration for inhibition. The mechanistic effects of CZNPs on the lytic bacterial contaminants were visualized through TEM involving osmium tetroxide fixation. Contaminants were exposed for 24h before fixation to a concentration 65.5mg/ml of CZNPs.**Results:** The MICs of CZNPs on *Pseudomonas, Micrococcus,* and *Bacillus* averaged over trials were 0.42, 3.33, and 1.46 mg/mL respectively. TEM performed on lytic bacteria revealed protrusions of microbial cell membranes. Observations of cellular structure, electron density, and cell wall appearance of primarily *Pseudomonas, Micrococcus,* and *Bacillus* were markedly impacted by CZNPs compared to microbial control cells.**Conclusions:** Synergism of chitosan and ZnO proved to be inhibitive of *Pseudomonas, Micrococcus,* and *Bacillus*. This broad spectrum of activity has not been noted before. TEM analyses demonstrated attachment and lysis of microbes at 24h past treatment. Conclusively, CZNPs inhibit the lytic bacterial group and is a promising *in situ* intervention agent.

Biodegradation of Aromatic Contaminants at Estuarine Frontal Boundaries

Author Block:

M. T. MONTGOMERY[1], J. N. Atar[2], T. J. Boyd[1], R. B. Coffin[3], C. L. Osburn[2]; [1]NAVAL RESEARCH LABORATORY, WASHINGTON, DC, [2]North Carolina State Univ., Raleigh, NC, [3]Texas A&M Univ., Corpus Christi, TX

Abstract Body:

Background: Though previously considered to be persistent in the environment, there is growing evidence that aromatic contaminants such as PAHs and nitrogenous explosives are metabolized relatively rapidly. Estuarine frontal boundaries are transitional zones within coastal waters that may harbor conditions promoting rapid aromatic organic matter biodegradation within a watershed. **Methods:** Bacterial production (leucine incorporation method) and mineralization rates of phenanthrene and energetics (*e.g.* TNT, RDX, HMX) were measured in coastal waters around the Lower Outer Banks, NC, Key West, FL, Charleston, SC, and Corpus Christi, TX. In addition to comparing metabolic rates at frontal transition zones between adjacent water mases, mixing experiments were performed to mimic conditions that may occur at fronts where nearshore waters (*e.g.* mangrove lagoons, Cypress bogs) mix with offshore water. **Results:** Bacterial production was often enhanced at discreet frontal boundary interfaces relative to the adjacent water masses on each side of the front (e.g. ca. 20-100%, Bogue Sound, NC) as was phenanthrene mineralization (ca. 5-fold increase, Bogue Sound, NC). Mixing experiments between DOC-rich end members (mangrove lagoon, FL; Cypress bog, NC) and estuarine or marine end members stimulated bacterial production above that predicted from conservative mixing and often disproportionately stimulated mineralization of phenanthrene and energetics (e.g. five-fold increase in ratio of mineralization to production). **Conclusions:** Transient but common estuarine features such as frontal boundaries appear to stimulate heterotrophic bacterial metabolism and may serve to attenuate anthropogenic contaminants released from terrestrial runoff. Boundaries between water masses may create important transition zones where organic matter is more rapidly metabolized and transformed than in adjacent coastal waters.

Detection of Fungal Capabilities to Metabolize 2,4,6-Trinitrotoluene Using Cyclic Voltammetry

Author Block:

J. E. Liquet y González, J. Castellanos, I. Cortez, V. Miranda, R. Padilla, F. Morales, C. Vega, S. Hernandez, C. Ríos-Velazquez; Univ. of Puerto Rico-Mayagüez, Mayagüez, Puerto Rico

Abstract Body:

2,4,6-Trinitrotoluene (TNT) is a man-made explosive used in military shells, bombs, and grenades, in industrial uses, and in underwater blasting. TNT is present in the environment throughout diverse locations, and also known to accumulate in animals and plants. Although its effects on human health are not completely understood, the Environmental Protection Agency, has classified it as a possible human carcinogen. Biodegradation is regarded as an option to clean up many environmental pollutants. However, there is a need for TNT biodegradation experiments using fungi where the metabolic activity can be easily detected. Cyclic voltammetry (CV) is an electrochemical technique that uses an alternating current, oxidizes and reduces molecules, producing a detectable signal. The main focus of this research is the use of CV as an effective technique to detect the TNT degradation capabilities of a fungal bioprospect isolated in Puerto Rico. Spores suspensions of the prospective TNT-degrader, *Aspergillus sp.*, were spreaded on Potato Dextrose Agar, and after 7 days of incubation, 5mm fungal disks were placed in tubes with Bushnell-Haas broth with 68ppm of TNT for 58 days. After applying CV for TNT, three oxidized peaks were found with the increasing current (called Peak 1, 2 and 3) and one that was reduced (Peak 4). In the first five days of incubation, the TNT concentration decreased almost 10ppm in average for Peak 1 and Peak 4. After 58 days of incubation, the TNT concentration had decreased almost 20 ppm on average for the mentioned peaks. For Peak 2 and 3 we did not found a drastic decrease in concentration, only a reduction of 8ppm on average after 58 days of incubation. There was no noticeable change in the fungus morphology after 58 days of incubation with exposure to TNT, determined by using a scanning electron microscope. Further studies to determine the biodegradation product are underway. These findings demonstrate not only that the fungal bioprospect is metabolizing TNT, but also confirm the use of a feasible method to detect metabolic activity in biological systems. The results will allow the discovery of enzymes with potential industrial application and could propose a cost-effective mechanism to biodegrade environmental TNT into a less-hazardous compounds.

Arsenic Detoxification by Geobacter Species

Author Block:

Y. Dang[1], D. Walker[1], K. E. Vautour[1], S. Dixon[2], D. E. Holmes[2]; [1]Univ. of Massachusetts Amherst, Amherst, MA, [2]Western New England Univ., Springfield, MA

Abstract Body:

Insight into the mechanisms for arsenic detoxification by *Geobacter* species is expected to improve the understanding of global cycling of arsenic in iron rich subsurface sedimentary environments. Analysis of thirteen different *Geobacter* genomes showed that all of these species have genes coding for an arsenic detoxification system (*ars* operon), 3 species (*G. uraniireducens*, strain OR-1, and *G. lovleyi*) have genes required for arsenic respiration (*arr* operon), and 3 (*G. uraniireducens*, *G. lovleyi*, and *G. metallireducens*) have a gene coding for L-methionine-dependent methyltransferase (ArsM) which is required for arsenic methylation. The *ars* operon from *G. sulfurreducens* consists of 10 genes, all of which show increased transcription in the presence of arsenite and arsenate. Four copies of an arsenic repressor-like protein were detected in the genome of *G. sulfurreducens*, however, only one of these genes (*arsR1*) encodes a protein that regulates transcription of the *ars* operon. Elimination of *arsR1* from the *G. sulfurreducens* chromosome resulted in enhanced transcription of genes coding for the arsenic efflux pump (Acr3) and arsenate reductase (ArsC). When the gene coding for Acr3 was deleted, cells were not able to grow in the presence of either the oxidized or reduced form of arsenic, while *arsC* deletion mutants could grow in the presence of arsenite but not arsenate. A number of other heavy metal efflux proteins besides Acr3 were identified in the *G. sulfurreducens* genome, however, transcriptomic studies showed that none of these proteins are likely to be involved in arsenic efflux, even when the gene coding for Acr3 has been deleted. These studies shed light on how *Geobacter* influences arsenic mobility in anoxic sediments and may help us develop methods to remediate arsenic contamination in the subsurface.

Mechanism of Iodate Reduction by Members of the Genus Shewanella

Author Block:

H-D. Shin[1], S-K. Wee[1], B. Lee[2], M. Lee[2], T. J. DiChristina[1]; [1]Georgia Inst. of Technology, Atlanta, GA, [2]Pacific Northwest Natl. Lab., Richland, WA

Abstract Body:

Background: An attractive remediation of iodine-contaminated environments is iodine immobilization via microbial iodine transformations, including iodate (IO_3^-) reduction, which is a major component of the iodine biogeochemical network. It has been proposed that IO_3^- is reduced by microbial NRs, although this hypothesis has not been extensively investigated. In this study, NO_3^-- and metal-reducing *Shewanella* species were examined for IO_3^- reduction activity and genetic mutagenesis were performed to identify the components shared by the metal, NO_3^-, and IO_3^- reduction systems of *Shewanella* species.**Methods:** 13 *Shewanella* species were anaerobically cultivated in modified marine broth with lactate as electron(e^-) donor and IO_3^- as e^- acceptor to determine IO_3^- reduction activities. The *crp* (cAMP-responsive regulator of catabolite repression)-deficient mutant of *S. oneidensis* (M3013) was also used to examine the involvement of *crp*-regulated anaerobic respiration. To study involvement of NRs on IO_3^- reduction, the mutant Δ*napA* (lacking the periplasmic NR of *S. oneidensis* MR-1) was constructed by in-frame gene deletion mutagenesis and the IO_3^- and NO_3^- reduction activities of Δ*napA* were compared to the wild-type.**Results:** 8 of the 13 species reduced IO_3^-, with extents of reaction varying from 23-97% of the initial IO_3^- amount. *S. putrefaciens* 200 displayed the highest IO_3^- reduction activity of the 8 species. However, the 5 marine species, *S. hanedai, S. frigidimarina, S. dinitrificans, S. baltica and S. liohica,* were unable to reduce IO_3^-. *S. oneidensis* Δ*napA*, on the other hand, was unable to reduce NO_3^-, yet displayed wild-type IO_3^--reduction activity. In addition, the *crp*-deficient mutant M3013 was unable to reduce IO_3^- or NO_3^- under anaerobic condition. Interestingly, *S. oneidensis* Δ*napA* and M3013 reduced NO_2^- faster and to larger extents of reaction than the wild-type. Δ*napAα* and Δ*napAβ* mutants of *S. putrefaciens* 200 were also constructed and both mutants displayed wild-type IO_3^- reduction activity.**Conclusions:** A variety of *Shewanella* species showed IO_3^- reduction activity, NR-deficient mutants of *S. oneidensis* MR-1 and *S. putrefaciens* 200 retained wild-type IO_3^- reduction activity, indicating that NR is not the primary enzymatic system for IO_3^- reduction. The *crp*-deficient mutant was unable to reduce NO_3^- or IO_3^-, which indicates that IO_3^- reduction may be regulated by the *crp* protein.

Comparative Tolerance Assessment of Fresh and Marine Water Phototrophic Microorganisms to Nano And Bulk Zinc Oxides

Author Block:

L. Gibson, D. Berthold, K. Jayachandran, **K. G. SHETTY**; Florida Intl. Univ., MIAMI, FL

Abstract Body:

Zinc oxide (ZnO) nanoparticles (NPs) have vast range of applications, release of these NPs into waste streams and further into the environment may adversely impact non-target organisms. Natural variations in tolerance to nano ZnO may exist among various aquatic phototrophic microbial species, and the availability of tolerant species may lead to better understanding of tolerance mechanism and potential applications in bioremediation. In order to elucidate the effects of zinc oxides on phototrophic microorganism growth, two fresh and marine water microalgae and cyanobacterial species, were used in a replicated study the cultures were tested using 3 growth media treatments, media containing no added zinc, and nano and bulk ZnO at 10 ppm. Fresh water species were grown in 75ml of BG-11 media and the marine species in BG-11 marine media. The culture flasks were incubated on a shaker at 25°C under continuous fluorescent lighting. Changes in terms of growth and morphology of the species to the treatments were assessed by measuring optical density and microscopic observations for a total of 20 days. Results showed marked difference among species tested to varying ZnO concentrations. Most of the microalgae showed morphological changes as a result of exposure to ZnO, which included decreased cell size and discoloration. Among species tested the cyanobacterial species *Limnothrix* and *Tolypothrix* were the most sensitive to both types of ZnO. Although slightly lower compared to the growth in bulk ZnO media the marine species *Neochloris* (OD 0.64) and fresh water species *Scenedesmus* (OD 0.52) showed the highest growth in nano ZnO media. The marine species *Neochloris* (OD 0.64) showed significantly higher growth than *Sphearocystis* (OD 0.09) when grown in nano ZnO media. Morphological changes as a result of exposure to ZnO included decreased cell size and discoloration. These findings provide strong impetus for screening larger collection of diverse indigenous microalgae for tolerance to NPs and which may yield potential candidates for bioremediation of NPs.

Identification and Genetic Analysis of Zinc Resistance in *Bacillus toyonensis*

Author Block:

V. S. Krawiec, R. B. Kumar; Minnesota State Coll.s and Universities (Minneapolis Campus), Minneapolis, MN

Abstract Body:

Heavy metal pollution in soil and water-systems neighboring mines and recycling yards are a major concern. Zinc (Zn) is of particular interest because it is not only essential to life but is also an anthropologically deposited and concentrated pollutant. Current methods utilize electrolytic plants for remediation; however this gestation period is long and may be unable to combat rising amounts of Zn deposition and subsequent pollution. Bioremediation utilizing microbes could supplement current phytoremediation methods by mobilizing and expediting Zn recovery and recycling. To assess the feasibility of Zn reclamation through bioremediation, we investigated the genetic basis of heavy metal tolerance in bacteria isolated from a recycling yard. Bacteria SR-13 was isolated from soil and water samples taken near a recycling yard by the Mississippi river in Minneapolis, Minnesota. Initial characterization of SR-13 was done using gram stain, biochemical testing and was found to be gram positive and catalase positive. Maximum tolerable concentration (MTC) analysis using Zinc (II) Chloride was determined in LB + Agar media. The MTC of SR-13 was found high and growth was observed up to a concentration of 4 millimolar (mM). SR-13 was then sequenced using 16s rRNA 1492R and 27F primers that amplified the host genome and identified the strain as *Bacillus toyonensis*. To further elucidate the genetic mechanism of Zn resistance, *B. toyonensis* was subjected to transposon mutagenesis using a conjugation method with F+ *Escherichia coli* (*E.coli*) that contained a pRL27 plasmid with a Tn5 transposable element, and kanamycin resistance. Transposon containing mutants were selected by plating on combination 25ug/mL kanamycin + 50ug/mL ampicillin + LB + Agar plates. Zn intolerable mutants were then observed using replica plating from the antibiotic plate onto a 2mM Zn (II) Chloride + LB + agar plate. Successful disruption of the host genome of *B. toyonensis* created a Zn intolerable mutant (MV-1) and was also sequenced. The mutant was also identified as the same as the non-mutagenized strain. Transposon mutagenesis concluded that *B. toyonensis* has a genetic element that gives resistance to Zn in its environment. Future experiments are being conducted to identify the disrupted gene as well as other resistance genes in *B. toyonensis* that could be used for bioremediation applications.

A Null Mutation in Sulfate Adenylyltransferase Supresses Lead Precipitation in Caulobacter Crescentus

Author Block:

R. E. McCorkle, K. A. Moore, M. J. Hickman, G. B. Hecht; Rowan Univ., Glassboro, NJ

Abstract Body:

Background: Microbial mineralization of lead is not well understood. Previous work by our group has demonstrated that microbes are able to precipitate lead in the form of $Pb_9(PO_4)_6$, which can otherwise only be produced synthetically at around 200°C. In contrast, bacterial mediation of this process occurs at room temperature, though the mechanism by which bacteria precipitates this lead phosphate is not known. We have isolated spontaneous lead hyper-precipitating (*hyp*) strains of *Caulobacter crescentus*, a freshwater oligotrophic bacterium that is normally not an efficient lead precipitator, and created several non-precipitating (*nop*) suppressor strains. Whole-genome sequencing revealed that the *hyp* mutants have changes in the CC3625 cysteine synthase gene. Some of the *nop* suppressor strains have additional changes in CC1117, a gene encoding a LysR transcriptional regulator. We report here the analysis of RCCR60, a suppressor strain where the *nop* mutation is unlinked to CC1117. **Methods:** Whole genome sequence analysis was performed to locate mutations unique to strain RCCR60. Cr30-mediated transductions were carried out to demonstrate which mutations are important for the precipitation phenotype. The growth of RCCR60 on minimal medium was compared to our CC1117 mutant strains. **Results:** Transductions using a selectable marker linked to a nonsense mutation in CC1482 demonstrated that locus is both necessary and sufficient for the *nop* phenotype of RCCR60. CC1482 encodes a sulfate adenylyltransferase that is an early step in converting sulfate into H_2S, an important substrate for CC3625. Unlike mutations in LysR, the CC1482 null allele does not confer cysteine auxotrophy and only confers a partial suppression of the lead precipitation phenotype. **Conclusions:** We propose that the CC1482 gene is important for cysteine synthesis but also that *Caulobacter* contains a second sulfur acquisition pathway independent of CC1482. Current experiments are aimed at quantifying the rate and efficiency of lead precipitation and cysteine synthesis in our strains, including the CC1117 and CC1482 mutant strains.

Cooper Reduction by *Shewanella* Isolated from the Chilean Antarctica

Author Block:

M. Valdivia[1], D. Loyola[2], M. Jara[3], C. Vasquez[1]; [1]Laboratorio Microbiología Molecular, Univ. de Santiago de Chile, Santiago, Chile, [2]Centro Natl. de Genómica y Bioinformática, Univ. de Chile, Santiago, Chile, [3]Laboratorio de Biología de Extremofilos y Bioinformática, Centro de Estudios Cientificos, Valdivia, Chile

Abstract Body:

Background: Several environmental microorganisms have adapted to the harsh conditions of the Antarctica, including temperature, pH, nutrient limitation, radiation and metals/metalloids, among others. A common bacterial genus that is found in these environments is *Shewanella*, which is characterized by the use of a wide range of electron acceptors during anaerobic respiration such as fumarate, nitrate, sulfur, Fe(III), Mn(III), Cr(VI), Cr(VI) and others. During an expedition to the Chilean Antartica, a marine bacterium belonging to this genus was isolated and compared with other *Shewanella* species regarding metal reduction.**Methods:** Metal quantification was accomplished through Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES).**Results:** The results indicate that *S. antartica* CH displays high tolerance to copper salts, whose concentration was determined in supernatants of treated cells. Growth curves for *S. antartica* CH, *S. oneidensis* MR1, *S. baltica* OS155 and *S. putrefaciens* growing under different concentrations of NaCl (1%-5%), pH (5,5-9,0) and copper (2-4 mM) were constructed.**Conclusions:** *S. antarctica* CH reduced copper (when added as Cu^{+2}) to elemental copper (Cu^{0}) in anaerobic conditions. This antarctic bacterium showed better growth regarding other *Shewanella* species exposed to different copper salts and/or high NaCl concentrations. The pH value of the culture medium was critical for the growth and metal reduction by the Antarctic strain.

Detection of Copper and Mercury Resistance Genes in Purple Non-Sulfur Bacteria from Different Aquatic Environments in Puerto Rico

Author Block:

K. M. Rodriguez-Nuñez, J. Rullan-Cardec, C. Rios-Velazquez; Univ. of Puerto Rico Mayaguez Campus, Mayaguez, Puerto Rico

Abstract Body:

Environmental Protection Agency revealed in 2014 that 79.7% of rivers and streams used as drinking supply in Puerto Rico (PR) were impaired with metals such as copper and mercury. Copper is the first metal and fifth cause of impairment along with mercury as the fourth metal contaminating the studied waters. Mercury is bio-accumulative and its consumption leads to kidney damage while copper intake can cause liver disease.There have been several reports of human intoxication by these metals. For example, Agency for Toxic Substances and Disease Registry recorded mercury poisoning of 290 civilians in PR by eating fish grown in contaminated waters. Techniques such as metal precipitation and ion exchange resins are employed internationally to remove such metals but their high cost and low effectiveness limit their use. Other approach include the use of microbes such as PNSB for the successfully removal of heavy metals from water. In PR, our Laboratory of Microbial Biotechnology and Bioprospecting has a collection of PNSB isolated from different aquatic environment such as Bromeliad phytotelmata and benthic hypersaline Microbial Mats (MM). However the biotechnological potential of these bacteria and its application in heavy metal bioremediation is unknown. In this study the presence of genes related to copper and mercury resistance was addressed molecularly by PCR, using specific primers for mercuric reductase (*merA*) and *cop*-like genes. From a total of 39 isolates (14 from MM and 25 from Bromeliad phytothelmata) evaluated in this study, positive amplification products for mercuric reductase genes (1,238 bp) and for *cop*-like genes (750bp) were found in 7% and 14% of the isolates respectively from MM, and 16% *cop*-like genes from Bromeliads isolates. Other amplifications of non-expected size were obtained and will be confirmed *in silico* to validate their genetic identity. The *in silico* analysis of the 16S rDNA of the isolates where amplified genes were detected suggest PNSB from *Rhodopseudomonas, Rhodospirillaceae and Rhodobacter* family. The results not only confirm the presence of genes related to metal resistance in isolates from extreme and unexplored microenvironments; but also its biotechnological potential applications in metal bioremediation.

Expression and NMR Studies of Membrane Proteins from Mercury-Resistant *Bacillus* Sp. and Its Use in Mercury Bioremediation

Author Block:

A. Amin[1], S. J. Opella[2], Z. Latif[1]; [1]Univ. of the Punajb, Lahore, Pakistan, [2]Univ. of California, San Diego, San Diego, CA

Abstract Body:

Background: Mercury exists naturally in small amounts in the environment. Its level is rising due to industrialization and other anthropogenic activities. Mercury resistant bacteria harboring *m*er operon encode for certain functional soluble and transmembrane proteins which are involved in bacterial mercury detoxification system.**Methods and Results:** Mercury (Hg) resistant bacterial isolate was isolated from wastewater polluted soil collected close to tanneries of district Kasur, Pakistan. Selected bacterial strain was screened out on the basis of Hg-resistance (40-50µg/ml). Biochemical characterization, 16S ribotyping and phylogenetic analysis revealed that the isolate characterized as *Bacillus* sp. AZ-1 (KT270477). Two genes (*mer*F and *mer*E) were amplified and expressed into small membrane proteins MerF (81-residues) and MerE (89-residues). In order to perform structural studies of MerF and MerE by NMR spectroscopy, it is necessary to produce milligram quantities of isotopically labeled protein; as is the case for most membrane-associated proteins, this is challenging. We described the successful expression of full-length of both proteins using a fusion partner in pHLV and pET31b(+) vectors that direct the over-expressed protein to the inclusion bodies. Following isolation of the fusion proteins by affinity chromatography, MerF was chemically cleaved with cyanogen bromide and MerE was cleaved by thrombin respectively. Both polypeptides were purified by size exclusion chromatography. Solution NMR two-dimensional HSQC spectra of uniformly ^{15}N-labeled MerF-polypeptides in SDS containing NMR buffer were fully resolved, with a single resonance for each amide site. Finally, *Bacillus* sp. AZ-1 was immobilized in sodium alginate beads and checked the Hg-detoxification potential. It showed an extensive capability to detoxify 88% (15 out of 17µg/ml) of mercury from industrial effluent. **Conclusions:** Mercury resistant Bacillus sp. possessing the mer operon including merF & E and other functional genes coding for resistance should be given prime consideration for use in bioremediation.

Biosorption of Lead by Microbes and Agro-Waste Materials: An Ecofriendly and Inexpensive Approach for Remediation of Heavy Metals from Environment

Author Block:

S. JANAKIRAMAN; Bangalore Univ., Bangalore, India

Abstract Body:

Accumulation of heavy metals in the environment is of major concern as they are not biodegradable and therefore causes serious health problem to living organisms. In recent years, biosorption of heavy metals by microbes and agro-waste materials have gained increasing attention over the conventional methods. A total of one hundred and twenty fungi were isolated from soil samples collected form heavy metal contaminated sites. Two species of *Aspergillus* exhibited resistance to 1500mM of lead (Pb) on agar medium. A biosorbent was designed by growing these fungal organisms on luffa sponge (an agro-waste material) under shaken condition for 72 hours at 30^0 C. The percentage of lead adsorption by the designed biosorbent was determined initially by gravimetry method and further confirmed by Atomic Adsorption Spectrophotometry (AAS) and Inductively Coupled Plasma- Optical Emission Spectrometry (ICP-OES) showing 35%, 56%, 63% respectively with *A niger*, whereas for *A terreus* it showed 32%, 44%, 59%. The Fourier Transform Infrared Spectroscopy (FTIR) analysis revealed that the functional groups OH^-, $=CH^+$ present on our designed biosorbents are facilitating the biosorption. The textural properties of the designed biosorbent was morphologically analyzed by Scanning Electron Microscopy (SEM).The practical applicability of the designed biosorbent for heavy metal removal from heavy metal contaminated environment is discussed.

Biological Treatment of Cyanide by Isolated Bacteria from Gold Leaching Plants in Colombia

Author Block:

V. López, **C. X. Moreno-Herrea**, M. A. Márquez, Grupo de Microbiodiversidad y Bioprospección (MICROBIOP), Grupo de MIneralogía Aplicada y Bioprocesos (GMAB); Univ. Natl. de Colombia, Medellín, Colombia

Abstract Body:

Background: The technologies used into cyanide contaminated water treatment depend of a combination of physic and chemistry factors. Due to cyanide is highly toxic, it must be treated before it to be discharged into effluents. It is unknown the bacterial communities diversity which are associated with places contaminated with cyanide who could have an *in situ* remediation process potential. The biological degradation is the process of breaking and transforming hazardous materials into simple nontoxic substances by a biological treatment. Despite the technological interest of cyanide-oxidizing bacteria, the ecology physiological role and diversity of bacteria in gold leaching plants from Colombian is still unknown. **Methodology:** In this research the microbiological treatment for the removal of cyanide compounds by 4 species isolated from gold leaching plants in two Colombian mines were studied. Theses were inoculated in LB medium with 200 ppm of cyanide as preliminary test of degradation and later were evaluated in M9 liquid medium with 200, 500 and 1000 ppm and monitored during 168 hours. **Results:** The pH was constant and the cell counting increased to 10^8 after 8 days of incubation under aerobic conditions. All the isolates revealed degradation in function of time. The isolated that showed higher degradation percentages using LB medium was identified as *Rhodococcus* sp., which degraded until 53% and the isolated which showed better performance in M9 medium had the affiliations to *Microbacterium* sp. which degraded until 40% of the cyanide in the medium. **Conclusions:** To the best of our knowledge, this is the first report of these bacteria as degraders and habitants of places contaminated with cyanide in Colombia. Our results indicate that there is a wide diversity of cyanide-oxidizing bacteria that could be applied for conventional gold leaching plants in aerobic conditions.

Characterization of *Pseudomonas veronii* 2E Extracellular Polymeric Substances as Cd(II) Ligand for Metal Removal

Author Block:

M. L. Ferreira[1], A. Casabuono[2], A. Couto[3], S. A. Ramirez[1], **D. L. Vullo**[1]; [1]Univ. Natl. de Gen. Sarmiento, Los Polvorines, Buenos Aires, Argentina, [2]FCEN-Univ. de Buenos Aires, Buenos Aires, Argentina, [3]FCEN-Univ. Buenos Aires, Buenos Aires, Argentina

Abstract Body:

Biological treatments are innovative technologies available for industrial wastewaters containing metals. Some bacteria are adapted to metal polluted environments as consequence of the development of survival strategies or just by secretion of extracellular polymeric substances (EPS). EPS are microbial products excreted (soluble) or associated to the cell surface and are composed by a complex mixture of proteins, polysaccharides, nucleic acids, lipids and other polymeric compounds. They can protect cells from metal toxicity due to the presence of different functional groups available as ligands. The aim of this study was to evaluate the complexing capacity of the major component in EPS produced by the indigenous strain *P.veronii* 2E for potential application in wastewater treatment. EPS were produced by growing cells at 32 ºC in a minimal medium M9-2% (v/v) glycerol, precipitated from culture supernatants with ethanol and purified by both dialysis (MW>12,400Da) and enzymatic treatments (DNase I and Proteinase K). After treating this last fraction (EPSenz) with sodium deoxycholate, two major fractions were obtained: lipopolysaccharide LPS and extracellular polysaccharide ExP, both in similar proportions. FT-IR spectroscopy was performed to study the functional groups present in LPS and ExP that may interact with Cd(II). The ability of EPS, EPSenz, LPS and ExP to complex Cd(II) was determined by an electrochemically monitored titration (ASV) at pH 7.5 (25±1°C). One family of moderate strength binding sites was observed in all fractions with a log K´ (conditional formation constant) of 5.5, while the ligand concentration (µmoles of binding sites/g dry weight) was 65 µmol/g EPS, 500 µmol/g EPSenz, 278 µmol/g LPS and 16 µmol/g ExP. LPS is the purified fraction with great affinity for the complexation of the cation, consistent with the high biosorptive capacity of the whole cells observed in previous studies. The simple production and purification of the soluble EPS is a promissory alternative as a metal retaining agent to minimize hazardous discharges of industrial wastes and to open the possibility of metal recovery.

Metal Accumulation by Sporulated Bacteria on Feathers

Author Block:

E. Góngora, L. N. Osorio, J. Dussán; Univ. de los Andes, Bogotá, Colombia

Abstract Body:

Background: Human activities release toxic metals to the environment polluting the air, water and soil. Sporulated bacteria (SB), ubiquitous in most habitats, have the ability to absorb/adsorb those metals. As birds can bioaccumulate metals and their feathers possess a microbiota that includes various SB, these may interact with the present metals.Here, we evaluate the ability of SB to accumulate Pb, both, *in vitro* and when present on feathers so that it may later be used for bioremediation processes. **Methods:** We sampled hummingbirds and swabbed their plumages to sample the SB present on feathers, grew them on single-feather liquid and solid media after performing heat shock (to isolate spores), and identified them by sequencing the 16S rRNA gene.We used two strains of *Lysinibacillus sphaericus* (obtained from feathers and beetle larvae) to evaluate the Pb adsorption on the surface of the spores after culture in a Pb-enriched liquid sporulation medium. We confirmed Pb adsorption with an energy dispersive X-ray analysis (EDX). Pb uptake was measured with a spectrophotometric analysis (SA) and analyzed with an ANOVA.The ability of 10 SB isolates to degrade keratin was determined by the presence of halos and degradation of feather particles in solid and liquid feather media, respectively. Then, we evaluated the capacity of SB to accumulate Pb using a single-feather medium by confirming the presence of Pb in cells and spores by EDX. **Results:** We confirmed the presence of metals on the feathers by EDX and SA. Over 50 morphotypes were obtained and 37 were sequenced. 65.7 % of them were SB (Bacillaceae), 8.6 % belonged to Pseudomonadaceae and the remaining 25.8 % were not identified.We observed that spores from both strains could adsorb Pb on their surface. The accumulation capacity varied between strains and with the initial Pb concentration and the adsorption time.30 and 100 % of the SB degraded keratin on the solid and liquid feather media, respectively. The SB could also accumulate Pb using feathers as their C and N substrate. **Conclusions:** We conclude that the evidence here presented suggests that there is a possible accumulation of Pb present on bird feathers as a naturally occurring process. We also demonstrated that the process may be potentially implemented for bioremediation in water sources, for example, using the spores of these SB.

Publishing Title:

Quantification of Biomass Production and Organic Acid Production for Three Fungal Candidates

Author Block:

A. Lobos; Univ. of South Florida, Tampa, FL

Abstract Body:

An environmentally friendly fungal bioleaching process with organic acids produced by *Aspergillus niger, Penicillium chrysogenum* and *Penicillium simplicissimum* will be investigated as an alternative leaching method for the recovery of lithium/cobalt from spent rechargeable Li-ion batteries. The first approach for this plan is to quantify fungal growth by recording the biomass production and measuring pH changes on two different mediums; high performance liquid chromatography will be used to quantify organic acid production for the three fungal species over 10 days to determine the best candidate for fungal bioleaching of lithium and cobalt from spent lithium-ion batteries. The three fungal candidates were cultured in sabouraud dextrose broth and czapek dox broth for 10 days at 30°C while shaking at 125rpm; samples were collected in triplicates every 24 hours and processed to determine dry biomass production, pH of medium and organic acid production. Preliminary results with fungi in sabouraud dextrose broth after 10 days of growth: pH of medium was measured before inoculation of fungi, mean pH (5.37 $\pm$ 0.042); *Aspergillus niger* dry weight biomass mean (3.35 g/L $\pm$ 2.254 g/L), mean pH (3.57 $\pm$ 0.899), mean concentration of oxalic acid (51.104 mM $\pm$ 2.187 mM); *Penicillium chrysogenum* dry weight biomass mean (1.862 g/L $\pm$ 0.905 g/L), mean pH (4.21$\pm$ 0.057), mean concentration of oxalic acid (11.16 mM $\pm$ 3.016 mM); *Penicillium simplicissimum* dry weight biomass mean (3.106 g/L $\pm$ 1.505 g/L), mean pH (4.89 $\pm$ 0.053), mean concentration of oxalic acid (5.26 mM $\pm$ 2.568 mM). Preliminary results indicate that *Aspergillus niger* will be the top candidate due to high production of oxalic acid. The data collected in this study will expand knowledge on the process for organic acid production in three fungal species and help select the top candidate for fungal bioleaching. After quantification of organic acid production and fungal growth is complete, metal tolerance tests will then be done to determine the toxicity of lithium and cobalt to each fungal candidate; bioleaching experiments will then be conducted to recover lithium and cobalt from spent rechargeable lithium-ion batteries.

Lab., Oak Ridge, TN, [3]Univ. of Georgia, Athens, GA, [4]Montana State Univ., Bozeman, MT, [5]Massachusetts Inst. of Technology, Cambridge, MA, [6]Univ. of Tennessee, Knoxville, TN, [7]Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

Background: Anthropogenic activities have significantly impacted the biosphere of Earth due to contamination of air, water and soil environments, thus decreasing biodiversity and destabilizing ecosystem functions. However, little is known about how environmental contamination affects the biodiversity of groundwater microbial communities and its feedbacks to ecosystem functioning.**Methods:** We used a comprehensive functional gene array (GeoChip 5.0) to analyze the functional diversity of groundwater microbial communities from 69 wells at the Oak Ridge Field Research Center (Oak Ridge, TN), representing a wide range of uranium, nitrate and other contaminant concentrations, as well as pH and dissolved gases (e.g., CO2, CH4, N2O).**Results:** It is hypothesized that the functional diversity would decrease as environmental contamination (e.g., uranium, nitrate) increased, or at low or high pH; however, specific populations capable of utilizing or resistant to those contaminants would increase. Thus, it would be possible to predict groundwater contamination and ecosystem functioning using those key microbial functional genes. Our results indicate that the functional richness/diversity significantly ($p < 0.05$) decreased as uranium (but not nitrate) increased in groundwater, and about 5.9% of specific key functional populations (e.g., dsrA, cytochrome genes, nirK, norB, nosZ, napA) significantly ($p < 0.05$) increased as uranium or nitrate increased. Also, we showed that microbial functional diversity could successfully predict uranium and nitrate contamination and ecosystem functioning.**Conclusions:** This study provides new insights into our understanding of the effects of environmental contamination on groundwater microbial communities and the potential for predicting environmental contamination and ecosystem functioning.

Mediation of Coal Mine-derived Acid Mine Drainage with the Introduction of Pristine Soil

Author Block:

S. Sharma; The Univ. of Akron, Akron, OH

Abstract Body:

Active or abandoned coal mines generate acid mine drainage (AMD), which are fluids systems with low pH and High Fe(II) Concentrations, produced by oxygenation of coal mine associated pyrite (FeS) exposed during mining activities. AMD remains one of the greatest threats to the quality of surface water in Appalachian coal mining regions of the U.S. Many remediation processes that focus on Fe removal are costly and require extensive maintenance. Therefore, there is a need to develop less costly and more sustainable AMD treatment approaches. The activities of Fe (II) oxidizing bacteria (FeOB) that are associated with AMD may be exploited to catalyze the oxidative precipitation of Fe from fluids. In this study we introduced AMD fluids collected from abandoned mine works to pristine soil and evaluated the rates of Fe (II) oxidation and abundances of FeOB over time. We are also evaluating the change in the microbial communities that occur when AMD infiltrates initially pristine soil using 454- pyrosequencing-derived 16S rRNA gene sequences. Our results indicate that upon mixing of AMD with pristine soil, microbial communities mediate rapid oxidative precipitation of Fe from AMD. Finally, this study presents an effective system to analyze the mediation of Fe oxidation of AMD by microbial community present in pristine soil, which further can be used to develop an effective and economical alternative to already present remediation methods.

Metagenomics Study of Endophytic Fungi of *Avicennia marina* Using Next Generation Technology

Author Block:

A. Bahkali[1], M. Abdel-Wahab[2], A. El-Gorban[1], M. Hodhod[1]; [1]King Saud Univ., Riyadh, Saudi Arabia, [2]Sohag Univ., Sohag, Egypt

Abstract Body:

Endophytic fungi are an excellent source of new pharmaceutical chemicals and may be potential sources of bioactive medicinal compounds. Metogenomics study of environmental samples enables rapid analysis of the composition and diversity of microbial communities at various habitats. We have assessed the endophytic fungi of *Avicennia marina* using next generation generation technology (NGS) by assessing its PCR amplicon of the partial LSU rDNA sequences using LROR and LR3 primers with Illumina metagenomics technique used to generate a total of 35,886 reads from four healthy looking samples of leaves of *A. marina*. Seventy-two OTUs were recorded from the four samples, of which 30 OTUs were single read. Yeast species dominating the fungal of the samples. The Basidiomycetous yeast genus *Malassezia* dominated the fungal community of the samples representing 98.6 % of the reads. Other common yeast genera were: *Hortaea, Candida* and *Schwanniomyces*. Common filamentous fungal genera were: *Trichoderma, Neocallimastix, Geranomyces, Ramaria, Laetiporus, Mucor* and *Gonapodya*.

The Genetic Diversity and Composition of the Rhizosphere Microbiome in Healthy and *Phellinus noxius* Infected Trees

Author Block:

K. S. W. Tsang, C. K. Wong, H. S. Kwan; The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Brown root rot is a fatal disease affecting over 200 plant host species globally. The pathogen is a soil-dwelling white rot basidiomycetes fungus *(Phellinus noxius)* and if left untreated, leads to host death within a year. The rhizosphere microbiome plays an important role in plant health. Currently there are limited studies that observe the changes occurring within the rhizosphere when the plant is faced with a pathogen. The purpose of this study is to investigate the changes a *P. noxius* infection has on the diversity and composition of bacteria and fungi present in the rhizosphere microbiome of two different plant species. Rhizosphere soil samples were taken in triplicates from 4 diseased and 2 healthy *Ficus microcarpa* and *Mallotus paniculatus* trees around Hong Kong. Each set of healthy and diseased samples were taken in the same immediate area to avoid bias. Bacterial 16S and fungal ITS amplification was and sequenced on the Ion Torrent PGM system. The resulting data was demultiplexed, quality filtered and analyzed using the QIIME pipeline. Representative OTUs were clustered at 97% similarity within each microbial group and aligned to reference sequences using Greengenes for bacteria and QIIME/UNITE for fungi. In general, the bacterial and fungal rhizosphere compositions between the two species of tree are vastly dissimilar. However, within each species, the composition trends remain relatively similar. There is also a significant shift in the rhizosphere composition between the diseased and healthy trees. Interestingly, there is an increased presence of pathogenic *Fusarium* species in the diseased samples of both species, which suggests an opportunistic colonization. The majority of fungal species found in diseased samples are saprotrophic, with the genus *Humicola* being particularly dominant in *M. paniculatus* diseased samples. The bacterial chao1 index shows the diversity of *P. noxius* infected trees was significantly reduced in comparison to healthy trees; however there is no such difference within the fungal samples. In conclusion, the rhizosphere composition is different between species, however retains similarities within a species. There is also a significant difference in the microbial composition between healthy and *P. noxius* infected tree samples.

Survey of *Methylobacteria* Species Found in Association with Several Genera of Fungi in Massachusetts

Author Block:

S. Drinan, M. James-Pederson, R. Hirst; Stonehill Coll., Easton, MA

Abstract Body:

Methylobacteria *(Methylobacterium spp.*) are pink pigmented facultative methylotrophs (PPFM) capable of utilizing one-carbon compounds, such as methanol, as a carbon source. Methylobacteria have been isolated from a variety of substrates including but not limited to soil, air, freshwater, dust, lake sediments, and plants. They have been found in association with over 70 different types of plants and the association can be symbiotic, epiphytic or endophytic; utilization of methanol released from plant stomata by *Methylobacterium* has been well documented. Although ubiquitous in nature and predominant in the phyllosphere, to date there have been no reports of *Methylobacterium* species isolated from white-rot fungi, which are also capable of releasing methanol as a byproduct of lignin degradation. Our laboratory recently identified a species of *Methylobacterium* living in association with the white-rot fungi, *Armillaria gallica*. To determine if this association extended beyond a single genus of fungi, we analyzed the *Methylobacterium* species colonizing the surface of a wide range of fungal genera collected from the Stonehill College campus in Easton, MA. 18S rRNA gene sequence analysis was used to identify the genus of each fungus collected from the wooded areas over a 3 month period of time running from July to October, 2015. Potential *Methylobacterium* species were isolated from fungal stamps using selective media containing methanol as the only carbon source. 16S rRNA gene sequence and comparative analysis using EZtaxon was used to identify the genus and species of the associated bacteria. The results showed that a diverse pool of *Methylobacterium* (*M. komagate, M. goesingense, M. mesophilicum, M. longum, M. pseudosasicola, and M. phyllostachyos*) are common colonizers of a wide range of fungi from the phylum basidiomycota including *Amanita, Megacollybia, Russula, Boletus and Gymnopus*. These results suggest that Methylobacteria may be widely associated with fungus providing candidate associations that could be investigated to better understand the role Methylobacteria may play in the ecology of fungi.

Study of the Ecology of Anthrax Foci on the Azerbaijan Border Areas with Georgia

Author Block:

M. Baghirova[1], S. Mammadova[2], N. Imamov[3], M. Hasanova[3], G. Ahmadov[3], G. Ahmadova[3]; [1]Azerbaijan Vet. Scientific Res. Inst., Baku, Azerbaijan, [2]Republican Vet. Lab., Baku, Azerbaijan, [3]Gakh Zonal Vet. Lab., Gakh, Azerbaijan

Abstract Body:

Background: Anthrax is a livestock-borne zoonotic disease that is endemic in the South Caucasus region. There is a lack of understanding of the regional epidemiology of this pathogen and the transboundary factors related to its persistence. This project is a regional collaboration between research institutes in Azerbaijan and Georgia aimed at increasing the local and regional understanding of anthrax ecology, ecological risk factors, and the genetic relationships and distribution among Azerbaijani and Georgian *B. anthracis* strains. This abstract will present data from the Azerbaijan activities of this joint project. **Methods:** Thirty villages in seven rayons along the Azerbaijan border with Georgia (Gazakh, Agstafa, Tovuz, Samukh, Gakh, Zagatala, and Balakan) which have had historic cases of both human and animal anthrax were included. At least 1,500 and up to 3,000 soil samples are being collected from four sites within each village. Sample collection sites were targeted to known burial sites and areas of previous contamination, as evidenced by livestock outbreaks or human case records. GIS (Geographic Information System) data is being collected and will be analyzed using ecological niche modeling. Soil samples will be tested by bacteriology and confirmed with PCR. **Preliminary Results:** Two sample collection sessions have been conducted with a total of 327 samples collected from Zagatala (96) and Gakh (231) rayons of Azerbaijan. Bacteriological tests indicated 37 suspected positive samples. All suspect samples were extracted for confirmation by PCR. All extracts of confirmed positive samples will be tested by real-time PCR in Azerbaijan and sent to the Lugar Center in Georgia for genotyping. **Conclusion:** The activities of this project are ongoing. This regional collaboration will provide the potential for the cooperative development of strategies for the control and trans-boundary management of anthrax in the South Caucasus.

Diverse Groups of *Escherichia coli* Persisting in Cattle Pasture

Author Block:

G. NandaKafle[1], T. Seale[2], T. Flint[1], M. Nepal[1], S. Venter[2], V. S. Brozel[1]; [1]South Dakota State Univ., Brookings, SD, [2]Univ. of Pretoria, Pretoria, South Africa

Abstract Body:

It is widely believed that *Escherichia coli* does not thrive for extended periods outside the intestines of warm-blooded animals, but recent studies show that *E. coli* strains can persist in soils without any known fecal contamination. The objective of this study was to determine whether any *E. coli* strains were able to persist in a cattle pasture, and whether these are different from *E. coli* occurring in bovine and human feces. Soil samples were collected from four pastures free from grazing animals since the previous summer. Cattle were introduced in July and soil, run-off and bovine feces samples were collected every week for four weeks. *E. coli* were isolated using Membrane Lactose Glucuronide agar. A Maximum- Likelihood tree of concatenated *uidA* and *mutS* sequences was constructed using MEGA6.06. Isolates were allocated to phylogroups using the Clermont protocol and analyzed by multi-linear logistic regression model. Survival was determined by incubating 45 isolates in sterile pasture soil from Fall to Spring under field conditions. Isolates were evaluated for propensity to form biofilm and curli, and for RpoS activity. Three types of clusters emerged from the 390 isolates, *viz.* bovine associated, clusters devoid of cattle isolates representing isolates endemic to the pasture environment, and clusters with both. All isolates clustered with *E. coli sensu stricto*, distinct from Clades I, III, IV and V. The soil endemic population was comprised largely of phylogroup B1. The phylogroup regression tree supported significant difference ($p < 0.001$) between bovine and soil-persisting clusters. Soil persisting cluster isolates displayed lower decline than bovine and human sewage cluster isolates ($p < 0.05$). Soil endemic isolates had a higher average RDAR score than other isolates but this did not correlate with degree of biofilm forming in either LB or liquid soil extract. All isolates but one displayed RpoS activity. The results indicate the existence of soil persistent *E. coli sensu stricto* that are distinct from the Clades and appear to maintain populations that persist in the soil environment.

Antimicrobial Activities of Actinomycetes Isolated from the Rhizosphere of *Genista umbellata* Collected from South-Eastern Spain (AlmeríA)

Author Block:

I. Gonzalez, F. J. Reche, M. M. Estevez, M. de la Cruz, C. Díaz, V. González, R. Serrano, N. de Pedro, J. Tormo, O. Genilloud; Fundación MEDINA, Centro de Excelencia en Investigación de Medicamentos Innovadores en Andalucía, Granada, Spain

Abstract Body:

It is well known that actinomycetes are one of the most productive microbial communities in soil and they are especially rich in plant rhizospheres. In an attempt to isolate novel actinomycetes to discover new potential producers of antimicrobial compounds with interest to be developed as novel antibiotics to fight human pathogens as well as phytopathogens, we studied the rhizosphere microbial community of *Genista umbellata,* an endemic plant in south-eastern Spain, from the area of Almerimar (Almería). To assess the diversity of the microbial community obtained following the different isolation approaches, all the isolates were initially identified to the genus level on the basis of their micromorphology, to be later characterized chemotaxonomically on their fatty acid composition. The microbial population was highly represented by a wide diversity of members of the genus *Streptomyces*, as well as isolates of the families *Micromonosporaceae, Nocardiaceae, Thermomonosporaceae, Streptosporangiaceae* and *Pseudonocardiaceae*. A selection of strains including the most diverse microorganisms from each cluster were selected to be cultivated and fermentation extracts were screened for the production of new antimicrobial agents active against a panel human pathogens (*Pseudomonas aeruginosa, Acinetobacter baumannii*, *Staphylococcus aureus* MRSA, *Candida albicans, Aspergillus fumigatus)* as well as phytopathogens (*Collecotrichum acutatum, Botrytis cinerea*). Our results confirm that rhizospheres are an extremely rich reservoir for the isolation of a wide diversity of actinomycetes, many of them still representing a rich untapped source of secondary metabolites with antimicrobial activities with potential application in different therapeutic areas and biotechnological fields.

Purification and Characterization of Potent Antimicrobial Agent with Antitumor Activitiy Recovered from Actinomycetes in Beni-Suef, Egypt

Author Block:

A. El-Gendy[1], A. Gaber[1], R. Rashad[2], M. Sayed[1], H. Hassan[1]; [1]Microbiol., Beni-Suef, Egypt, [2]Histology, Beni-Suef, Egypt

Abstract Body:

Background: The emergence of extensive antibiotics resistant bacteria increased the demands for digging out new sources of antimicrobial agents. Actinomycetes, especially *Streptomyces spp.,* have recently grasped considerable attention worldwide due to production of many useful bioactive metabolites, however few studies regarding Actinomycetes isolated from soil niche in Beni-Suef had been conducted. **Methods:** Actinomycetes were isolated from 24 soil samples using ISP4 agar and screened for production of antimicrobial activities against 7 clinical bacterial pathogens and 1 yeast using modified spot on lawn technique from which ethyl acetate total extracts of the most potent isolates were screened for their antitumor activities against two cell lines; MCF-7 and HEPG-2 cells. Genotypic characterization by 16s rRNA gene sequencing and presence of genes encoding for PKS and NRPS were conducted for one most potent isolate followed by optimization of its production using different growth parameters; carbon and nitrogen sources, pH, incubation time and starting inoculum size from which a successive purification steps using RP-HPLC followed by Ms and H NMR analysis were achieved.**Results:** A number of 52 Actinomycetes were recovered, from which 20 showed antimicrobial activities to at least one tested organism. The most potent isolate AGM12-1, which was active against all tested organisms and with IC50; 3.3 and 1.1 µg/ml against MCF-7 and HEPG-2 respectively, was characterized as *Streptomyces vinaceusdrappus* with presence of PKS and NRPS genes. Mannitol, ammonium sulfate, pH 7, 5% starting inoculums and incubation for 11 days at 30 °C were the optimum conditions used to maximize the production and hence allowed purification of one active compound to homogeneity using RP-HPLC, with m/z 488.05 and the NMR structural elucidation showed that this compound was a derivative of diketopiperazine.**Conclusions:** We isolated several Actinomycetes from soil samples in Beni-Suef from which a compound with potent antimicrobial and antitumor activities had been purified and characterized. These results have to shed light for the importance of Actinomycetes, especially those from soil reservoir, as vital source for the discovery of many novel and useful biological active compounds.

Isolation, Identification and Characterization of Nitrogen-Fixing Bacteria from the Rhizosphere of Plants Inhabiting the Mine "El Bote" from Zacatecas, Zac. Mexico

Author Block:

A. Castanon; Univ. Autonomous of Zacatecas, Zacatecas, Mexico

Abstract Body:

Mining site's soils represent a hostile environment for vegetal life, however, nitrogen-fixing bacteria might be key for the health of these ecosystems through the nitrogen input. A search for nitrogen-fixing bacteria of the rhizosphere of plants inhabiting mine tailings was carried out in order to understand the nitrogen cycle's flux from this environment. Methods employed to seek these microorganisms are focused on the identification of genes that participate in the nitrogen fixation like the gene *nifH* through PCR. However, due to the enormous phylogenetic diversity among the nitrogen fixing bacteria and the complexity of such genes it's hard to get accurate results.Enrichment cultures in nitrogen-free medium inoculated with soil rhizosphere coming from a mine tailing were made in order to isolate possible diazotrophic bacteria. Once we obtained the strains, a molecular analysis was carried out on the same by first isolating genomic DNA and then amplifying through PCR the ribosomal gene 16S (rDNA 16S) and thus identify such strains. We concluded with the amplification through PCR of the gene *nifH* using 4 sets of primers specific for diazotrophs species previously reported and 3 pairs of primers degenareted to cover more genetic diversity.We obtained a total of 11 strains that were capable of growing in nitrogen-free medium and the the gene sequence analysis showed that most of them corresponded to nitrogen fixing bacteria genera highly studied like *Rhizobium* and other diazotroph genera also reported like *Serratia, Acinetobacter, Xanthomonas* and *Streptomyces*. As for the identification of the gene *nifH*, from the 7 pairs of primers tested, only one of the degenarated primers amplified an expected DNA fragment size in all of the strains tested, nevertheless, the sequenciation of one those amplicons showed that it does not match the *nifH* gene.The results obtained in this work suggest that a considerable diversity of nitrogen fixing rhizobacteria might exist in the rhizosphere of plants that inhabit the mine "El Bote". Molecular methods for detecting functional genes like *nifH* represent a good tool for the identification of nitrogen-fixing bacteria despite of the results; however, an analysis of the great variety of primers that target this gene should be done first in order to get more accurate results.

Microbial Diversity in Armenian Mining Areas Revealed by Molecular Approach

Author Block:

A. Margaryan[1], N-K. Birkeland[2], H. Panosyan[1], A. Trchounian[1]; [1]Yerevan State Univ., Yerevan, Armenia, [2]Univ. of Bergen, Bergen, Norway

Abstract Body:

Background: Metal-rich natural and factitious habitats are extreme environments for the development and evolution of unique microbial communities, which could have important applications in bioremediation of heavy-metal contaminated environment. The main objective of this study was to determine the bacterial and archaeal diversity in Alaverdi Copper mine waste (sludge), Akhtala tailing, and Shamlugh copper stone rock using molecular approaches. **Methods:** PCR-DGGE fingerprinting and 454 pyrosequencing have been used to reveal the microbial community in the collected samples. **Results:** The bacterial community structure analysis by PCR-DGGE fingerprinting method revealed an abundance of the representatives of *Modestobacter, Microbacterium, Rhodococcus* and *Saccharomonospora* genera in Alaverdi sludge. In Shamlugh copper stone rock the members of the genera *Stenotrophomonas, Massilia, Dechloromonas, Limnobacter, Thiobacillus, Thalassospira, Actinobacterium* and uncultured phylawere found. Akhtala tailing was rich in representatives of the genera *Acidobacteria*, as well as uncultured groups of Acidobacteriaceae and other uncultured bacteria. Tagged 16S rRNA gene pyrosequencing data confirmed a domination of *Alphaproteobacteria, Gammaproteobacteria* and *Bacteroidetes* in Akhtala tailings, and also revealed the presence of *Verrucomicrobia, Acidobacteria, Actinobacteria,* etc. and some uncultured bacterial groups.Archaeal PCR-DGGE analyses indicated the presence of uncultured lineages in Alaverdi sludge, *Ferroplasma acidiphilum* in Akhtala tailing, Candidatus *Nitrososphaera gargensis, Methanosphaera* sp. and uncultured groups of Methanobacteriaceae in Shamlugh copper stone rock samples. **Conclusions:** The majority of the bacteria detected by DGGE fingerprinting were most closely related to uncultivated organisms. Most of the bacterial sequences shared less than 95% identity with their closest match in GenBank, indicating the presence of a unique bacterial community in Armenian Mines..

Chemoheterotrophic Bacteria Contribute to Biogenic Evolution of Speleothems in Cave Formations

Author Block:

S. JOSHI; NORTH EASTERN HILL Univ., SHILLONG, MEGHALAYA, India

Abstract Body:

Background: Caves offer a stable and protected environment devoid of all light sources. The microbial community living in such aphotic conditions in caves are dependent on sources of energy other than light and derive energy from the surrounding atmosphere, minerals and rocks. The present work explored the role of bacterial biofilms of various texture and colourations in caves in North-east India which represent some of the longest caves in the subcontinent and have not received much attention of scientists.**Methods:** Chemohererotrophs isolation was done from the speleothems of the caves in the region. Bacterial morphology, precipitated microstructural crystal morphologies, mineral compositions and association of microbial colonies with crystals were examined by SEM-EDX. Quantitative analysis of the mineral precipitated was done in Sequential X-ray Fluorescence Spectrometer (XRF). The ultrastructural morphology of calcium carbonate (CaCO3) crystals precipitated by the bacteria associated were studied using electron microscopy.**Results:** Thirty-two bacterial species belonging to sixteen genera majority being *Bacillus* and *Pseudomonas* isolated from these caves indicated the capability to precipitate calcite. SEM studies revealed crystal polymorphs generated *in vitro* by the isolates resembling the microscopical observations of natural speleothems. The EDX spectrum showed the *in vitro* precipitated crystals predominately composed of calcium carbonate hypothesizing the relevance of bacterial biofilm in cave geomicrobiology and biogenic evolution of cave which was supported by XRF analysis and Raman spectroscopy. The isolated bacteria under *in vitro* conditions precipitated CaCO3 in the media when supplemented with proper calcium source which was not the case in dead cells suggesting that calcification required metabolic activity in the speleothemic environment.**Conclusions:** The findings indicate the geomicrobiological contribution in the precipitation of calcium carbonates in caves and subterranean environments. Thus, microbiological investigations along with SEM studies, XRF and Raman spectroscopic observations add evidences to the hypothesis about the biogenic influence to the genesis of speleothem.

Molecular Characterization of a Novel Partitivirus Infecting the Bats White Nose Syndrome Etiological Fungus *Pseudogymnoascus destructans*

Author Block:

P. Ren, S. Rajkumar, H. Sui, P. Masters, S. Chaturvedi, V. Chaturvedi; Wadsworth Ctr., NYSDOH, Albany, NY

Abstract Body:

From the White Nose Syndrome (WNS) etiological fungus *Pseudogymnoascus destructans*, we isolated a mycovirus (named PdPV-1). The virus is a bipartite virus since it contains two double-stranded RNA (dsRNA) segments designated as LS and SS. The cDNAs from PdPV-1 genomic dsRNAs were constructed and sequenced. The LS dsRNA was 1,683 bp in length with an open reading frame (ORF) that encodes 539 amino acids (molecular mass of 62.7 kDa). The SS dsRNA was 1,524 bp in length with an ORF that encodes 434 amino acids (molecular mass of 46.9 kDa). Both LS and SS ORFs were embedded only on the positive strand of each dsRNA segment. The predicted amino acid sequence of LS contained motifs representative of RNA-dependent RNA polymerase (RdRp); whereas the amino acid sequence of SS showed homology with the putative capsid proteins (CPs) from various mycoviruses. Phylogenetic analysis using the RdRp and CP sequences of mycoviruses suggests that both segments constitute the genome of a new virus that belongs to the family *Partitiviridae*. In agreement with the phylogenetic result, virus particles were successfully purified from this WNS causative fungus *P. destructans*. Electron microscopy analysis showed that the purified virions were isometric with an estimated diameter of 33 nm. Reverse transcription PCR (RT-PCR) and its sequences revealed that all isolates of *P. destructans* collected from various states of US were infected with this novel partitivirus; however, its closely related fungal species, such as *P. roseus* and *P. appendiculatus*, did not contain the virus.

Hlth.., Tbilisi, Georgia, [2]Ctr.s For Disease Control and Prevention, Fort Collins, CO, [3]Ctr.s For Disease Control and Prevention, Fort Collines, CO, [4]CDC, Atlanta, GA, [5]Ilia State Univ., Tbilisi, Georgia

Abstract Body:

Background: Bats (Order: Chiroptera) are hosts of a wide range of zoonotic pathogens**.** The importance of chiropterans as reservoirs of viruses potentially transmissible to humans and other animals has become more evident with the passage of time. Little is known though about presence of bacterial infectious agents in bats, and no studies on this subject have been conducted in Georgia.**Objectives:** Bats of 10 species were sampled in 7 localities of Georgia in June 2012. Tissue specimens from 245 bats were available for testing for the presence of bacterial pathogens. **Methods:** A real-time PCR assay was performed in a triplex for detection of *Brucella* (IS711), *Bartonella* (tmRNA), and *Yersinia* (pal) from bat spleen tissues. An individual real-time PCR assay was used for detection of *Leptospira* (LipL32) in bat kidney tissues**.** Conventional PCR targeting the 16SrRNA gene was performed for detection of multiple strains of other bacteria in spleen tissues. Culturing was used for detection and identification of *Bartonella* species in blood samples and a phylogeny of *Bartonella* isolates was evaluated by sequence analysis of the *gltA* gene.**Results**: 113 of 221 bats (51%) were positive for at least one bacterial agent. *Bartonella* and *Leptospira* species were the most frequently detected agents with 20% *Leptospira*-positive bats and 51% *Bartonella*-positive. The *gltA* sequence analysis differentiated nine unique *Bartonella* phylogenetic clusters with a divergence corresponding to species levels. Four spleen samples were found positive for *Brucella* DNA by IS711 with two of them further confirmed by *Brucella*-specific csp31 and one by 16S rRNA. Sequence analysis of the three targets demonstrated 99.0% identity to known *Brucella* species.**Conclusion:** The proposed study was the first investigation of multiple bacterial agents conducted in bats from Georgia. Further analysis and interpretation of the bacteriological and genetic results will benefit surveillance systemsfor emerging pathogens in bats and outline potential risks to human and animal health in Georgia.

Detection of *Borrelia, Ehrlichia,* and *Rickettsia* spp. in Ticks in Adair County of Northeast Missouri

Author Block:

D. A. Hudman, N. J. Sargentini; ATSU/Kirksville Coll. of Osteopathic Med., Kirksville, MO

Abstract Body:

Background: The most common ticks in Missouri, all of which are associated with human pathogen transmission, are the lone star tick (*Amblyomma americanum*), American dog tick (*Dermacentor variabilis*), and the black-legged tick (*Ixodes scapularis*). Ticks are especially common in Northeast Missouri, but poorly studied despite the fact that Missouri is one of five states that accounts for over 60% of all Rocky Mountain spotted fever cases and one of three states that accounts for 30% of all reported *E. chaffeensis* infections. We conducted this research to improve our understanding of tick populations and tick-borne pathogen presence. **Methods:** Actively questing ticks were collected using a tick drag-flag method and by carbon dioxide traps. Ticks were identified and pooled by species and life stage (adults = 5; nymphs = 25, larvae = 100). Tick pools were tested for the presence/absence of *Borrelia* spp., *Ehrlichia* spp., and *Rickettsia* spp. using polymerase chain reaction (PCR). All positive reactions were confirmed by a second round of PCR and representative positive PCR products were purified and sent off-site for sequence verification. **Results:** A total of 15,162 ticks were collected, of which 13,980 were grouped in 308 pools. Infection rates were calculated as the maximum likelihood estimation (MLE) with 95% confidence intervals (CI). Of the 308 pools tested, 229 (74.4%) were infected with bacteria and the overall MLE of the infection rate per 100 ticks was calculated as 2.9% (CI 2.6-3.2). Infection rates varied among life stages, 28.6% (CI 24.0-34.0) in adults, 7.0% (CI 5.1-9.9) in nymphs, and 0.95% (CI 0.8-1.2) in larvae. In the 116 adult lone star pools, infection rates for *Borrelia*, *Ehrlichia*, and *Rickettsia* spp. were 4.3%, 13.2% and 19.1%, respectively. In the 52 nymph lone star pools, infection rates for *Borrelia*, *Ehrlichia*, and *Rickettsia* spp. were 1.6%, 2.4% and 2.7%, respectively. In the 20 adult American dog tick pools, the infection rate for *Ehrlichia* spp. was 18.3%. **Conclusions:** We have performed the first in-depth survey of ticks and tick-borne human disease in Northeast Missouri. We not only determined the presence of *Borrelia, Ehrlichia* and *Rickettsia* species, but have also implicated high prevalence. One novel finding was the presence of *E. chaffeensis* and *E. ewingii* in five of the 120 lone star larvae pools, which is suggestive of transovarial transmission.

Reduced Pathogenic Potential of Environmental *Campylobacter jejuni* Carried by the American Crow

Author Block:

K. Sen[1], K. Francisco[1], J. Ton[1], J. Lu[2], D. Lye[2]; [1]Univ of Washington, Bothell, WA, [2]EPA, Cincinnati, OH

Abstract Body:

Campylobacter spp. are major causes of gastroenteritis worldwide. Recent studies have implicated wild birds in the zoonotic transmission of these bacteria. The virulence potential of *Campylobacter* shed in crow feces obtained from a wetland area in Bothell, Washington (where over 10,000 crows roost nightly) was studied. *Campylobacter* was isolated from 64 % of the fecal (n=58), and 20% (n=20) of the water samples collected during 2014 - 2015 by a unique filter method. PCR analysis confirmed the isolates to be *C. jejuni*. Similar analysis for virulence gene markers flagellin A (*fla*A) and CadF revealed 95% and 90% of the fecal, and 100% of the water isolates to have *flaA* and *cad*F genes, respectively. PCR analysis for the major toxin, cytolethal distending toxin (CDT), encoded by the *cdt*ABC gene cluster, revealed 89% of the fecal and 100% of the water isolates to have the cluster. A functional CDT toxin is produced by the expression of three tandem genes, *cdt*A, *cdt*B, and *cdt*C. Sequence analysis of *cdt*ABC in the isolates revealed a truncated cluster. Two kinds of mutation were observed. Some strains had a 668-bp deletion across *cdt*A and *cdt*B and a further 51 bp deletion within *cdt*B. Other strains had an additional 20 bp deletions in *cdt*B. In either case, a functional toxin is not expected. Source tracking studies using restriction fragment length polymorphism and sequencing of the *fla*A gene correlated the water isolates to crows. To investigate the possibility of a niche specific selection of these strains (with truncated *cdt*ABC) by the crows, additional fecal samples (n=11) were obtained from two other non-wetland locations within Washington. *C. jejuni* was isolated from 5 samples and all isolates demonstrated a truncated *cdt*ABC. Although the former deletion pattern has been reported in one study (<3% of isolates), the source was not correlated to crows (1). Examination by tissue culture assay did not demonstrate a CDT toxin activity in these isolates. Patients suffering from *Campylobacteriosis* have been clearly shown to elicit circulating antibodies to the entire CDT toxin (1). Our study suggests that North American crows (*Corvus brachyrhyncous*) carry the bacteria *C. jejuni,* but with a dis-functional toxin protein that is expected to drastically reduce its potential to cause diarrhea. Whether this phenomenon is host (crow) specific, needs to be explored further.

Prevalence of *Brucella Suis, Campylobacter jejuni, Escherichia coli* O157:H7, and *Yersinia enterocolitica* in Georgia's Feral Pig Communities

Author Block:

J. K. Lama, D. Bachoon; Georgia Coll. & State Univ., Milledgeville, GA

Abstract Body:

Feral pigs carry zoonotic pathogens and can disseminate these pathogens to domestic pigs, other animals, and humans. Fecal samples were collected from 64 feral pigs from ten counties in Georgia. DNA was extracted from the fecal samples and assayed using qPCR for *Brucella suis*, *Campylobacter jejuni*, and *E. coli* O157:H7, and *Yersinia enterocolitica*. Out of 64 samples analyzed, *B. sui*s was detected in 21% of the pigs and *E. coli* O157:H7 were detected in 14% of the feral pigs. However, *Campylocater jejuni* was not detected in any of the pig samples. These pathogenic bacteria carried by feral pigs represent a growing threat to public health and agriculture in the State of Georgia.

Prevalence and Enumeration of Campylobacter at Different Steps of Broiler Slaughterhouses in South Korea

Author Block:

J-S. Moon; Animal, Plant, and Fisheries Quarantine and Inspection Agency, Anyang-si Gyeonggi-go, Korea, Republic of

Abstract Body:

Background: In this study, prevalence and enumeration of Campylobacter in carcasses at different steps of the broiler slaughterhouses were investigated between April and November 2012 in South Korea. **Methods:** The two differently sized typical chicken processing plants accredited HACCP system was managed the critical control points for fecal contamination reduction and chlorinated water concentration (20ppm) at air chiller step and body core temperature (4.4°C) of carcasses at final storage step. Sampling was conducted at four points (anus swap of live chicken, post-evisceration/pre-washing, post washing/pre-chilling, and post chilling) in the slaughter process of whole chicken carcasses. **Results:** All experimental procedures for isolation, identification and enumeration of C. jejuni, C. coli, and C. lari were conducted according to the culture method by Food Safety and Inspection Service. In both plants, the prevalence of Campylobacter increased considerably after evisceration (from 5.8% to 20.5% in plant A; from 5.8% to 15.4% in plant B) and decreased after the chilling step (from 20.5% to 10.9% in plant A; from 15.4% to 2.9% in plant B). However, distribution of quantification of Campylobacter contamination against carcasses reduced from evisceration (41.7%) to final carcasses (20.0%) in the more than 103 CFU/ml. Among isolates from 119 samples, C. coli (52.9%) were the most prevalent species in plants. **Conclusions:** Our finding suggested that low level of Campylobacter contamination imply during broiler processing from two plants accredited HACCP system.

Molecular Subtyping and Source Attribution of *Campylobacter* Isolated from Food Animals

Author Block:

G. H. Tyson[1], H. Tate[1], J. Abbott[1], T-T. Tran[1], C. Kabera[1], E. Crarey[1], S. Young[1], P. McDermott[1], M. Campbell[2], S. Thitaram[2], S. Zhao[1]; [1]U.S. Food and Drug Admin., Laurel, MD, [2]USDA, Athens, GA

Abstract Body:

Campylobacter spp. commonly cause gastrointestinal illness in humans, and poultry meats have long been considered the predominant source of these infections. Nevertheless, few in-depth source attribution studies have attempted to compare *Campylobacter* isolated from food animals to isolates causing human illness. As a result, we obtained over 1,300 *Campylobacter* isolates from a number of sources, including dairy and beef cattle, pigs, poultry, and retail poultry meat. Each isolate was subtyped using pulsed-field gel electrophoresis (PFGE), and queried against the CDC PulseNet database to identify human isolates with indistinguishable patterns. As expected, many of the patterns from poultry (49.5%) had indistinguishable patterns from those of human isolates, suggesting retail poultry are a likely source of some human illnesses. Isolates from beef and dairy cows had an even higher proportion of PFGE patterns indistinguishable from those from human patients, with 56.6% and 65.0%, respectively. In contrast, only a small portion of *Campylobacter* PFGE patterns from pig isolates (9.5%) were found to have indistinguishable patterns from human isolates. These data suggest that food sources or environmental contamination associated with cattle may be larger contributors to *Campylobacter* infections than previously recognized, and help further our understanding of potential sources of human campylobacteriosis.

WGS of S*almonella* Subspecies *enterica* Serotype Tennessee Obtained from Peanut Butter Outbreaks

Author Block:

M. W. Allard; U.S. FDA, College Park, MD

Abstract Body:

Establishing an association between possible food sources and clinical isolates requires discriminating the suspected pathogen from an environmental background, and distinguishing it from other closely-related foodborne pathogens. We used whole genome sequencing (WGS) to *Salmonella* subspecies *enterica* serotype Tennessee (*S.* Tennessee) to describe genomic diversity across the serovar as well as among and within outbreak clades of strains associated with contaminated peanut butter. We analyzed 71 isolates of *S.* Tennessee from disparate food, environmental, and clinical sources and 2 other closely-related *Salmonella* serovars as outgroups (*S.* Kentucky and *S.* Cubana), which were also shot-gun sequenced. A whole genome single nucleotide polymorphism (SNP) analysis was performed using a maximum likelihood approach to infer phylogenetic relationships. Several monophyletic lineages of *S.* Tennessee with limited SNP variability were identified that recapitulated several food contamination events. *S.* Tennessee clades were separated from outgroup salmonellae by more than sixteen thousand SNPs. Intra-serovar diversity of *S.* Tennessee was small compared to the chosen outgroups (1,153 SNPs), suggesting recent divergence of some *S.* Tennessee clades. Analysis of all 1,153 SNPs structuring an S. Tennessee peanut butter outbreak cluster revealed that isolates from several food, plant, and clinical isolates were very closely related, as they had only a few SNP differences between. SNP-based cluster analyses linked specific food sources to several clinical S. Tennessee strains isolated in separate contamination events. Environmental and clinical isolates had very similar whole genome sequences; no markers were found that could be used to discriminate between these sources. Finally, we identified SNPs within variable *S.* Tennessee genes that may be useful markers for the development of rapid surveillance and typing methods, potentially aiding in traceback efforts during future outbreaks. Using WGS can delimit contamination sources for foodborne illnesses across multiple outbreaks and reveal otherwise undetected DNA sequence differences essential to the tracing of bacterial pathogens as they emerge. M. ALAM[1], J. Miranda[1], J. McPherson[1], A. Anu[1], A. Apu[1], E. Z. Kao[1], G. T. Chao[1], K. R. Wasko[1], W. Chowdhury[2], M. Ali[3], S. Parveen[4], J. Masuoka[5], K. W. Garey[1]; [1]Univ. of Houston Coll. of Pharmacy, Houston, TX, [2]Georgia Southern Univ., Statesboro, GA, [3]Metropolitan State Univ. of Denver, Denver, CO, [4]Univ. of Maryland Eastern Shore, Princess Anne, MD, [5]Midwestern State Univ., Wichita Falls, TX

Abstract Body:

Background: Based on U.S. population-based data, community-acquired *C. difficile* infection (CA-CDI) is associated with 32% of all CDI cases. Environmental spores of *C. difficile* from human and animal fecal contamination can persist for months. The objectives of this study were to investigate the ribotype diversity of *C. difficile* strains, and their molecular characteristics from a wide-range of environmental sources.**Methods:** Non-clinical environmental surface swab samples were collected from from 4 countries (6 States of USA (n=1938), Germany (n=100), France (n=100), and Taiwan (n=200) and analyzed using anaerobic culture and molecular methods. Samples were enriched in 25 ml of brain heart infusion (BHI) broth with 0.1% Na-taurocholate and incubated at 37C in an anaerobic chamber for 48h. One ml of culture broth was centrifuged, and treated with 70% ethanol. Ethanol treated culture were plated on to CCFA and incubated 48h anaerobically. Suspected colonies were then identified and characterized by PCR (tcdA, tcdB, tpi, ctdA and ctdB genes) and ribotyped using fluorescent PCR ribotyping. **Results:** Of the 2,338 total samples 8.8% (205) were positive for *C. difficile*. Toxigenic *C. difficile* were present in 61.4% (126/205) among isolates. Twenty different ribotypes (001, 002, 012, 017, 014-020, 027, 078-126, UM9, UM10, UM11, UM12, UN13, UM14, UM16, UM18, UM24, UM26, UM41, UM78, and UM87) of *C. difficile* were found among 144 strains screened. Most common ribotyes were 014-020, UM11, UM12, 002, and 078-126.**Conclusions:** Non-clinical environmental samples were frequently positive for potentially pathogenic *C. difficile* with diverse ribotypes in all geographical locations. Further studies are needed to prevent and control environmental sources of toxigenic *C. difficile* in and around our community environs.

Isolation and Molecular Analysis of Waterbloom-Forming Cyanobacterial Genus *Microcystis* Occurred in Agricultural Water Reservoir with Biotope

Author Block:

T. Nishizawa[1], M. Sutou[1], A. Satou[1], K-I. Harada[2], M. Shirai[3]; [1]Ibaraki Univ., Ibaraki, Japan, [2]Meijo Univ., Nagoya, Japan, [3]Aikoku Gakuen Univ., Chiba, Japan

Abstract Body:

There has been increased concern over the effects on wildlife of toxins, particularly those associated with harmful algal blooms in water reservoirs and recreational areas. Cyanobacteria, which include the genera *Anabaena, Microcystis, Nostoc*, and *Planktothrix*, produce structurally diverse peptides as secondary metabolites. The best known are the heptatoxic cyclic peptides, microcystins which are synthesized on large enzyme complexes comprising non-ribosomal peptide synthetase and polyketide synthase. This type of toxin has been responsible for the deaths of wild birds that have drunk water contaminated with cyanobacterial waterblooms in Japan. In 2008, a mass death of egrets and herons with steatitis were found at the agricultural reservoir with biotope, Kanagawa Prefecture, Japan, occurring cyanobacterial waterblooms. The objective of this study was to elucidate cyanobacterial community structure in the agricultural reservoir according to molecular analysis. To assess the cyanobacterial community, 16S rRNA-based terminal restriction fragment length polymorphism and clone library analysis have been utilized, as well as for the typing and monitoring of the cyanobacterial strains. Our results indicated that the *Microcystis* strain was observed to be the dominant species of cyanobacteria in the reservoir. In this study, a total of 59 axenic *Microcystis* strains were obtained from the reservoir. Phylogenetic analysis of the 16S-23S internal transcribed spacer region indicated that these strains classified into two groups of the genus *Microcystis*. Two microcystin biosynthetic gene (*mcy*)-possessing strains were identified according to the *mcy*-based PCR amplification. These results suggested that the *Microcystis* strains occurred in the reservoir have a taxonomic status different from toxic *Microcystis* strains which are obtained from other eutrophic freshwater in Japan to date.

Phenotypes And Virulence Among *staphylococcus Aureus* Usa100, Usa200, Usa300, Usa400, And Usa600 Clonal Types

Author Block:

J. M. King, K. Kulhankova, C. S. Stach, B. G. Vu, W. Salgado-Pabon; The Univ. of Iowa, Iowa City, IA

Abstract Body:

Background: *S. aureus* lineages circulating worldwide and frequently associated with serious illness include clonal complex (CC) 5/USA100, CC30/USA200, CC8/USA300, CC1/USA400, and CC45/USA600. The USA300 (the current community epidemic lineage in the U.S) causes predominantly severe skin and soft tissue infections. The USA100/CC5, 200/CC30, and 600/CC45 lineages cause the majority of bloodstream infections and infective endocarditis (IE) worldwide yet remain largely uncharacterized. To elucidate key characteristics common to invasive *S. aureus* strains, we characterized a subset of isolates from five USA types associated with human disease. **Methods:** To test strains in vitro we used PCR and immunoblotting to determine superantigen gene profile and expression levels, respectively, rabbit erythrocyte assays to determine cytolytic potential, microtiter plate assays to determine biofilm formation, and blood survival assays. We also tested these strains in vivo in our rabbit model of IE and sepsis. **Results:** Intraclonal variation in hemolysis, biofilm formation, and blood survival is seen among strains from different lineages while expression of a high-level superantigen (SAg) (e.g. TSST-1, SEB, or SEC) or the egc is consistently seen in USA100, USA200, USA400, and USA600 strains. Isolates from each clonal group induce similar lethality in rabbits but USA300 isolates are deficient at causing IE. **Conclusions:** Intraclonal variability is common in the parameters frequently used to determine virulence of S. aureus strains however, strains most frequently associated with serious illness encode a high level SAg or the egc SAgs. Therefore, studies relating to S. aureus virulence should include USA100, 200, 400, and 600 isolates and consider SAg profiles.

Leveraging a Real-Time PCR Assay for the Determination of the Germination-State of *Bacillus* Spores in Context of Wide-Area Spore Decontamination Efforts

Author Block:

T. M. Mott, **A. M. Woodson**, S. L. Welkos, C. K. Cote; USAMRIID, Frederick, MD

Abstract Body:

The events following the intentional release of *Bacillus anthracis* spores in 2001 strongly reinforced the need for reliable methods of decontamination and remediation of affected sites. Furthermore, identifying methods that are cost-effective, safe and minimize environmental damage is top priority. Given the inherent resistance of the spores to inactivation and the greater sensitivity of germinated bacilli, the main focus of this work is to evaluate germination as an enhancement to *B. anthracis* decontamination methods. The evaluation and validation of such a method relies on the accurate quantification of germinated and ungerminated spore populations in a given test-sample. Current means of quantification, such as culture-based methods, are labor and time intensive. To overcome these caveats, our lab has leveraged a real-time qPCR assay that uses changes in threshold cycle to detect viable germinated spores recovered from different coupon surfaces. A magnetic bead-based DNA extraction and purification step is employed prior to evaluation with our real-time PCR assay that targets a 159 bp fragment of the 30s ribosomal protein S21gene *rpsU*. Evaluated for both *B. anthracis* and its surrogate *Bacillus thuringiensis*, this method can accurately detect 50 femtograms of chromosomal DNA harvested from germinated spores. Using the resulting cycle threshold values, the percentage of viable germinated spores can be extrapolated from a DNA standard curve generated from a known amount of bacteria. Such methods of quantification are essential for testing the efficacies of secondary decontaminants in a laboratory setting or field trial and potentially confirming the remediation of sites affected by the intentional or accidental release of *B. anthracis* spores.

Prevalence of Lysogens and Virulence Genes Show That Tropical Soil Environment as a Gene Reservoir

Author Block:

A. A. Gonzalez[1], J. Marrero[1], A. Baerga[2], G. A. Toranzos[1]; [1]Univ. of Puerto Rico,Rio Piedras Campus, San Juan, PR, [2]Univ. of Puerto Rico,Med. Sci. Campus, San Juan, PR

Abstract Body:

Pangenomic studies indicate that *E. coli* are adaptable to survive in the environment. However, few studies are available of the impact these have on public health. Bacteria harboring virulence genes to colonization and control host defense represent a concern to public health. Previous work in our laboratory has demonstrated the presence of virulence genes as part of the environmental microbiota. Mobile genetic elements contribute to bacterial genome evolution by increasing virulence capabilities. As a follow-up to previous studies we demonstrate the presence of batteries of virulence genes present in mobile elements and they diversity within environmental populations. Our aim is to determine the prevalence of lysogenic virus and virulence genes in 83 environmental *E. coli* isolates from pristine areas of tropical rainforest in Puerto Rico. Primers were designed to amplify integrases, fimbriae and pro-inflammatory genes. Chemical lysogenic phage inductions indicated a total of (23.8%) isolates to be positive for lysogens. Integrases were present as follows: P2 (53.8%), P4 (26.3%), Hk97 (22.5%), Lambda (18.8%), Wphi (17.5%), Hk022 (7.5%) and phiV10 (1.3%). Conserved domain of colonization factor (*eae*) was detected in (7.5%) in previous studies. Interestingly, some of the isolates positive for (*eae*) previously failed to amplify the variable portion, decreasing the prevalence to (5%). Sequencing demonstrated diversity and presence of two different (*eae*) alleles: Zeta (ζ) and Kappa (κ). To our surprise, its co-receptor (*tir*) was also absent in some (*eae*) positive. Another unexpected finding was the amplification of unknown product, sequencing revealed a Type II secretion system (TIISS). One strain isolate harbored pro-inflammatory TcpC (0.01%). Our findings clearly indicate that the environmental microbiota indeed a gene reservoir. This is one of the first reports that aimed to identify virulence genes in pristine environments, indicating the presence of novel genes critical in colonization and control host response.

Study of the Role of Avin03910 Depolymerase in the Metabolism of Polyhydroxybutyrate Polyester (Phb) in *Azotobacter vinelandii*

Author Block:

L. A. Adaya[1], J. Guzman[1], D. Pfeiffer[2], D. Jendrossek[2], G. Espin[1], D. Segura[1]; [1]Univ. Natl. Autonoma de México, Cuernavaca, Mexico, [2]Univ. of Stuttgart, Stuttgart, Germany

Abstract Body:

Background: Polyhydroxybutyrate (PHB) is polyester that is synthesized and intracellular accumulated as a carbon and energy reserve in several bacteria. In *A. vinelandii* the genes coding for the PHB biosynthetic enzymes, as well as several regulatory elements involved in the control of its synthesis, have been characterized. However, little is known about the mobilization process allowing the utilization of accumulated PHB when it is needed. The sequence of *A. vinelandii* DJ revealed seven genes that are thought to encode intracellular PHB depolymerase (the enzymes responsible for the mobilization of PHB). However, direct evidence for the *in vivo* roles of their gene products is missing.**Methods:**In this study, we selected a gen (*Avin03910*), representing the most probable candidate to be involved in the catabolism of PHB and investigated the physiological function of their gene product: (i) with *Escherichia coli* recombinant strains expressing AvinPhbZ$_1$ (*Avin03910*), protein; (ii) with a mutant *A. vinelandii*.**Results**: Evidence for significant PHB depolymerase activity *in vitro* was obtained for the product of *Avin03910* expressed in *E. coli*. The protein was active on amorphous and artificial granules only, but not on crystalline PHB, like other intracellular depolymerase.On the other hand, we found that the protein Avin03910 is associated with the granules of PHB. The mutant AvinPhbZ$_1^-$ had a phenotype of increased PHB accumulation and its purified native granules showed a diminished PHB mobilization and degraded more slowly than the wild type.**Conclusions**: This phenotype, together with its inability to degrade intracellular PHB under conditions stimulating mobilization in the wild type strain, suggest that the depolymerase AvinPhbZ$_1$ is the main responsible for intracellular PHB degradation. The presence of other PHB depolymerase in this bacterium cannot be discarded and will also be discussed.

Genetic Regulation of Omega-3 Polyunsaturated Fatty Acid Synthesis in the Deep Sea Bacterium *Photobacterium profundum* Strain Ss9

Author Block:

M. N. Allemann, E. E. Allen; Univ. of California San Diego, La Jolla, CA

Abstract Body:

One of the better-characterized bacterial adaptations to the deep sea environment includes the biosynthesis and incorporation of polyunsaturated fatty acids, such as eicosapentaenoeic acid (20:5n-3; EPA) into membrane phospholipids. There is considerable biomedical interest in these molecules due to their beneficial role in cardiovascular health and neural development. In *Photobacterium profundum* strain SS9 the biosynthetic pathway for EPA has been previously characterized and consists of five genes *pfaA-E,* which encode a polyketide synthase. The *pfaA-D* genes form an operon that consists of two transcriptional units. While it is known that a variety of culture parameters, such as temperature and hydrostatic pressure, can influence the levels of EPA in SS9, there is no information about regulatory mechanisms behind these changes. Additionally, this secondary lipid pathway and the dissociated Type II fatty acid synthase appear to coordinate with one another by an unknown mechanism. Genome sequencing of an SS9 chemical mutant, designated EA2, that overproduces EPA with reduced monounsaturated fatty acid content revealed no changes in the *pfa* operon or its promoter regions. Previous transcript analyses of the *pfa* operon in EA2 had indicated elevated transcript abundance. Given this information we hypothesize that an uncharacterized *trans* regulatory mechanism controls *pfa* expression. To begin to address what genes regulate the *pfa* operon, we have prepared a gene fusion between the *pfaA* gene and the E.coli *lacZ* gene and crossed this into the SS9 genome using allelic exchange. We report the use of a variety of transposons in this reporter strain and the isolation of mutants with altered *pfaA::lacZ* activity. An enhanced understanding of the genetic determinants controlling microbial omega-3 polyunsaturated fatty acid synthesis will expand opportunities to direct high-level production of these molecules in native or recombinant microbial strains.

Growth of *Sphingomonas wittichii* Rw1 on Dibenzo-*p*-Dioxin Requires Plasmid and Chromosomally Encoded Genes

Author Block:

T. Mutter, H-K. Chang, G. Zylstra; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Sphingomonas wittichii RW1 is one of a few strains known for the ability to grow on the related compounds dibenzofuran (DBF) and dibenzo-*p*-dioxin (DD) as the sole source of carbon. The genes for the initial steps in the DBF catabolic pathway (ring hydroxylating dioxygenase, ring cleavage dioxygenase, and a hydrolase) which result in the formation of salicylate and a five carbon fragment have been localized to a megaplasmid designated pSWIT02 in RW1. Plasmids highly similar to pSWIT02 have been found in other DBF degrading *Sphingomonas* strains. However, despite having the pSWIT02-encoded DBF degradation pathway these other bacteria are not capable of growth on DD. We hypothesized that the unique ability of *S. wittichii* RW1 to grow on DD is due to a combination of the DBF degradation genes on pSWIT02 and chromosomally encoded genes specific to DD degradation. We initially targeted the ring cleavage enzyme encoded by the *dbfB* gene on pSWIT02 as previous studies indicated that this enzyme has very low activity against the DD pathway intermediate trihydroxybiphenylether and high activity against the DBF pathway intermediate trihydroxybiphenyl. We knocked out the pSWIT02 *dbfB* gene through disruption with a kanamycin resistance cassette. Growth curves indicate that RW1delta*dbfB* grows extremely slowly on DBF and accumulates the ring cleavage substrate trihydroxybiphenyl. Growth curves also indicate that RW1delta*dbfB* grows normally on DD as the sole source of carbon indicating that *dbfB* is not necessary for the DD catabolic pathway. Previously published proteomic and transcriptomic data indicated that the ring cleavage enzyme encoded by the chromosomal gene SWIT3046 is upregulated during growth on DD but not on DBF. Knockout of gene SWIT3046 resulted in a strain RW1delta3046 that grows normally on DBF but that does not grow on DD. The double knockout RW1delta*dbfB*delta3046 does not grow on either DBF or DD. These results prove that separate ring cleavage enzymes are absolutely necessary for DBF and DD degradation. These results also show that a combination of plasmid (pSWIT02) and chromosome genes are necessary for growth of RW1 on DD.

Atypical Iron Sulfur Cluster Biosynthesis in Sulfate Reducing Bacteria

Author Block:

V. Trotter[1], A. Saini[1], M. N. Price[1], J. He[1], J. V. Kuehl[1], K. M. Wetmore[1], N. L. Liu[1], G. M. Zane[2], S. R. Fels[3], T. R. Juba[2], M. Shatsky[1], A. P. Arkin[1], P. D. Adams[1], J-M. Chandonia[1], J. D. Wall[2], A. M. Deutschbauer[1], **G. P. Butland**[1]; [1]Lawrence Berkeley Natl. Lab, Berkeley, CA, [2]Univ. of Missouri, Columbia, MO, [3]Yale Univ., New Haven, CT

Abstract Body:

Iron sulfur (FeS) cluster containing proteins make essential contributions to many key cellular processes but can readily be damaged by environmentally encountered oxidative stress, exposure to toxic metals or reactive N-oxyanions. Damage of key FeS enzymes such as pyruvate-ferredoxin oxidoreductase (PFOR) has been proposed as the source of inviability of sulfate reducing bacteria (SRBs) and other anaerobes when encountering oxygen. Using *Desulfovibrio vulgaris* Hildenborough (DvH) as a model SRB, we have characterized DvH strains harboring mutations in known FeS cluster biosynthesis factors and assayed the relative contributions of these factors to FeS cluster biosynthesis by monitoring activity of FeS dependent enzymes including PFOR. To date, enzymatic assays suggests that mutations in DVU1021(*sufB*), DVU1382 (*sufA*) and DVU0664 (*nifS*) have a detrimental effect on multiple FeS enzymes, although functional redundancy between biosynthesis factors appears to be significant. Only DvH strains lacking DVU1021 or DVU1382 displayed severe growth defects in rich growth media, consistent with the hypothesis that the SufBC predicted FeS scaffold complex is the likely primary site of *de novo* FeS cluster assembly in DvH and may work with DVU1382 to mature multiple FeS enzymes, deficiencies in which can impact the growth rate of the cell. In order to fully uncover the relationships between DvH FeS cluster biosynthesis factors, we have utilized a TnSeq-based procedure (RB-TnSeq) to conduct high throughput genetic interaction screening. We have observed synthetic lethality between SufBC and NifSU systems (no *sufB*/*C* transposon insertions in *nifS*/*U* background or *v.v.*) which is consistent with partial functional redundancy. Strikingly, the observed viability of a *nifS* mutant in DvH where it is predicted to be the sole cysteine desulfurase, contradicts current FeS cluster biosynthesis dogma regarding the essentiality of cysteine desulfurases as a sulfur source for *de novo* FeS cluster formation. Further work is ongoing to confirm *nifS* genetic interactions.

Characterization of Three Different Diphenylmethane Degrading *Pseudomonas* Species from the New Jersey Passaic River

Author Block:

A. J. Roberts, G. J. Zylstra; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Diphenylmethane (DPM) is a hazardous compound produced by a number of industries. It is known that some (but not all) biphenyl degrading organisms are also capable of metabolizing DPM using the same enzymes as those that are involved in the biphenyl catabolic pathway. This is not surprising given the structural similarities between the two compounds. We hypothesized the reverse situation that DPM degrading organisms would also be capable of degrading biphenyl with the secondary hypothesis that the same catabolic enzymes would be involved for both DPM and biphenyl degradation. Starting with Passaic River (NJ) sediment we isolated three different *Pseudomonas* species capable of growth on DPM as the sole source of carbon. Subsequent testing showed that all three isolates could grow on biphenyl. Using PCR primers previously shown to amplify a wide variety of genes encoding the large subunit of biphenyl dioxygenase we identified a putative *bphA1* gene in all three *Pseudomonas* species. Sequence analysis of the PCR product revealed that even though each Passaic River strain was a different species they all had the exact same nucleotide sequence. The sequence is 91% identical to the canonical *bphA1* gene of *Burkholderia xenovorans* LB400 with the majority of the differences in the wobble position of the codons. Comparison of the three Passaic River isolates *bphA1* to other sequences in the GenBank database show that the Passaic River sequences represent a new subgroup within the LB400 family. Using reverse transcriptase PCR of mRNA extracted from succinate, DPM, and biphenyl grown cells we showed that the same *bphA1* gene sequence was induced during growth on DPM and biphenyl demonstrating that the same initial dioxygenase is involved in both DPM and biphenyl degradation. Interestingly, we isolated a spontaneous variant of *Pseudomonas* sp. strain AJR09 that lost the ability to grow on DPM, biphenyl, and salicylate (strain AJR10). PCR analysis showed that strain AJR10 lost the *bphA1* gene confirming that DPM and biphenyl are metabolized by the same initial dioxygenase and that the genes for salicylate degradation may be linked by an excisable element to the genes for DPM and biphenyl degradation. Because we found three different species containing the exact same gene for DPM degradation we conclude that the DPM degradation genes are horizontally transferred among bacteria in the Passaic River.

***Sphingomonas wittichii* Rw1 Dibenzofuran 4,4a Angular Dioxygenase Attacks Biphenyl at a Lateral Position**

Author Block:

R. Faisal[1], H-K. Chang[2], G. Zylstra[2]; [1]Rutgers Univ., New brunswick, NJ, [2]Rutgers Univ., new brunswick, NJ

Abstract Body:

Sphingomonas wittichii RW1 is one of only a few microorganisms known to degrade dibenzo-*p*-dioxin (DD) and dibenzofuran (DBF). Due to the toxic, carcinogenic, and endocrine disruption characteristics of dioxin-like compounds the molecular and biochemical study of the enzymes involved in the DD and DBF degradative pathways is of great interest. Dibenzofuran 4,4a-dioxygenase (DBFDO) is the first enzyme involved in the DD and DBF degradation pathway. This enzyme is a heterodimer of two polypeptides DxnA1 (45KDa) and DxnA2 (23KDa) and catalytically adds two atoms of molecular oxygen at two adjacent carbon atoms where one of the carbons is a bridge atom between the two benzene rings. This enzyme is thus often called an angular dioxygenase. Based on studies with the purified enzyme DBFDO is known to hydroxylate other aromatic compounds. We hypothesized that DBFDO would oxidize biphenyl at the 2,3 (nonangular lateral) position and that the enzymatic activity would be sufficient to allow growth on biphenyl as the sole carbon source in an organism with the remainder of the biphenyl catabolic pathway. We initially cloned the four genes necessary for DBFDO into *E. coli* in the pET30a expression vector. This included the genes for the two oxygenase subunits *dxnA1* and *dxnA2*, the reductase *redA2*, and the ferredoxin *fdx3*. *E. coli* BL21 strains harboring this clone when induced had the ability to attack DD and DBF at the angular position and biphenyl at the 2,3 lateral position as determined by HPLC and GC-MS. In order to prove that this observed activity is sufficient to allow growth we cloned the *S. wittichii* RW1 *dxnA1-dxnA2- fdx3-redA2* genes into the biphenyl degrading organism *S. yanoikuyae* B1 in place of the *bphA1-bphA2* genes encoding the oxygenase component of biphenyl dioxygenase thus placing the RW1 DBFDO under control of the B1 biphenyl pathway promoter. The engineered B1 strain with the RW1 DBFDO grew on biphenyl with a growth rate similar to that of the wild type B1 strain. Our work shows that RW1 DBFDO has both angular and lateral dioxygenase activity depending on the substrate and that this activity can be sufficient for growth on alternate substrates.

Screening and Identification of Motility Defective *H. volcanii* Mutants

Author Block:

E. Yang, R. Esquivel, M. Pohlschroder; Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Archaeal flagella are structurally related to bacterial type IV pili and thus present a novel, yet still poorly understood mechanism for swimming motility in prokaryotes. Previous studies in the model archaeon *Haloferax volcanii* have utilized a random genomic insertion mutant library generated by transposon mutagenesis with the Mu transposon for efficient gene discovery of components involved in colony pigmentation and metabolite biosynthesis. Recently, we have conducted motility assays with mutants from this insertion library in order to screen for mutants of *H. volcanii* lacking swimming motility.Over 7000 transposon mutants were screened for non-motile phenotypes using low percentage agar motility assays. Subsequently, genomes of non-motile mutants without a significant growth defect were submitted for sequencing to identify the Mu-Transposon insertion sites.The screen resulted in the identification of 28 non-motile *H. volcanii* mutants of which 19 have been sequenced thus far. A subset of the transposon insertions was identified to be located adjacent to or in genes encoding known flagella biosynthesis or regulatory components, thus confirming that the screen could successfully identify motility mutants. These included the prepilin peptidase (PibD) that processes the flagellins as well as components of the chemotaxis machinery. Additional insertions were identified in genes encoding: an ABC transporter permease, an adjacent ABC transporter ATP-binding protein, an arylsulfatase, a cell division inhibitor, and a diaminopimelate decarboxylase. These genes have not previously been identified to play a role in flagella biosynthesis or regulation. Insertions in several hypothetical genes were identified; HVO_2876, which is adjacent to a methyltransferase is most intriguing because recent mass spectrometry has revealed that the major flagellin is methylated. The machinery required for this post-translational modification, which seems essential for H. volcanii flagellin stability, remains elusive.Our findings have demonstrated that the screen successfully identifies critical components for either the biosynthesis or regulation of archaeal flagella-dependent motility. The characterization of the several diverse motility mutants obtained from our motility screen will provide a foundation for a better understanding of this crucial archaeal cellular process.

Endogenous Internal Ribosome Entry Site Mediates Protein Synthesis in *Pichia pastori*s

Author Block:

C. Li, Male, Y. Lin, S. Liang; South China Univ. of Technology, Guangzhou, China

Abstract Body:

Background: Most eukaryotic mRNAs are translated in a cap-dependent manner. But under conditions it is compromised , an alternative initiation pathway, internal ribosome entry site (IRES), is used for protein synthesis. *Pichia pastoris* is widely used for high-level production of recombinant industrial proteins. However, an endogenous IRES elements have not been reported in *P. pastoris*. Co-expression of two or more genes, which is achieved using functional IRES element, is an important and useful method for improving recombinant protein production and metabolic engineering. **Methods:** The endogenous 5'-UTR of AOX1 was investigated using bicitronic assays containing an upstream *Rhizomucor miehei* lipase (Rml) cistron and a downstream LacZ ORF in *P. pastoris* (Figure 1A). Real-Time PCR and Western blot are used to detect the expression. **Results:** As shown in Figure 1C and D, *lacZ* was expressed in the pRml-AOX-LacZ but not in pRml-Null-LacZ, indicating that a requirement for 5'-UTR of AOX1 in the translation of the downstream ORF. However, the pAOX-LacZ clones remained white on MDX plates (Figure 1C). And detected by Real-Time PCR and Western blot (Figure 1D), the *lacZ* was not expressed in pAOX-LacZ. These suggested that 5'-UTR of AOX1 did not contain a cryptic promoter that subsequent cap-dependent translation. These combined data demonstrated that insertion of the 5'-UTR of AOX1 upstream of the LacZ resulted in translation of the second ORF. The expression of Rml resulted from a cap-dependent ribosome scanning mechanism when the production of LacZ reflected the IRES activity of 5'-UTR of AOX1. **Conclusions:** The 5'-UTR of AOX1 is an endogenous IRES elements and the IRES-dependent translation initiation mechanism existed in *P. pastoris*.

Evidence-Based Validation of Quorum Quenching from *Lysinibacillus sphaericus* in the Bioremediation of Oil Sludge

Author Block:

C. Gómez, J. Dussán; CIMIC, Univ. de los Andes, Bogota, Colombia

Abstract Body:

Quorum quenching (QQ) is the disruption of quorum sensing (QS), mainly by enzymatic degradation of autoinducers. A well-known case of QQ are AHL-lactonases. Since pathogenicity is usually a QS-regulated process, QQ is a promissory base to develop novel strategies against pathogenic bacteria. Its effects are also remarkable in the performance of bacterial consortia in applications as bioremediation. Herein, we describe a potential novel AHL-lactonase gene from *L. sphaericus* and the interaction of this bacterium with a commercial consortium in the bioremediation of oil sludge in soil.We evaluated the presence of the locus in the studied strains by PCR; sequenced and characterized them by the following strategies: searching for homology (BLAST), for conserved domains and motifs (multiple alignments), and a phylogenetic analysis (ML). Then, we assessed the expression of the locus by RT-qPCR. The locus was expressed in *E. coli* in order to determine its effects over the pathogenicity of *Pectobacterium carotovorum* in an *in vivo* assay. The experiment was performed by triplicate and the results were analyzed with a Kruskal-Wallis test. These results were contrasted with data collected from a bioremediation assay carried out using the evaluated strains together with a commercial consortium made up by AHL-producing bacteria.The locus was present in five *L. sphaericus* strains. All the sequences exhibited the characteristic motifs and domains involved in Zn-binding from AHL-lactonases. Sequences were grouped in one clade within the phylogeny of the lactonases from firmicutes, showing 70 % aa identity with the lactonase AhlS. Bootstrap values were between 60 - 100. The locus is transcribed in the evaluated strains and its presence is correlated with an antagonist effect over *P. carotovorum* when bacilli or transfected *E. coli* titer was three magnitude orders higher than *P. carotovorum* titer. In field experiments, *L. sphaericus* inhibited the bacterial consortium on an oil sludge-contaminated soil: *L. sphaericus* titer increased gradually, whereas the consortium titer decreased to <10 CFU/mL after 60 days from inoculation.The presented evidence supports the existence of QQ activity from *L. sphaericus*, possibly due to a lactonase. This enzyme would be able to suppress the pathogenicity in *P. carotovorum* and to inhibit the function of a bacterial consortium for bioremediation.

LasM, a Novel Membrane Protein Essential for *Legionella pneumophila* to Survive in Water

Author Block:

L. Li, S. P. Faucher; McGill Univ., Ste-Anne-de-Bellevue, QC, Canada

Abstract Body:

Background: *Legionella pneumophila* is an opportunistic pathogen that can infect human and result in a severe form of pneumonia called Legionnaires' disease. This bacterium is found ubiquitously in freshwater, both natural and man-made water systems, and is typically transmitted through inhalation of contaminated aerosols. Therefore, the ability of *L. pneumophila* to survive in water is essential for the propagation to human. It is known that a gene, *lpg1659*, is highly up-regulated in *L. pneumophila* exposed to water. This gene encodes a hypothetical protein with no putative functions, but a similar protein is found in many *Legionella* species and other aquatic bacteria, suggesting an important role of this protein for the survival in aquatic environment. **Objective:** The primary goal of this study is to characterize the *lpg1659* gene, particularly on its importance for the survival of *L. pneumophila* in water and its regulation. **Methods:** Bioinformatic analysis was done to predict the potential functions of Lpg1659. Deletion mutant and over-expression strains were constructed and their survival in water was monitored by CFU counts. RT-qPCR was used to test if *lpg1659* is regulated by RpoS, a known stress response regulator in *L. pneumophila*. Wet mount analysis, live/dead staining and heat shock assay were performed to study the effect of *lpg1659* deletion on cell morphology, membrane integrity and heat tolerance. Infection assay was also done to test the effect on intracellular growth. **Results:** Lpg1659 was predicted to be a membrane protein involved in transport and binding. Deletion of *lpg1659* resulted in a survival defect in water at 42°C. Interestingly, over-expression was found to promote the survival of *L. pneumophila* in water. Result of RT-qPCR shows that the expression of *lpg1659* is positively regulated by RpoS in water. In addition, deletion of *lpg1659* did not affect the cell shape and length, as well as membrane integrity. Both the deletion mutant and the wild-type had similar CFU reduction after short-term heat shock. Lastly, *lpg1659* was found to be dispensable for intracellular growth in the amoebae *Acanthamoeba castellanii* and human macrophage-like THP-1 cells. **Conclusion:** The novel membrane protein encoded by *lpg1659*, which was found to be regulated by RpoS, is important for the survival of *L. pneumophila* in water and is therefore named LasM (for *Legionella* aquatic survival membrane protein).

Enhanced Expression of a Luxi Homolog and Utilization of Ahl Binding Resin Xad-16 Improve the Detection of Accumulated Ahl Signals from the Grapevine Crown Gall Bacterium *Novosphingobium sp.* Rr 2-17

Author Block:

L. Dailey[1], H. M. Gan[2], N. Halliday[3], P. Williams[3], A. Hudson[1], M. Savka[1]; [1]Rochester Inst. of Technology, Rochester, NY, [2]Monash Univ. Malaysia Genomics Facility, Selangor, Malaysia, [3]Univ. of Nottingham, Nottingham, United Kingdom

Abstract Body:

This research is focused on investigating the acyl-homoserine lactone (AHLs) signaling compounds produced by the grape crown gall tumor colonizing bacterium, *Novosphigobium* sp. Rr2-17, whose genome sequence was recently determined by our laboratory. The luxI homolog (novI) responsible for AHL synthesis was identified from its genome sequence based on a similarity search and cloned into the IPTG inducible expression vector, pSRKKm. This recombinant plasmid was then transferred into the parent wild type Rr2-17 strain to enable the inducible expression of novI. Inducible expression of novI is predicted to enhance the identification of additional AHLs signals not previously identified from the wild type bacterium. The AHLs produced by strain Rr2-17 (pSRKKm::novI) were analyzed by LC-ESI MS/MS after ethyl acetate extractions from varying concentrations of the AHL binding resin XAD-16. This enabled the major and minor AHL of *Novosphingobium* to be identified and quantified, and demonstrate the use of XAD-16 resin as a more effective method for optimal AHL signal recovery. The major AHL produced was identified as OH-C8-homoserine lactone and IPTG induction of novI expression in Rr2-17 (pSRKKm::novI) increased its concentration 6.8-fold when compared to the wild type Rr2-17 (pSRKKm), vector only. Similar increases were identified with two minor AHLs, OH-C10-homoserine lactone and C8-homoserine lactone. The presence of 20% w/v of XAD-16 resin in the extraction procedure bound 99.3 percent of the major AHL produced by IPTG-induced Rr2-17 (pSRKKm::novI) strain. Through the identification and quantification of the AHLs produced by *N. sp.* Rr2-17, we expand our knowledge of its quorum sensing system and are the first in the genus *Novosphingobium*.

Methanotrophically Mediated Bioaggregation to Control Sand Dust

Author Block:

A-M. Harik, T. Hazen; Univ. of Tennessee, Knoxville, Knoxville, TN

Abstract Body:

Sandstorms are commonplace in many parts of the world including Qatar, these storms have negative impacts on the economy, environment, infrastructure, and public health. Traditional prevention techniques use chemical stabilizers and cementing agents; however, their application is expensive and may have negative impacts on public health. We proposed using native extracellular polysaccharide (EPS) producing methanotrophic bacteria for bioaggregation. The proposed technique would involve application of an EPS producing methanotrophic bacterial culture to the sand's surface followed by application of purified EPS. The preference is for native methanotrophic bacteria to be used, to minimize the disruption to the native ecosystem. We have collected native methanotrophic bacteria from Qatar sand. Until they can be identified and researched, two well studied strains of Methanotrophs are being used for preliminary EPS testing. Application of purified EPS to sand has shown signs of significant aggregation, along with increases in shear strength. Once a strain of bacteria is chosen by the research team, and the EPS production optimized, a bioreactor will be built to produce EPS for lab scale sand stabilization studies. Lab scale studies will monitor time dependent changes in shear strength during application, microbial community changes, and ability to withstand critical threshold wind velocities. Future plans include field scale studies and the construction of a fluidized bed bioreactor for production of the liquid medium and EPS. Bioaggregation with EPS producing bacteria utilizing methane - an indigenous resource to Qatar - has cost saving benefits specific to Qatar.

Divergent Taxonomic and Functional Responses of Microbial Communities to Field Simulation of Aeolian Soil Erosion and Deposition

Author Block:

X. Ma[1], C. Zhao[2], Y. Gao[1], B. Liu[2], T. Wang[1], T. Yuan[3], L. Hale[3], J. D. Van Nostrand[3], S. Wan[2], J. Zhou[3], Y. Yang[1]; [1]Tsinghua Univ., Beijing, China, [2]Henan Univ., Kaifeng, China, [3]Univ. of Oklahoma, NORMAN, OK

Abstract Body:

Aeolian soil erosion and deposition have worldwide impacts on agriculture, air quality and public health. Aeolian soil erosion, exacerbated by anthropogenic perturbations, has become one of the most alarming processes of land degradation and desertification. In contrast, dust deposition imposes a potential fertilization effect. Therefore, determining microbial responses to soil erosion and deposition is crucial for elucidating the mechanistic underpinnings in driving soil nutrient cycling, which remains little understood. Here we report the first in-depth, holistic study via 16S rRNA gene amplicon and GeoChip techniques to analyze microbial communities subjected to field simulation of soil erosion and deposition. In a semiarid grassland of Inner Mongolia, China, we found that microbial communities were altered (P<0.039) by simulated soil erosion and deposition, with substantial increase in abundance of biocrust-forming *Cyanobacteria*. *amyA* genes encoding α-amylases were increased (P=0.01) in relative abundance by soil deposition, which was positively correlated (P=0.02) to increased dissolved organic carbon (DOC) content in dust. However, most of the microbial functional genes associated with carbon, nitrogen, phosphorus and potassium cycling were decreased or unaltered by both erosion and deposition, probably arising from acceleration of organic matter mineralization by aeolian breakdown of soil aggregates. These divergent responses suggest that microbial communities are sensitive to soil erosion and deposition, supporting the necessity to include microbial components in evaluating ecological consequences. In addition, Mantel tests showed strong, significant correlations between soil nutrients and functional gene composition but not taxonomic composition, demonstrating close relevance of microbial function traits to nutrient cycling.

Phylogenetic Diversity of Bacterial Community on Asian Dust Assessed by Pyrosequencing Analysis

Author Block:

S. Srinivasan, E. Joo, E. Kim, S. Jeon, M. Kim; Seoul Women's Univ., Seoul, Korea, Republic of

Abstract Body:

Background: Asian dust or yellow sand events in the East Asia are the major issue of environmental contamination and human health, with increasing concern. The high amount of dust particles especially the coarse particles (PM_{10}) is transported by the wind from the arid and semi-arid tracks to Korean Peninsula bring the bacterial population that alters the terrestrial and atmospheric microbial communities. **Methods:**In this study, we aimed to explore the bacterial population of Asian dust samples collected during November-December 2014. The dust samples were collected using high volume samplers, and the genomic DNA was isolated using commercial kit. The variable regions (V3-V6) of 16S rRNA gene were amplified using PCR and pyrosequencing were performed using Roche-454 (454 GS FLX, Roche). The data was analysed using Mothur and V programs. **Results:** The pyrosequence data showed the genus *Sphingomonas* (~50%) belonged to the phylum *Proteobacteria* (~86%) are the predominant population in the atmosphere. The genus *Bacillus* (7%) belonged to the phylum *Firmicutes* (~15%) are increased during Asian dust compared to non-Asian dust samples. **Conclusions:**This study showed that the significant relationship of bacterial populations between Asin dust samples and non-Asian dust samples in Korea, which could significantly affect the microbial population in the environment.

Indoor Microbial Air Quality of a 42-Year-Old Elementary School

Author Block:

L. Sturmer; Skyline Coll., San Bruno, CA

Abstract Body:

Background: The average public school building in the U.S. is over 40 years old and 29% have never been renovated (1). Almost any building surface can nourish microbial growth. The high occupant density in schools increases the concentration of airborne particulate matter from human microbiota (2). Schools are required to meet ventilation standards, but despite this, there are still no concentration standards or personal exposure limits for airborne microbes (3). Additionally, children may more susceptible to indoor pollutants than the general population.**Aim:** The objective of this study was to perform a survey of indoor microbial air quality of a water-damaged, 42-year-old school operating as a child development center in the San Francisco Bay Area.**Methods:** A total of 496 air samples were collected within the old building and 180 air samples were collected from nearby newer buildings and outdoor locations. Air samples were taken with an impact air sampler onto nutrient media selected for bacteria and fungi. Data were examined using a three-dimensional approach and multivariable analysis.**Results:** Indoor airborne bacteria were 139% higher in the old building compared to neighboring renovated buildings and 76% higher than outdoor air. Airborne fungi were 128% more numerous compared to the renovated buildings and 112% lower than outdoors. The variety and number of microorganisms inside the older building were different than outdoors. No direct source of contamination was found, however, open windows correlate with a 105% increase in indoor fungal concentration ($P<0.001$).**Conclusions:** Data confirm that ventilation and filter maintenance help lower microbial aerosols and should be maintained in accordance with California regulations.

Metagenomic Profiling of Antimicrobial Resistance Genes from Airborne Microbial Communities

Author Block:

T. L. Dickerson, D. Swales, M. Krause, A. Ferris, J. L. Jacobs; MRIGlobal, Rockville, MD

Abstract Body:

Since the adoption of antibiotics in the early 20th century, a plethora of clinical pathogens have acquired resistance to one or more modern-day antibiotics. Consequently, antimicrobial resistance (AMR) is recognized as a severe threat to human and animal health worldwide. Recent work has demonstrated that AMR bacteria are widely prevalent in the environment, perhaps exacerbated by the widespread use of antibiotics for clinical or agricultural purposes. Along these lines, the principal objective for this study was to assess the temporal dynamics of airborne bacterial communities and the dispersion of AMR genes present within them. Dry air filter units were used to collect air samples daily at four locations in- and outside a transit center in the National Capital Region. Microbial biomass was eluted from each filter, concentrated by ultrafiltration, and DNA was extracted for downstream shotgun metagenomic sequencing on a ThermoFisher Ion Proton. In addition, DNA libraries were prepared from pooled samples and subjected to a functional metagenomics screen for susceptibility testing against seven antibiotics. Antibiotics tested include chloramphenicol, ciprofloxin, trimethoprim, colistin, tetracycline, penicillin and meropenem and resistance was found against many of these antibiotics at the Clinical and Laboratory Standards Institute (CLSI) minimum inhibitory concentration (MIC) level. The prevalence of AMR genes was also assessed within the shotgun metagenomics data. Bacterial profiles from the four sites surveyed showed a diverse population of bacteria, with the genus Pseudomonas representing the largest proportion of sequences. These results suggest that airborne microbial communities may serve as a dynamic reservoir for the dispersion of antimicrobial resistance factors in the environment, potentially complicating the existing world-wide public health crisis to combat AMR pathogens.

Proteins Expressed by *Sphingomonas aerolata* in Response to Aerosolization

Author Block:

V. Krumins[1], M. Abadjev[1], S. Boeren[2], T. Kruse[2], P. Schaap[2], H. Smidt[2], L. J. Kerkhof[1], G. Mainelis[1], D. E. Fennell[1]; [1]Rutgers Univ., New Brunswick, NJ, [2]Wageningen Univ., Wageningen, Netherlands

Abstract Body:

Background: The objective of this study was to analyze the proteomic response of an atmospheric microorganism, *Sphingomonas aerolata*, to aerosolization and the presence of a volatile substrate while airborne. **Methods:** The genome of *Sphingomonas aerolata* strain NW12 (AJ429240.1), a psychrotolerant bacterium isolated from ambient air, was sequenced using the Illumina HiSeq2000 platform, resulting in 3344 predicted protein sequences. *S. aerolata* was grown in liquid minimal media containing acetic acid as the sole substrate, aerosolized into rotating gas-phase bioreactors, and incubated in the airborne state for two days. Cells were collected onto membrane filters, and proteins extracted and run on SDS PAGE gels. Peptides were fragmented by in-gel trypsin digestion and analyzed by LCMS-MS. Putative proteins were identified by referencing the sequenced genome. The proteomes of stationary phase liquid-grown, acetate-fed cells; airborne cells in the presence of 20 ppmv ethanol; and airborne cells without ethanol, were compared.**Results:** After aerosolization and 2 days of airborne incubation, 20 to 80 x 10^6 cells were recovered. The protein digest yield was 25-30%, and 1370 putative *S. aerolata* proteins were identified from the aerosolized cells. Compared with the *S. aerolata* proteome in liquid culture, 109 proteins were downregulated and 37 increased. These included several related to the TCA cycle, cell membrane and cell wall transporters, and ribosomes, suggesting an active response to the stresses of aerosolization.There were relatively few differences between aerosolized cells presented with a gaseous substrate and starved aerosols. Six proteins were significantly and positively correlated with culturability, all of which are related to cell membranes, protein synthesis or DNA repair.**Conclusions:** *S. aerolota* respond to aerosolization stress by activating the TCA cycle, membrane and cell wall proteins involved in transport and secretion, and ribosomal proteins. Six proteins were identified that correlate with culturability, indicating that protein, membrane and DNA repair are critical to maintenance of viability.

Effect of E-Cigarette Vapour and Cigarette Smoke Extract on S. *pneumoniae* Virulence

Author Block:

L. Miyashita, J. Grigg; Queen Mary Univ. of London, London, United Kingdom

Abstract Body:

Background: The potential for Electronic cigarettes (EC) to cause adverse health effects remains unclear, yet their popularity have significantly increased over the past few years. Vulnerability to invasive pneumococcal disease is associated with exposure to tobacco smoke (Grigg *et al.* 2012). Cigarette smoke extract increases oxidative stress which in turn mediates the adhesive response of airway epithelial cells, allowing increased invasion of *S. pneumoniae* via the host expressed platelet-activating factor receptor (PAFR). Hydrogen peroxide, a reactive oxygen species, is a major pneumococcal virulence factor produced in quantities known to be cytotoxic to lung cells. At present the direct effect of CSE and EC vapour (ECV) on pneumococcal virulence remains unclear. In this initial study we sought to determine whether oxidative stress is increased in *S. pneumoniae* during CSE and ECV exposure.**Methods:** Hydrogen peroxide concentration was measured in *S. pneumoniae* D39 cultures exposed to either 2% or 0% ECV/CSE for one hour. Cultures were filter sterilised and the supernatant was quantified for H_2O_2 levels against a standard curve using a colorimetric assay. Catalase was included as a control.**Results:** H_2O_2 production significantly increased in pneumococcal cultures exposed to ECV and CSE ($p<0.0001$) compared to unexposed controls. Catalase control reduced H_2O_2 concentration.**Conclusions:** We have for the first time assessed the effect of ECV and CSE on pneumococcal virulence. H_2O_2 production significantly increased in cultures exposed to ECV/CSE, thus suggesting a direct effect on pneumococcal virulence. This research can now be expanded by assessing the effect of supernatant H_2O_2 on pneumococcoal adhesion to lower airway cells, as preliminary data suggests adhesion is increased in ECV/CSE exposed bugs.

Concentration and Particle Size Distribution of Endotoxin and Beta-glucan Present in Ambient Particulate Matter

Author Block:

A. L. Pabon, E. Gonzalez-Figueroa, W. Torres-Rivera, L. B. Mendez; Univ. del Este, Carolina, PR

Abstract Body:

Asthma is the most common chronic childhood disease in the US. Among the environmental factors associated with increased asthma morbidity are exposures to indoor allergens, bioaerosols (e.g. endotoxins and beta-glucans) and air pollutants, such as particulate matter (PM). The main objective of this study was to determine the concentration and size distribution of endotoxin and beta-glucans present in ambient PM. Air samples were obtained in the vicinity of an elementary school in Puerto Rico. Samples were collected for 2 consecutive weeks with an 8-stage cascade impactor and particles were extracted from the filters with pyrogen-free water by sonication for 2 hours. Endotoxin and beta-glucans present in each stage were measured using a kinetic chromogenic limulus amebocyte lysate and glucatell assay, respectively. The mass median aerodynamic diameter (MMAD) and the geometric standard deviation (GSD) were calculated using the log-probability method. Endotoxin concentrations varied between 0.78 and 18.80 pg/m^3. In contrast, the beta-glucans levels ranged between 87.52 and 522.77 pg/m^3. Approximately 50% of the detected endotoxins and beta-glucans were associated with particles of 2.5 μm or less in diameter. This data will be used as complimentary information for exposure assessments to evaluate if endotoxin and beta-glucans present in ambient PM are associated with respiratory effects in asthmatic children.

Effect of Soil Type, Composting, and Antibiotic Use on Fate of Antibiotic Resistant Bacteria and Resistance Genes in Dairy and Beef Manure Applied Soil

Author Block:

C. Pankow, C. Chen, R. Williams, G. Guron, K. Xia, M. Ponder, A. Pruden; Virginia Tech, Blacksburg, VA

Abstract Body:

Application of livestock manure to land is known to increase antibiotic resistant bacteria (ARBs) and antibiotic resistance genes (ARGs) in soil. The objective of this study was to determine the effect of soil type (sandy loam, clay loam or silty clay) on the fate of ARBs and ARGs in soil microcosms, which may be used to predict fate in land applied cattle manure. Four manure types (beef or dairy, with or without chlortetracycline, sulfamethazine, and tylosin or pirlimycin and cephapirin antibiotics, respectively) with or without composting were amended to three locally-available soil types at a rate achieving 10% bioavailable nitrogen content for a total of 39 experimental conditions. Three sacrificial replicate samples were collected over time to culture bacteria resistant to cefotaxime, ceftazidime, clindamycin, tetracycline, erythromycin, and vancomycin on R2A (heterotrophs) and MacConkey (enteric bacteria) agar. There were significant reductions ($p < 0.0001$) in heterotrophs resistant to clindamycin, erythromycin, tetracycline, and vancomycin from day 1 to day 57. Significant reductions ($p < 0.0001$) to erythromycin and tetracycline resistant enteric bacteria also occurred. Soil type only had a significant effect on enteric bacteria resistant to erythromycin ($p < 0.0001$), with the highest log CFU/g in the silty clay condition. Heterotrophic and enteric bacteria showed no significant difference in log CFU/g with respect to the type of compost amended or whether the cattle were administered antibiotics. Ongoing analysis with metagenomics and quantitative polymerase chain reaction will serve to further illustrate overall microbial community changes and quantify ARGs. Results thus far indicate that prior antibiotic use or composting did not have a measureable effect on culturable ARBs once applied to soil, while soil type may have limited influence on certain culturable bacteria.

Impact of Different Arable Farming Systems on the Abundance and Diversity of Bacterial Community and Antimicrobial Resistance Determinants

Author Block:

E. Gómez-Sanz[1], S. Jaenicke[2], R. Wittwer[3], A. Goesmann[2], M. M. van der Heijden[3], B. Duffy[1], T. H. M. Smits[1]; [1]Zurich Univ. for Applied Sci., Waedenswil, Switzerland, [2]Justus-Liebig-Univ., Giessen, Germany, [3]Agroscope, Zürich, Switzerland

Abstract Body:

This study examines soil management systems for abundance, diversity and dynamics of microbial communities and antimicrobial resistance (AMR) genes in a Swiss experimental farming trial with four setups: Organic production with plough (OCP) and reduced tillage (ORT) and Conventional production with plough (CCP) and no tillage (CNT). The organic treatments were fertilized with slurry and the conventional systems with mineral fertilizer (N, P, K and Mg). A combination of amplicon sequencing and total DNA metagenomics was used to generate an overview of the complete diversity, while qPCR assays were employed to examine the AMR gene abundance and dynamics. Actinobacteria and Alphaproteobacteria were the Bergey's classes most abundant in all systems. Beta- and Gamma-proteobacteria, and Sphingobacteria were also predominant in diverse order relative to the system. Within the 5 most abundant Bergey's genera, Gp6, Gaiella and Sphingomonas were present in all systems, with Gp6 as predominant in all but C-NT, for which Gaiella was dominant. Gp4 was abundant in the same 3 systems, while Gemmatimonas was only present in C-NT system. Lysobacter was abundant in O-RT and C-T whilst Spartobacteria genera incertae sedis was rich in O-T and C-NT. Based on ARG-ANNOT database, resistance genes to most clinically relevant families were detected in low counts. The fluoroquinolone resistance gene *oqxB* was the most abundant in all systems (yet plasmid -confering resistance- or chromosomal -normally do not confer resistance- location need to be role out), followed by the fluoroquinolone *qepA* (O-RT, N-T) or tetracycline resistance *otrA* (O-T, C-NT) genes. Currently, we are examining the temporal dynamics of the four soil management systems. From preliminary data, it appears that higher bacterial counts were observed in both organic systems (mean 4.1 versus 2.9 billion g/soil). Temporal increase in bacterial counts was observed in all systems a few days after fertilization with highest counts on day 21. Ongoing qPCRs on all soils and slurry samples are quantifying a set of AMR genes of interest, including those most abundant by the sequencing methods.

Effect of Antibiotic Exposure on the Presence and Abundance of Resistance Genes in Cattle Manure and Ranch Soil

Author Block:

B. Weeder[1], D. Nguyen[1], E. Layton[2], G. Nyerges[1]; [1]Pacific Univ., Forest Grove, OR, [2]North Powder Charter Sch., North Powder, OR

Abstract Body:

Antibiotic resistance is considered a major threat to human health. Half of the antibiotics produced are used for agricultural purposes in the United States. The use of antibiotics in animal husbandry was showed to contribute to the dissemination of resistance genes in environmental microbial communities, and potentially plays a crucial role in creating a major reservoir of resistance genes.Our study investigated the presence and abundance of 14 different tetracycline resistance genes and 2 sulfonamide resistance genes in samples collected from areas of varying animal exposure on a beef cattle ranch in North Powder, Oregon, using qualitative polymerase chain reaction (PCR) and quantitative polymerase chain reaction (qPCR) methods. In addition, PCR amplification targeting conserved regions that flank a variable middle region of class 1 integrons and subsequent DNA sequencing were used to examine the presence and structure of these genetic elements in the collected samples.Of the 14 tetracycline genes tested for, 13 were present in samples from the farm. 6 genes (*tetO, tetM, tetA, tetQ, tetS,* and *tetW*) were further tested for copy number in the samples. After adjusting for variation in bacterial presence between samples (using 16S rDNA copy number), levels of both *tetM* and *tetS* were significantly higher (one way nested ANOVA with a Tukey post-hoc test) in the feedlot area (high exposure) when compared to the rangeland (low exposure). *tetM* presence was also significantly higher in the quarantine pen samples (highest exposure). Furthermore, sequence data of the integrons revealed resistance to aminoglycosides and trimethoprim.Our study indicates that the use of antibiotics creates a selective pressure favoring the survival of bacteria with various mechanisms to tolerate exposure to these drugs and results in elevated level or resistance genes in manure and in soil.

Effect of Composting Method and Antibiotic Residue in Manure on the Fate of *E. coli* and Antibiotic Resistance Genes in Cattle Manures

Author Block:

R. K. Williams, P. Ray, K. Knowlton, L-A. Krometis, M. Ponder, A. Pruden; Virginia Tech, Blacksburg, VA

Abstract Body:

Cattle manure can be an abundant source of antibiotic resistant bacteria (ARBs) and resistance genes (ARGs) and thus its use as a soil amendment poses an emerging concern with respect to its potential to contribute to the spread of antibiotic resistance along the farm to fork continuum. The objective of this study is to determine the effect of composting on the abundance and antibiotic resistance profiles of *Escherichia coli* and ARGs relative to raw manures. Four manure types (beef with or without chlortetracycline, sulfamethazine, and tylosin or dairy with or without pirlimycin and cephapirin antibiotic administration) were mixed with alfalfa hay, pine bark mulch, and sawdust (C:N = 23-26%) and composted at small-scale (wet mass: 20-22 kg) using compost tumblers [71 cm (L) × 64 cm (dia.)] under static versus turned conditions, for a total of 8 treatments, which were each performed in triplicate. Compost samples were collected on day 0, 4, 7, 14, 21, 28, 35 and 42 to enumerate *E. coli* and total heterotrophs using MacConkey and R2A agars, respectively. At the conclusion of composting, *E. coli* colonies were isolated and screened for antibiotic resistance using the Kirby-Bauer disk diffusion test. Results indicate that composting was associated with an increase in resistance to ampicillin, chloramphenicol, and cefotaxime for *E. coli* that survived the composting procedure. A second round of small-scale static composting was performed using only dairy manures (with or without pirlimycin and cephapirin residues) where the thermophilic phase (>55°C) was maintained for fifteen days using an external heat source to evaluate the effect of prolonged thermophilic phase on *E. coli*. In the first round, *E. coli* counts persisted and actually increased by 2 logs over the course of the experiment for all manure types and composting methods. In the second round, non-detectable levels of *E. coli* were achieved by the final day of composting (day 42). Metagenomic analysis is currently underway to explore more deeply how the antibiotic and composting treatment affected profiles of ARGs and gene transfer elements. This study demonstrates that composting may actually increase antibiotic resistance of *E. coli* if it is not effectively eliminated during treatment.

Prevalence and Diversity of Antibiotic Resistant of *Escherichia coli* in Food Animals in Ibadan, Nigeria

Author Block:

E. Amosun, O. Olatoye; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Background: Beef and chickens are the generally acceptable protein sources across meat consumers in Nigeria. Foodborne diseases and superbug transmission along the food chain result from contamination by gut microbiota of which Escherichia coli is an indicator organism **Methods:** The prevalence and diversity of antibiotic resistant of Escherichia coli in slaughtered cattle, dairy cows and free-range local chickens in Ibadan were investigated by phenotypic and genotypic methods. Escherichia coli was isolated using EMB agar; isolates were confirmed by PCR method following DNA chelex extraction from 70 faecal samples of cattle in abattoir, another 70 bovine raw milk from dairy farms and 50 free range local chicken cloacae swab samples. The antibiotic resistance profile of the isolates was determined using breakpoint assays on LB Agar plates **Results:** A total of 96 (50.53%) E. coli isolates were obtained from 190 samples. The isolates included 60 (85.71%) of 70 faecal samples of cattle in abattoir, 26 (37.14%) of 70 bovine raw milk and 10 (20%) of 50 free range local chicken cloacae swab samples. This primer produced positive amplified DNA bands of identical molecular weight all isolates of Escherichia coli. Overall, Escherichia coli showed resistance to streptomycin (39.58%), sulfamethoxazole/trimethoprim (28.5%), ampicillin (28.1%), amoxillin / clavulanic acid (17.7%), kanamycin (13.5%), chloramphenicol (12.5%), cefoxitin (9.4%), florfenicol (6.3%) and nalidixic acid (3.13.%). All the ten Escherichia coli isolated from free range chicken showed sensitivity to all the nine antibiotics. Multi drug resistance in three or more antibiotics was observed in (75.0%). Forty-one (42.7%) were sensitive to all the antimicrobial agents while fifty-five (57.3%) were resistant to at least one of the tested antibiotic agents. Twenty-five unique resistant patterns were detected.**Conclusions**: This study showed that antibiotics resistance genes are circulating among the cattle. This could either results from misuse of antibiotics in these animals or acquired resistance through horizontal gene transfer (HGT) and they also serve as reservoirs for pools of resistance genes.

***Robinsoniella peoriensis*: A Model Anaerobic Commensal Bacterium for Acquisition of Antibiotic Resistance?**

Author Block:

T. R. Whitehead; USDA/ARS/NCAUR, Peoria, IL

Abstract Body:

Background: *R. peoriensis* was characterized in our laboratories from swine manure and feces as a Gram-positive, anaerobic bacterium. Since then strains of this species have been identified from a variety of mammalian and other GI tracts, suggesting it is a member of the commensal microflora. *R. peoriensis* has also been isolated from human infections. Recently our laboratory isolated new antibiotic resistant (AR) *R. peoriensis* strains. Therefore it is of interest to determine the AR profiles of *R. peoriensis* strains from different ecosystems and locations worldwide. **Methods:** *R. peoriensis* strains were collected from the US, France, Sweden and Germany. Sources included human wounds, turtle feces, and mouse GI tract. AR profiles were determined using agar plate disc-diffusion technique. Strains were plated onto BHI agar and antibiotics (10 µg) were added to blank discs. The plates were then transferred to an anaerobic glovebox for growth at 37°C and observed for resistance. Strains resistant to antibiotics were subjected to PCR analyses to determine the presence of resistance genes. **Results:** All strains of *R. peoriensis* shared resistance to ampicillin, gentamycin, kanamycin, and nalidixic acid, and were sensitive to vancomycin and fusidic acid. Variation in resistance was observed with tetracycline, erythromycin, and tylosin. The type strain, PPC31, another swine strain and a strain from turtle feces were found to be sensitive to all three antibiotics. One Swedish strain from a wound infection was also sensitive to the three antibiotics, whereas a second strain from human blood was resistant to tetracycline only. A strain from a French neonate was resistant to erythromycin/tylosin but not tetracycline. Initial studies indicate at least several of the strains are resistant to ciprofloxacin. PCR analyses indicated the presence of the *tet*(L) gene in at least one strain. **Conclusions:** All strains of *R. peoriensis* shared similar profiles to certain antibiotics, but the presence and absence of resistance to tetracycline and erythromycin suggests that strains may have acquired resistance genes, as indicated by the presence of *tet*(L). Strains may serve as models for testing for movement of resistance genes from other commensal and pathogenic bacteria. Further analyses of resistance genes in strains may provide insight into movement of resistance genes in the GI tract of various animals.

Low Carriage Rate of Esbl-Producing *Enterobacteriaceae* in Companion Animals on the Island of Barbados

Author Block:

T. A. R. Alleyne, N-A. McMillan, **S. N. Workman**; Univ. of the West Indies, Cave Hill Campus, Bridgetown, Barbados

Abstract Body:

Companion animals have been identified as reservoirs of extended-spectrum beta-lactamase-(ESBL-) producing enteric bacteria and there is evidence of their role in zoonotic transmission. This study sought to determine the carriage rate of ESBL-producing *Enterobacteriaceae* in local companion animals and to assess the susceptibility of isolates to commonly used antibiotics. Rectal swabs from 305 dogs and 63 cats from 6 veterinary clinics and one rescue pound were screened for ESBL-producing Enterobacteriaceae by plating on eosin methylene blue agar supplemented with 2 mg/L cefotaxime. ESBL production was confirmed by the combined disc test and ESBL type was determined by multiplex PCR with primers specific for conserved regions of TEM-, SHV- and CTX-M genes. The susceptibility of isolates to a panel of 10 antibiotics was determined. The carriage rate of ESBL-positive enterics was 5.3% and 1.6% in dogs and cats, respectively. There was no significant difference in carriage rate between cats and dogs (χ^2= 1.586; p = 0.326). Higher carriage rates were reported for sick animals (χ^2= 7.976; p = 0.005) and animals treated with antibiotics within the six months prior to sampling (χ^2= 7.185; p = 0.014). Of the 19 canine isolates, most were *Klebsiella pneumoniae*. The feline isolate was *E.coli*. High levels of resistance to tetracycline (95%), sulphamethoxazole-trimethoprim (90%) and ciprofloxacin (65%) were observed. Isolates were susceptible to carbapenem antibiotics. Most isolates (85%) exhibited co-resistance and carried CTX-M-type ESBLs. The bla_{TEM} and bla_{SHV} genes were detected in 75% and 40% of isolates, respectively.This is the first investigation into carriage of ESBL-producing enteric bacteria in companion animals on the island and, to our knowledge, the first report of its kind for the region. It revealed that local companion animals can harbour multi-drug resistant ESBL-producing *Enterobacteriaceae.* Further investigation into the role of pet dogs and cats as reservoirs of human infection on the island is warranted.

Microbial Diversity and Antibiotic Resistance in the Chesapeake Bay and Upper Watershed (Winter of 2013)

Author Block:

V. Lahanda Wadu, J. Rivers, N. Boire, S. Riedel, N. Parrish; The Johns Hopkins Med. Inst.s, Baltimore, MD

Abstract Body:

Background: Antimicrobial resistance (AR) is an emerging threat. The Chesapeake Bay (CB) and upper watershed (UW) were previously found to harbor AR in multiple bacteria during the summer months. During the winter of 2013, we conducted a pilot study to survey bacterial diversity and resistance in isolates from the CB and UW.**Methods:** Water samples were collected from 9 sites on the CB and UW. Samples (500 ml) were collected and passed through a 0.2 µm filter. Filters were inoculated into Mueller Hinton broth and incubated at 35°C. All bacterial isolates were identified to the species level using MALDI-ToF MS. Antimicrobial susceptibility testing (AST) was performed for all enteric Gram-negative (G-) isolates using Etest and 14 antibiotics.**Results:** A total of 36 bacterial isolates were recovered from all sites including 6 Gram-positive (G+) and 30 G- organisms. Of the G+ isolates, nearly all (5/6, 83.3%) were *Bacillus* spp; a single *Enterococcus faecium* was found at the Baltimore Inner Harbor. Of the G- bacteria, 36.7% (11/30) belonged to the *Enterobacteriaceae*. The remainder of the G- organisms included predominantly *Pseudomonas* spp (2/30, 0.07%) and *Aeromonas* spp (13/30, 43.3%). A single strain of *Plesiomonas* was recovered from the Potomac River. No enteric bacteria were isolated from Gunpowder Falls State Park or the Monocacy River. Most enteric isolates were susceptible to the fluoroquinolones, cephalosporins and aminoglycosides. However, all isolates were resistant to ampicillin with MIC's ranging from 48 to >256 µg/ml. Eight isolates (72.7%) were resistant to chloramphenicol and tetracycline with MIC's ranging from 8 to 32 and 4 to >256 µg/ml, respectively. Two isolates recovered from the UW, an *Enterobacter cloacae* and a *Citrobacter freundii* were resistant to imipenem (MIC's, 1.5 and 16 µg/ml, respectively).**Conclusions:**Resistance to chloramphenicol and tetracycline exist in the CB and UW, a finding consistent with those of a prior study conducted in the summer of 2012. In that study, both the number of enteric bacteria and the amount of AR was increased versus the winter study. Taken together, these data suggest that resistance to these 2 antibiotics persists, regardless of season. Further studies are needed to better understand potential sources of antibiotic exposure in the CB and UW and the patterns of resistance seen in this study.

Are Carbapenemases Produced by *Vibrio* Species Isolated from Bottlenose Dolphins (*Tursiops truncates*) in the Gulf of Mexico?

Author Block:

G. A. Pankey[1], D. S. Ashcraft[1], S. Shen[2], D. J. Grimes[2]; [1]Ochsner Clinic Fndn., New Orleans, LA, [2]Univ. of Southern Mississippi/Gulf Coast Res. Lab., Ocean Springs, MS

Abstract Body:

Background: Antimicrobial resistance is a global problem. *Vibrio* species from bottlenose dolphins have not been studied for carbapenemase-production. The Gulf of Mexico shoreline water allows contact between dolphins and humans, which might allow transference of carbapenemases. **Methods:** Fifteen bottlenose dolphins from Sarasota Bay, Florida and 16 from Barataria Bay, Louisiana were cultured during the 2011 National Oceanic and Atmospheric Administration (NOAA) Health Assessment. A total of 899 bacterial isolates were originally collected from the 31 dolphins, and 350 isolates were viable for testing. Identification and susceptibility testing was performed on 71 *Vibrio* spp. Forty-nine were collected from dolphins in the Sarasota Bay; 22 were from dolphins in the Barataria Bay. Isolates were collected from the following areas: blowhole (29), genital (12), fecal (11), and water (19) from immediate area where dolphins were captured. Identification was determined by 16s rRNA PCR and Sanger sequencing. Susceptibility testing was performed using the Vitek® 2 System. Any isolate found to be non-susceptible to carbapenems was screened for carbapenemase by a Neo-Rapid CARB kit. *Vibrio* spp. that were tested included: *V. alginolyticus* (n = 35), *V. harveyii/owensii/campbellii* (n = 17), *V. parahaemolyticus* (n = 13), and *V. fluvialis* (n = 6). **Results:** MICs (µg/mL) determined by the Vitek were: imipenem < 4 (99% susceptible), 8 (1% intermediate); meropenem < 0.5 (100% susceptible); and doripenem < 1. There are no Clinical and Laboratory Standards Institute breakpoints for testing doripenem and *Vibrio*. The one *V. alginolyticus* isolate with an imipenem MIC of 8µg/mL was negative when screened for carbapenemase. **Conclusions:** No carbapenemases were detected in any of the *Vibrio* species collected from dolphins in the Barataria Bay or Sarasota Bay area in 2011. Current studies are needed to determine if carbapenemase-production by *Vibrio* has occurred.

Antibiogram Characterization of *Vibrio* Isolates Recovered from Aquaculture Environment

Author Block:

E. O. Igbinosa; Univ. of Benin, Benin City, Nigeria

Abstract Body:

Background: The use of antimicrobial agent to control livestock infection, for prophylaxis and growth promotion has development resistant strains of pathogenic bacteria. This issue is of major concern to human and animal health, as it leads to a greater risk of therapeutic failure of standard infection management. The aim of this study was to evaluate the presence of *Vibrio* isolates recovered from some fish pond facilities in Benin City, Nigeria, and determining their antibiogram properties and evaluating the public health implications of the findings. **Methods:** Samplings were conducted during the months of March and September 2014. Samples were screened for the isolation of vibrios using standard culture-based methods. Polymerase chain reaction (PCR) was used to confirm the identities of *Vibrio* species using the genus specific and species-specific. *Vibrio* species were detected at all studied sites between the order of 10^3 and 10^6 CFU/100 ml. A total of 550 presumptive *Vibrio* isolates were subjected to PCR confirmation for *Vibrio* organisms, 334 isolates tested positive, giving an overall *Vibrio* prevalence rate of 60.7 %.**Results:** Overall, 334 isolates from fish pond were obtained and identified of which 32.63% were *V. fluvialis*, 20.65% *V. parahaemolyticus*, 18.26% *V. vulnifcus* and 28.44 % *Vibrio* species. In all, 167 confirmed *Vibrio* isolates were randomly selected from a pool of 334 confirmed *Vibrio* isolates for antibiogram profiling. The susceptibility profiles to 20 antimicrobial agents of isolates were typical for the genus, high level of resistance was revealed in AMP^R, ERY^R, NAL^R, SUL^R, TRM^R, SXT^R, TET^R, OTC^R and CHL^R. The percentage of multiple drug resistance of *Vibrio* isolates was 67.6%. The multiple antibiotic resistances (MAR) index mean value of 0.365 of *Vibrio* isolates indicated that vibrios were exposed to high-risk sources of contamination where antibiotics were frequently used.**Conclusions:** The findings in this study revealed aquaculture environment can act as reservoirs for potential spread of multi-resistant bacteria. The presence of resistant *Vibrio* strains could serve as important medium transmitting through the food chain to humans constitute a risk for public health.

Phenotypic and Genotypic Characterization of *Salmonella, E. coli,* and *Enterococcus* Isolated from the Upper Oconee Watershed, Georgia

Author Block:

S. Cho[1], L. M. Hiott[2], C. R. Jackson[2], J. G. Frye[2]; [1]Univ. of Georgia, Athens, GA, [2]USDA-ARS, Athens, GA

Abstract Body:

This study was conducted in order to monitor *Salmonella, E. coli,* and *Enterococcus* found in the Oconee River in Athens, Georgia.Water samples were collected once each season of 2015 at different locations along the Oconee River. The number of water samples varied from 30 to 100, with 222 total samples collected. Cellulose filter powder (Aqua Dew™) was added to 1L of water and filtered onto 47-mm glass fiber filter (Pall Corporation). The filter and powder were incubated overnight (O/N) in buffered peptone (BP) water (BD).*Salmonella* isolation: BP enrichment was added to selective enrichment media (Gram negative Hajna (BD), tetrathionate (BD), Rappaport-Vassiliadis (BD) broths), incubated O/N, and then streaked onto brilliant green sulfa (BD) and xylose–lysine tergitol 4 (BD) agar plates. After O/N incubation, *Salmonella* colonies were assayed with triple sugar iron (BD) and lysine iron agar slants (BD). Positive *Salmonella* isolates were serotyped by PCR.*E. coli* and *Enterococcus* isolation: BP enrichment was streaked onto selective agar plates (CHROMagar ECC (CHROMagar™), m-TEC (HiCrome™) for *E. coli*; and CHROMagar *Enterococcus* (CHROMagar™), Enterococcosel (BD), m-*Enterococcus* (BD) for *Enterococcus*). *E. coli* and *Enterococcus* isolates were genotyped by PCR.260 *E. coli* were isolated, one-third of which belonged to a potentially pathogenic group B2. Enteropathogenic and Shiga toxin genes were detected in 5.0 and 0.4% of the isolates respectively. Few multidrug resistant (MDR) *E. coli* were detected. 405 *Enterococci* were isolated and separated into 8 different species, including *E. avium, E. casseliflavus, E. faecalis, E. faecium, E. gallinarum, E. hirae, E. mundtii,* and *E. pallens.* Almost all the isolates were intermediate or resistant to more than two drugs. Resistances to daptomycin and lincomycin were seen. 315 *Salmonella* were isolated, some of which were serotypes also isolated from humans. MDR *Salmonella* were detected.This study indicates the presence of pathogens, such as *Salmonella, E. faecalis, E. faecium,* and virulent *E. coli* in the Upper Oconee Watershed, many of which are resistant to antimicrobials. Widespread occurrence of *Salmonella* in the surface water suggests that water can serve as a reservoir for *Salmonella* and play a role in its transmission.

Multiple Antibiotic Resistance Phenotypes of *Plesiomonas shigelloides* Recovered from Some Freshwater Environments in Southwest Nigeria

Author Block:

I. M. Adesiyan[1], M. A. Bisi-Johnson[1], A. I. Okoh[2]; [1]Obafemi Awolowo Univ., Ile Ife, Nigeria, [2]Univ. of Fort Hare, Alice, South Africa

Abstract Body:

We evaluated the antimicrobial resistance indexing of *Plesiomonas shigelloides* isolated from some rivers in Osun and Oyo States, Southwestern Nigeria. Water samples were collected over a period of 4 months (May to August, 2015) and analysed using standard procedures. A total of 150 presumptive isolates were recovered and confirmed by polymerase chain reaction technique using PS gene. Thirty-eight (25%) of the isolates were confirmed as *Plesiomonas shigelloides* specie and were screened for *in vitro* antimicrobial resistance profile using disc diffusion assay. All the isolates were resistant to sulphamethoxazole and erythromycin, and variously resistant to other antibiotics in the order: ampicilin (97%), cefuroxine (97%), neomycin (84%), chloramphenicol (74%) and cefotaxine (68%). Overall, antibiotics resistance index obtained across the sampling locations was approximately 0.9 which was by far greater than the 0.2 threshold value, with modal multiple antibiotic resistance pattern TM-E-CTX-NE-C-SMX-KF-NAL-AP-ENR-TS, both suggesting our isolates to be of high risk sources. Our findings signify high prevalence of antimicrobial resistance in the selected water bodies, which could be attributable to excessive antimicrobial usage, thereby necessitating for proper sanitation and hygiene, and enforcement of legislation against indiscriminate use of the conventionally prescribed antimicrobials among inhabitants of the communities

High Frequency of Isolation of Multi-Resistant Esbl- and Carbapenemase-Producing *Enterobacteriaceae* from Wastewater on the Island of Barbados

Author Block:

E. G. Knaizeh, S. N. Workman; Univ. of the West Indies, Cave Hill Campus, Bridgetown, Barbados

Abstract Body:

ESBL- and carbapenemase-producing *Enterobacteriaceae* have emerged in the community setting in several countries and present a serious public health threat. There is little knowledge of local community reservoirs of these pathogens. This investigation sought to screen local sewage for the presence of ESBL- and carbapenemase-producing enterics, and to determine the susceptibility of isolates to antibiotics commonly recommended for treatment of clinical infections. Influent and effluent sewage samples, collected bi-monthly from the two local wastewater management facilities over a 12-month period, were screened for ESBL- and carbapenemase-producing enterics using selective enrichment and plating techniques, with cefotaxime and meropenem, respectively. The combined disc test and modified Hodge test were used for phenotypic confirmation of ESBL- and carbapenemase-production, respectively. Antimicrobial susceptibility of isolates was determined by disk diffusion assay. ESBL-producers (n = 263) were recovered from 77% of influent and 80% of effluent samples. Carbapenemase-producers (n = 59) were detected in 22% of influent and 27% of effluent samples. For both facilities, isolation rates for ESBL-producers significantly exceeded those for carbapenemase-producers (Fisher's exact, $p < 0.0001$). There was a significant difference in isolation rate of carbapenemase-producers between the two facilities (Fisher's exact, $p = 0.0006$), with more frequent recovery from that receiving sewage from an area inclusive of our public hospital (Fisher's exact, $p = 0.0003$). ESBL-producers were predominantly *E. coli* (67%) and *Klebsiella pneumoniae* (20%). The majority of carbapenemase-producers were *K. pneumoniae* (63%) and *Enterobacter intermedius* (25%). High levels of resistance to cefepime (92%), ciprofloxacin (74%) and sulphamethoxazole-trimethoprim (72%) were observed amongst ESBL-producers. Carbapenemase-producers were generally resistant to amikacin (93%), doxycycline (53%), gentamicin (31%) and tigecycline (53%), but susceptible to fosfomycin (95%). The findings indicate a high frequency of isolation of multi-resistant ESBL- and carbapenemase-producing enterics from wastewater in Barbados and suggest the presence of reservoirs in the community.

Quantitation of Antibiotic Resistance Genes Pollution in Hospital Waste Water Effluent and Urrban River Water

Author Block:

S. K. Walia, A. Kumar; Oakland Univ., Rochester, MI

Abstract Body:

Background: Anthropogenic activities play a major role in the dissemination of bacterial antibiotic resistance genes in the environment. Chemicals of concerns including antibiotics are inadvertently released in the water bodies via hospital waste water effluent, municipal water and storm water. **Methods:** In this study, we assessed the presence of antibiotic resistance genes (ARG) in hospital effluent and urban river water as a potential reservoir of bacteria containing ARG. A total of 156 bacteria isolated from hospital waste water treatment plant were analyzed for ARG including extended spectrum beta-lactamase (ESBL, SHV, TEM and CTX-M-1) genes commonly found in the environment. **Results:** Analysis of antibiotic sensitivity data revealed that 35-60% bacteria were susceptible to cefotaxime, 60-75% to chloramphenicol, 60--70% to tetracycline, 35-75% to ciprofloxacin and 70-50% to gentamicin. Of these 156 bacteria, 34 (22%) were found to be ESBL producing bacteria. The copy number of gene/mL of Hospital Effluent (WBHE) for bla_{SHV}, $bla_{TEM,}$ and $bla_{CTX\text{-}M\text{-}1}$ were 10^2,10^4 and 10^3 respectively. The abundance of bla_{SHV} and $bla_{CTX\text{-}M\text{-}1}$ remained similar in hospital waste water effluent and river water whereas the quantity of bla_{TEM} decreased to an order of 10^2 in Urban Clinton River Water (UCRW).**Conclusions**::The genetic relatedness of ARG among hospital waste water effluent and urban river water bodies is worrisome and cautions the public health authorities for its potential to spread highly resistant "SUPER BUG" in the community.

Ges-type Extended-spectrum β-Lactamases in *Aeromonas* spp Isolates from a Hospital Effluent in Southern of Brazil

Author Block:

A. A. Bavaroski[1], J. K. Palmeiro[2], L. S. Rodrigues[1], D. Conte[1], **L. M. Dalla-Costa**[1]; [1]Inst. de Pesquisa Pelé Pequeno Príncipe, Curitiba, Brazil, [2]Hosp. de Clínicas, Curitiba, Brazil

Abstract Body:

Aeromonas spp are ubiquitous bacteria mostly isolated from aquatic environment, reported as emerging human pathogens and important carrier and reservoir of antibiotic resistance genes. We investigated the presence of genus *Aeromonas* in effluents from a pediatric hospital, community health care and from domestic sewage. Matrix assisted laser desorption ionization time of flight (MALDI-TOF) mass spectrometry was used to identify *Aeromonas* spp. To evaluate extended-spectrum β-lactamases (ESBL) production the combined disc methods (ceftazidime and cefotaxime with and without clavulanic acid) were used.. *Aeromonas* spp. representing 18.8% (26/138) of the isolates of the study and out of them 42.3% (11/26) were ESBL producers. PCRs and sequencing performed on the isolates exhibiting an ESBL phenotype using specific primers (*bla*$_{SHV,}$ *bla*$_{TEM,}$ *bla*$_{CTXM,}$ *bla*$_{PER}$ and *bla*$_{GES}$) and resistance genes *bla*$_{TEM}$ (3/27%), *bla*$_{CTXM-2}$ (2/18%) and *bla*$_{GES}$ (3/ 27%) were identified. Nucleotide sequence analysis of *bla*$_{GES}$ showed the occurrence of *bla*$_{GES-7}$, *bla*$_{GES-1}$, and *bla*$_{GES-16,}$ the last two have not been previously described in this genus. These findings suggest a water reservoir of ESBL genes and emphasized the importance of resistance genes search in environmental microorganisms that might represent a potential risk for human health.

Does Water Stress Increase the Incidence of Antibiotic Resistance Genes in Drinking Water Supplies?

Author Block:

M. Sevillano[1], C. W. Knapp[2], S. T. Calus[3], A. J. Pinto[1]; [1]Northeastern Univ., Boston, MA, [2]Strathclyde Univ., Glasgow, United Kingdom, [3]Univ. of Glasgow, Glasgow, United Kingdom

Abstract Body:

Increasing water stress due to population growth, industrial/agricultural demand, and drought has resulted in direct or indirect use of reclaimed water (i.e. treated wastewater) to boost existing drinking water supplies (DWS). This raises concerns about the risk of introduction of anthropogenic contaminants into DWS. To this end, extensive work has been carried out to characterize and quantify chemical contaminants (e.g. pharmaceuticals) in DWS. In contrast, little has been done to evaluate the implications of using reclaimed water for potable use on the exposure to emerging biological contaminants like antibiotic resistance genes (ARGs).We conducted a sampling campaign to characterize the incidence and concentration of ARGs across a gradient of water stress across the United Kingdom in the summer of 2015. 30 samples were collected at drinking water taps from 12 densely populated cities in mainland UK, with variable water stress classification ranging from low to medium, to extremely high. Water quality was assessed by measuring a range of chemical parameters including pH, DO, TOC, inorganic nitrogen species, phosphate, and dissolved metal cations. Samples were filtered to harvest bacterial cells from by filtration through 0.2 μm sterivex filters, followed by DNA extraction. Samples were characterized for a range of clinically relevant ARGs using qPCR. In addition, samples have been submitted for shotgun DNA sequencing for non-targeted detection of a range of ARGs.Preliminary results indicate the presence of a range of ARGs in treated drinking water supplies. Specifically, sul1, acrB, czcA and czcD, and blaTEM were elevated in certain drinking water samples. This work will expand on these preliminary results by providing quantitative information about all ARGs targeted in this study, including assessment of links between ARGs incidence/quantitation and water stress categorization according to sample location. Further, using metagenomic assembly and genome binning we will attempt to place these detected ARGs into genome bins to determine their presence/absence in bacteria that are likely to be relevant from a public health perspective.

Multi-State Surveillance Study of Esbl and Carbapenemase-Producing *Enterobacteriaceae* in U.S. Drinking Water

Author Block:

W. D. Tanner[1], A. Gundlapalli, 84047[1], J. Olstadt[2], J. VanDeVelde[3], P. Higgins[4], J. VanDerslice[1]; [1]Univ. of Utah, Salt Lake City, UT, [2]Wisconsin State Lab. of Hygiene, Madison, WI, [3]Illinois Dept. of Hlth., Springfield, IL, [4]Pennsylvania Dept. of Environmental Protection, Harrisburg, PA

Abstract Body:

Background: Community-acquired carbapenemase and extended-spectrum beta-lactamase (ESBL) infections are increasing. Environmental sources of resistant bacteria have been confirmed; however, community drinking water is rarely considered as a source of resistant enteric organisms, especially in the United States. Approximately 1 to 2% of U.S. drinking water samples contain enteric bacteria (1). The purpose of this study was to investigate whether tap water samples containing *Enterobacteriaceae* are also positive for ESBL or carbapenemase genes. **Methods:** Tap water samples testing positive for *Enterobacteriaceae* were acquired from state health laboratories in New York, Illinois, Pennsylvania, Wisconsin, and Utah. Coliform-positive samples were screened for SHV, TEM, and CTX-M ESBL genes and OXA-48, KPC, NDM, and VIM genes by multiplex PCR. PCR products from positive samples were sequenced to confirm the specific genes present. ESBL and carbapenemase-producing bacteria were subsequently isolated, identified, and tested for susceptibility to various antibiotics.**Results:** Of 150 coliform-positive samples tested to date, more than 20 were confirmed to have ESBL genes. The most predominant ESBL-producers were Serratia fonticola and Klebsiella oxytoca, although these were primarily intrinsic ESBL genes with some corresponding ESBL phenotypes. One CTX-M-producer and four SHV-producing enteric isolates were also identified. Sequencing results of SHV PCR products produced multiple GeneBank matches with ESBL and non-ESBL types. Two samples tested positive by PCR for OXA-48 genes and sequencing of the PCR products showed 99% and 100% GeneBank matches to OXA-48-like gene sequences.**Discussion:** While *Enterobacteriaceae* detection in treated U.S. tap water is uncommon, some of these bacteria do carry ESBL and carbapenemase genes, indicating that there is a potential for ingestion of these organisms via U.S. tap water. Although many of the detected ESBL genes were intrinsic, many environmental bacterial species serve as the original source of ESBL and carbapenemase genes of clinical concern (2).

Publishing Title:

Analysis of Surface Longevity of *Klebsiella pneumoniae carbapenemase* (Kpc)-Producing Enterobacteriaceae on an Environmental Surface

Author Block:

R. P. Orr, A. Cheruvanky, W. Chai, M. Denecke, J. Carroll, A. Mathers; Univ. of Virginia Hlth.System, Charlottesville, VA

Abstract Body:

Background: KPC-producing Enterobacteriaceae have been identified as an urgent threat to hospitalized patients around the world. However, our understanding of nosocomial transmission of these organisms is incomplete and may involve the environment. Little is known about the surface longevity on inanimate objects of different species that carry KPC and cause nosocomial infections. This would be critical information for targeting infection control measures. We examined the difference in surface survival between the two most common KPC-positive nosocomial pathogens *Klebsiella pneumoniae* (KPC-Kp) and *Enterobacter cloacae* (KPC-Ec). **Methods:** Three independent 30-day trials of clinical strains of KPC-Kp and KPC-Ec were performed using a bleach-sterilized surface outlined with a grid design. Each cell was inoculated with $5X10^7$ colony forming units (CFU)s. Sterilized, pre-soaked cotton swabs were applied approximately every 24 hours to a new cell along with a swab from a paired surface without added organisms as a negative control. Collected samples were incubated overnight in tryptic soy broth with a 10µg ertapenem disk. If growth was visually detected, the sample was plated on KPC selective chromogenic agar and pigmented colonies consistent with KPC-Kp or KPC-Ec were considered positive.**Results:** A total of 129 samples were processed throughout the duration of the experiment. Both KPC-Kp and KPC-Ec had some samples that survived the entirety of the 30-day trial. Surface samples were 100% (21/21) and 100% (21/21) week 1, 52% (11/21) and 100% (18/18) week 2, 54% (13/24) and 91% (22/24) weeks 3 and 4 for KPC-Kp and KPC-Ec, respectively. Comparison of surface survival from day 8 to 30 demonstrated KPC-Ec had more persistence then KPC-Kp (40/42 versus 24/45; p=0.001 by Fischer exact).**Conclusion:** We conclude that KPC-Kp and KPC-Ec have the capacity to survive on an environmental surface for prolonged periods of time. This indicates that the hospital environment could play a larger role in KPC-positive Enterobacteriaceae transmission than currently recognized. KPC-Ec persisted slightly longer in the environment than KPC-Kp, which may point to a larger role of the environment in hospital transmission of this species and will require further investigation.

Isolation and Antibiotic Screening of Halophilic Actinomycetes from the Cabo Rojo Solar Salterns

Author Block:

L. Casillas, Valentin, L., E. Bayala, X. Alejandro, M. Claudio,L.M. Casillas, I. Garcia; UPR-Humacao, Humacao, Puerto Rico

Abstract Body:

As microbial resistance has been rising at alarming rates in the last decades, there is an urgent need to find new antibiotic to fight against such resistant pathogens. Extremophiles have unique genetic and chemical characteristics, thus they are attractive targets for drug discovery. Microbes inhabiting the Cabo Rojo solar salterns live in an extreme environment (high salinity, temperature and UV radiation) composed of a series of salt ponds surrounded by microbial mats. In order to isolate for halophylic Actinobacteria, we initially set up enrichments with samples from the salt ponds and microbial mats using commercially available Actinomyces broth supplemented with 4-20% NaCl. More than twenty morphologically distinctive *Actinomyces* fungus like-colonies were identified with differential antibiotic resistance patterns after traditional Kirby Bauer tests. As *Actinomyces sp*. are known to produce a variety of antibiotics, we tested six of these isolated strains for their ability to inhibit the growth of five clinically relevant pathogens (*Staphylococcus aureus, Pseudomonas aeruginosa, Klebsiella pneumoniae, Salmonella typhimurium,* and *Escherichia coli*). Isolates 18, 41, 72, 78, 87, and 88 were sub-cultured into Marine broth (MB) and incubated for 48 hours at 37ºC prior to the bioassay. The filtered supernatant was deposited in wells within each pathogen inoculated in the agar plates. Antibiotic activity was determined after 48-72 hours. Ampicillin (c = 0.0125 mg/mL) was used as positive control for antibiotic activity. By using the agar well diffusion assay we detected antibiotic activity in four of the six tested strains. Our results indicate that isolates 18 and 41 produced antibiotics active against *S. aureus*, *P. aeruginosa* and *K. pneumoniae* with inhibition zones in a range of 11-20 mm. Interestingly, Isolate 87 exhibited broad antibacterial activity inhibiting all pathogens tested but resulting in smaller inhibition zones (7-10 mm). Crude extracts from Isolate 72 began to show antibacterial activities only after 72 hours of incubation. Our next steps are to chemically identify the components in these crude extracts by HPLC-MS and phylogenetically identify these halophylic *Actinomyces*.

Methicillin-resistant *Staphylococcus aureus* Isolated from Surfaces and Mobile Devices at a Caribbean Medical School

Author Block:

J. C. Harrington; Univ. of Med. and Hlth.Sci., Basseterre, Saint Kitts and Nevis

Abstract Body:

Background: The island of Saint Kitts is home to a medical school, University of Medical and Health Sciences, which include rotations at JNF Hospital in the curriculum. Students frequently interact with patients with diabetes mellitus (adult population incidence = 13.2%), a condition associated with opportunistic and life-threatening microbial infections. Previous studies have identified campus surfaces and mobile devices as transient fomites for *Staphylococcus aureus* contamination, thus medical student may be acting as a transmission vector to compromised patients. The objective of this study was to characterize methicillin susceptibility of *S. aureus* isolates present on campus surfaces and mobile devices from medical students at UMHS-St Kitts campus, and to determine if alcohol swabs are an effective means for microbial reduction. **Methods:** A campus survey was conducted to culture non-fastidious fungal and bacteria isolates with the use of sterile swabs, tryptic soy agar plates, and standard microbiological and biochemical assays for identification. 100 hard surfaces were sampled on campus. 60 mobile devices of students were sampled pre- and 24-hour post-disinfection with 70% isopropyl alcohol wipes. Putative *S. aureus* isolates were confirmed with BactiStaph agglutination and assayed for oxacillin susceptibility with Oxoid disks.**Results:** For the campus surfaces sampling, 23 surfaces (23%) were positive for *S. aureus* contamination, predominantly from commonly touched surfaces. Of the confirmed bacterial colonies cultured from surface samples, 6 isolates (26%) demonstrated resistance to oxacillin. For the mobile device sampling, 31 (52%) phones were positive for *S. aureus* prior to disinfection, from which 3 isolates (9%) displayed resistance to oxacillin. After 24 for hours post-cleaning with 70% alcohol, 35 phones (58%) were positive for *S. aureus* and 5 (14.8%) of the isolates were oxacillin resistant. All test isolates were susceptible to vancomycin.**Conclusions:** Methicillin-Resistant *S. aureus* is prevalent on the UMHS campus, including majority of the student mobile devices tested. Alcohol swabs were ineffective at reducing the *S. aureus* on the mobile devices; thus, alternative disinfectant methods should be explored.

Susceptibility of 194 *Salmonella* Isolates to 17 Chemicals Used as Sanitizers and Biocides

Author Block:

S. B. Humayoun, L. Hiott, C. R. Jackson, J. G. Frye; USDA, Athens, GA

Abstract Body:

Salmonella is a major cause of foodborne illnesses in the United States. Meat processing facilities use a wide variety of antimicrobial interventions to reduce *Salmonella* contamination. The objective of this study was to determine the minimum inhibitory concentration (MIC) of sanitizers and biocides against *Salmonella*. The biocide used in this study were: Acidified sodium chlorite (ASC), Acetic acid (AA), Arsenite (ARI), Arsenate (ARA), Benzalkonium chloride (BC), Cetylpyridinium chloride (CC), Citric acid (CA), 1,3 Dibromo, 5,5 dimethylhydantoin (DBH), Dodecyltrimethylammonium chloride (DC), Hexadecyltrimethylammonium bromide (HB), Hexadecyltrimethylammonium chloride (HC), Lactic acid (LA), Peroxyacetic acid (PXA), Sodium hypochlorite (SHB), Sodium metasilicate (SM), Trisodium phosphate (TP), Chlorhexidine (CH). 194 animal associated *Salmonella* isolates representing 84 serotypes were assayed for susceptibility. Isolates were grown on Blood Agar plates. Colonies were picked and suspended in Mueller Hinton broth (MHB), and inoculum concentration was adjusted to 10^5 cells/ml following protocols for Sensititre^{TM} (ThermoFisher, Pittsburgh, PA). MIC assay was done in 96 well plates using two-fold serial dilutions of chemicals in MHB. Plates were incubated at 37ºC for 24 hrs and turbidity was used as indicator of bacterial growth. Results were recorded using the Sensititre vision system. The lowest concentration at which no growth was observed was reported as the MIC to the chemical in µg/ml. The median MIC (µg/ml) for 194 isolates was: DC =256, CC=40, LA=7556, CA=6316, BC =40, AA =1640, TP =37952, HB=82, HC =78, ARI =30, ARA 408, SM =120640, SHB=55500, PXA=884, ASC = 1272, DBH =1248, and CH =3.5. Most of the isolates showed similar susceptibilities to each chemical with MICs within +/- one two-fold dilution from the median MIC. However, 16 *Salmonella* isolates had a four-fold higher MIC than the median MIC to Arsenate and 19 isolates had a four-fold higher MIC to Arsenite. Additionally, 5 isolates had a four-fold lower MIC to Arsenate. This variability in MIC may indicate reduced susceptibility or hyper susceptibility in some *Salmonella* isolates to these compounds.

A Survey of Microbial Contamination of Antiseptics and Disinfectants in Lagos, Nigeria

Author Block:

A. E. OMOTAYO, M. S. Sanusi, C. J. Nsofor, S. A. Adesida; Univ. of Lagos, Lagos, Nigeria

Abstract Body:

Background: Antiseptics and disinfectants have been widely used as a germicidal agents, they are believed to be highly effective against microorganisms though they are prone to microbial contamination. This study was carried out to assess the microbial contamination of antiseptics and disinfectants.**Materials:** Fifty (50) samples were purchased from different pharmacies, supermarkets, local markets and hawkers in Lagos State. The samples were pre-enriched in Tryptone Soya Broth and Sabouraud Dextrose Broth. Isolation of bacteria and fungi were done by culturing on Tryptone Soya Agar, Mannitol Blood Agar, Centrimide Agar, MacConkey Agar and Sabouraud Dextrose Agar using the spread plate method. The bacterial isolates were identified by standard biochemical test, the use of Analytical Profile Index (API) kit and Microbact kit. The fungal isolates were identified by cultural and morphological characteristics. The antifungal and antibiotic sensitivity test of the isolates were determined by the disk diffusion method using commercially available antimicrobial agents.**Results:** Bacterial and fungal contamination rate of 80% and 86% were observed respectively. The isolates identified were *Acinetobacter baumanii, Bacillus* spp., *Corynebacterium* spp., *Paenibacillus macerans, Pseudomonas* spp. *and Staphylococus* spp. All the isolates showed variable sensitivity to antibiotics with *Pseudomonas aeruginosa, P. fluorescens and A. baumanii* having the highest Multiple Antibiotics Resistance (MAR) Index of 0.69 and *S. aureus* with the lowest MAR index of 0.07. The fungi isolated were *Penicillium chrysogenum, Aspergillus flavus, Chrysosporium tropicum, Alternaria solani, Fusarium solani, Penicillium marneffei* and *Aspergillus niger.* The isolates were resistant to the three antifungal agents (Nystatin, Voricinazole and Fluconazole) used, with some having MAR Index of up to 1.00.**Conclusion:** This study revealed the high level of microbial contamination of antiseptics and disinfectants including some potentially pathogenic organisms that could have serious medical consequences.

Publishing Title:

Prevalence of Multiple Antibiotic Resistant Bacteria in University of Ibadan Library Books and Library Indoor Air

Author Block:

H. G. Johnsons; Univ. of Ibadan, Ibadan, Nigeria

Abstract Body:

Resistance to antimicrobials by bacteria has become worrisome worldwide specially in developing nation like Nigeria, threatening the ability to treat infections. Poorly ventilated closed settings like libraries in our institution may provide occasions for the transmission of multiple antibiotic resistant bacteria between immune-compromised and normal individuals. Although, studies have shown the presence of pathogenic bacteria in formites like toys and magazines in hospitals, little or nothing is documented about pathogenic bacteria in library books especially in Nigeria. Thus this study not only analyzed the possibility of pathogenic bacteria on books and air in these libraries but also considered the possibility of multidrug resistance among the bacteria and also assessed if these media can serve as latent reservoirs of multiple drug resistant bacteria.The settle plate method was used to collect indoor air samples while surfaces of books were swabbed. Sensitivity of 40 out of the isolated bacteria to broad spectrum antibiotics was done using the Kirby-Bauer agar disk diffusion method.Bacteria counts were statistically significant at $p < 0.05$ with mean count from air (using the Commission of European Communities (1993) standard) and books ranging from $0.23 \times 10^3 \pm 0.065$ CFU/m^3 to $1.99 \times 10^3 \pm 0.655 \times$ CFU/m^3 and $5.83 \times 10^4 \pm 0.0247$ CFU/ml to $1.32 \times 10^4 \pm 0.0283$ CFU/ml. Species of *Bacillus, Staphylococcus*, *Proteus, Micrococcus*, *Yersenia*, *Erwinia*, *Klebsiella Serratia, Pseudomonas* and *Providencia* were isolated. *Bacillus* spp. were the most (27.5%) followed by *Staphylococcus* spp. (22.5%), *Erwinia* and *Providencia* spp. (2.5%) each. Resistance ranged between 17.5% for ciprofloxacin to 75% for tetracycline. Irrespective of species, 46.25% of the isolates were resistant to all the drugs while 42.5% were susceptible to all drugs. Also, 100% were resistant to at least one or more antibiotics while 82.5% were multidrug resistant. *Staphylococcus aureus, Bacillus subtilis* and *Staphylococcus cohnii* were 100% resistant to all the antibiotics.The high counts of multiple drug resistant bacteria in these libraries showed that air and books in these libraries serves as reservoirs of multidrug resistant bacteria and thus indicating a treat in health of the library staff and other users.

***Staphylococcus aureus* and Methicillin-Resistant *Staphylococcus aureus* in Nursing Homes**

Author Block:

S. Cheatham, D. Thapaliya, M. Taha, K. Milliken, M. Dalman, J. Kadariya, D. Grenier, T. C. Smith; Kent State Univ., Kent, OH

Abstract Body:

Staphylococcus aureus is a common pathogen that can cause a wide range of infectious diseases. For the past few decades, methicillin-resistant *S. aureus* (MRSA) has become a deadly nosocomial infection in many institutions such as hospitals, community centers, and nursing homes. The bacterium can be transmitted directly person-to-person, or via contact with contaminated fomites. Nursing homes (NH) can be a major risk when it comes to nosocomial infections due to transporting residents to and from appointments, the rate of discharges per day including discharges home and to the hospital, the number of new admits on a weekly basis, and transferring patients from room to room. The purpose of this study was to examine the prevalence of both *S. aureus* and MRSA in NHs and obtain molecular and epidemiological information in order to implement new ways of infection control within. A total of 259 environmental cultures were obtained from 7 different nursing homes within 3 geographical areas in Northeast Ohio; rural, urban, and suburban, from July 7, 2015 to July 12, 2015. Samples were processed within 24 hours of collection. DNA amplification and PCR was run to identify the presence of the *mec*A and PVL genes for all *S. aureus* isolates. Finally, *spa* and multi-locus sequence typing (MLST) were performed in order to identify strain types. The overall prevalence of *S. aureus* was 29.0% (75/259). Of positive isolates, 64.0% (48/75) were MRSA. The presence of the PVL gene was 32.0% (24/75). Of 75 positive isolates, there were 18 different *spa* types with t002 the most common and found in urban and suburban NHs When comparing urban, rural, and suburban, the urban area had the highest prevalence of *S. aureus* (47.2%) with 80% being MRSA. It also had the highest frequency of the PVL gene at 42.9%. Suburban NHs had 27.0% positive for *S. aureus* with 53.3% of those MRSA and 26.7% positive for PVL. Lastly, rural NHs only had 10.8% prevalence of *S. aureus* with 37.5% MRSA and none that were PVL-positive. Part of these differences may result from transfers from hospitals; the urban NHs had anywhere between 4-15 hospitals nearby whereas suburban and rural had 1-3 hospitals within the area. The results of this study indicate that infection control in both hospitals and nursing homes could possibly contribute to the high prevalence of environmental MRSA in urban nursing homes.

Pilot Study to Explore MSSA and MRSA Nasal Carriage in Female College Students

Author Block:

S. Donovan, G. Chiumento, J. Richards, M. O'Seaghdha, S. M. Duty, E. Scott; Simmons Coll., Boston, MA

Abstract Body:

Background: *Staphylococcus aureus (S. aureus)* is a Gram-positive bacterium that causes localized and systemic infections. Methicillin-resistant *S. aureus* (MRSA) is a strain of *S. aureus* that has developed resistance to beta-lactam antibiotics. According to CDC, MRSA infects approximately two million people per year and accounted for 11,285 deaths in the USA in 2013.[1] Methicillin-sensitive *S. aureus* (MSSA) can be carried and transmitted from person to person. Approximately 33% of people are *S. aureus* carriers [1] and up to 7% are colonized with MRSA.[2]**Methods:** The aim of this research is to explore potential predictors of nasal carriage rates for MSSA and MRSA including factors such as face touching frequency, hormonal contraceptive use, public transport use, hospital work, roommates, URT symptoms, antibiotic use, and other variables obtained by survey.This study comprised 111 female microbiology students. Subjects were directed to swab their own nares. Samples were tested for the presence of MSSA and MRSA by analysis of growth on Baird Parker agar. Positive isolates were examined by Gram's stain and assayed for coagulase and catalase production. Finally, putative isolates were grown on Oxacillin agar and CHROMagar™ before being classified as MSSA or MRSA.**Results:** Preliminary data indicated that 18 (16.2%) subjects were *S. aureus* positive and that 7 (6.3%) were MRSA positive in at least one nostril. Survey data showed that 29.7% of subjects have had hospital work experience within the past year, 73% of subjects used public transportation more than once a week, and 98.1% of subjects lived with at least one roommate. Nearly half of all subjects had recently used, or were using hormonal contraceptives at the time of the study. 18.2% of subjects were suffering from URT symptoms at the time of nasal swabbing and 9.3% were using an antibiotic. More than 95% of subjects frequently touched their faces.**Conclusion:** At this juncture no significant predictors for MSSA or MRSA nasal carriage in the student population have been identified.

Determination of Sensitivity Pattern of Microorganisms Isolated from Hospital Environment (One Center Study)

Author Block:

n. afshan; Jinnah Univ. for Women, karachi, Pakistan

Abstract Body:

Hospital-acquired infections are a major challenge to patient safety that is most commonly associated with invasive medical devices or surgical procedures. Multidrug resistant especially Methicillin resistant *S.aureus* (MRSA) as well as gram-ve bacteria become a growing problem in many parts of the developing world. So according to severity of hospital acquired infection. We here at microbiology department in Jinnah university for women, Karachi design a study project in which we evaluate the resistivity pattern of different microorganisms isolated from Intensive care Unit, Neonate Intensive care unit, general ward, labor room, operation theater and kitchen All samples were collected aseptically and platted right after the collection. Identification had done by standard microbiological methods, such as Gram staining, colony morphology, biochemical tests.Antibiograms were done on Mueller-Hinton agar plates with disk diffusion according to Kirby Bauer method .Disks were tested: (Oxoid Ltd., England) The results were interpreted according to the Guidelines of the Clinical and Laboratory Standards Institute.(CLSI).Result showed the presence of *Staph aureus* in 44%, S.epidermidis 7% *Neisseria* in 15%, *Klebsiella 6%, Pseudomonas 6%*, *E.coli* 7% *Aspergillus* in 6.% and *Bacillus* in 9%. All *staph* isolates were resistant to Methicillin and sensitive to Vancomycin , all *Neisseria* isolates were resistant to ceftriaxone and sensitive to ofloxacin, *Bacillus* were sensitive to Chloromphenicol and Doxycyclin where as resistant to Gentamycin and *Klebsiella* sensitive to Chloromphenicol and Doxycyclin and resistant to Penicillin, *E.coli* and *Pseudomonas* are resistant to penicillin,Gentamycin & cephalosporin groups. Presence of multidrug resistant organisms in Hospital environment is a challenge for infection control authorities.Key words:*Multidrugresistant,infection,CLSI*

Detection of ESBL, AmpC and MBL among the Clinical Bacterial Isolates

Author Block:

R. Anandan, D. Lakshmipriya, V. Nithyakalyani, C. Banurekha, S. Rajkumar; Dr MGR Janaki Coll. of Arts and Sci. for, Chennai, India

Abstract Body:

Background: Emergence multi drug resistant (MDR) bacterial clones among the clinical isolates complicates the clinical outcomes. This extent the patient hospital stay thereby adds considerable burden on the public health system and jeopardize the patient prognosis. This assumes greater importance in developing and underdeveloped countries where the clinical outcome is further marred by the socio-economic status of the patient and overcrowded hospitals. These factors ensures the persistence of pathogens and facilitate horizontal transfer of drug resistance trait. More surveillance data especially in third world countries is required to facilitate Governments and public health agencies to take informed policy decisions. In this background, we screened various clinical specimens from a semi-urban private hospital for multi-drug resistant bacterial isolates and further differentiated their resistant profile for various drugs.**Methods:** A total of 50 isolates were isolated from a semi-urban private hospital that included blood (n=30), sputum (n=10), endotracheal aspirate (n=6), pus and other fluids (n=4) using standard bacteriological isolation techniques. Conventional antibiotic disc diffusion technique was used for preliminary screening of these clinical isolates and isolates manifesting resistance to $\geq$3 antibiotics were segregated as MDR and proceeded for targeted analyses to delineate them into ESBL, AmpC and MBL clones.**Results:** Among the clinical Gram negative bacterial isolates 36% (18/50) were found to be MDR as they exhibited resistance to over 3 antibiotics tested by conventional disk diffusion technique. While 16/50 isolates were ESBL producers, 12/50 isolates were found to borne the AmpC phenotype. Interestingly, all isolates were found resistant to imipenem.**Conclusions:** Incidence of MDR bacterium in various clinical specimens is indeed a cause of concern. Stringent measures that includes, better hospital and personal hygiene practices, discriminate and prudent use of antibiotics guided by laboratory tests need to be enforced to address this growing public health burden.

Companion Animals Are Reservoirs of High-Risk Human Esbl and Ampc-Producing *Escherichia coli* Lineages

Author Block:

A. Belas, C. Marques, A. Franco, **C. F. Pomba**; Faculty of Vet. Med., Univ. of Lisbon, LISBON, Portugal

Abstract Body:

Background: The increase of ESBL and AmpC β-lactamases in companion animals is a great public health concern as they may act as reservoirs to humans. This study aimed to detect and characterize the *E. coli* lineages resistant to 3rd cephalosporin (3GC) causing urinary tract infection (UTI) in companion animals over 17 years in Portugal.**Methods:** Antimicrobial susceptibility of 324 uropathogenic *E. coli* isolated from dogs and cats (1999 to April 2015) was studied by the disk diffusion method. The phylogenetic groups were determined for all strains by PCR. 3GC-resistant *E. coli* strains were typed by MLST and screened for 8 pathogenicity islands markers and 8 virulence genes.**Results:** *E. coli* isolates were resistant to ampicillin 48% (n=154/324), 14.0% (n=45/324) to amoxicillin/clavulanate and 9.6% (n=31/324) to 3GC. *E. coli* B2 group was the most common (57.4%, n=186/324). 3CG-resistant *E. coli* group B2 and D strains had pathogenicity profiles and virulence-associated genes belonging mostly to $I_{536}II_{J96}IV_{536}II_{CFT0T3,}$ $I_{536}II_{J96}IV_{536}I_{CFT0T3}II_{536}$, *ecpA-hly*A-*cnf1-sfaDE-papEF*, and $II_{536}II_{J96}IV_{536}I_{CFT0T3,}$ *ecp*A-*pap*, respectively. In 2004, the first CTX-M-15-producer *E. coli* belonged to O25b:H4-ST131 human pandemic clone. About 33% (n=15/45) from group D *E. coli* were 3GC-resistant. Moreover, 29% (n=13/45) group D *E. coli* were pAmpC producers (harbouring bla_{CMY-2}) and 2.2% were pAmpC and ESBLs producers (harbouring bla_{CMY-2} and $bla_{CTX-M-9}$). From 2010 group D 3GC-resistant *E. coli* belonged mostly to ST648 (n=9), followed by ST1775 (n=3), ST405 (n=1) and ST354 (n=1) lineages. Among group B1 strains, 6.8% (n=3/44) were 3GC-resistant. Group B1 strains belonged to ST539 (n=1), ST533 (n=1), ST224 (n=1) and were found to harbour bla_{CMY-2}, $bla_{CTX-M1group}$ and $bla_{CTX-M-32}$ respectively. Group A 3GC-resistant *E. coli* (16.3%, n=8/49) harboured, $bla_{CTX-M-15}$ (n=1), $bla_{CTX-M-32}$ (n=1) and $bla_{CTX-Mgroup}$ (n=2) and belonged to ST23 (n=1), ST48 (n=1), ST88 (n=1) and ST609 (n=1).
Conclusions: The detection of *E. coli* lineages highly important for humans causing UTI in companion animals raises great public-health concerns regarding their role as reservoirs and the risk of transfer to humans.

Molecular Epidemiology of Carbapenem Non-Susceptible (Carb-Ns) Clinical Isolates in Detroit

Author Block:

M. Veve[1], S. L. Davis[2], R. J. Tibbetts[1]; [1]Henry Ford Hosp., Detroit, MI, [2]Wayne State Univ., Detroit, MI

Abstract Body:

Background: The emergence and spread of carbapenem resistant organisms (CRO) is a significant burden to healthcare systems worldwide. Bacteria that possess enzymatic resistance mechanisms to carbapenems are associated with poor patient outcomes. We describe the molecular *bla*-characterization of CARB-NS isolates found in our institution.**Materials/Methods:** The molecular epidemiology and mechanisms of resistance for CARB-NS clinical blood, urine, respiratory tract and other isolates were determined at a single center institution in Detroit from 1/2013 to 12/2015. Whole genomic DNA from CARB-NS *Pseudomonas aeruginosa* (PA) and Enterobacteriaciae (EB) was purified before undergoing real-time polymerase chain reaction using SYBR Green (Bio-Rad). Primers and control organisms (CDC, Georgia) for the following *bla* sequences (NDM, KPC, VIM, SME, GES, IMP) were confirmed using melt-curve analysis relative to control organisms. Clinically relevant PA isolates were tested for susceptibility to ceftolozane/tazobactam (TOL/TAZ) and EB to ceftazidime/avibactam (CAZ/AVI).**Results:** 142 isolates screened positive for potential carbapenemase production; PA 67 (47%), EB 76 (54%). 34 (24%) were found to harbor bla_{KPC} (EB 32, 94%; PA 2, 6%). Isolate characteristics are shown in Table 1. TOL/TAZ and CAZ/AVI susceptibility was 67% and 100%, respectively.**Conclusions:** The mechanisms of CARB-NS in Detroit are not commonly related to carbapenemases. The only *bla*-sequence isolated was KPC. An understanding of the regional genomic sequence of CARB-NS is beneficial for clinicians to target appropriate antibiotic therapy and to improve infection control procedures.Table 1. Characteristics of clinical isolates

Bacterial strains, *n* = 142 (*n*, %)	Culture site (*n*)				Percentage bla_{KPC}, *n* = 142
	Urine	Respiratory	Blood	Other	
K. pneumoniae (29, 20%)	15	4	9	1	13%
E. coli (20, 14%)	12	1	4	3	5%
C. freundii (2, 1%)	2	0	0	0	1%

E. cloacae (16, 12%)	8	2	3	3	1%
P. aeruginosa (67, 47%)	1	64	1	1	1%
*M. morganii (*1, 1%)	1	0	0	0	1%
S. marcescens (4, 3%)	2	0	2	0	1%
P. mirabilis (3, 2%)	2	0	1	0	0%

*PCR for NDM, VIM, SME, GES and IMP were not confirmatory

Characterization of Type I-F of CRISPR-Cas System in Strains of Serratia spp. from the Mosquito Gut

Author Block:

D. Pei, W. Yu, 88003, J. Xu, 88003; New Mexico State Univ., Las Cruces, NM

Abstract Body:

The mosquito Anopheles gambiae midgut ecosystem accommodates a diverse and dynamic microbiome. Within this microbiome, Serratia is an abundant genus. CRISPR-Cas system is an adaptive immune system in bacteria and archaea, which targets different types of invaders. In this study, two strains of Serratia spp., Ag1 and Ag2, were isolated from the mosquito midgut. Draft genome sequences were determined and annotated. There are two subtypes of type I CRISPR-Cas system, I-E and I-F, present in the genome. The I-F subtype consists of six cas genes and two CRISPR arrays, which includes 28 spacers and 15 spacers, respectively. I-E subtype consists of seven cas genes and one CRISPR array with 19 spacers. Possible origins of the spacer sequences of the CRISPR systems were examined by comparing spacers against the databases of phages and conjugative plasmids. Phage or conjugative plasmid derived spacers were identified. Based on phylogenetic analysis, I-F cas3 of Serratia was closer to the cas3 of Yersinia than to the cas3 of E. coli and Pseudomonas. Interestingly, there is an insertion in the I-F cas3 gene in Ag2 strain. The inserted DNA fragment was 1.5 kb with three coding regions. The inserted fragment is 96% identical to plasmid pYAB, carried by a strain of Yersinia pseudotuberculosis. The type I-F system of both Serratia strains was functional. It was able to degrade the plasmids that carried engineered protospacers. Apparently, in the strain Ag2, the insertion in cas3 did not affect its function. In Serratia spp., we found one self-targeting spacer that hit to a prophage tail protein coding sequence in its own genome. Since Serratia is predominant in the microbial community in the mosquito gut. It will be interesting to know if the CRISPR system plays a role in shaping and stabilizing of the mosquito microbiome.

The Ecology of Algal Polysaccharide Utilization: Novel *Verrucomicrobia* Isolates Efficiently Degrade Fucoidan

Author Block:

C. H. Corzett[1], J-H. Hehemann[2], E. J. Alm[1], M. F. Polz[1]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]Max Planck Inst. for Marine Microbiol., Bremen, Germany

Abstract Body:

Marine macroalgae are vital players in the global carbon cycle, and polysaccharides represent a significant output of their primary production. Identifying the microbes and metabolic pathways responsible for degrading these sugars is not only crucial to understanding marine carbon flow, but also offers potential for biofuel production using seaweed feedstocks. Fucoidans are an important class of structurally heterogeneous sulfated polysaccharides found in brown seaweeds, yet few organisms have been shown to metabolize this abundant carbohydrate. Enrichment cultures from coastal samples yielded numerous isolates from diverse genera (*Vibrio, Stappia, Neptunomonas, Alteromonas, Tenacibaculum*) implicated in the breakdown of fucoidan polysaccharides, and novel *Verrucomicrobia* isolates performing an especially critical role in facilitating this process were sequenced. Draft genomes reveal Polysaccharide Utilization Loci (PULs) enriched with numerous and diverse Carbohydrate-Active Enzymes (CAZymes), with some isolates encoding as many as 60 genes with homology to established fucosidases. Differences in the dynamics and extent of fucoidan utilization among closely related isolates suggest variation in enzymatic capabilities and may reflect resource partitioning. Specific combinations of natural isolates appear to complement one another and yield greater overall biomass accumulation, suggesting engineered organisms or communities with a full repertoire of enzymatic machinery may facilitate the efficient conversion of algal biomass.

Discovery of a Novel Prodigiosin Producing *Vibrio* from the Gulf of Mexico

Author Block:

S. F. Morgan[1], E. Warrick[2], B. J. Gasper[3], K. Walstrom[4]; [1]New Coll. of Florida, Bradenton, FL, [2]State Coll. of Florida, Bradenton, FL, [3]Florida Southern Coll., Bradenton, FL, [4]New Coll. of Florida, Sarasota, FL

Abstract Body:

Prodigiosins are a group of often brightly colored pigment molecules produced by a variety of bacterial organism as secondary metabolites. Most notably, prodigiosin is known as the pigment responsible for both the bright red appearance and antibiotic activity of *Serratia marcescens.* The biomolecules consist of a pyrrolylpyrromethene core with varying alkyl substituent groups. Prodigiosin compounds have been studied for their antibacterial, anti-malarial and anti-cancer properties. The compounds also have potential applications in industry, as their brightly colored appearance makes them ideal candidates for natural dyes.Environmental samples taken from a salt flat in Bradenton, FL led to the discovery of a novel halophillic bacteria capable of producing a bright pink compound. Full genomic sequencing of the isolate and analysis of the genomic sequence utilizing the genome browser Artemis, NCBI's BLAST and Clustal Omega was performed. Additionally, the pigment compound was isolated using a multistep purification procedure and analyzed with UV-Visible spectroscopy, IR spectroscopy, nuclear magnetic resonance spectroscopy and liquid chromatography mass spectrometry.The bacterial isolate was identified as a member of the *Vibrio* genus most closely related to *Vibrio rhizosphaerae* and *Vibrio gazogenes.* A crude extract of cultured bacterial cells contained a broad spectrum antibiotic capable of inhibiting growth of ESKAPE safe relatives: *Staphylococcus epidermidis, Bacillus subtilis, Enterobacter aerogenes, Citrobacter* f*reundii* and *Chromohalobacter salexigens.* A prodigiosin biosynthesis gene cluster was found within the genome similar in sequence and structure to the prodigiosin gene cluster in *S. marcescens.* Spectroscopy of the compound(s) shows similar chemical properties to the prodiginine family.

Complete Genome Analysis of *Vibrio parahaemolyticus* FORC_023, Isolated from Storage Water for Raw Fish

Author Block:

H. Chung[1], S. Kim[1], B. Lee[1], E. Na[1], J-H. Lee[2], S. Choi[1]; [1]Seoul Natl. Univ., Seoul, Korea, Republic of, [2]Kyung Hee Univ., Yongin, Korea, Republic of

Abstract Body:

Vibrio parahaemolyticus is a Gram negative halophilic bacterium and consumption of seafood contaminated with this bacterium can cause gastroenteritis. *V. parahaemolyticus* FORC_023 strain was isolated from the storage water for raw fish, and its whole genome sequence was determined using two different platforms of PacBio RS II platform and Illumina MiSeq platform. The genome FORC_023 is composed of two circular chromosomes without plasmid. Chromosomes consist of 4,227 predicted open reading frames (ORFs), 131 tRNA genes, and 37 rRNA genes. The FORC_023 strain does not include major virulence factors such as thermo-stable direct hemolysin (TDH) and TDH-related hemolysin (TRH). However, the genome of FORC_023 contains various genes related to hemolysin, secretion, and iron uptake. Among various *V. parahaemolyticus*, FORC_023 shows the highest average nucleotide identity (ANI) value with UCM-V493 which is one of the most virulent strains, indicating that FORC_023 is virulent as well. Furthermore, comparative genome analysis of the two strains revealed that FORC_023 carries an additional genomic region encoding strong virulence factors such as repeats-in-toxin (RTX) and type II secretion, which could lead to host cell death. In addition, *in vitro* cytotoxicity testing suggests that FORC_023 exhibits a higher level of cytotoxicity toward the INT-407 human epithelial cells as determined by lactose dehydrogenase (LDH) release. All these results suggest that the FORC_023 isolated from storage water for raw fish is one of the most virulent strains of *V. parahaemolyticus*, providing new insights into the necessity for rapid detection as well as epidemiological investigation to prevent food-borne outbreaks by *V. parahaemolyticus.*

Complete Genome Analysis of *Vibrio parahaemolyticus* FORC_018, Isolated from Sea Bass

Author Block:

E. Na[1], S. Kim[1], H. Chung[1], B. Lee[1], J-H. Lee[2], S. Choi[1]; [1]Seoul Natl. Univ., Seoul, Korea, Republic of, [2]Kyung Hee Univ., Yongin, Korea, Republic of

Abstract Body:

Vibrio parahaemolyticus is a Gram negative halophilic pathogen that causes gastroenteritis following consumption of contaminated seafood. Ten strains of the species were obtained from Korean Ministry of Food and Drug Safety to help characterize *V. parahaemolyticus* isolated from foodborne outbreaks in South Korea. To select the most virulent strain for genome sequencing, gDNA samples were prepared from the ten strains and subjected to virulence gene-specific PCR. The results indicated that they all have the genes encoding a trans-membrane protein involved in regulating virulence genes (ToxR), a component of putative type III secretion system (VopS), and a collagenase (ColA). Furthermore, the cytotoxicity of *V. parahaemolyticus* strains was evaluated by measuring the activity of cytoplasmic lactate dehydrogenase (LDH) that was released from the INT-407 human epithelial cells. Because the cytotoxicity of *V. parahaemolyticus* #331 was either comparable to or higher than that of *V. parahaemolyticus* KCTC 2471 (positive control), the #331 isolate, which is from sea bass, was selected for genome sequencing and designated as FORC_018. The FORC_018 genome consists of two circular chromosomes of 3,273,522 bp (chromosome I) and 1,772,038 bp (chromosome II), with a G+C content of 45.37 and 45.53, respectively. The entire genome contains 4,498 open reading frames, 37 rRNAs, and 132 tRNA genes. Virulence factors of the *V. parahaemolyticus* FORC_018 were identified using BLAST against Virulence Factor Database (VFDB), demonstrating that *V. parahaemolyticus* FORC_018 has genes encoding thermolabile hemolysin (TLH) and type III secretion system, and lacks genes encoding thermo-stable direct hemolysin (TDH) and TDH-related hemolysin (TRH). This report provides a deeper understanding of *V. parahaemolyticus* and will help future studies on rapid detection, epidemiological investigation, and prevention of foodborne outbreaks of the pathogen.

The Complete Genome Analysis of *Confluentimicrobium naphthalenivorans* Ns6 and Its Naphthalene Degradation Property

Author Block:

H. Jeong, K. Kim, C. Jeon; Chung-Ang Univ., Seoul, Korea, Republic of

Abstract Body:

Confluentimicrobium naphthalenivorans NS6, responsible for naphthalene degradation, was isolated from a tidal flat and naphthalene degradation tests using ^{13}C-naphthalene showed that strain NS6 completely mineralized naphthalene via the gentisate pathway that *Ralstonia* U2 and *Polaromonas naphthalenivorans* CJ2 utilize. In this study, the whole genome of strain NS6 was sequenced for better understanding of its biodegradation properties of polycyclic aromatic hydrocarbons. The complete genome sequencing of strain NS6 is characterized by a circular chromosomal genome of 3.65-Mb with a 64.5% G+C content and three plasmids with 184.7 kb, 157.3 kb, and 156.1 kb sizes. The informatics genome analysis revealed that the genome harbors genes encoding diverse oxygenases, indicating a broad range of degradation ability toward polycyclic aromatic hydrocarbons of strain NS6. However, we could not find out a naphthalene dioxygenase responsible for naphthalene degradation from the genome of strain NS6 by the bioinformatics genome analysis. Therefore, we constructed a phylogenetic tree using Rieske domain sequences of all hydroxylase alpha subunits found from the genome and eventually chose four putative naphthalene dioxygenase genes. To investigate the substrate ranges of the four putative naphthalene dioxygenase genes, they were knock-outed using a double cross-over recombination approach, respectively and the biodegradation abilities of the four knock-out mutant strains were tested against various aromatic hydrocarbons. Eventually, we found complete naphthalene-degrading genes from the genome and we will discuss these in more details in the poster section.

Genomic Comparisons And Pathogenic Potential Of *campylobacter* Isolates

Author Block:

A. M. Weis, D. B. Storey, C. C. Taff, A. K. Townsend, B. A. Byrne, S. A. Woutrina, B. C. Weimer; Univ. of California, Davis, Davis, CA

Abstract Body:

Campylobacter jejuni is the leading cause of gastroenteritis in humans worldwide with recent studies indicating wild birds as zoonotic vectors. American crows, abundant in urban, suburban, and agricultural settings, carry *C. jejuni* as a commensal organism. Studies demonstrating that the crow is a *Campylobacter* zoonotic reservoir are lacking, and no studies have investigated these *Campylobacter* genomes that are distributed among the crow population. To examine pathogenic potential, zoonotic exchange and genomic phylogeny, we sequenced 160 *Campylobacter* genomes from crow, chicken, cow, sheep, goat, and non-human primate origin from the Sacramento Valley, CA. Many genomes displayed high similarity to sequences of isolates implicated in human disease, suggesting these isolates as potential pathogens of public health importance. Tetracycline resistance gene *tetO* was present in 21.9% of the isolates, and 22 isolates (8 *C. jejuni*, 11 *C. coli*, 3 *C. lari*) contained mutations in *gyrA* indicative of Fluoroquinolone resistance. Cytolethal Distending Toxin genes were present in 95% of isolates, 100% contained invasion and adherence genes, and 20% of genomes contained Type IV SS genes. Although resistance and virulence genes were broadly distributed throughout these isolates, specific genotypes were associated with individual host species and a sub-set of isolates were associated with several hosts (i.e. crows, primates, sheep, humans), suggesting that these genotypes may be from zoonotic exchange. This study, utilizing whole genome sequencing (WGS), associated specific *Campylobacter* genotypes that have high potential zoonotic transmission opposed to host adapted genotypes in the samegeographic area to show antibiotic resistance, virulence potential, and zoonotic potential.

Partial Characterization of the Novel Plasmid Pec6.2 Isolated from *Enterococcus casseliflavus* in Puerto Rico

Author Block:

C. Muriel Mundo, N. Rodriguez-Bonano; Univ. Del Este, Carolina, PR

Abstract Body:

Plasmids are extrachromosomal DNA elements associated with the acquisition of new bacterial metabolic and virulent traits. It is well known that these elements contribute significantly to gene flux, evolution and adaptation of bacteria in the environment. Recently, we recovered an Enterococcus casseliflavus isolate harboring a 6.2 kb plasmid (pEC6.2) from a recreational water sample in Puerto Rico. The isolate exhibited susceptibility to 18 antibiotics tested including tetracycline, vancomycin and penicillin. It is unknown if pEC6.2 encodes for antibiotic resistance to other antibiotics besides the ones tested in the laboratory. However, it is also unknown whether pEC6.2 is related to any metabolic traits in E. casseliflavus. The aim of this project was to characterized pEC6.2 and determine which traits are encoded by the plasmid. Prolonged subculturing without selective pressure, DNA extraction and agarose gel electrophoresis demonstrated that pEC6.2 is a stable and high copy number plasmid. Based on sequence analysis, we have determined that there is no similarity between pEC6.2 and other known and characterized E. casseliflavus plasmids, like pEC30. We have not identified antibiotic resistant traits in pEC6.2. Yet, we have identified the replication region (rep) and it exhibits similarity with rep regions from other enterococcal plasmids. Well characterized plasmids from other Enterococcus spp. do not share the same size, stability and copy number with pEC6.2. For these reasons, we believe that pEC6.2 is a new enterococcal plasmid. More recently, we have perform next generation sequencing for pEC6.2 and de novo assembly of pEC6.2 is currently in progress.

Community Stability and Dynamics, Novel Organisms, and Draft Genomes from an Anode-Respiring Microbial Consortium

Author Block:

T. J. Arbour[1], B. Gilbert[2], J. F. Banfield[1]; [1]Univ. of California - Berkeley, Berkeley, CA, [2]Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

Understanding soil microbial communities is a grand challenge due to the vast number of co-occurring species and strains. To obtain a system of reduced complexity and focus on organisms capable of extracellular respiration using insoluble electron acceptors (as well as their syntrophic partners), we used a bioelectrochemical system to enrich for a subset of the total soil community present in subsurface aquifer at the DOE field site at Rifle, CO. Our main aims were to discover potential novel iron(III)-oxide reducers and to examine the stability and dynamics of the microbial community over a range of timescales. In our bioelectrochemical system, a graphite anode poised at a voltage to mimic the redox potential of iron(III) oxide minerals serves as the only added electron acceptor, and acetate served as electron donor. We sampled anode-biofilm and planktonic communities over a period of almost three years under varying conditions of acetate abundance or limitation. We used next-generation metagenomic sequencing and genome assembly to profile the microbial community present in each sample. We recovered ~130 near-complete and partial genomes across more than 10 phyla/classes, including that of a novel Deltaproteobacteria that was the most abundant organism in anode biofilm samples. Outside of the Deltaproteobacteria, several other organisms not known to perform extracellular electron transfer have an abundance of multiheme *c*-type cytochromes that suggests this ability. The stability of the community through time, species co-occurrence patterns, and new metabolic insights will be presented.

Physiology Of *Pseudomonads* isolated From Groundwater That Proliferate More Effectively In Co-Culture Than In Monoculture Under Denitrifying Conditions

Author Block:

A. B. Aaring[1], A. Pettenato[1], A. M. Deutschbauer[1], M. W. W. Adams[2], **R. Chakraborty**[1];
[1]Lawrence Berkeley Natl. Lab., Berkeley, CA, [2]Univ. of Georgia, Athens, GA

Abstract Body:

As part of the Ecosystems and Networks Integrated with Genes and Molecular Assemblies (ENIGMA) consortium, we study the microbial community at the U.S. Department of Energy's Field Research Center (FRC) in Oak Ridge. The groundwater at this site contains plumes of nitrate with concentrations up to 14,000mg/L among other contaminants. Several strains of *Pseudomonas* were isolated from the same background groundwater sample. These isolates utilized diverse carbon sources ranging from acetate to glucose while growing under denitrifying conditions. Analysis of their genomes revealed that each strain contains circa 1000 genes distinct from each other. Full genome sequencing supported by metabolite analysis showed that some strains lacked any genes for nitrite reduction, leading to buildup of nitrite. The strains were also screened for nitrate tolerance and a couple of them were shown to be tolerant to 300-375 mM nitrate under anaerobic conditions. In the field site the bacteria live in consortia rather than in isolation, therefore we hypothesized that growth of these strains will be more robust in co-culture, as the denitrification pathway was segmented between the species. Three of the isolates (*Pseudomonas fluorescens* strains N1B4, N2E2, N2E3) were selected for in-depth analysis based on growth in pairwise co-cultures relative to monocultures, and the availability of the relevant genetic tools, such as transposon mutant libraries. Our results show strain N1B4 (with truncated denitrifying pathway) grows more quickly and to greater density in co-culture than in monoculture. Utilizing RB-TnSeq libraries of our strains, it was also found that some genes involved in nitrate reduction, sulfate permeability, molybdenum utilization, and anaerobic reduction are important for growth under these conditions. In addition, a few uncharacterized genes were also shown to be positively correlated to growth. These data help to broaden our understanding of how bacteria interact and grow in conditions that are relevant to the environment and enable us to probe the ways in which bacterial communities interact and overcome genetic deficiencies of individual strains to deal with environmental conditions.

Mechanisms of the Antagonistic Interaction between *Phaeobacter inhibens* and Fish Pathogenic Vibrios

Author Block:

B. Rasmussen, C. Phippen, K. Nielsen, L. Gram, M. Bentzon-Tilia; Technical Univ. of Denmark, Kgs. Lyngby, Denmark

Abstract Body:

Bacteria of the prevalent marine *Roseobacter* clade, e.g. *Phaeobacter inhibens*, are capable of antagonizing fish pathogenic bacteria such as *Vibrio anguillarum* and *V. harveyi*. Adding *P. inhibens* as a probiotic in fish larvae and live feed have congruently been shown to inhibit the proliferation of fish pathogenic vibrios and to increase survival of the larvae. One antibiotic compound, tropodithietic acid (TDA), is important in this interaction. It is, however, not exclusively responsible for the observed antagonism as TDA deficient mutants only exhibit reduced inhibitory activity. Hence, the mechanisms behind the antagonistic interaction between *P. inhibens* and vibrios are not fully understood and the purpose of the present study was to investigate if other bioactive compounds could potentially be involved. By combining genome mining, bioassays and UHPLC-DAD-QTOFMS analysis we examined closely related TDA producing strains of which some do, and some do not show TDA-independent inhibition of vibrios. We identified several gene clusters encoding potential bioactive compounds, which could be attributed to TDA-independent inhibition, including a siderophore cluster, a linaridin-like cluster, and a putative nonribosomal peptide synthetase cluster. Extracts of wild type strains and TDA-negative mutants were made to isolate potential bioactive compounds. The strains were pre-cultured under different conditions prior to testing in inhibition assays. Inhibition zones only emerged when strains were grown on plates with vibrio embedded before extraction and only if they were pre-cultured in nutrient rich medium. We were able to extract one or more bioactive compounds directly from *P. inhibens* biomass from vibrio-embedded plates, but not from liquid culture, or the plates themselves. Hence, it is likely that multiple secondary metabolites are involved in the antagonism of vibrios by *P. inhibens*.

Physiological and Molecular Characterizations of the Microbial Interactions in Cocultures for Methane Production from Cellulose

Author Block:

H. Lu, P. Lee; City Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

Biomethanation can be harnessed for both effective waste treatment and sustainable energy production. This process in nature is driven by a complex microbial community mainly consisting of three metabolic groups of anaerobes: fermentative, acetogenic and methanogenic microorganisms. The interspecies interactions in the biomethanation community play a vital role in biomass degradation and methane formation. However, the physiological and molecular mechanisms of how these microbes interact remain poorly understood due to the lack of an experimentally tractable model system. In this study, we successfully established two experimentally and genetically tractable models combining the cellulose-degrading bacterium *Clostridium cellulovorans* 743B (*CC*) with *Methanosarcina barkeri* str. Fusaro (*MB*) and *Methanosarcina mazei* Gö1 (*MM*) respectively for the direct conversion of cellulose to methane. Physiological characterizations of these models revealed that the methanogens were able to efficiently utilize hydrogen, formate and acetate produced from *CC* during cellulose degradation, for methanogensis through the CO_2 reduction pathway and aceticlastic pathway. In return, the consumption of hydrogen, formate and acetate helped to maintain a thermodynamically favorable condition and a neutral pH for *CC* in the coculture systems, resulting in enhanced cellulose degradation. Interestingly, although formate consumption was observed in cocultures of *MB* and *CC*, *MB* monocultures were not able to utilize formate for growth. Furthermore, next-generation sequencing was used to query the global transcriptomic responses of these models to obtain a more comprehensive understanding of the interspecies interactions. Overall, the combination of physiological and molecular characterizations of these two models deepens our understanding on interspecies interactions for methane production from cellulose, providing useful insights for better industrial biomethanation process design.

Metatranscriptomic and Metaproteomic Insights into Long-Term Cellulose and Xylan Enrichments from Anaerobic Digesters

Author Block:

Y. Jia, P. K. H. Lee; City Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract Body:

A number of amplicon 16S rRNA gene and metagenomic studies have previously investigated cellulosic biomass anaerobic digestion microbial communities. However, genome-based study alone cannot provide information related to the activity of the microbial populations. In contrast, transcriptomics sequencing and mass-spectrometry based proteomics can provide comprehensive information on the active metabolic pathways and enzymes within a microbial community.In this study, based on our previous 16S rRNA gene sequencing and metagenomic results, metatranscriptomics and metaproteomics were applied to five enrichment cultures at the mid-exponential phase of growth in batch systems. The enrichments originated from two different anaerobic digesters and have been fed cellulose or xylan as the sole carbon source at 35 or 55 ^{o}C for over 3 years. A 15-days time course experiment was also carried out to reveal the dynamics of the microbial activities in two mesophilic cellulose cultures. Results of one of the time course mesophilic cellulose cultures showed that, transcripts assigned to the order *Clostridiales* had a relative abundance of 74% by day 5 and then gradually decreased to ~45%, indicating *Clostridiales* were one of the key functional populations. Reads belonging to *Methanobacteriales* did not make up a significant portion (~2.7% by day 15) of the entire transcriptome. Functional analysis of the metatranscriptomes indicated that protein metabolism, motility and chemotaxis, and carbohydrates were the three most highly transcribed subsystems. From the metaproteomics analysis, more than 900 unique proteins were identified against a customized database constructed using reads from both the metagenomes and metatranscriptomes. Besides basic central metabolism, proteins involved in carbohydrate and membrane transport were highly expressed, which is consistent with the cellulose-digestion functions in the enrichments. Overall, multi-omics tools have shed new insights into the cellulose- and xylan-digestion enrichments, and such detailed understanding could aid the development of cellulosic biofuels.

Revealing the Complexity of Electrode Respiration Using Tnseq in *Geobacter sulfurreducens*

Author Block:

C. Chan, C. Levar, F. Jimenez, D. Bond; Univ. of Minnesota Twin Cities, St. Paul, MN

Abstract Body:

G. sulfurreducens grows with poised graphite electrodes as terminal electron acceptors by transmitting electrons through a system of membrane and surface proteins. Thus far, the genes important for sensing and responding to this environment have been identified by first screening mutants defective in Fe(III) reduction, or from predictions based on expression analyses. To directly identify mutants impaired in electrode respiration, we constructed a *mini*Himar RB1 transposon library in *G. sulfurreducens* using a transposon modified to contain Type IIS MmeI recognition site, enabling Illumina adapter ligation for mass sequencing to identify genomic insertion sites. About 45,000 insertional mutants were pooled and grown on soluble acceptors or poised electrodes. By comparing the frequency of insertions in each library after the same number of doublings, transposon insertions in 126 genes were identified that resulted in at least a calculated growth rate decrease of 25%. We categorize these broadly in five groups- cytochromes (5 genes), protein secretion and lipoprotein maturation (14), regulation and sensing (41), exopolysaccharides and attachment (38) and hypotheticals (28). Unexpectedly, after reconstruction of mutants identified from this analysis, many of these mutants are defective in electrode reduction, but retain wild type Fe(III) reduction activity. These include a cytochrome conduit cluster, and genes encoding cell signaling pathways. This suggests that *G. sulfurreducens* possesses dedicated pathways for sensing and colonizing surfaces that poised electrode mimic, and that electrodes do not always simulate Fe(III) as an electron acceptor. Additionally, genes encoding extracellular cytochromes were not detected in our analysis, suggesting these cytochromes could be shared when growing on electrodes. Analysis of the parent *G. sulfurreducens* TnSeq library also revealed essential genes for growth on the soluble acceptor fumarate, many of of which were not predicted in previous modeling studies due to insufficient data or having multiple homologs on the chromosome. Future work will focus on these new molecular mechanisms and regulatory networks specific for electrode respiration.

A Comprehensive Comparative Transcriptomic Analysis of *Penicillium chrysogenum* Treated with Two Enantiomers of 1-Octen-3-ol

Author Block:

G. Yin[1], Y. Zhang[2], K. Pennerman[1], G. Wu[3], J. Yu[4], W. Jurick II[4], S. Lee[1], L. Bu[5], Q. Huang[2], J. Bennett[1], A. Guo[2]; [1]Rutgers, The State Univ. of New Jersey, New Brunswick, NJ, [2]Chinese Academy of Tropical Agricultural Sci., Haikou, China, [3]US Dept. of Energy, Oak Ridge, TN, [4]Dept. of Agriculture, Beltsville, MD, [5]Dept. of Biology, Albuquerque, NM

Abstract Body:

Fungal volatile organic compounds have different roles in many biological processes. Well-known for its "mushroom" odor, the aliphatic alcohol 1-octen-3-ol is gaining attention because of its irritant and Parkinsonism neurodegenerative effects. The R and S enantiomers of 1-octen-3-ol have distinguishable influences on the health and behavior of diverse organisms. However, the molecular basis for these effects is poorly understood. Therefore, a comprehensive comparative transcriptomic analysis of *Penicillium chrysogenum* was performed via treatment with the two enantiomers. Altogether, about 80% of clean reads could be mapped to the reference genome and the transcriptome data were annotated to 11,396 genes. The top three active pathways were metabolic (978 transcripts), biosynthesis of secondary metabolites (420 transcripts), and microbial metabolism in diverse environments (318 transcripts). With respect to the control, treatment with R affected the transcription levels of 91 transcripts, while S affected only 41 transcripts. Additionally, 136 transcripts were up-regulated and 3 were down-regulated in fungi treated with R compared to S enantiomer (FDR < 0.05). Go functional enrichment analysis demonstrated that most differential expressed genes (DEGs) were annotated to be involved in biological process. Comparing S to R treatment, it was determined that transport, establishment of localization, transmembrane transport were significantly altered (*p*-value < 0.001). Alternative splicing and SNPs analyses indicated that R could impose greater effects on *Penicillium* than S. The qRT-PCR analyses of DEGs such as ABC transporter, MFS transporter, PPos *etc*., confirm the transcriptome data. This study represents the first step in elucidating the global molecular mechanisms by which 1-octen-3-ol enantiomers differentially affect fungal growth and development. Data from this pioneering investigation provide foundational information to target specific genes for functional analysis to better understand fundamental processes of volatile signaling in fungi.

Unraveling Lanthanide-Dependent Methylotrophy

Author Block:

N. M. Good, C. Suriano, **N. Martinez-Gomez**; Michigan State Univ., East Lansing, MI

Abstract Body:

The recent finding that rare earth elements like lanthanides are essential cofactors for many methylotrophic bacteria provides opportunities to investigate discoveries surrounding biological acquisition and biochemistry with potential changes in carbon distribution during methylotrophic growth. The role of methylotrophs in global carbon cycling and global warming is pivotal, as methane and methanol are the two most abundant organic compounds in the atmosphere and methane is a potent green-house gas.[1] Metabolism of both methane and methanol require the oxidation of methanol, which can be catalyzed by methanol dehydrogenases (MeDHs). Recently, it was shown that some types of MeDHs, specifically XoxF-MeDHs, are induced by and use lanthanides as cofactors.[2,3] Our preliminary Illumina-based transcriptome data (RNA-seq) from *M. extorquens* grown in methanol medium in the presence and absence of La^{3+} has allowed us to predict additional components involved in La^{3+}-dependent methylotrophic growth. Of special interest among the La^{3+}-upregulated genes are those encoding a quinoprotein ethanol dehydrogenase (ExaF). Purified ExaF was found to contain PQQ and La^{3+}, and have relatively poor methanol dehydrogenase activity but high catalytic efficiency with formaldehyde. Both phenotypic and biochemical analyses have demonstrated that ExaF directly produces formate from methanol. Such oxidation has important consequences for metabolism including the benefit of decreasing toxic formaldehyde production, but also the disadvantage of bypassing a formate production pathway which produces NAD(P)H for carbon assimilation. Also of interest, upregulation of genes involved in oxalate and formate metabolism such as formate dehydrogenase (Fdh4), formyl-CoA transferase (Frc12), and oxalyl-CoA reductase (Oxr) was found in our RNAseq studies. It has been suggested that Fdh4 is the most crucial Fdh in methanol metabolism although it is the one we know the least about;[4] it may be that Fdh4 activity can only be measured in cells grown with lanthanides. Our preliminary HPLC analyses corroborate increased accumulation of formate and oxalate in extracts from cells grown on methanol with La^{3+}. Our results confirm that the lanthanide-dependent metabolic network includes novel methanol oxidation systems and changes in carbon assimilation suggesting that the methylotrophic bacterial community may be underestimated.

***Vibrio fischeri* as a Biosensor of Emerging Contaminants**

Author Block:

N. Rosario-Meléndez, M. Tolentino, D. M. García, J. Pérez, Z. Y. Mercado, L. Díaz, Z. Flores-Cruz; Univ. of Puerto Rico-Rio Piedras, San Juan, PR

Abstract Body:

Fertilizers, pesticides, pharmaceuticals, and personal care products are used in everyday life by millions of people. However, the disposal of these substances is not regulated; therefore they are not being removed in treatment facilities, which cause them to end up in the ocean. The effect these chemicals might have on living organisms, or their combination is not known and there are no efficient ways to detect them. As an alternative to these problems we used the marine bioluminescent bacterium *Vibrio fischeri* as a biosensor. *V. fischeri* is a well studied bacteria known for its ability to emit bioluminescence. For this purpose we grew the bacteria in the presence of various emerging contaminants. The growth of *V. fischeri* was not affected by the tested contaminants, with the exception of known antibiotics. In contrast, bioluminescence changed significantly in presence of caffeine (dietary supplement) and amlodipine besylate (prescription medication). These results suggest that *V. fischeri* could be used for the detection of emerging contaminants. Future work includes testing other emerging contaminants, and a metabolomic analysis to observe how *V. fischeri* is metabolizing the contaminants.

Effects of Water Temperature and Toc Leached from Pex Pipes on the Occurrence of Bacterial in Household Water Distribution Systems

Author Block:

M. Wang, M. E. Salehi, A. J. Whelton, Z. Zhou; Purdue Univ., West Lafayette, IN

Abstract Body:

Background: Although tap water is treated in drinking water treatment plants before it reaches our faucets, bacteria may still grow in the household water distribution systems and pose potential health risks. However, studies on the factors that may affect the occurrence of bacteria in drinking water pipes are still limited. The objective of this study was to examine the effects of water temperature and total organic carbon (TOC) leached from PEX pipes on the occurrence of bacteria in domestic water distribution systems. **Methods**: Tap water samples from eight locations in a three-story domestic residential house in Indiana were collected in this study. Culture-based heterotrophic plate count (HPC) method was used to measure the numbers of heterotrophic bacteria in tap water, and culture-independent real-time PCR assays were used to quantify gene copy numbers of bacteria in tap water. Samples were collected at day 0, 3, 15, 30, 60 and 90 after a 30-minute flushing before sample collection. **Results**: During the 90 days, the bacterial gene copy numbers increased from 2.82×10^{3}-1.5×10^{6} to 2.41×10^{4} -1.67×10^{7} per liter. The results showed that the occurrence of bacteria in hot water pipes in the drinking water distribution systems was 55.49 times higher than those detected in cold water pipes. A positive correlation between TOC levels and bacterial gene copy numbers was detected ($R^2 = 0.61$, $p = 0.065$) in the hot water pipe in the basement. **Conclusion**: The results suggested that the temperature and TOC leached from PEX pipes may promote bacterial growth in drinking water distribution systems.

Response of Bacteria Isolated from Segment of River Asa to Linear Alkylbenzene Sulfonate (LAS)

Author Block:

K. I. T. Eniola[1], T. M. Kayode-Isola[2]; [1]Joseph Ayo Babalola Univ., Ikeji-Arakeji, Ilesa, Osun State, Nigeria, [2]Adeniran Ogunsanya Coll. of Ed., Otto-Ijanikin, Lagos, Nigeria

Abstract Body:

Responses of bacterial species isolated from segments of river Asa in Ilorin Nigeria to linear alkylbenzene sulfonate (LAS) were assessed in terms of ability or failure of the organisms to grow in the presence of varying concentrations of LAS. A total of twenty two (22) bacterial strains belonging to eight (8) species: *Alcaligenes odorans*(3 strains), *Bacillus subtilis* (3strains), *Citrobacter diversus*(3 strains) ,*Escherichia coli* (3 strains), *Klebsiella* spp (3 strains), *Micrococcus luteus* (2 strains), *Pseudomonas* spp (3 strains), and *Staphylococcus* spp (2 strains) were isolated. The isolates varied in their responses to different concentrations of LAS and were categorized as LAS-sensitive bacteria (LSB), LAS-tolerant bacteria (LTB) and LAS-utilizing bacteria (LUB). Fifteen (15) of the strains were tolerant of LAS (0.1% w/v) (LTB) and Seven (7) isolates were sensitive to LAS (0.1% w/v) (LSB). Seven (7) of the LAS tolerant bacteria showed potential to degrade LAS. Strains of the same species isolated from sediment (biofilm) were more tolerant of LAS than their planktonic counterparts, this difference could be genetic, and hence a detailed comparative study of the genome of the organisms would be desirable. The pattern of their responses may be relied upon in assessing water bodies for detergent pollution and some of the strains may be explored for bio-treatment of detergent bearing waste.

Screening of Algicidal Bacteria and Development of Bio-Eco Ceramic System for Controlling Harmful Algal Blooms (*Cochlodinium polykrikoides*) in Fish-Raising Farm

Author Block:

S. Moon[1], J. Kim[1], S. Kim[1], J. Bang[2], T. You[3], T-K. Lee[4], S-S. Lee[1]; [1]Kyonggi Univ., Suwon, Korea, Republic of, [2]North Carolina Central Univ., Durham, NC, [3]Campbell Univ., Buies Creek, NC, [4]Korea Inst. of Ocean Sci. & Technology, Geoje, Korea, Republic of

Abstract Body:

Harmful algal blooms (HABs) have made massive economic losses and marine environmental disturbances. Normally, loess was scattered to control HABs in Korea, but it arises secondary contamination problems. Therefore, development of highly effective and eco-friendly strategies are required to control the HABs. In the present study about 300 bacterial strains were screened which kills the *Cochlodinium polykrikoides*, a major kind of HABs in Korea. From the screening result, strain 2R1 was selected for further study which showed 98.9% algicidal activity against *C. polykrikoides* at their optimal growth conditions (modified marine broth with 1% NaCl at 28℃). Moreover, selective algicidal activity of strain 2R1 was also tested against few more HABs in Korea such as *Chatonella marina, Heterocapsa triquetra, Heterosigma akashiwo, Scrippsiella trochoidea, Skeletonema costatum* and *Prorocentrum minimum*. Strain 2R1 did not showed any activity against these algal blooms. To supply and preserve strain 2R1 continuously, an algicidal reactor with bio-eco ceramics was developed consisting of the strain and multi-pore ceramics. This system resulted in more than 94.0% of algicidal activity when the bacteria grown on their optimal conditions. From this study, it was determined that the strain 2R1 have selective algicidal activity against *C. polykrikoides* and the strain had no efficiency about other six kinds of HABs. The extracted algicidal activity materials were further analyzed by GC-MSD which indicated them as 7-Methyl-8-hydroxyquinoline and 1-Methyl-β-carboline. In conclusion, the present research have devised an innovative bioreactor system which have very high potential to control HABs. In addition, two promising algicidal compounds are also identified having HABs removal activity.

Enrichment and Isolation of Lead-Resistant Bacteria from Saint Claire River Sediments

Author Block:

N. Bowman, M. Fenner, R. Gismondi, D. Patel, A. Oest, D. Azzopardi, S. Tiquia-Arashiro; Univ. of Michigan-Dearborn, Dearborn, MI

Abstract Body:

One of the most common heavy metals present in polluted waters is lead (Pb). Certain bacteria have the ability to resist and reduce lead's toxic effects and play a role in bioremediation. Two enrichment experiments using LB and R2A broths containing 10g of sediments and increasing concentrations of Pb (NO3)2 were carried out to isolate Pb-resistant strains. The enrichments were incubated at room temperature and shook at 250 rpm; aliquots were transferred to fresh media after 48 hours three times. Cells that grew in LB (1500 mg/L) and R2A (1250 mg/L) were serially-diluted and plated. Colonies on the plates were isolated, purified, and the resulting 92 pure cultures were transferred onto slants. Optical density (550 nm) was used to measure cell viability and Pb-resistance. The specific growth rates in LB and R2A enrichments were 0.604h-1 and 0.426h-1, respectively. Relative growth rates of cells in high Pb concentration enrichments did not grow as much as lower concentration enrichments, however they grew well compared to the control. Bio-flocculation assay was performed on each isolate using Kaolin solution and CaCl to assess their ability for extracellular Pb sequestration. For R2A, seven out of 20 isolates produced optimal flocculent product, ranging from 23-40%. For LB, eight out of 21 isolates produced optimal flocculent product, ranging from 25-57%. To continue the research, various lead resistant mechanisms such as efflux mechanism, extracellular sequestration, biosorption, precipitation, enhanced siderophore production and intracellular lead bioaccumulation must be tested on these isolates to determine the best strains for Pb bioremediation.

Influence of Natural Coagulants and Biosand Filtration on the Characteristics of Cassava Starch Processing Wastewater and Its Reuse in Irrigation

Author Block:

J. O. OLAITAN, Dr, S. B. AKINDE, Dr, S. A. Adebisi, I. O. AWONIYI, O. O. OLUWAJIDE, O. R. AKANGBE, C. O. BABATUNDE; Osun State Univ., Osogbo, Nigeria

Abstract Body:

This study evaluated the effectiveness of natural coagulants and biosand filter in the reduction of physico-chemical and microbiological hazards in wastewater from cassava starch processing plant. Cassava wastewater was collected fresh from a large-scale cassava starch-processing factory in Ogbese, Southwest Nigeria. The experimental setup was conducted at the Biology Laboratory of Osun State University, Osogbo, Nigeria. The natural coagulants used include *Moringa oleifera* seeds, activated charcoal of *Manihot esculenta* (cassava) peel, activated charcoal from *M. oleifera* husk and laterite. Jar test experiment was used to determine the effective coagulation-flocculation dosage of the natural coagulants. The physico-chemical parameters and microbiological analysis were determined in accordance with internationally acceptable methods. The result showed high improvement in the turbidity and cyanide contents and high reductions in heavy metals concentration after each treatment. A significant improvement on the BOD, COD and TSS was also observed after each treatment. The BOD value was reduced within the range of 19.17 and 7.43mg/l while COD was within 96.23mg/l and 38.4mg/l. The total suspended solid reduced drastically between 151.66mg/l and 19.00mg/l. In terms of the microbial characteristics, the total coliform count was greatly reduced compared to reduction in both THB and THF. It was observed that the use of biosand filter was highly effective and economically friendly in the treatment of cassava wastewater compared to the natural coagulants thus significantly reducing the potential hazard to the environment.

A Bacterium *Nocardioides kribbensis* Isolated from Sekoto River Produces a Thermostable Glycoprotein Flocculant

Author Block:

M. Agunbiade; Univ. of Free State, Qwaqwa, South Africa

Abstract Body:

Background: Chemical flocculants have been widely used in waste water treatment, potable water production and fermentation industries. However, despite the low cost and high efficiency, there usage has posed a negative threat on aquatic life and environment. Hence there is a need to replace synthetic flocculants with environmentally friendly flocculants.**Methods:** Twenty five bioflocculant producing actinomyces strains were isolated from the Sekoto River in Eastern Free State Province of South Africa. Strain SR7 exhibited the highest flocculating activity out of these strains. The 16S ribosomal DNA confirmed the bacteria to have 100% similarity to *Nocardioides kribbensis* strain DS4-2B and the nucleotide sequence was deposited in GenBank as *Nocardioides kribbensis* accession number KM891548.1.**Results:** Optimum flocculating activity was attained at 48 h using galactose, yeast extract and Ca^{2+} as sole sources of carbon, nitrogen and cations respectively at an alkaline pH of 11. Inoculum size of 3% (v/v) supported the efficiency of bioflocculant production and 3.97 g was recovered from 1 Litre of the culture broth. The chemical composition of the purified bioflocculant revealed 78.5% sugar and 20.2% protein content. Energy Dispersive X- ray analysis confirmed elemental composition of the purified bioflocculant in mass proportion (%w/w): carbon (7.13), oxygen (40.6), sodium (30.58), phosphorous (20.86) and potassium (0.82).**Conclusions:** The purified bioflocculant exhibited highest flocculating activity when compared with other conventional flocculants. Thus, its application could serves as a replacement for chemical flocculants in the treatment of waste and drinking water.

Characterization of Sulfate Reducing Bacteria for Removing Selenate from Flu Gas Desulfurization Wastewater

Author Block:

T. Wu; Georgia Southern Univ., Statesboro, GA

Abstract Body:

Selenate, SeO_4^{2-}, is the most oxidized form of selenium. It is water soluble and highly toxic. Selenate is currently found at high levels in coal power plant Flu Gas Desulfurization (FGD) wastewater; the United States Environmental Protection Agency (EPA) requirement for selenate is up to10 ppb. This study involves selecting a biological method to reduce selenate, selecting selenate reducing bacteria, and determining the carbon source affecting the selenate reduction rate. Sulfate reducing bacteria are able to reduce selenate, and are obtained from activated sludge. The bacteria were cultured using Sulphate Reducing HiVeg Medium. The carbon sources tested were sodium lactate and methanol. DNA was extracted and partially nested Polymerase Chain Reaction (PCR) approach was used to amplify *dsrB* gene (350bp). Primer sets used for amplification include DSRmixF/DSRmixR and DSRp2060-GC/DSR4R. The *dsrB* gene contains the sequence for enzymatic activity known to reduce sulfate. Denaturing Gradient Gel Electrophoresis (DGGE) was applied to detect the presences of *dsrB* gene in samples. Samples were analyzed by inductively coupled plasma triple quadrupole mass spectrometry (ICP-QQQ-MS) for selenate reductions. DGGE confirmed the presences of *dsrB* gene in samples and presented a community outlook of sulfate reducing bacteria based on band intensity. Selenate reduction was significant in sodium lactate medium. Dissolved selenium decreased 73 % at day five and additional 56% at day ten. In the samples of methanol as carbon source, dissolved selenium decreased 58% at day five and additional 67% at day ten. At day ten there is no significant difference between methanol and sodium lactate. Biological components to selenate removal utilizing microbial agents have been found to be the key entities in the biogeological cycling of selenium in the environment and have a great potential for the removal of selenate from FGD wastewater.

Development of Microorganisms Based Effluent Treatment System to Remove Nitrogen and Phosphorus from Land Fish Farms

Author Block:

K. Kim[1], J. Kim[1], S. Kim[1], J. Bang[2], T. You[3], T-K. Lee[4], S-S. Lee[1]; [1]Kyonggi Univ., Suwon, Korea, Republic of, [2]North Carolina Central Univ., 1801 Fayetteville St, NC, [3]Campbell Univ., 143 Main st., NC, [4]Korea Inst. of Ocean Sci.&Technology, Geoje, Korea, Republic of

Abstract Body:

Background: Red tide blooms have made massive economic losses and marine environmental disturbances in coastal region of Korea. This research was focused to develop an effective biological Anaerobic/Anoxic/Oxic (A^2O) treatment system for Land Fish-farm with highly efficient nitrogen and phosphorus removing bacteria and sediments.**Methods:** High efficient bacteria were isolated from the emerging algal blooms sites at Southern coastal of Korea. A total of 960 strains were determined by their nitrogen and phosphorus removal efficiency.**Results:** From screening, *Bacillus aryabhattai* strain KGN1 and *Vibrio neocaledonicus* strain KGP1 showed more than 86.0% nitrogen and 99.9% phosphorus removal efficiency in 10 h, respectively. Interestingly, when consortia of strain KGN1 and KGP1 were made they were able to remove both nitrogen and phosphorus up to 98.0% for 10 h in a batch culture. Furthermore, both strains with sediments were employed to lab-scale A^2O biological treatment system and then operated for 7 months with various operating factors such as different HRT, F/M ratio, aerobic/anaerobic time, volumetric ratio. The optimal conditions for highest effluent treatment were as HRT 6 h, F/M ratio 0.27, intermittent aeration for 30min, volumetric ratio of 1:0.95:1.4 and internal recycle of 1 Q. The reactor showed T-N of 95.6%, NH_3-N of 97.3%, T-P of 97.6% and PO_4^{3-}-P of 96.0% removal efficiency, respectively. The kinetic parameters of the optimal operating condition were 0.17 d^{-1} for specific growth rate (μ) and 2.26 $mgMLVSS/mgSCOD_{Cr}$ for yield (Y). At the optimal operating condition, 20% of both the strains in the microbial community of eco-friendly sludge were maintained and confirmed by NGS analysis. **Conclusions:** In conclusion, this study will be contributed on study of efficient saline wastewater treatment system of land fish farms and near costal area. Finally, the study could be one of helpful tools to solve the cause of red tide blooms in a long-term aspect.

Abstract Body:

Research has been rarely reported to develop saline wastewater from land fish-farm. Unfortunately, several systems require very high costs to operate and treat saline wastewater from land fish-farm and coastal area. Thus, there are urgent requirements to develop the low cost and eco-friendly systems for land fish farms. This study was conducted to apply eco-friendly sediment with high efficient bacteria to lab-scale biological SBR system for saline wastewater from land fish-farms. Nitrogen and phosphorus high removal efficient bacteria were screened of 960 strains isolated from seawater and sediment. Nitrogen removal high efficient bacteria *Bacillus aryabhattai* strain KGN1 and phosphorus removal high efficient bacteria *Vibrio neocaledonicus* strain KGP1 were designed as 86.0% nitrogen removal efficiency and 99.9% phosphorus removal efficiency in 10 h, respectively. High efficient bacteria were applied to marine sediment as eco-friendly material, and adapted to make eco-friendly sludge. The eco-friendly sludge was applied to lab-scale SBR system and operated for 7 months with various operating 7 conditions. Lab-scale biological SBR system showed nitrogen and phosphorus removal efficiency with 87.0% and 76.6%, respectively in optimal operating condition (3h/cylcle): aeration for 1 hour, settle for 1 hour and idle for 1 hour at the total volume of 40 L. The optimal kinetic parameters were 0.33 of food-to-mass ratio (F/M ratio), 0.41 of cell yield coefficient (Y), 0.64 of specific growth coefficient (μ) and 0.63 of sludge volume index (SVI), respectively. In addition, NGS (next generation sequencing) and qPCR analysis showed the abundance of *Vibrio neocaledonicus* strain KGP1 was maintained and adapted up to 32% of total microbial community of activated sludge in the lab-scale SBR reactor. From the study, our findings will give possible solution to develop biological treatment of saline wastewater from land fish-farm eco-friendly.

Carbapenemases among *Acinetobacter* spp. Isolated from NICU of a Tertairy Care Hospital in Karachi

Author Block:

F. uddin[1], A. Bux[1], M. A. Durrani[1], M. Sohail[2]; [1]Basic Med. Sci. Inst., Jinnah Postgraduate Med. Ctr., Karachi, Pakistan, [2]Univ. of Karachi, Karachi, Pakistan

Abstract Body:

Background: Resistance to multiple classes of antibiotics and especially to the carbapenem is an increasing global problem. The gravity of the problem is ever increasing in the developing counteries where infection control practices are limited. Carbapenem-resistant Acinetobacter spp. has emerged in healthcare facilities and considered as just a tip of an ice berg. The resistance to carbapenem is mainly due to loss of porin or carbapenemases. The current study was designed to determine the carbapenemases in carbapenem-resistant Acinetobacter spp. **Methods:** Study was carried out at the Department of Microbiology, Basic Medical Sciences Institute, Jinnah Postgraduate Medical Centre. The carbapenem-resistant *Acinetobacter* strains were collected from NICU of a tertairy care hospital of Karachi. The *Acinetobacter* at species level were identified by using the API 20NE and screening of carbapenem resistance was performed by meropenem and imipenem discs and MICs, by IMP 32 µg/ml Etest strips. The carbapenemase production was detected by RAPIDEC® CARBA NP (Biomeriux, France). The Class B and A carbapenemase production was detected by phenotypic EDTA and boronic acid double disc diffusion test respectively. **Results:** A total of 100 *Acinetobacter* species were collected from the clinical speciemens of neonates. The samples were blood and tracheal aspirates. The patients age ranged from 1-28 days. The main species (95%) was *Acinetobacter calcoaceticus baumannii complex* (ABC), followed by *Acinetobacter lwoffii (*5%). The overall resistance to carbapenem was 95% but higher (100%) in *Acinetobacter lwoffii* in comparision to *Acinetobacter calcoaceticus baumannii complex* (ABC) which was 94.7%. Phenotypic characterization revealed that 93.6% of both the species were class D carbapenemase producers, of which 2.10% were MBLs and 4.2% were non-producers. **Conclusions:** The study revealed that amongst Carbapenem-resistant *Acinetobacter spp*. the class D carbapenemases are the main mode of resistance to carbapenems.

Comparison of Maldi-Tof MS Speciation of *Acinetobacter* with Antibiotic Susceptibility Results at a Tertiary Healthcare Facility

Author Block:

P. DeMoss[1], M. Roiko[2], B. H. Schmitt[3]; [1]Univ. of Mississippi Med. Ctr., Jackson, MS, [2]Altru Hlth.System, Grand Forks, ND, [3]Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Background: *Acinetobacter baumannii* can be an highly resistant nosocomial infection, with other Acinetobacters reported as less resistant. Differentiation of *Acinetobacter* spp. has been difficult historically. Other Acinetobacters, thought to be less pathogenic, are reported as possibly incorrect species, due to practical laboratory limits. MALDI-TOF MS, shown capable of unambiguously identifying many organisms to the species level, provided fidelity in speciation of Acinetobacter. Here we investigate whether *Acinetobacter* spp. identified by MALDI-TOF MS have differing antibiotic susceptibility profiles, supporting the clinical utility of further speciation of *Acinetobacter* spp. **Methods:**223 clinical isolates of *Acinetobacter* species were compared. Due to previous reporting standards, MALDI-TOF results were initially reported to the genus level, with O/F glucose tests used to further classify as *A. baumannii* or *A. lwoffii*. with some isolates identified by Vitek-2. Subsequently, only five species of *Acinetobacter* were reported during the study timeframe. Antimicrobial susceptibility testing was performed on all isolates. **Results:**Analysis of MALDI-TOF MS results alone identified 13 different species. 148 *A. baumannii* species complex and 68 *A. lwoffii* were identified, among others. 57% of reported *A. baumannii* species were identified as *A. baumannii* by MALDI-TOF and 29% identified as *A. pittii*. For reported *Acinetobacter lwoffii* species, isolates were identified as *A. ursingii* (32%), *A. lwoffii* (26%), *A. radioresistens* (18%), and *A. junii* (15%). MALDI-TOF MS identified *A. baumannii* displayed a much higher level of resistance compared with other members of the *A. baumannii* complex ($p<0.005$), with 70% non-susceptible to five or more antibiotics (compared to none for other members of *A. baumannii* complex). No statistical difference was seen in susceptibiltiy between *A. lwoffii* and others previously identified as *A. lwoffii*.**Conclusions:**Analysis of MALDI-TOF identification in conjunction with susceptibility testing demonstrated that true *A. baumannii* demonstrated significantly less susceptibility than other complex members, while *A. lwoffii* members did not show a statistical difference in non-susceptibility.

Susceptibility of Carbapenem-Resistant *Acinetobacter baumannii* and *Pseudomonas aeruginosa* to Cephalosporin and Beta-Lactamase Inhibitor Combinations

Author Block:

C. Quarshie[1], K. Bobbili[1], J. Lawhorn[2], J. Koirala[1]; [1]Southern Illinois Univ Sch. of Med., Springfield, IL, [2]Mem. Med. Ctr., Springfield, IL

Abstract Body:

Background: There are limited options available for treatment of carbapenem-resistant *Acinetobacter baumannii* and *Pseudomonas aeruginosa*. We evaluated activity of ceftazidime-avibactam, ceftolozane-tazobactam and colistin against carbapenem-resistant *A. baumannii* and *P. aeruginosa*. **Methods:** We obtained 41 clinical isolates of MDR *A. baumannii* and 20 isolates of MDR *P. aeruginosa* from our local hospitals. We subcultured of these isolates and plated on MHA agar (Mueller-Hinton agar, Sigma-Aldrich, St. Louis, MO) for susceptibility testing. We evaluated susceptibility against imipenem, colistin, ceftazidime-avibactam, and ceftolozane-tazobactam using E-test method following instructions from the manufacturer (bioMérieux) and guidelines provided by the Clinical and Laboratory Standards Institute (CLSI document M100-S25).**Results:** Of the 41 selected isolates of *A. baumannii* and 20 isolates of *P. aeruginosa*, 33 isolates of *A. baumannii* and 18 isolates of *P. aeruginosa* were resistant to imipenem. Among the imipenem-resistant *A. baumannii* (MIC50 >32 µg/mL), all 33 (100%) isolates were susceptible to colistin (MIC ≤2 µg/mL), whereas only 2 (6%) were susceptible to ceftazidime-avibactam (MIC ≤8 µg/mL), and none to ceftolozane-tazobactam (MIC ≤2 µg/mL). MIC50 of colistin, ceftazidime-avibactam, and ceftolozane-tazobactam for these isolates were 0.25, 48 and 16 µg/mL, respectively. Among the imipenem non-susceptible *P. aeruginosa* (MIC50= 24 µg/mL), all 18 (100%) isolates were susceptible to colistin (MIC ≤2 µg/mL) and ceftolozane-tazobactam (MIC ≤4 µg/mL), whereas only 9 (50%) were susceptible to ceftazidime-avibactam (MIC ≤8 µg/mL). MIC50 of colistin, ceftazidime-avibactam, and ceftolozane-tazobactam for these isolates were 1, 10 and 1.5 µg/mL, respectively.**Conclusions:** Newer antibiotics with combination of cephalosporins and beta-lactamase inhibitors were found active only against carbapenem-resistant isolates of *P. aeruginosa*, but not against *A. baumannii*. Ceftolozane-tazobactam performed better than ceftazidime-avibactam against *P. aeruginosa*. Colistin remains highly active against all carbapenem-resistant isolates of *A. baumannii* and *P. aeruginosa* at our institution.

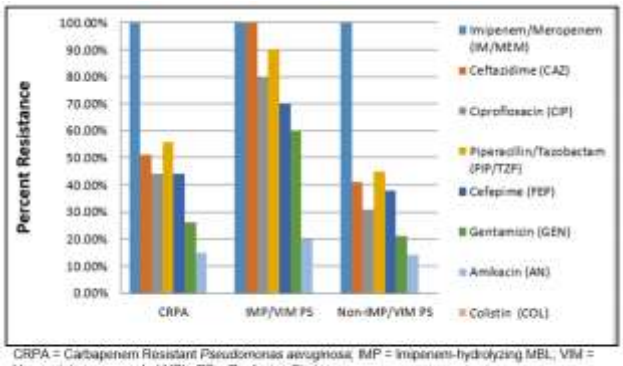
Antibiotic Profiling and Detection of *bla*VIM, *bla*IMP, and *bla*SPM in Carbapenem-Resistant *Pseudomonas aeruginosa* in Selected Tertiary Hospitals in Metro Manila, Philippines

Author Block:

S. Tesalona[1], E. Lagamayo[2], A. Cabal[3]; [1]De La Salle Hlth.Sci. Inst., Cavite, Philippines, [2]Univ. of Santo Tomas, Manila, Philippines, [3]Adamson Univ., Manila, Philippines

Abstract Body:

Antibiotic resistance profile and the presence of several metallo-β-lactamase (MBL) genes conferring resistance to carbapenem were investigated in this study. Previously identified carbapenem-resistant Pseudomonas aeruginosa (CRPA) were tested for the presence of MBL enzyme using E-test. Amplification of blaVIM, blaIMP, and blaSPM was done using conventional polymerase chain reaction (PCR). Antibiotic resistance pattern of each antibiotic tested among MBL and non-MBL producing strains were statistically tested using Fisher exact test. Any $p \leq 0.05$ were considered significant. Of the 39 CRPA tested, 10 MBL producing strains were detected, 9 (23.1%) carried the *bla*IMP and 1 (2.5%) carried the *bla*VIM gene, whereas *bla*SPM was not observed. Increased resistance against ceftazidime, piperacillin/tazobactam, and ciprofloxacin in *bla*IMP and *bla*VIM-producing strains showed significant difference compared to non-*bla*IMP and non-*bla*VIM producing strains ($p<0.05$). On the other hand *bla*IMP and *bla*VIM producing strains with increased resistance to cefepime, and gentamicin has no significant difference, ($p>0.05$). Colistin appeared to be the most effective antimicrobial agent, with 0% resistance to both *bla*IMP and *bla*VIM producing and non-producing strains (Figure 1). The *bla*IMP and *bla*VIM gene were mostly detected from strains isolated from respiratory specimens, 6 (15.4%), followed by urine specimens, 4 (10.2%). These study suggest the presence of *bla*IMP and *bla*VIM-producing *P. aeruginosa* in the Philippines represented by the selected tertiary hospitals in Metro Manila.



CRPA = Carbapenem Resistant Pseudomonas aeruginosa; IMP = Imipenem-hydrolyzing MBL; VIM = Verona-integron encoded MBL; PS = Producing Strains

Comparison of the *In Vitro* Activity of Ceftolozane-Tazobactam and Ceftazidime-Avibactam against Ceftazidime Non-Susceptible *Pseudomonas aeruginosa*

Author Block:

D. Sneed, K. G. Van Horn; Kindred Hosp., Rancho Cucamonga, CA

Abstract Body:

Multi-drug resistance in *P. aeruginosa* has increased, including strains resistant to ceftazidime, an anti-pseudomonal cephalosporin. Two newer antimicrobials, ceftolozane-tazobactam (CEF-TAZ) and ceftazidime-avibactam (CAZ-AVI) have both been recently FDA cleared with indications for use against *P. aeruginosa* in select infections. CEF is a newer beta-lactam and TAZ is a penicillanic acid sulfone beta-lactamase inhibitor. CAZ is an established cephalosporin combined with AVI, a non-beta-lactam beta-lactamase inhibitor that inactivates select beta-lactamases and protects ceftazidime from degradation. This study compares the in vitro activity of CEF-TAZ and CAZ-AVI against 87 recent clinical isolates from a variety of sources (respiratory 65, urine 12, wound 9, blood 1) of *P. aeruginosa* that have tested previously as intermediate (I, 16 mcg/mL) or resistant (R, ≥32 mcg/mL) to CAZ by the VITEK 2 system and obtained from selected Southern California hospitals. CEF-TAZ and CAZ-AVI were tested by the Etest method according to manufacturer's instructions. A 0.5 McFarland suspension of pure organism was rolled with a swab onto the surface of a Mueller-Hinton II agar plate then incubated at 37ºC for 16-24 h and the MIC read as the point where the ellipse of inhibition met the Etest strip. Quality control was performed with *P. aeruginosa* ATCC 27853 and results were acceptable according to the FDA ranges. There were 31 CAZ intermediate strains and 56 resistant strains tested. 76 (87%) of the isolates were susceptible to CEF-TAZ and 61 (70%) isolates were susceptible to CAZ-AVI. CEF-TAZ isolates were 87% S (27/31 if I and 49/56 if R) for both CAZ I and R isolates. However, CAZ-AVI showed 77% S (24/31) if CAZ was I and 66% S (37/56) if the *P. aeruginosa* isolates were CAZ R. No isolates were S to CAZ-AVI when the CEF-TAZ was R.CEF-TAZ appears to have better in vitro activity than CAZ-AVI against ceftazidime non-susceptible *P. aeruginosa*.

Hypermutable *Pseudomonas aeruginosa* (PA) Linked with Antibiotic Resistance in Australian Cystic Fibrosis Patients

Author Block:

V. E. Rees[1], J. B. Bulitta[2], A. Y. Peleg[1], T. Kotsimbos[1], R. L. Nation[1], A. Oliver[3], C. B. Landersdorfer[1]; [1]Monash Univ., Melbourne, Australia, [2]Univ. of Florida, Orlando, FL, [3]Hosp. Son Espases, Palma, Spain

Abstract Body:

Background: Hypermutable Pa isolates have a greatly increased mutation rate and have been found in chronic respiratory infections. They have an enhanced ability to become resistant and are associated with reduced lung function in CF-patients. This study aimed to provide the first characterization of clinical Pa isolates from Australian CF-patients, and to determine the prevalence of hypermutation and antibiotic susceptibility. **Methods:** 59 clinical Pa isolates from Australian CF-patients, PAO1 and PAOΔ*mutS* (hypermutable) were characterized. Mutation frequencies (MF) on 300 mg/L rifampicin-containing agar plates were assessed in triplicate. Hypermutation was defined by the rifampicin MF being ≥20-fold greater compared to PAO1. MICs were performed by Etest and susceptibility judged by EUCAST breakpoints.**Results:** Of all clinical Pa isolates 22% were hypermutable. Multidrug-resistance (MDR; resistance to ≥1 agent from ≥3 different antimicrobial categories) was significantly higher in hypermutable (38%) than non-hypermutable isolates (13%; Chi-square test, $p<0.05$). Hypermutable isolates were more commonly resistant to 2 or more antibiotics in comparison to non-hypermutable isolates (62% *vs.* 28%; Chi-square test, $p<0.05$). Among hypermutable isolates, resistance was 77% for ciprofloxacin, 46% for ceftazidime, and 38% for meropenem and tobramycin. In non-hypermutable isolates, resistance was common for ciprofloxacin (52%), but less frequent for tobramycin (22%), ceftazidime (20%) and meropenem (13%).**Conclusions:** The prevalence of hypermutable isolates in Australian CF-patients was similar to that in European CF-patients. Hypermutable isolates had a significantly higher proportion of MDR and were more often resistant to all tested antibiotics in comparison to non-hypermutable isolates. Therefore, hypermutable Pa are playing a critical role in the antibiotic resistance problem in Australian CF-patients.

Susceptibility of *Pseudomonas aeruginosa* Bloodstream Isolates to Ceftazidime-Avibactam in Northeastern United States

Author Block:

M. Wungwattana[1], S. D. Mahlen[2], A. M. Casapao[3]; [1]Maine Med. Ctr., Portland, ME, [2]Affiliated Lab., Inc., Bangor, ME, [3]Husson Univ., Bangor, ME

Abstract Body:

Background: Ceftazidime-avibactam (CAZ-AVI) has *in vitro* activity against certain Gram-negative and Gram-positive bacteria. Avibactam (AVI), a novel beta-lactamase inhibitor, is unique from all other currently available beta-lactamase inhibitors due to its diaza-bicyclo octane structure and allows ceftazidime (CAZ) to regain activity in the presence of class A and class C beta-lactamase enzymes. Reductions in the minimum inhibitory concentrations (MICs) of CAZ with the addition of AVI have ranged from 4- to 1024-fold among Enterobacteriaceae and 4-fold for *Pseudomonas aeruginosa*. The aim of this study was to analyze the susceptibility of ceftazidime-avibactam against *P. aeruginosa* bloodstream isolates obtained from patients in the northeastern region of the United States.**Methods:** Clinical *P. aeruginosa* isolates obtained from blood cultures from multiple sites in Maine between 2011 and 2015 were tested against CAZ-AVI E-test strips. Demographics and MICs from automated susceptibility testing were also collected and analyzed.**Results:** We report the results of 20 *P. aeruginosa* bloodstream isolates that were tested against CAZ-AVI. The MIC_{50} and MIC_{90} were 1 mg/L and 2 mg/L, respectively [0.75 - 6 mg/L]. The MIC_{50} and MIC_{90} to CAZ alone were 1 mg/L and 4 mg/L, respectively [≤0.5 - >32 mg/L]. Of the 16 patients who received empiric antibiotic therapy, 15/16 (93.8%) received an agent with anti-pseudomonal activity and 3/16 (18.8%) received combination therapy. Patients were bacteremic for a median time of 2 days [1-6 days] and received antibiotic therapy for a median time of 14.5 days [5-51 days]. For the isolate displaying CAZ MIC >32 mg/L, the CAZ-AVI MIC was 6 mg/L.**Conclusions:** Ceftazidime-avibactam displayed good activity against *P. aeruginosa* bloodstream isolates. The MIC_{50} between CAZ and CAZ-AVI did not differ. However, we detected a 1-fold dilution decrease in the MIC_{90} between CAZ (2 mg/L) and CAZ-AVI (4 mg/L). Based on the Clinical & Laboratory Standards Institute breakpoint of ≤8/4 mg/L, all of our *P. aeruginosa* isolates were susceptible to CAZ-AVI. The results from our study show that ceftazidime-avibactam may be a therapeutic option for patients infected with *P. aeruginosa* displaying elevated ceftazidime MICs.

High Prevalence of FosA Among Clinical *Pseudomonas aeruginosa* Isolates Accounts for Decreased Fosfomycin (FOF) Susceptibility

Author Block:

E. B. Hirsch[1], P. C. Zucchi[1], A. Chen[1], A. Phung[1], C. L. Emery[2], T. Bias[3]; [1]Northeastern Univ., Boston, MA, [2]Drexel Univ. Coll. of Med., Philadelphia, PA, [3]Hahnemann Univ. Hosp., Philadelphia, PA

Abstract Body:

Background: FOF is often used to treat urinary or systemic infections caused by multidrug-resistant (MDR) pathogens for which few treatment options remain. It has gained traction in treatment of *P. aeruginosa* infections though limited data regarding susceptibility or resistance mechanisms among clinical isolates have been reported. We determined the in vitro activity of FOF and identified resistance mechanisms among a set of recent clinical *P. aeruginosa* isolates. **Methods:** Thirty-one clinical *P. aeruginosa* isolates (1 per patient episode) from two US centers were included. Isolates were collected between 2013-2015 from urine (n = 27), sputum (n = 2), or wound (n = 2) and were screened for the presence of *fosA* gene and mutations in the *glpT* gene via PCR and gene sequencing. FOF MICs were determined in duplicate, on separate days, by both the reference method of agar dilution (AD) and Etest (ET). The CLSI susceptibility breakpoint for *Escherichia coli* (≤ 64 mg/L) was used for interpretation. **Results:** Twelve (39%) isolates were considered MDR (non-susceptible to ≥ 1 agent in at least 3 antibiotic classes). All but one isolate was positive for the plasmid-mediated enzyme *fosA* by PCR. Sixteen of 30 FosA+ isolates had wild-type (WT) copies of the gene while the other 15 contained mutations resulting in truncated proteins. MICs by AD were higher for the WT FosA group, ranging from 32-256 (MIC_{50}=64) mg/L compared to the non-WT FosA group (range, 4-128; MIC_{50}=16 mg/L). Nine (56%) of 16 isolates with WT FosA were considered susceptible when applying the CLSI interpretive criteria for *E. coli*. Essential agreement of ET with AD was 77%; in 4 of 8 isolates without agreement, WT FosA was present and ET more accurately classified them as resistant (≥ 256 mg/L). Preliminary screening of 4 isolates revealed no mutations in the glpT transporter necessary for FOF uptake. **Conclusion:** In this small collection of clinical *P. aeruginosa* isolates, the presence of FosA was common and contributed to increased FOF MICs. Application of the CLSI *E. coli* breakpoints for *P. aeruginosa* may be inappropriate and result in false susceptibility. Identification of additional resistance mechanisms and susceptibility determinations among a larger group of isolates are ongoing.

Evaluation of Cefolozane/Tazobactam Susceptibilities of *Pseudomonas aeruginosa* Blood Isolates at Two Major Tertiary Referral Medical Centers

Author Block:

C. Wilson[1], J. Graffam[1], M. Wungwattana[2], S. D. Mahlen[3], A. M. Casapao[1]; [1]Husson Univ, Bangor, ME, [2]Maine Med Ctr, Portland, ME, [3]Affiliated Lab Inc., Bangor, ME

Abstract Body:

Background: Ceftolozane/tazobactam (TOL/TAZ) is a newly approved antimicrobial indicated to treat Gram-negative bacteria that cause complicated intra-abdominal infections (IAI) & complicated urinary tract infections (UTI), including *Pseudomonas aeruginosa* (PSAR). The aim of this study was to evaluate the minimum inhibitory concentrations (MICs) of TOL/TAZ in PSAR blood isolates from patients at two major medical centers in Maine. **Methods:** A retrospective, epidemiological study that included patients whom had at least one positive blood culture of PSAR admitted to multiple sites in Maine. Isolates stored at -20ºC were grown on Mueller-Hinton blood agar media and TOL/TAZ Etest MICs were recorded. PSAR isolate data was collected through medical records from 2011 to 2015. Data collected included demographics and antimicrobial therapy. PSAR is considered susceptible to TOL/TAZ at MICs ≤4/4 mg/L & resistant at MICs ≥16/4 mg/L. **Results:** Total of 50 patients had PSAR bacteremia; of these patients, 41 (82%) were treated at one of the top two major medical centers in Maine. The median Pitt bacteremia score was 2 (range 0-9) and 43.9% were admitted to the critical care unit. A total of 38/41 (93%) of patients were treated with one empiric antipseudomonal agent and 3/41 (7%) patients received an antipseudomonal empiric agent that was resistant. The most common antimicrobial included cefepime (48%) & piperacillin/tazobactam (35%). Median total hospital duration of therapy was 7 days (1-23). Outpatient therapy was continued in 61% of patients were discharged. Median length of stay was 11 days (3-92). Hospitalization mortality was 29.3%. A total of 50 (100%) isolates were susceptible to TOL/TAZ. TOL/TAZ MICs ranged from 0.125-1.5 mg/L with MIC50 of 0.38mg/L and MIC90 of 1mg/L. PSAR resistance rates were highest with aztreonam (12%), piperacillin/tazobactam (8%), meropenem (8%), ciprofloxacin (6%), and cefepime (4%).**Conclusions:** TOL/TAZ is a potent antipseudomonal agent and our PSAR MIC90 value is two-fold lower than the upper susceptible breakpoint. TOL/TAZ may be a good option for UTI and IAI resulting from PSAR. TOL/TAZ may potentially be used as empiric therapy especially if caused by PSAR*;* although follow up susceptibilities are still warranted.

Activity of Ceftazidime-Avibactam against Resistant *Enterobacteriaceae* and *Pseudomonas aeruginosa*

Author Block:

K. G. Van Horn; Kindred Hosp., Rancho Cucamonga, CA

Abstract Body:

Resistance to β-lactams including carbapenems continues to increase in Gram negative bacilli. The new antimicrobial combination of ceftazidime with avibactam (CEF-AVI) a non-β-lactam β-lactamase inhibitor, inactivates β-lactamases and protects ceftazidime from degradation. In vitro activity has been demonstrated against Enterobacteriaceae (ESBL, AmpC, KPC) and *Pseudomonas aeruginosa* (AmpC and some OprD) producing isolates. We studied the susceptibility of CEF-AVI to organisms isolated from long-term acute care hospital (LTACH) patients. A total of 304 recent clinical isolates collected from March to December 2015 were obtained from various Southern California LTACHs and tested against CEF-AVI by the Etest method according to manufacturer instructions. A 0.5 McFarland suspension of pure organism was rolled with a swab onto the surface of a Mueller-Hinton II agar plate then incubated at 37ºC for 16-24 h and the MIC read as the point where the ellipse of inhibition met the Etest strip. Quality control with *Escherichia coli* ATCC 25922, *Klebsiella pneumoniae* ATCC 700603, and *P. aeruginosa* ATCC 27853 was performed and results were acceptable according to the CEF-AVI FDA ranges. All 29 ESBL-producing Enterobacteriaceae (carbapenem-susceptible) were susceptible to CEF-AVI. There were 245 carbapenem-resistant Enterobacteriaceae (232 *Klebsiella pneumoniae*) tested and 228 were susceptible (98.3%). The MIC_{50} and MIC_{90} for carbapenem-resistant *K. pneumoniae* respectively were 2/4 (CEF-AVI) mcg/mL and 4/4 mcg/mL. The susceptible breakpoint value for Enterobacteriaceae is ≤ 8/4 mcg/mL. There were a total of 30 *P. aeruginosa* strains tested. All 6 ceftazidime susceptible (MIC ≤ 8 mcg/mL) isolates were also susceptible to CEF-AVI. Of the 24 ceftazidime intermediate/resistant strains (MIC >8 mcg/mL), 19 (79.2%) were susceptible to CEF-AVI . Ceftazidime-avibactam appears to be an active agent in vitro against carbapenem-resistant Enterobacteriaceae and ceftazidime resistant *P. aeruginosa*.

***In Vitro* Activity of Three Antibiotic (Abx) Combination (Combi) against *Stenotrophomonas maltophilia* (Sm) Isolates in Singapore**

Author Block:

T-P. Lim[1], C-X. Gao[2], J. Teo[1], Y. Cai[1], S-X. Tan[1], W. Lee[1], T-H. Koh[1], N. Tee[3], T-T. Tan[4], A-L. Kwa[1]; [1]SINGAPORE GEN. HOSP., SINGAPORE, Singapore, [2]Natl. Univ. of Singapore, SINGAPORE, Singapore, [3]KK Women's & Child. Hosp., SG, Singapore, [4]SINGAPORE GEN. HOSP., SG, Singapore

Abstract Body:

Background: The prevalence of SM with reduced susceptibilities to trimethoprim-sulfamethoxazole (TS) is increasing in Singapore, leaving few treatment options available. Combi therapy may be the only therapeutic option till new abx are available. We previously found that only levofloxacin (LEV) + polymyxin B (PB) were inhibitory against XDR SM. This study aimed to evaluate the bactericidal activity of 3-abx combi against SM. **Methods:** Non-repeat SM isolates were collected from Oct 14 - Dec 15. Aztreonam (AZT), LEV, PB, tigecycline (TG), ticarcillin-clavulanic acid (TC), TS & ceftazidime (CFZ) MICs were determined using Etest. Presence of L1, L2 & Sul genes were identified using PCR. Time-kill studies (TKS) were conducted with approximately 10^5 CFU/ml at baseline with maximally clinical achievable concentrations (mg/L) of AZT (24), LEV (8), PB (2), TG (2), TC (60/2), TM (2/38) & CFZ (35), in 3-abx combi. **Results:** 160 SM isolates were collected. 64% were from respiratory cultures (73/160 from upper respiratory & 29/160 from lower respiratory cultures), 8% were from blood cultures, 4% were from urine cultures & the remaining were tissue cultures. MIC50/MIC90 (mg/L) of AZT, LEV, PB, TG, TC, TS & CFZ were >=512/>=512, 0.75/8, 1.5/16, 1.5/4, 32/>=512, 0.125/4 & 4/>=512, respectively. Four XDR SM isolates were included in TKS. 35 3-abx combi were evaluated against each isolate. The 4 selected XDR SM isolates had MICs (mg/L) of AZT, LEV, PB, TG, TC, TS & CFZ as >=512 (for all), 12/2/8/>=64, 8/1/2/0.5, 2/3/6/12, 16/16/32, >=64 (for all) & 12/4/12/16, respectively. In TKS, LEV+TG+TC was synergistic against SM1; PB+TG+TC was synergistic against SM2; AZT+PB+TC was synergistic against SM4 while PB+CFZ+TS was bactericidal against SM4. PCR confirmed the presence of L1, L2 & Sul genes in all isolates. **Conclusions:** Potential abx combi as pre-emptive therapy for XDR SM infections are highly strain-specific. 3 Abx combi may be useful for XDR SM in our institution.

Antimicrobial Susceptibility to β-Lactam Antibiotics and the Production of BRO β-Lactamase in Clinical Isolates of *Moraxella catarrhalis* from a Japanese Hospital: Does BRO Inactivate Ceftriaxone?

Author Block:

K. Yamada[1], K. Arai[1], R. Saito[2]; [1]Tokyo Metropolitan Hlth.and Med. Treatment Corp. Toshima Hosp., Itabashi-ku, Japan, [2]Tokyo Med. and Dental Univ., Bunkyo-ku, Japan

Abstract Body:

Background: *Moraxella catarrhalis* is an important respiratory pathogen. However, there is little information regarding the susceptibility of this organism to β-lactam antibiotics. In this study, we investigated the antimicrobial susceptibility to β-lactam antibiotics and the BRO β-lactamase production of clinical *M. catarrhalis* isolates.**Methods:** In total, 233 *M. catarrhalis* clinical isolates obtained between January 2013 and July 2015 in Tokyo were examined. Phenotypic and genotypic production of BRO β-lactamase were tested using cefinase disk and PCR analyses, respectively. Antimicrobial susceptibility was tested using the Etest.**Results:** Among the 233 clinical isolates tested, 232 (99.4%) were BRO producers, while only one (0.6%) was BRO-negative. Among the 232 BRO-producers, there were 224 BRO-1-producing strains (96.6%) and eight BRO-2-producing strains (3.4%). The geometric mean minimum inhibitory concentration (MIC), MIC_{50}, and MIC_{90} values of amoxicillin, amoxicillin clavulanate, cefaclor, and ceftriaxone for BRO-1 producers were significantly higher than those for BRO-2 producers ($P < 0.01$). Notably, four of the BRO-1-producing isolates exhibited elevated ceftriaxone MIC values (2.0 mg/mL), but only the cefaclor MIC breakpoint was exceeded. Based on the results of ceftriaxone inactivation tests, ceftriaxone decomposition activity was confirmed against BRO-1 producers. However, ceftriaxone inactivation activity was not investigated in BRO-2 producers.**Conclusions:** Our results indicated that *M. catarrhalis* infections should be treated with amoxicillin clavulanate instead of cephalosporin antibiotics. The number of *M. catarrhalis* isolates with acquired resistance to β-lactam antibiotics is expected to increase in the near future. Therefore, we plan to continue our study of antimicrobial susceptibility in clinical *M. catarrhalis* isolates.

Plasmid Profile of Resistant (MAR) Bacteria from Leachate in Some Rural Communities of Ekiti State, Nigeria

Author Block:

A. T. Odeyemi; Ekiti State Univ., Ado-Ekiti, Ekiti State, Nigeria, Ado-Ekiti, Nigeria

Abstract Body:

profile of bacteria isolated from leachate samples of some rural communities in Ekiti State, Nigeria were analyzed. Antibiotics sensitivity and plasmid profile were assayed using disk diffusion and gel electrophoresis techniques respectively; while the plasmids were cured using acridine orange. The total bacterial, total coliform and total enteric bacteria counts of the leachate samples ranged from 0.64×10^8 to 0.85×10^9CFU/ml, 0.78×10^8 to 0.76×10^9CFU/ml and 1.90×10^8 to 2.30×10^9CFU/ml respectively. *Escherichia coli* with 29.2% had the highest frequency of occurrence while *Enterobacter aerogenes* had the lowest occurrence of 7.5%. The antibiotics sensitivity test showed that the least percentage (3%) of the isolates were resistant to ofloxacin while the highest percentage (99%) of the isolates were resistant to cefuroxime. Multiple Antibiotics Resistant bacteria were subjected to plasmid analysis showing that nine (9) were devoid of plasmid while other six (6) isolates carry plasmid with high molecular weight, ranging from 9.41kbp to 23.1kpb. Three MAR isolates (*Escherichia coli*, *Pseudomonas aeruginosa* and *Enterococcus faecalis*) were selected for curing. The three (3) retained resistance pattern to all antibiotics used aside *Escherichia coli* and *Pseudomonas aeruginosa* that became susceptible to ofloxacin after curing. Incidence of such MAR bacterial isolates in leachate samples is however an indication of possible environmental hazard.

Multidrug-Resistant Bacteria in Postoperative Wound Infection at Tikur Anbessa Specialized Hospital, Addis Ababa, Ethiopia

Author Block:

M. Hailu; Addis Ababa Univ., Coll. of Hlth.Sci., Addis Ababa, Ethiopia

Abstract Body:

Background: Postoperative wound infection is a major problem throughout the world even in hospitals with most modern facilities. Infections get worsen due to Multidrug resistance (MDR) which is the challenge for controlling now days. Hence the aim of this study was to determine the prevalence of multidrug resistant bacteria in postoperative wound infection.**Method:** A cross sectional study was conducted from March 30 to August 28/2015. A total of 197 surgical patients who developed postoperative wound infections were included. Wound swabs were collected using sterile cotton swab and dipped into sterile transport media. All wound swabs were cultured on Blood, MacConkey and Mannitol salt agar. All culture positive samples were characterized by gram stain and standard biochemical tests. Antimicrobial susceptibility test was performed on Muller-Hinton agar using Kirby-Bauer method. Data was analyzed using SPSS version 20.**Results:** The overall prevalence was 75.6% (n=149/197) and the predominant bacteria isolated were *S. aureus33.3%* (n=56/168) and *E. coli 14.3% (n=24/168.* Double infections 11.4% (n=17/149) were seen in which *S. aureus* and *Pseudomonas species* 23.5% (n=4/17) showed common association. Highest proportion of bacteria 28.2% (n=42/149) were isolated from orthopedics followed by General Surgery 24.8% (n=37/149). Multidrug resistances (MDR) were recorded in 65.5% (n=110/168) of all bacterial isolates. Gram positive and Gram negative bacteria showed 55.3% (n=42/76) and 73.9% (n=68/92) MDR respectively. Among the antibiotics tested amoxicillin (93.5%), Ceftriaxone (85.3%), Penicillin (84.5%) and Cefotaxime (82.7%) showed high level of resistance. Clindamycin (7.9%) and Amikacin (1.1%) showed high sensitivity for Gram Positive and Gram negative respectively**Conclusion:** Choice of drugs for treatment of bacterial isolates from postoperative wound infections is quite narrow today due to the wide scale resistance to common drugs. Hence rational use of antibiotics and regular monitoring of antimicrobial resistance patterns are essential and mandatory to prevent further emergence and spread of multidrug resistance bacterial pathogens.

Molecular Characteristics of Extended-spectrum β-Lactamase-Producing *Escherichia coli* Isolates from Retail Food Products, Healthy Workers and Patients: Horizontal Transfer of Ctx-M-55 Plasmids

Author Block:

Q. P. Le[1], S. Ueda[2], T. N. H. Nguyen[1], T. T. N. Tran[1], T. A. V. Hoang[1], T. N. D. Nguyen[1], T. V. K. Dao[1], M. T. Tran[1], T. T. T. Le[1], T. L. Le[1], I. Hirai[2], T. Nakayama[3], T. H. Do[1], Q. M. Vien[1], Y. Yamamoto[4]; [1]Nha Trang Pasteur Inst., Nha Trang, Viet Nam, [2]Univ. of Ryukyus, Okinawa, Japan, [3]Osaka Univ., Osaka, Japan, [4]Osaka Prefectural Inst. of Publ. Hlth., Osaka, Japan

Abstract Body:

Background: There is widespread dissemination of extended-spectrum β-lactamase (ESBL)-producing *Escherichia coli* worldwide, with the emergence of CTX-M type ESBLs. In particular, dissemination in communities in developing countries is an urgent public health issue. However, the dissemination mechanisms are not clear. Therefore, the current study was conducted to determine the molecular characteristics of ESBL-producing *E. coli* isolated from both food and humans.**Methods:** Retail food (pork meat) samples (n = 147), fecal samples of healthy workers selling retail food products at a market (n = 156), and *E. coli* clinical isolates from patients with infection (n = 86) were collected from Nha Trang, a central province of Vietnam, from 2013 to 2015. ESBL-producing *E. coli* was isolated, and ESBL genotypes, phylogroups, plasmidomes, and antibiotic-resistance profiles were determined.**Results:** The prevalence of ESBL-producing *E. coli* in samples from workers (71.8%) was significantly higher than that for retail food products (32.0%). A CTX-M type *E. coli* strain was the dominant strain in ESBL-producing *E. coli* isolates obtained from food (43/47, 91.5%), workers (115/117, 98.3%), and patients (35/36, 97.2%); PCRs and DNA sequencing revealed that CTX-M-55, CTX-M-27, and CTX-M-15, respectively, were dominant in these sample types. Phylogroups B2 and D were common in isolates from workers and patients, whereas B1 and A were predominant in food isolates. S1-PFGE and southern blotting showed variation in the size of plasmids with CTX-M-55 (105-240 kb). However, several isolates obtained from food, workers, and patients showed a similar size for the plasmid with the CTX-M-55 gene, indicating possible horizontal transfer of the plasmid with the ESBL-encoding gene.**Conclusions:** The results indicate that ESBL-producing *E. coli* disseminates not only in retail food products but also in communities and nosocomial settings. Furthermore, such dissemination may be caused by transfer of a plasmid with CTX-M genes.

Molecular Characterization of Extended Spectrum Betalactamase Producing Genes in *E. coli* from Zaria, Nigeria

Author Block:

J. A. Onaolapo; Ahmadu Bello Univ., Zaria, Zaria, Nigeria

Abstract Body:

Background: Poor therapeutic outcome and high economic burden have been associated with extended spectrum betalactamase (ESBL) producing *E. coli* due to the expression of multidrug resistance (MDR) to penicillins, cephalosporins and monobactams, which are commonly prescribed in the hospitals. **Methods:** This study evaluated the presence of ESBL in *E. coli* isolated from urinary tract infection (UTI) and diarrhea patients in Zaria, Nigeria using double disc diffusion method and molecular techniques.**Results:** Using Microgene identification kit 87 of the 132 presumptive *E. coli* isolates from UTI and diarrhea patients in selected hospitals in Zaria, Nigeria were confirmed as *E. coli* and subsequently evaluated for the presence of ESBL. The result showed that 70.6% (51) of the isolates produced ESBL phenotypically while the PCR characterization of the 21 most resistant isolates showed that 90.5% (19) harbored the $CTXM_{15}$ gene, 81% (17) of the isolates encoded the TEM gene, 38.1% (8) harbored the OXA gene while one percent (1%) had the SHV gene. The susceptibility profile of the isolates to some selected betalactam antibiotics showed that 93.1% of the isolates were resistant to amoxicillin, 90.8% to cefpirome, 77% to cefotaxime, 69% to cefpodoxime, 36.8% to azetreonam while 26.4% were resistant to ceftriaxone.**Conclusions:** This study showed that among the commonly prescribed betalactam antibiotics, ceftriaxone (cephalosporin) and azetreonam (monobactam) are the most effective antibiotics and this calls for the need for review of the use of betalactam in hospitals, as most of the clinical isolates of *E. coli* evaluated in this study harbored gene(s) that encode for resistance to betalactams.

Antibiotic Susceptibility Pattern of Organisms Isolated from Gall Bladder

Author Block:

A. Ghazal, A. Hannan, **S. Saleem**, S. Sarwar, U. Arshad; Univ. of Hlth. Sci.s Lahore, Lahore, Pakistan

Abstract Body:

Background: Pyogenic cholecystitis and cholangitis are common causes of cholestectomy. Culture reports are worthy for the planning of treatment with antibiotics and prophylaxis. There is very limited data available on it from Pakistan.**Methods:** In our study we collected 60 samples of Gallbladder with its bile. All the clinical samples were cultured directly on blood and MacConkey agar and also inoculated in RCM (Robertsom cooked medium) broth to support anaerobic organisms. The isolated organisms were identified by the standard morphological, cultural and biochemical profile. Antibiotic susceptibility was done by Kerby beur disc diffusion method and organisms were also screened for ESBL production.**Results:** Out of sixty patients, forty (66%) were positive for bacteria either in bile or gall bladder wall or in both gall bladder wall and bile. Gram negative microorganisms were most frequently isolated from 40 culture positive patients. The commonest gram negative bacteria were Pseudomonas aeruginosa (39% n=30), E.coli (25% n=19), Klebsiella pneumonia (13% n=10), Enterobacter clocae (12% n=09), Enterococcus fecalis (4% n=03), Enterobacter sakazakki (3% n=02), Enterobacter aerugenes (1.3% n=01), Citrobacter fereuddii (1.3% n=01), Proteus mirabullus (1.3% n=01). Organisms were mostly resistant to all cephalosporin and Augmentin due to ESBL production while Carabapanum, aminoglysides and combination drugs were found to be most effective.**Conclusions:** Significant culture positive rate shows the importance of obtaining cultures from Gall bladder wall and bile at the time of cholecystectomy so that appropriate antibiotics could be administrated and necessary changes could be made according to the antibiotic sensitivity tests to prevent serious complications of resistant pathogens and septicemia .

Detection And Characterization Of Extended Spectrum Beta-Lactamase And Cabapenemase Genes Among Enterobacteriaceae In Lagos, Nigeria

Author Block:

K. O. AKINYEMI[1], B. A. Iwalokun[2], A. O. B. Oyefolu[1], C. O. Fakorede[1]; [1]Lagos State Univ., Ojo, Lagos, Lagos, Nigeria, [2]Natl. Inst. of Med. Res.,, Lagos, Nigeria

Abstract Body:

Background: The worldwide spread of extended spectrum beta -lactamase (ESBL) and cabapenemase producing gram negative bacteria in the family enterobacteriaceae remains a serious public health challenge in the light of the poor chemotherapeutic outcomes due to increasing multiple drug resistant (MDR) pathogens encountered in our hospitals and community in recent times. This study evaluated the presence of ESBL and Cabapenemase genes among enterobacteriaceae isolates and detected the genetic basis for production**Methods:** A total of one-hundred and twenty-seven enterobacteriaceae isolates (*Escherichia coli* = 57, *Klebsiella pneumoniae* = 43, *Salmonella* spp =27) were isolated from clinical samples by standard methods and were subjected to *in vitro* susceptibility test by disk diffusion methods. Isolates that were resistant to cefoxitin and third generation cephalosporin (3GC) were screened for ESBL {Double Disc Synergy Test Method (DDST). ESBL genes were detected by multiplex PCR and random amplified polymorphic DNA (RAPD) analysis was performed on the isolates by standard procedures.**Results:** In all over 60% of the enterobacteriaceae isolates produced ESBL and were MDR positive Specifically, 37/57 (64.9%) and 31/43 (69.8%) of *E.coli* and *K. pneumoniae* strains were ESBL positive respectively. Over 60% of *E. coli* and *K. pneumoniae* were MDR with with 15 and 11 resistant patterns observed respectively and were found to contain at least one of the three markers Bla-TEM, Bla-SHV, Bla-CTX. Three strains of *K. pneumoniae* developed resistant to carbapenem. None of the strains of Salmonella spp produced cabapenemase as done in one strain of *E. coli* in this study.**Conclusions:** The study revealed circulation of multiple drug resistant ESBL producing pathogens among enterobacteriaceae. It also indicated the emergence in patients of MDR *K. pneumoniae* with ESBL and cabapenemase production, thus poses further and serious challenges for the possibility of spread to other members of enterobacteriaceae in hospital and community.

Colistin Resistance in *Enterobacter cloacae* and *Enterobacter aerogenes* Isolates from South Korea

Author Block:

Y-K. Hong, J-Y. Lee, K. Ko; SungKyunKwan Univ. Sch. Of Med., Suwon, Korea, Republic of

Abstract Body:

Background: *Enterobacter* spp. are common pathogens responsible for nosocomial infections, especially blood stream infections in intensive care units. Colistin is often the only therapeutic option to treat infections caused by multidrug-resistant (MDR) Gram-negative bacterial pathogens. Colistin resistance is rarely described in *Enterobacter* spp. compared with other pathogens.**Methods:** Antimicrobial susceptibility testing was performed for 211 *E. cloacae* and 143 *E. aerogenes* isolates. For genotyping, multilocus sequence typing (MLST) and AP typing were performed for colistin-resistant *E. cloacae* and *E. aerogenes* isolates, respectively. *pmrAB* and *phoPQ* genes, which are known to be associated with colistin resistance in other Gram-negative bacterial species, were sequenced and their amino acid alterations were identified. The isolates showing skip-well phenomenon were compared colistin-resistant and -susceptible isolates by time-kill assay and population analysis.**Results:** A total of 50 *E. cloacae* (23.7%) and six *E. aerogenes* (4.2%) isolates were resistant to colistin, and eight *E. cloacae* (3.8%) and three *E. aerogenes* (2.1%) isolates showed skip-well phenomena against colistin. The 50 colistin-resistant *E. cloacae* isolates showed diverse STs, and ST53 were the most common (eight isolates, 16.0%). In addition, the AP typing showed that six colistin-resistant *E. aerogenes* belonged to different clones. While the isolates of skip-well phenomenon showed similar to colistin-resistant isolates in time-kill assay, they were similar to colistin-susceptible isolates in population analysis. Most of colistin-resistant *E. cloacae* isolates showed amino acid alterations in *pmrB*, Thr295Ile.**Conclusions:** In this study, we report high colistin resistance rates especially in *E. cloacae*, and their diverse genotypes, indicating that colistin resistance occurred independently. In addition, we identified that PmrAB alteration was the common mechanism of colistin resistance in *E. cloacae.*

Antibiotic (Abx) Combinations (Combi) for Ndm-Producing *Providencia rettgeri* & *Citrobacter spp.* Clinical Isolates

Author Block:

J. Teo[1], K. Lin[2], T-P. Lim[1], Y. Cai[1], W. Lee[1], T-H. Koh[1], T-T. Tan[1], A-L. Kwa[1]; [1]Singapore Gen. Hosp., SG, Singapore, [2]Natl. Univ. of Singapore, SG, Singapore

Abstract Body:

Background: Carbapenem resistance is increasing in Singapore. Aside from occurring in common Enterobacteriaceae like *E.coli*, *Klebsiella* & *Ente*robacter species, it has emerged in less common Enterobacteriaceae locally. We aim to identify effective abx combi for these highly resistant isolates.**Methods:** 3 clinically significant isolates were selected [*P. rettgeri* (EC1) from foot tissue, *C. sedlakii* (EC2) from urine, *C. freundii* (EC3) from blood]. All 3 harbored TEM/CTXM, AmpC & NDM. MICs were tested using CLSI broth dilution, except for fosfomycin (Etest). 24-h time-kill studies (TKS) were performed with approximately 5 log CFU/ml at baseline using maximally achievable clinical, unbound concentration (mg/L) of levofloxacin (L) (8), aztreonam (A) (24), cefepime (C) (50), piperacillin/tazobactam (Taz) (35/7), meropenem (M) (20), ertapenem (E) (15), rifampicin (R) (2), tigecycline (T), polymyxin B (P) (2) & fosfomycin (F) (160) alone & in combi. 34 M-, Az-, R-, Taz-, P- & F-based combis were tested.**Results:** EC1 was pandrug-resistant. EC2 & 3 remained susceptible to T, P & F. The MICs of Az, C, Taz, M & R were ≥32 mg/L for all isolates. L/E/T/P/F MICs were ≥32/≥32/16/≥32/128, ≥32/≥32/2/0.25/1 & 4/16/0.5/1/0.5 mg/L for EC1, 2, 3 respectively. In single Abx TKS, all drugs were not bactericidal (>3 log reduction from baseline) for all 3 isolates at 24h, including those with low MICs (P, T, F). AzE was the only bactericidal combi for EC1. For EC2, P-based combis (Az, Taz, M, R, T, F) were bactericidal. For EC3, P-based combis (L, Taz, E, M, R, F) & ME were bactericidal. The following combinations were synergistic - EC1 (AzTaz, AzF); EC2 (CP, CF); EC3 (MC, MAz, MTaz, MR).**Conclusions:** No one combi was bactericidal for all 3 isolates, in spite of similar beta-lactam resistance mechanisms. Selected P-based combis are effective if P MIC is ≤ 1 mg/L. E as a sacrificial drug may allow beta-lactams like Az & M to be used. Low MIC results in P,T,F susceptibility testing may not be sufficient to predict clinical success as a lack of bactericidal activity was observed in *in vitro* TK. While P & T heteroresistance has been reported, further work on emergence of resistance to F is warranted. In addition, profiling of other resistance mechanisms might be required to understand why select combinations were bactericidal.

Antimicrobial Activity of Tigecycline and Colistin Against Multi-drug Resistant Isolates of *Enterobacteriaceae*

Author Block:

V. Khare, F. Haider; Era's Lucknow Med. Coll. and Hosp., Lucknow, India

Abstract Body:

Background: In view of the increasing prevalence of multi-drug resistance in *Enterobacteriaceae*, there is a need to keep an eye on the sensitivity pattern of limited drugs available for their treatment. Carbapenems are being frequently prescribed to treat infections by Extended Spectrum Beta Lactamase (ESBL) producers and this has lead to an increased isolation of Carbapenem Resistant Enterobacteriaceae (CRE) isolates in our hospital. Tigecycline and Colistin are two important treatment options. This study was undertaken to evaluate the in-vitro activity of Tigecycline and Colistin against multi-drug resistant *Enterobacteriaceae* isolates.**Methods:** The study was carried out at Era's Lucknow Medical College and Hospital, a 1000 beded tertiary care hospital in Lucknow.The duration of the study was from January to December 2015. Antimicrobial susceptibility was done for all isolates of *Enterobacteriaceae* by disk diffusion (Kirby-bauer) as per CLSI 2015 guidelines and all suspected ESBL producers showing resistance to third generation Cephalosporins were confirmed by combined disk testing. Tigecycline was tested by using 15ug disk (Hi-Media) and Colistin was tested by using E test (Ezy MIC TM CL strips , Hi Media). Quality control was done using *E.coli* ATCC 25922. In view of the lack of CLSI guidelines for disk diffusion for Tigecycline, EUCAST 2015 guidelines were used.**Results:** 297 multi-drug resistant *Enterobacteriaceae* were isolated from various samples including pus, sputum, endotracheal aspirates etc. (excluding urine) from patients admitted in ICUs, HDU, surgical and medical wards of the hospital. These included 128 *Escherichia coli* , 108 *Klebsiella spp.* and 61 Others (*Enterobacter spp.* and *Citrobacter spp.*). Of these, Carbapenem resistance was 64% and 57.4% in *E.coli*, and *Klebsiella spp.* respectively with an overall resistance of 63.4%. Overall Tigecycline was resistant in 12 (4%) isolates, mostly *Klebsiella spp*. (8/12). When CRE were considered, Tigecycline resistance was 6.3%. None of the isolates showed resistance to Colistin.**Conclusions:** There is a need to test Tigecycline routinely in *Enterobacteriaceae* and we need to keep in mind the threat of emerging resistance.

Publishing Title:

Antimicrobial Resistance in Shiga Toxin- producing *Escherichia coli* (Stec) and Non-typhoidal *Salmonella* in Michigan

Author Block:

S. Mukherjee[1], P. Singh[1], R. Mosci[1], J. T. Rudrik[2], S. D. Manning[1]; [1]Michigan State Univ., East Lansing, MI, [2]Michigan Dept. of Hlth.and Human Services, Lansing, MI

Abstract Body:

Foodborne pathogens such as STEC and non-typhoidal *Salmonella* are a serious health burden in the US, with the CDC reporting approximately 265,000 cases and 1.2 million cases per year, respectively. Treatment of infections caused by these pathogens is hindered due to the emergence of resistance and the possibility of lateral transfer of resistance genes to other bacteria adds to the threat of antibiotic resistance. An accurate representation of the prevalence and mechanisms of resistance in Michigan is not present because antibiotic resistance has not been widely researched among STEC and systematic collection of susceptibility data for non-typhoidal *Salmonella* has not been carried out. Here, clinical isolates of STEC (N=398) and non-typhoidal *Salmonella* (N=107) were obtained from MDHHS and the frequency of resistance was determined using disk diffusion and broth microdilution respectively. Overall, 8.02% (15) of the STEC O157 isolates (N=187) and 10.4% (22) of the STEC non-O157 isolates (N=211) were resistant to at least one antimicrobial. Our study showed higher percentages of resistance to ampicillin and trimethoprim-sulfamethoxazole in STEC O157 isolates in Michigan, compared to national levels reported by NARMS. Genotypic studies showed that resistance to ampicillin for most isolates was not associated with chromosomal *ampC* while SNP genotyping of the O157 isolates demonstrated that the resistant isolates belonged to separate clades. Resistance to important antimicrobials was also observed in non-typhoidal *Salmonella*, with 10.27% of all isolates resistant to at least one antimicrobial. The frequency of resistance varied by serovar and 5.6% of all isolates were multidrug-resistant with four distinct resistance patterns. Future studies should focus on analyzing resistance trends for larger populations and identifying genotypic factors associated with resistance. Factors such as geographical location, serotypes & serovars, source of isolates etc. determine resistance frequencies and hence continuous monitoring of antibiotic resistance in enteric pathogens is important from a public health perspective to combat resistance.

Mepm and Cl Heteroresistance in *Enterobacteriaceae* Isolates in Japan

Author Block:

K. UECHI[1], T. TADA[2], K. SHIMADA[2], I. NAKASINE[1], T. KIRIKAE[2], J. FUJITA[1]; [1]Univ. Hosp. of the Ryukyus, Okinawa, Japan, [2]Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan

Abstract Body:

Background: The rapid spread of carbapenem- resistant *Enterobacteriaceae* (CRE), with the emergence of colistin (CL)- resistant CRE, has become an urgent health concern worldwide. We described here that the first identification of two isolates, a MEPM- heteroresistant *Klebsiella pneumoniae* and a meropenem (MEPM)- resistant and CL- heteroresistant *Enterobacter cloacae*.**Methods:** We conducted active surveillance to find patients colonized with CRE in a university of Ryukyu hospital in Okinawa Japan. Rectal swabs were screened for CRE using ESBLs selective agar (in house), and CHROMagar KPC (CHROMagar: France) according to Laboratory Protocol for Detection of Carbapenem-Resistant or Carbapenemase-Producing, *Enterobacteriaceae*. As for the phenotype check, Modified Hodge Test (MHT) and CarbaNP test were performed. Drug susceptibility tests were done by both a two-fold dilution method and disk method / Etest according to CLSI guidelines. Antibiotics heteroresistance was defined as a phenomenon where subpopulations of presumed isogenic bacteria exhibited a range of susceptibility to MEPM or CL. The whole genomes of CRE isolates were determined by sequencing with Illumina's MiSeq.**Results:** Of 20 *Enterobacteriaceae* isolates, 8 showed MICs of MEPM (2-32 ug/ml). However, MHT and CarbaNP test were negative. of them, a *K. pneumoniae* isolate showed heteroresistance to MEPM, and an *E. cloacae* isolate did heteroresistance to CL as determined by using a disk method, but both did resistance to MEPM or CL, when determined by using a microdilution method. Whole genome sequence analyses revealed that the *K. pnemoniae* isolate harbored $bla_{\text{CTX-M-55}}$, $bla_{\text{TEM-1}}$ and $bla_{\text{SHV-11}}$ but not any carbapenemase- encoding genes, and that the *E. cloacae* did $bla_{\text{TEM-1}}$, $bla_{\text{SHV-12}}$ and $bla_{\text{ACT-2}}$ but not any carbapenemase-encoding genes. The CL- heteroresistant *E. cloacae* isolate had mutations in encoding genes of two-component systems *(pmrABC* and *phoPQ*) associated with CL resistance.**Conclusions:** This is the first identification of MEPM- heteroresistant *K. pneumoniae* and CL-heteroresistant *E. cloacae* in Japan.

US Gulf-Like Toxigenic 01 *Vibrio cholerae* Causing Sporadic Cholera Outbreaks in China

Author Block:

Y. Luo[1], S. Octavia[2], D. Jin[1], J. Ye[1], Z. Miao[1], T. Jiang[1], S. Xia[1], R. Lan[2]; [1]Zhejiang Provincial Ctr. for Disease Control and Prevention, Hangzhou, China, [2]Univ. of New South Wales, Sydney, Australia

Abstract Body:

Background: Toxigenic O1 *Vibrio cholerae* causes pandemic cholera with the current 7th pandemic clone still causing epidemic or endemic cholera in developing countries. China has had no epidemic cholera reported in recent years.**Methods:** In this study we identified and characterised 76 non-7th pandemic O1 toxigenic *V. cholerae* isolates from diarrhoeal patients from 2009 to 2014 in Zhejiang Province, China. These isolates were analysed by multilocus sequence typing (MLST) and pulsed field gel electrophoresis (PFGE) to determine their overall genetic relatedness and their relationship to other O1 toxigenic strains.**Results:** By MLST, 19 sequence types (STs) were found. Thirty three isolates belonged to ST75 which also contains the US Gulf coast clone. The genomes of 13 isolates were also sequenced. PFGE and genome sequencing revealed multiple linked cases suggesting small outbreaks. Genome sequencing further showed that the US Gulf coast clone and the Chinese ST75 isolates can be separated into two distinct lineages, ST75a and ST75b. ST75b was the predominant O1 in our survey of O1 isolates collected from 2009 to 2014 in Zhejiang, China. The ST75b lineage carried unique features differing from the ST75a lineage with a CTX prophage identical to the 7th pandemic clone and carriage of a VSP-1. However, the VPI-1 encoding the toxin-coregulated pilus is very similar between ST75a and ST75b strains with only six SNP differences.**Conclusions:** ST75b strains may pose significant threat to public health and epidemiological surveillance is required to further understand their epidemic potential.

Whole Genome Sequence Analysis of Antimicrobial Resistant *E. coli* Isolated from Irish Retail Meats

Author Block:

C. Brehony[1], B. Mahon[1], S. Kavanagh[1], M. Cormican[1], R. H. Madden[2], C. Kelly[2], L. Moran[2], C. Carroll[1], J. Bray[3], K. A. Jolley[3], M. C. J. Maiden[3], D. Morris[1]; [1]Natl. Univ. of Ireland, Galway, Ireland, [2]Food Sci. Branch, Agri-Food & BioSci.s Inst., Belfast, United Kingdom, [3]Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Background: The appropriate and inappropriate use of antimicrobial agents in human and veterinary medicine and agriculture, for several decades has resulted in the emergence and dissemination of antimicrobial resistant bacteria. Such antimicrobial resistance is recognised globally as a major public health concern. This study examined the role of food in the dissemination of antimicrobial resistant bacteria. **Methods:** 600 raw meat samples were purchased from retail outlets throughout the island of Ireland Nov 2013 - Sept 2014. All samples were tested for antimicrobial resistant E. coli (AREC) and 496 AREC isolates were obtained. All AREC isolates were characterised by a series of phenotypic and genotypic tests and based on these results 96 isolates were selected for whole genome sequencing. Isolate genomes were hosted in and analysis was performed using a local installation of BIGSdb. The O25b:H4-ST131 EC958 reference genome was used for whole genome pairwise comparisons amongst the genomes.**Results:** 54 isolates were extended spectrum beta lactamase (ESBL) producers. 33 of these had blaCTX-M, 19 blaTEM, 18 blaSHV, and none had blaOXA. There were 46 7 locus sequence types (STs) and 12 clonal complexes. There were 61 ribosomal sequence types (rSTs) with the most common, rST-1544, accounting for 15% of isolates. There was an association with this rST and source as 92.9% were from chicken samples (13/14). The majority of rSTs were diverse but there were some groupings and, the largest of which, rST-1544, consisted of two groups: ST162 (469 Cplx) and ST1431 (Unassigned). 4981 loci were compared for all genomes and the fewest differences (n=39) were found in 2 chicken meat isolates within the rST-1544 grouping. None of the rST-1544 group were ESBL producers.**Conclusions:** AREC found in Irish retail meats were relatively diverse. Although blaCTX-M predominated amongst ESBL E. coli other ESBL genes were also common. Interrogation of whole genome databases for emerging antimicrobial resistance determinants provided a rapid low cost approach to evaluate the extent of dissemination prior to recognition and will become a more powerful tool as databases expand.

Plasmid Mediatedcolistin Resistance Encoding Gene Mcr-1 Not Detected in *E. coli* Isolated inIreland from Retail Meats and People

Author Block:

C. Brehony[1], B. Mahon[1], S. Kavanagh[1], M. Cormican[1], R. H. Madden[2], C. Ludden[1], C. Kelly[2], L. Moran[2], C. Carroll[1], J. Bray[3], K. A. Jolley[3], M. C. J. Maiden[3], D. Morris[1]; [1]Natl. Univ. of Ireland, Galway, Ireland, [2]Food Sci. Branch, Agri-Food & BioSci.s Inst., Belfast, United Kingdom, [3]Univ. of Oxford, Oxford, United Kingdom

Abstract Body:

Background: The plasmid-mediated colistin resistance gene, mcr-1, was first described in November 2015 by Liu et al in E. coli isolated from food, animals and humans. Colistin resistance is a major cause for concern as it is one of the very few antimicrobial agents available for treatment of infection associated with carbapenemase producing Enterobacteriaceae. Subsequently, others have isolates E. coli harbouring mcr-1 from meat and human specimens, as well as in Salmonella Typhimurium isolated from food samples. Prior to these findings, colistin resistance was found to be mediated by mutations in chromosomally encoded genes and the dissemination of such resistance required the spread of carrier organisms. However, the plasmid can be carried by many different genera of bacteria, raising concerns of the rapid and widespread dissemination of colistin resistance. **Methods:** Whole genome sequences of 96 E. coli isolates collected from retail meats in Ireland and Northern Ireland (November 2013 - September 2014) and 96 E. coli isolates collected (2005 - 2011) primarily from residents of long term care facilities were examined. Genomes were hosted in and analysis was performed using a local installation of BIGSdb. The mcr-1 sequence of Liu et al was used to conduct a BLASTN search against all 192 Irish human and food E. coli genomes.**Results:** No significant matches were returned indicating the absence of the gene in this set of genomes.**Conclusions:** The absence of mcr-1 in this limited collection of food and human genomes from Ireland suggests that it has not yet been disseminated widely in food animals or humans in this region though further testing including retrospective will be required to confirm this. Use of colistin and related compounds in human health care on the island of Ireland is very limited. The recent finding of a transferable colistin resistance mechanism in China and more recently in Europe and North America is of major concern and underlines the necessity of continuous surveillance.

Emerging Biofilm Forming Enteroinvasive *E. coli* (Bf-Eiec): Analysis of Whole Genome Sequencing

Author Block:

J. Iqbal, O. G. Gomez-Duarte; Vanderbilt Univ., Nashville, TN

Abstract Body:

Emergent intestinal *E. coli* pathogens pose a serious threat to human health. We have recently identified an emergent biofilm forming enteroinvasive *E. coli* (BF-EIEC) from Colombian children suffering from severe diarrhea. EIEC are closely related to *Shigella* spp. and cause Shigellosis-like disease. Biofilm is a unique feature to this BF-EIEC emergent pathotype and we believe that it may be involved in pathogenesis. The objective of this study was to identify known EIEC and emergent virulence genes and pathogenicity islands in this BF-EIEC strain by whole genome analysis. Genome sequencing was performed on the BF-EIEC 52.1 strain using NextGen Illumina and Pacific Biosciences (PacBio) platforms. Data was analyzed using different publically available software and databases. BF-EIEC genome consists of 5,193,449 bp long chromosomal DNA, 269589 bp large invasion plasmid and 45997bp long additional plasmid. BF-EIEC genome analysis identified 57 genomic islands, 26 pathogenicity islands and 12 prophage integrations. Virulence associated genes identified in the genome included: i) type three secretory system (TTSS), which plays a central role in EIEC/*Shigella* cell invasion and cell spread; ii)cell adhesion and colonization, iii) biofilm formation, iv) survival in host cell and v) cytotoxicity. Other putative gene function detected included, iron chelation, stress response, evasion of immune response, inflammation and proteolytic degradation of host factors. Antibiotic resistance-associated genes were also detected including efflux pumps and antibiotic degradation enzymes genes among others. These studies indicate that BF-EIEC 52.1 strain contains virulence genes known to be associated with *Shigella* and EIEC pathogenesis, especially the TTSS genes. The identification of virulence genes and multiple episomal elements may provide evidence of horizontal transfer from other pathogens. Sequencing of BF-EIEC genome not only shed light on the evolution and pathogenesis of this emerging *E. coli* but may also open opportunities for exciting new discoveries.

Phylodynamics of *Vibrio cholerae* O1 Isolated in Rural Coastal Area of Bangladesh

Author Block:

S. M. Rashed[1], S. Y. Choi[2], N. A. Hasan[2], D. Ceccarelli[1], M. Alam[3], D. A. Sack[4], R. B. Sack[4], A. Huq[1], R. R. Colwell[1]; [1]Univ. of Maryland, College Park, MD, [2]CosmosID Inc, Rockville, MD, [3]icddr,b, Dhaka, Bangladesh, [4]Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD

Abstract Body:

Vibrio cholerae, the causative agent of cholera, is autochthonous to the aquatic environment worldwide. Cholera remains a serious threat to millions in several countries of Asia, Africa, and South America. Microevolution of the bacterium in the aquatic reservoir and human host enables emergence of new clones, which contribute significantly to the dynamics of cholera. Cholera outbreaks in the coastal areas of Bangladesh are triggered by seasonal influences annually. In this study, 23 clinical and environmental isolates of *V. cholerae* O1 collected during 2010 - 2011 in Mathbaria, Bangladesh, were characterized by genotyping, antimicrobial susceptibility, and whole-genome sequencing and compared with outbreak isolates from Asia, Africa, and South America. All *V. cholerae* O1 isolates possessed the virulence genes *tcpA*, *ctxA*, *hlyA*, *ace*, and *zot*. Of 23 isolates, 17 had classical cholera toxin gene (*ctxB1*), whereas six had Haiti type cholera toxin (c*txB7*). Resistance to streptomycin (S), nalidixic acid (NA), and trimethoprim/sulfamethoxazole (SXT) was uniformly present in the isolates, whereas tetracycline (TE) and erythromycin (E) resistance varied. Multidrug resistant isolates from Bangladesh showed three distinct patterns:(1) S^R, NA^R, SXT^R (65.21%); (2) S^R, NA^R, TE^R, SXT^R (30.43%); (3) S^R, NA^R, E^R, TE^R, SXT^R (4.35%), and all contained SXT integrase gene int_{SXT}. Minimum inhibitory concentration (MIC) for ciprofloxacin was 0.25 - 0.75 µg/mL (MIC_{50} = 0.38 µg/mL and MIC_{90} = 0.5 µg/mL), suggesting reduced susceptibility to ciprofloxacin. Phylogenetic analysis based on single nucleotide polymorphisms (SNPs) showed *V. cholerae* O1 isolates of Bangladesh belong to two different clusters in the seventh pandemic clade, correlating with cholera toxin genes, *ctxB1* or *ctxB7*. The six *V. cholerae* O1 isolates from Bangladesh harboring *ctxB7* were closely related to Haitian strains isolated during 2010 - 2012, whereas those possessing *ctxB1* showed clonal relatedness to *V. cholerae* O1 altered El Tor from Asia and Africa.

Emergence of a Highly Virulent *Shigella sonnei* Clone in California

Author Block:

V. Kozyreva[1], G. Jospin[2], A. Greninger[1], J. Eisen[2], V. Chaturvedi[1]; [1]California Dept. of Publ. Hlth., Richmond, CA, [2]Univ. of California, Davis, CA

Abstract Body:

Background: *Shigella sonnei* has caused large outbreaks in California recently. We constructed and analyzed *S.sonnei* whole genome sequencing (WGS) database to probe public health significance of these outbreaks. **Methods:** Sixty one CA *S.sonnei* human isolates (1980-2015), were identified by standard methods. WGS of paired-end libraries was performed using Illumina MiSeq Sequencer. *De novo* assembly was done on CLCbio GW 8.0.2. Genomes were annotated with prokka v1.1, CGE online tools, and JGI IMG database. *In silico* MLST was performed with CGE tool. Phylogenetic analysis was performed based on SNP calling with min coverage 30x and min base quality 200; and using PhyloSift pipeline, COG- and Pfam-based clustering. **Results:** All *S.sonnei* CA isolates except one were assigned to sequence type 152 (ST152) and clustered together based on PhyloSift phylogeny. In both historical and contemporary outbreak isolates, following resistance markers were identified: *bla*$_{TEM1}$*; bla*$_{OXA2}$; *aph(3'')-Ib; aph(6)-Id; aac(3)-IId; aadA1/2*; *mphA*; *sul1/2*; *catA1*; *dfrA1/8/12*; *tetA/B.* A single amino acid substitution in DNA-gyrase *gyrA* gene conferring a low-level FQ resistance was present in few isolates prior to 2008. However, recent isolates had a combination of double mutation of *gyrA* and one mutation of topoisomerase IV *parC* genes, mediating high-level FQ resistance. Significantly, most recent isolates carried Shiga toxin gene *stx1* in association with a novel lambdoid phage. The phage is homologous with the phage found in *E.coli* O104:H4 outbreak strain from 2011 German outbreak. Hierarchical clustering based on COG and Pfam profiles shows that CA *S.sonnei* isolates cluster together with non-O157 *E.coli*, particularly with European O104:H4 STEC, and are distinct from other *S.sonnei* isolates. **Conclusions:** *S.sonnei* ST152, a historical clone in CA, has increased its antibiotic resistance and virulence. The data suggests a high potential for more future *S.sonnei* ST152 outbreaks with serious consequences.

Population Genomics of *Campylobacter jejuni* Associated with Sheep Abortion

Author Block:

Z. Wu[1], B. Periaswamy[2], S. Chen[2], O. Sahin[1], Q. Zhang[1]; [1]Iowa State Univ., Ames, IA, [2]Genome Inst. of Singapore, Singapore, Singapore

Abstract Body:

Campylobacter infection is a leading cause of ovine abortion worldwide. Outbreaks of *Campylobacter*-associated ovine abortion are traditionally caused by multiple species and strains of this zoonotic organism. However, a highly-pathogenic and tetracycline-resistant clone of *C. jejuni* (clone SA for sheep abortion) has recently emerged as the persistently predominant cause of sheep abortions in the USA. This finding is quite surprising and indicates that clone SA is ecologically well adapted and pathologically hypervirulent in sheep as a result of its increased fitness. To ascertain the evolution and the adaptive genetic changes responsible for the emergence and predominance of clone SA, we analyzed the whole genomes of 99 *C. jejuni* isolates from a historical collection encompassing clinical isolates from sheep abortion cases collected from geographically distinct regions since early 1990s. A whole-genome phylogeny confirmed the clonal expansion of clone SA, with a monophyletic origin close to ST50 *C. jejuni* strains in clonal complex 21, a reduced recombination subsequent to the emergence and a reduced haplotype diversity, and led to an estimate of its emergence in the 1970s. However, the non-clone SA abortion isolates are paraphyletic and genetically indistinguishable from non-abortion isolates. Population genetic tests suggested that mutations of an outer membrane protein and integration of *tet(O)* into the genomes might have favored the expansion of clone SA. These findings provide significant insights into the molecular genetic events underlying its emergence, evolutionary history and increased fitness.

Clade-Specific Production Of Hemolysin Bl And Nonhemolytic Enterotoxin Nhe By *bacillus Cereus* Group Dairy Isolates

Author Block:

J. Kovać, R. A. Miller, L. M. Carroll, J. Jian, D. J. Kent, M. Wiedmann; Cornell Univ., Ithaca, NY

Abstract Body:

Background: The *Bacillus cereus* Group comprises the human pathogens *B. cereus* (BC), *B. cytotoxicus* and *B. anthracis* (BA), the insect pathogen *B. thuringiensis* (BT), the psychrotolerant food spoilage organism *B. weihenstephanensis,* probiotic *B. toyonensis* and environmental *B. mycoides* and *B. pseudomycoides*. *B. cereus* Group isolates often contaminate rice, meat, and dairy products and can present food poisoning and food spoilage risks. Due to the high genetic similarity of different BC group species, identification at the species level and prediction of the risk an isolate poses for human health remains a challenge.**Methods:** We have sequenced 22 dairy-associated *B. cereus* Group isolates on Illumina HiSeq platform (2x100 bp) and compared their draft genomes with 47 closed reference genomes acquired from NCBI Genome to i) identify 22 dairy-associated isolates at the species level based on maximum likelihood phylogeny (RaxML version 8) constructed using core genome SNPs (kSNP v2), ii) identify virulence gene profiles specific for individual species using protein BLAST, and iii) investigate the correlation of *hblACD* an *nheABC* gene presence/absence and sequence variability with hemolysin BL and nonhemolytic enterotoxin NHE production at 37°C, as determined using Duopath Cereus Enterotoxin kit.**Results:** A maximum likelihood tree revealed nine distinct clades and whole-genome sequence (WGS) data enabled the identification of monophyletic *B. weihenstephanensis* and *B. toyonensis*, but failed to identify polyphyletic BC, BA and BT. Production of two diarrheal toxins, hemolysin BL (HblC) and nonhemolytic enterotoxin (NheB) revealed evidence for differences in hemolysin BL production among phylogenetic clades. Among the 4 BC/BT clades, one clade was negative for toxin production due to the gene absence, two were positive, and one showed variable production among isolates. Isolates from the *B. weihenstephanensis* clade carried atruncated variant of hemolysin BL binding component (*hblA*) and did not produce hemolysin BL toxin.**Conclusions:** Results of our analyses suggest that WGS data has the potential to be used to predict the diarrheal toxin production and pathogenicity of *B. cereus* Group isolates.

Toward Diagnosis of Diarrheal Disease Using 16s Rrna Taxonomic Profiling and Metagenomics

Author Block:

A. V. Pena Gonzalez[1], J. K. Hatt[1], G. Trueba[2], W. Cevallos[3], J. N. S. Eisenberg[4], K. Levy[5], K. T. Konstantinidis[1]; [1]Georgia Inst. of Technology, Atlanta, GA, [2]Univ. San Francisco de Quito, Quito, Ecuador, [3]Univ. Central de Ecuador, Quito, Ecuador, [4]Univ. of Michigan, Ann Arbor, MI, [5]Emory Univ., Atlanta, GA

Abstract Body:

Diarrheal disease continues to be a significant cause of mortality around the world. Consequently, better characterization of the causative agents and the compositional alterations that occur in the gut microbiome during the pathological state continue to be critical. In this study we used a 16S rRNA taxonomic profiling combined with shotgun metagenomic sequencing to investigate several cases of human diarrheal disease of undefined etiology in individuals from Northern Coastal Equador, and compare them with diarrheal cases where the etiological agent was determined by PCR. By sequencing the V4 region of the 16SrRNA gene, we assessed changes in OTU richness, evenness and diversity in both diseased and healthy samples from the same individual and determined the effects of additional demographic variables such as age, race, and geographical distance. In addition, we developed bioinformatics approaches to characterize the pathogens at the strain level in the cases where the etiological agent was identified. We observed a significant reduction in OTU richness and diversity in individuals with diarrhea of undefined origin when compared with their matched healthy samples, and higher species richness in individuals from more remote communities (Pearson's R= 0.30756). Despite these differences, multidimensional analysis failed to separate healthy from diseased samples. When the causative agent was specified, such as in acute rotavirus or E. coli+ infections, we were able to distinguish healthy from diarrheal samples and detect significant differences in the taxonomic composition and metabolic potential in the gut microbiome. Together, these results highlight the potential of using sequence-based methods to understand better the impact of diarrheal diseases in the diversity of the gut microbiota.

Differential Evolution in Mitochondrial Metabolism and Invasion-related Proteins in Cryptosporidium

Author Block:

S. Liu[1], D. M. Roellig[2], Y. Guo[1], N. Li[1], M. A. Frace[2], K. Tang[2], L. Zhang[3], **Y. Feng**[1], L. Xiao[2]; [1]East China Univ. of Sci. and Technology, Shanghai, China, [2]CDC, Atlanta, GA, [3]Henan Agricultural Univ., Zhengzhou, China

Abstract Body:

Cryptosporidium spp. are important apicomplexan parasites causing diarrhea in humans and animals. They differ from each other in host specificity and predilection sites. The genomes of three *Cryptosporidium* species, including *C. parvum*, *C. hominis* and *C. muris*, have been sequenced and are available in public databases. In this study, we sequenced the genomes of *C. ubiquitum* and *C. andersoni* and conducted a comparative genomic analysis of *Cryptosporidium* spp. All *Cryptosporidium* species share common genomic features such as gene content and organization. Major metabolic differences among *Cryptosporidium* spp. are in mitochondrial energy metabolism. Comparing to *C. parvum* and *C. hominis*, *C. andersoni* possesses more aerobic metabolic pathways, whereas *C. ubiquitum* has further reduction in mitochondrial metabolism. Minor metabolic differences among *Cryptosporidium* spp. were seen in the biosynthesis of *N*-glycan and GPI-anchor precursors and inter-conversion of amino acids and nucleotides. In addition to these metabolic differences, the comparative genomic analysis has shown distinct host cell invasion-related proteins among *Cryptosporidium* species. In agreement with the previously observed reduction in the number genes of secreted MEDLE and insulinase-like proteins in the subtelomeric regions of chromosomes 5 and 6 in *C. hominis*, these genes are lost in *C. ubiquitum* and *C. andersoni*. Mucin-type glycoproteins associated with host cell adhesion and invasion are highly divergent between the gastric *C. andersoni* and intestinal *Cryptosporidium* species analyzed. Thus, rapidly evolving mitochondrial metabolism and secreted invasion-related proteins could be responsible for the distinct host specificity and tissue tropism among *Cryptosporidium* spp.

Wgs Analysis of *Salmonella enterica*, Isolated from Food Animals to Identify Antibiotic, Metal, and Biocide Resistance Genes

Author Block:

S. K. Gupta[1], C. R. Jackson[1], P. T. Desai[2], M. McClelland[2], J. G. Frye[1]; [1]United States Natl. Poultry Res. Ctr., Athens, GA, [2]Univ. of California, Irvine, CA

Abstract Body:

Background: Whole-genome sequencing (WGS) has superior sensitivity to conventional genetic techniques for the investigation of infections and outbreaks. WGS data of *Salmonella enterica* isolated from food animal sources were analyzed to identify resistance genes (RG) for various antibiotics, metals, and biocides.**Methods:** *Salmonella enterica* (n = 194) with different patterns of antibiotic resistance isolated from food animals (chicken, swine, etc.) were selected and subjected to WGS using an Illumina HiSeq 2500. Sequences were assembled using A5-miseq assembler and annotated with Prokka. Contigs were analyzed using ARGANNOT, BacMet metal and BacMet biocide RG databases, to detect known antibiotic, metal, and biocide RG, respectively.**Results:** A total of 883 antibiotic RG from nine different antibiotic classes (aminoglycosides (Agly), beta-lactamase, tetracycline, phenicol, sulfonamide, macrolide (Mls), fosfomycin, rifampicin (Rif), trimithoprim) were detected in the *S. enterica* isolates. Approximately 36% of the 194 isolates had at least one antibiotic RG and 3% had 14 antibiotic RG detected. Ninety-nine percent of the isolates were resistant to Agly. Rif (*arr*2) and Mls (*ere*A/*mef*A/*mph*) RG, which are rarely reported in *Salmonella,* were detected in 1% and 3% of isolates, respectively. Major metal and biocide RG were detected in 100% of the strains: *mdt*A/B/C:zinc; *sit*A/B/C:arsenic; *mod*A/B/C/E:tungsten/molybdenum; *teh*A/B:Quaternary ammonium compounds/EtBr; *ydd*g:methyl viologen; and *sod*A:Se/H_2O_2. Gold (*ges*A/B/C), copper (*pco*A/B/D/R/S) and silver (*sil*A) RG were detected in 94%, 22% and 21% of isolates, respectively. The *bae*S/R-*tol*C genes were detected in all the isolates and may confer multidrug and metal resistance.**Conclusions:** WGS can be implemented as a powerful tool to detect different RG. Our findings suggest that the selection or maintenance of resistance in *Salmonella* isolated from food animal sources could be due to exposure to metals in addition to antibiotics. WGS data can improve our ability to predict resistance patterns, emerging outbreaks, and detect markers for molecular diagnostics.

Development of a Genome Sequence Database for Foodborne Pathogenic Bacteria in Hong Kong

Author Block:

H. Kwan; The Chinese Univ. of Hong Kong, Shatin, Hong Kong

Abstract Body:

Background: In Hong Kong, *Salmonella enterica* serovars Enteritidis and Typhimurium and *Vibrio parahaemolyticus* causes most of outbreaks. Foodborne diseases demand medical attention and reduce productivity. Besides, the emerging multidrug-resistant (MDR) *S.* Typhimurium strains has complicated treatments, posing a serious threat to the public. Here we constructed the first genome sequence database for Hong Kong foodborne pathogens *S.* Typhimurium (ST) and *V. parahaemolyticus* (VP).**Methods:** We seqeunced genomes of 20 Hong Kong clinical isolates of ST and 10 VP Hong Kong isolates using Roche 454 FLX-Titanium pyrosequencer. Sequencing reads were assembled using GS De Novo Assembler (Roche Diagnostics). Nucleotide-level variations, such as single nucleotide polymorphism (SNP), insertion and deletion (indel) , and inversion among local isolates and several foreign strain sequences were identified using GS Reference Mapper (Roche Diagnostics). Protein genes were predicted from the assemblies using GeneMark and other prediction tools.**Results:** VP genome assemblies have 130 to 1205 contigs of N50 contig length from 7kb to 305kb whereas the assembly of ST yielded 32 to 90 contigs of N50 contig length between 192kb and 458kb. The foodborne pathogen genome database was constructed based on the Ensembl genome annotation system using Perl scripts. Genome DNA sequences can be input into the platform via a user-friendly web-based interface. A suite of useful computational tools was added for comparative sequence analysis and data mining such as multi-locus sequence typing (MLST), restriction enzyme typing and detection of genetic variations using local and foreign typed VP and ST genome data. Genome-wide comparison based on 2151 conserved genes SNPs to show the relationship between local and foreign VP O3:K6 isolates of MLST sequence type ST3. We used 7962 SNPs to differentiate local ST isolates from the foreign ST isolates with MLST sequence type ST19. We have identified 184 orthologs as candidate multi-drug resistance determinants in ST.**Conclusions:** We have developed the first genome sequence databases of Hong Kong foodborne pathogenic bacteria as a user-friendly platform to analyze the genome sequences and annotations of the two pathogens, *Vibrio parahaemolyticus* and *Salmonella enterica* serotype Typhimurium. The platform will be used to monitor trends of foodborne outbreaks.

Comparative Genomics Reveals *Cyclospora cayetanensis* Possesses Coccidia-Like Metabolism and Invasion Components but Unique Surface Antigens

Author Block:

S. Liu[1], L. Wang[1], H. Zheng[2], Z. Xu[1], D. M. Roellig[3], N. Li[1], M. A. Frace[3], K. Tang[3], L. Zhang[4], Y. Feng[1], **L. Xiao**[3]; [1]East China Univ. of Sci. and Technology, Shanghai, China, [2]Chinese Natl. Human Genome Ctr. at Shanghai, Shanghai, China, [3]CDC, Atlanta, GA, [4]Henan Agricultural Univ., Zhengzhou, China

Abstract Body:

Background: *Cyclospora cayetanensis* is an apicomplexan that causes diarrhea in humans. The investigation of foodborne outbreaks of cyclosporiasis has been hampered by a lack of genetic data and poor understanding of pathogen biology. In this study we sequenced the genome of *C. cayetanensis* and compared it with genomes of other apicomplexans. **Results:** The genome organization, metabolic capabilities and potential invasion mechanism of *C. cayetanensis* are very similar to those of *Eimeria tenella*. Propanoyl-CoA degradation, GPI anchor biosynthesis, and N-glycosylation are some apparent metabolic differences between *C. cayetanensis* and *E. tenella*, suggesting that metabolism within monoxenous coccidian parasites is highly conserved. The similar repertoire of host cell invasion-related proteins possessed by all coccidia suggests that *C. cayetanensis* has an invasion process similar to the one in *T. gondii* and *E. tenella*. However, the significant reduction in the number of rhoptry protein kinases, phosphatases and serine protease inhibitors indicates that the capabilities of host cell regulation especially the interruption of host cell nuclear activities are limited in monoxenous coccidia, especially *C. cayetanensis*. *C. cayetanensis* does not possess any SAG1 related proteins seen in *T. gondii*, has only a few homologs of the TA4-type SAG surface antigens seen in *E. tenella*, and may use a different family of surface antigens in host cell recognition and attachment. **Conclusions:** Our findings indicate that *C. cayetanensis* possesses coccidia-like metabolism and invasion components but unique surface antigens. Amino acid metabolism and post-translation modifications of proteins are some major differences between *C. cayetanensis* and other apicomplexans. *C. cayetanensis* likely has only limited in modulating host cell signaling pathways. The whole genome sequence data of *C. cayetanensis* improve our understanding of the biology and evolution of this major foodborne pathogen and facilitate the development of intervention measures and advanced diagnostic tools.

Clinical Metagenomics for Rapid Detection of Diarrheagenic Pathogens and Characterization of Intestinal Microbiome in Health and Disease

Author Block:

N. A. Hasan[1], K. Moffat[2], P. Subramanian[2], R. Isom[2], S. Choi[2], S. M. Rashed[1], J. Li[2], H. Li[2], A. Huq[3], G. Nair[4], T. Ramamurthy[4], R. R. Colwell[1]; [1]Univ. of Maryland, College Park, MD, [2]CosmosID, Rockville, MD, [3]Univ. of Maryland, College park, MD, [4]Natl. Inst. of Cholera and Enteric Diseases, Kolkata, India

Abstract Body:

Versatility, reduced cost, and faster turnaround time of sequencing suggest high-throughput, and high-resolution metagenomic analysis can be used as a diagnostic tool for clinical management of intestinal and extra-intestinal infectious diseases. A retrospective case-control study of 65 fecal samples was done that included 45 patients (17 known and 28 unknown disease etiology) and 20 healthy individuals. Samples were collected during a systematic surveillance at the National Institute of Cholera and Enteric Diseases, Calcutta, India. Samples were sequenced using Illumina GAIIx and results analyzed by CosmosID MetaGenID bioinformatics package and curated GenBook® databases. Metagenomic analyses identified pathogens, *i.e., Vibrio cholerae, Shigella, Escherichia coli,* and *Campylobacter,* in samples of known etiology, whereas samples of unknown etiology contained predominantly members of the *E. coli* super family, namely pathogenic *E. coli*, *Shigella,* and *Salmonella enterica,* as well as *Aeromonas caviae*, *C. jejuni,* and *Cryptosporidium*. Multiple pathogens were detected. Patients were differentiated from healthy individuals based on organism abundance and diversity. Patients exhibiting profound watery diarrhea carried pathogens primarily of the *Escherichia coli* complex. The antibiotic resistome that was detected, comprised major classes of antibiotics, including beta-lactam, aminoglycoside, tetracycline, and trimethoprim. Microbiomes of healthy individuals of Indian descent were markedly different from those of Western descent and contained low numbers of pathogens. This study showed the intestinal microbiome could differentiate healthy, diseased, asymptomatic carriers, and individuals in early stages of disease. Clinical metagenomics potentially will revolutionize diagnostics, prophylactics, and therapeutics of infectious disease.

Genomic Insight Into A Sustained Multi-Centre Outbreak Of Yersinia Pseudotuberculosis

Author Block:

S. Baines, A. Gonçalves da Silva, T. Seemann, G. Carter, T. Stinear, B. Howden, D. Williamson; The Univ. of Melbourne, Melbourne, Australia

Abstract Body:

Yersinia pseudotuberculosis (Yptb) is a zoonotic pathogen and the second most common cause of human yersiniosis after *Y. enterocolitica*. Although most infections with Yptb are thought to be sporadic, outbreaks of foodborne infection have been reported. Between August 14th and November 1st 2014 a sustained outbreak of yersiniosis due to Yptb occurred across all major cities in New Zealand (NZ), with a total of 220 laboratory-confirmed cases.In addition to an epidemiological investigation, a detailed genomic examination of the outbreak was undertaken, with whole genome sequencing (WGS) being performed on 128 NZ isolates of Yptb. This collection represented isolates recovered during the outbreak period (n=95), as well as 10 years prior (n=28), and one year following (n=5) the outbreak. These isolates were further supplemented with the publicly available genome sequences of 52 global Yptb.Reconstruction of the population structure for these 180 Yptb isolates identified that the outbreak was caused by a single clade of Yptb belonging to the globally prominent multi locus sequence type 42. This extremely genetically restricted clade comprised 82 of the 95 outbreak isolates; the population differing by only 13 core genome single nucleotide polymorphisms. Furthermore, WGS enabled the exclusion of isolates that were genetically distinct from the outbreak clade but thought to be associated based on epidemiological classification. Amongst the outbreak isolates no temporal, geographic, or genomic signals were detected to identify potential transmission networks, instead supporting a single point source contamination of the food chain, with subsequent distribution of contaminated produce across NZ.This outbreak of Yptb in NZ represents, to date, the largest laboratory-confirmed outbreak of Yptb globally. The use of WGS enabled robust classification of outbreak and non-outbreak isolates, and provided strong support for a single point-source contamination event as the cause of this outbreak. WGS is particularly useful in investigating outbreaks of yersiniosis, for which existing typing methods are non-discriminatory and should be used routinely as a first-line epidemiological tool in investigating outbreaks of yersiniosis.

Molecular Epidemiology and Resistome Analysis of Toxigenic *Clostridium difficile* in Asia-Pacific Countries

Author Block:

K. Aoki, Y. Ishii, K. Tateda; Toho Univ., Ota-ku,, Japan

Abstract Body:

Background: *C. difficile* epidemiology is well studied in North America and Europe, whereas in Asia-Pacific countries is less often performed. In this study, we analyzed *C. difficile* isolated from diarrhea stool samples collected prospectively in 12 Asia-Pacific countries using next-generation sequencing (NGS). **Methods:** Four hundred and fourteen *C. difficile* were isolated from diarrhea stool samples between April, 2014 and February, 2015. To determine the genome-wide draft sequence, all isolates were analyzed by MiSeq (Illumina). Multilocus sequence typing (MLST), the presence of toxin encoding genes(*tcdA*, *tcdB* and *tcdC*), the binary toxin encoding genes (*cdtA* and *cdtB*) and antimicrobial resistance genes including substitution of quinolone-resistance determining regions (QRDRs) in *gyrA* and *gyrB* and Rifamycin-resistance determining regions (RRDRs) in *rpoB* were analyzed from the draft genome contigs.**Results:** The 378 isolates were classified into 53 STs. Thirty-six isolates were assigned novel STs (ST numbers not yet assigned). ST37 (associated with PCR ribotype[RT]017) was the most dominant ST with 62 isolates (15.0%), followed by ST17(53 isolates, 12.8%), ST2(38 isolates, 9.2%) and ST8(30 isolates, 72%). Characteristically, ST37 isolates were *tcdA*(-), *tcdB*(+), *cdtA*(-),*cdtB*(-) and had no mutations in *tcdC*. Among the six countries with over 38 *C. difficle* isolated, the dominant STs were ST2(Australia[20/50 isolates]), ST8(Taiwan[21/88]), ST17(Korea[34/88] and Japan[15/46]), ST35(China[6/45]) and ST37(Thailand[19/38]), respectively. Hypervirulent clones belonging to ST1(3 isolates[RT027]) , ST5(5 isolates[RT023]), ST11(6 isolates[RT078]), ST35(1 isolates[RT002]) and ST42(1 isolates[RT106]) had an insertion, a deletion or a point mutation in *tcdC* resulting in frameshift or nonsense mutation. Isolates belonging to ST1, ST5, ST11 and ST228 were *cdtA* and *cdtB* positive. The QRDR mutations of GyrA Thr82Ile, GyrB Asp426Asn/Val were harbored in 150(36.2%) and 32(7.7%) of all isolates, respectively. Two hundred (48.3%), 147(35.5%) and 87(21.0%) of all isolates possessed *erm(B)*, *tet(M)* and *aac(6')-aph(2")*, respectively. There were no mutations in RRDRs.**Conclusions:** Compared with North America and Europe, Asia-Pacific countries had major differences in hypervirulent clones. Interestingly, ST37 lacking *tcdA* was the most common clone.

Missed Opportunities for Treatment: Implementation of a Molecular Diagnostic for Pediatric Acute Gastroenteritis (Ge): The Filmarray Gi Panel Impact Study

Author Block:

K. M. Bourzac[1], GI IMPACT Study Team, A. T. Pavia[2], K. C. Chapin[3]; [1]BioFire Diagnostics, Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT, [3]Rhode Island Hosp., Providence, RI

Abstract Body:

Background: The FilmArray Gastrointestinal (GI) Panel (BioFire Diagnostics) is a fully automated ~1hr PCR-based test for identification of 22 different pathogens from stool specimens. Previous studies have demonstrated very good analytical sensitivity and specificity. Here, we present preliminary results of a pre/post intervention study to measure patient outcomes following implementation of the FilmArray GI Panel for children with gastroenteritis (GE) presenting to Emergency Departments (ED). **Methods:** Children with chief complains of GE were recruited at five US EDs. Data collection included pre- and post-enrollment questionnaires and medical chart abstraction. Stool specimens were collected at the time of presentation to the ED or within two days. During the pre-intervention period, FilmArray GI Panel testing was performed but results were not reported to clinicians or families. Clinicians ordered standard of care (SOC) GI testing as they determined appropriate. The number of additional healthcare encounters, total healthcare costs, antibiotic prescription rates and appropriateness, lost time from school/work/daycare, and subject satisfaction with management of the illness were analyzed.**Results:** To date, 310 subjects have been enrolled in the pre-intervention period and returned stool for analysis. FilmArray identified 222 specimens positive for one or more potential pathogens (222/310; 72%). In contrast, SOC testing was ordered in only 56 subjects, yielding 17 positives (17/310; 5%). Significantly, the FilmArray identified treatable pathogens in 63/310 (20%) subjects that were not diagnosed by clinicians including *Campy* (N=8), ETEC (N=10), *Shigella* (N=25), *Crypto* (N=10), and *Giardia* (N=9). Other organisms identified only by FilmArray and missed by SOC that could potentially modify care included *Salmonella* (N=9) and STEC (N=10). Viruses were identified in 101.**Conclusions:** These preliminary data suggest that clinicians in EDs may under-diagnose treatable infections in pediatric patients with GE. Data collected during the pre- and post-intervention periods will measure whether the availability of this information will lead to improved patient outcomes.

Increased Incidence of Infections Due to *Streptococcus anginosus* between 2006 and 2015

Author Block:

E. O. Hand[1], B. Duhon[1], C. Pickard[1], S. Hallowell[1], K. Traugott[2]; [1]The Univ. of Texas at Austin Coll. of Pharmacy, San Antonio, TX, [2]Univ. Hlth.System, San Antonio, TX

Abstract Body:

Background: Recently a rise in infections due to *Streptococcus anginosus* was noted at our institution, particularly a rise in bacteremias. It was unclear whether this increased incidence was purely anecdotal or part of a larger trend in changing epidemiology. The purpose of this study was to evaluate the rates and types of infections caused by *S. anginosus* at our institution over the preceding decade.**Methods:**A query of the microbiology laboratory database was performed to identify all positive cultures growing *S. anginosus* from January 2006 to October 2015. This list was then organized by year and site of infection.**Results:**A total of 1667 separate cultures were identified, corresponding to 1129 unique patients. In 2006, 76 patients accounted for 107 positive cultures. The number of individual patients with a positive culture for *S. anginosus* doubled by 2014 (n=158) and number of cultures increased to 235. The most common site of infection in all years studied was described as “body fluid” or “exudate” (n=1031/1667, 62%) with the number of positive cultures increasing from 72 in 2006 to 140 in 2014. Respiratory infections were relatively uncommon (n=50/1667, 3%) but increased from three cultures to 14 between 2006 and 2014. Notably, the number of positive blood cultures increased from 8 in 2006 to 24 in 2014. When 2015 data were extrapolated to a full calendar year, both number of patients (n=190) and number of positive cultures (n=279) were project to be the highest values in any year studied.**Conclusions:**Infections caused by *S. anginosus* have continually risen at our institution between 2006 and 2015. The cause of this increase has yet to be fully elucidated, but further investigations will focus on changes in antimicrobial susceptibility over the time frame as well as predisposing factors that may put patients at increased risk of *S. anginosus* infections.

Inst., Addis Ababa, Ethiopia, [5]Oslo Univ. Hosp., Oslo, Norway

Abstract Body:

Background: Among children diagnosed to have chronic rheumatic valvular heart disease many were observed to develop recurrence of rheumatic fever despite the secondary prophylaxis. This study determined *emm* gene type and protein profile of *S. pyogenes* and *S. dys*galactiae isolated from children having rheumatic heart disease who were receiving on-going prophylaxis.**Methods:** The *emm* gene typing of four *S. pyogenes* and another four *S. dysgalactiae subsp.* Equisimilis was determined by PCR sequencing. Protein of these strains was analysed by Q-exactive mass spectrometry.**Results:** Six different *emm* gene types were identified including one newly discovered subtype (*stGrobn.1*) associated with an *S. dysgalactiae subsp.* Equisimilis isolate which possess Lancefield group A. The streptococcal glycosyltransferase in strain *S. pyogenes* emm 68.2 had N-linked glycosylation carrying a unique N-acetylhexoseamine (HexNAc)-deoxyhexose; a novel post-translational modification (PTM) not previously recognized. **Conclusions:** The strains from S. pyogenes and S. dysgalactiae assessed here had different emm gene types and PTM patterns, enabling distinction of subgroups of these closely related strains with pathogenic potential in rheumatic fever disease.

Serotype Distribution of *Streptococcus pneumoniae* in Clinical Isolates after the Introduction of Pneumococcal Vaccines in Japan

Author Block:

H. Miyazaki[1], N. Midorikawa[1], R. Shibuya[2], A. Haque[1], R. Kobayashi[1], K. Ohkusu[1], T. Oguri[3], T. Matsumoto[1]; [1]Tokyo Med. Univ., Tokyo, Japan, [2]Saiseikai Yokohama Tobu Hosp., Yokohama, Japan, [3]Tokyo Hlth.Care Univ., Tokyo, Japan

Abstract Body:

In Japan, introduction of pneumococcal vaccines has reduced invasive diseases caused by *S. pneumoniae*. For children, the seven-valent pneumococcal conjugate vaccine (PCV7) was licensed in 2009, which was replaced by PCV13 in 2013. For adults, the 23-valent pneumococcal polysaccharide vaccine (PPSV23) is being used and PCV13 was licensed in June, 2014. However, relative increase in non-vaccine serotypes has been reported since the introduction of these vaccines. To assess the dynamic seroepidemiology of this pathogen, capsular serotyping using multiplex PCR was performed on 150 pneumococcal isolates obtained from a hospital in Yokohama, Japan during October 2014 to March 2015. One hundred ten isolates (73.3%) were obtained from sputum, and others from samples like; bronchial lavage, nasopharyngeal discharge, blood, cerebrospinal fluid, and otorrhea. Seventy-nine strains (52.6%) were isolated from children under 5 years of age, forty strains (26.7%) were from patients ≧65 years old, and others were from age group between 5 to 64 years. The strains from under 5 years included 1 (1.2%) PCV7-targeted serotype, 13 (16.4%) PCV13 serotypes, and 48 (60.7%) non-PCV13 serotypes. Predominant serotypes in isolates from children were 35B (non-PCV13 serotype), serogroup 15 (non-PCV13 serotypes), and 19A (PCV7 but non-PCV13). These results indicate replacement of the vaccine types by non-vaccine types. Although increasing trend of serotype 19A isolates in the post-PCV7 period was still observed, this serotype is predicted to decrease. Whereas, the strains isolated from ≧65 years included 7.5% PCV7 serotypes, 30.0% PCV13 serotypes, 37.5% PPSV23 serotypes, and 17.5% non-PPSV23 serotypes. These results suggest emergence of indirect effects following introduction of PCV7 for children. PPSV23 serotypes in the ≧65 years population are predicted to decrease, because immunization program of the age based recommendation has been launched in 2014. Predominant serotypes in the strains from age group between 5 to 64 years were 3 and 19A, which are both PCV13 and PPSV23 serotypes.Continuous monitoring of pneumococcal serotypes is necessary to follow the changing epidemiology of pneumococcal diseases.

A Rapid, Reference-Free Tool for Simplifying Whole Genome Strain Typing

Author Block:

K. E. Simmon[1], M. A. Fisher[2]; [1]ARUP Lab., Salt Lake City, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Background: Comparing bacterial strains is important for outbreak investigation. Whole genome sequencing (WGS) has the potential to provide more clinically actionable information than current methods, however the data analysis and interpretation are often more complex. WGS strain typing is typically performed by alignment to a reference genome, but some strains may have DNA regions not present in the reference, leading to sub-optimal alignment and strain comparison. We developed a tool called StrainTypeMer (STM) that performs rapid, reference-free comparison of strains using kmers. STM can compare multiple strains in minutes and generates easy to interpret similarity tables displaying percent identity between strains. **Methods:** Raw sequence files were processed to remove adapters and poor quality reads. Rarefaction analysis to determine optimal sequence coverage was performed by calculating the number of reads required to obtain the predicted kmer quantity. STM was developed using python and requires jellyfish [github.com/gmarcais/Jellyfish]. We assessed STM's performance for typing >125 isolates from both internal and previously published data comparing PFGE and WGS using a reference-based approach. **Results:** Rarefaction curves show that nearly all kmers were observed when average sequence coverage is ≥25X. Strain comparisons are performed in ~30 min for ~20 strains, with a rapid mode allowing comparisons in <5 min. Dendrograms created from kmer distance matrices show strain relationships very similar to those derived from reference genome alignment. Mean kmer identity was 99.8% for replicates. Mean kmer identity for PFGE categories of identical, closely/possibly related, and different were, 99.2%, 94.6%, and 58.3%, respectively. **Conclusions:** Unlike current methods, STM does not require a reference genome, allowing comparison of sequences present in strains of interest but not in the reference. Additional features include the: 1) Ability to filter kmers to allow separate comparison of the pan- and core-genomes; 2) Creation of compact data files that can be used to create screenable strain libraries; 3) Ability to directly correlate with MLST. STM demonstrates that kmer-based approaches can facilitate rapid and simple reporting for strain typing, which will ultimately allow for wider adoption of WGS epidemiological techniques in diagnostic laboratories.

First Report of *Candida auris* in the American Continent: Clinical and Microbiological Data of 18 Episodes of Candidemia

Author Block:

B. Calvo[1], **A. S. A. Melo**[2], M. Hernandez[1], E. C. Francisco[2], J. Meis[3], A. L. Colombo[2];
[1]SAHUM, Maracaibo, Venezuela, Bolivarian Republic of, [2]EPM-UNIFESP, Sao Paulo, Brazil, [3]Dep Med Microbiol Radboudumc, Nijmegen, Netherlands

Abstract Body:

Background: *Candida auris* has been described as an emerging fungal human pathogen that may cause invasive infections in risk populations including critically ill and eventually cancer patients exposed to broad-spectrum antibiotics and invasive medical procedures. Nosocomial *C. auris* infections has been recently described in Korea, India and South Africa. The real prevalence of this pathogen may be underestimated once *C. auris* has been misidentified as *C. famata* or *C. haemulonii* when tested by phenotypic commercial systems, instead of molecular methods. Here we first describe in America the isolation of *C. auris* from 18 critically ill patients admitted in a single institution.**Methods:** We studied 18 blood stream isolates of *C. auris* from different patients admitted at a tertiary medical center in Maracaibo: "Servicio Aotónomo Hospital Universitario de Maracaibo" from March, 2012 and July, 2013. Species identification was initially obtained by the Vitek 2C system and further by ITS rDNA sequencing. Susceptibility tests were performed by using the CLSI broth microdilution method and 5 antifungal drugs.**Results:** All cases were critically ill pediatric (13) and adult (5) patients (26D median age), who had been previously exposed to antibiotics and multiple invasive medical procedures including central venous catheter (100%) and surgery (10 out of 18). Clinical management included catheter removal and antifungal therapy. Thirteen patients (72%) survived up to 30 days after developing candidemia. The isolates were identified as *C. haemulonii* by Vitek 2C, but the molecular method identified all of them as *C. auris.* All strains were considered resistant to FLC and VOR, but were susceptible to AMB, 5-FC and AND. **Conclusions:** This is the first report of *C. auris* in the American continent enrolling adult and pediatric critically ill patients. All isolates were resistant to triazoles but exhibited high susceptibility to candin. Crude mortality rate was lower than previously reported in the literature due to the large participation of children as well as prompt CVC removal and early therapy with appropriate antifungal therapy.

Notable Trend of Increase in Azole Non-Susceptible *Candida tropicalis* Causing Invasive Candidiasis in China, August 2009 to July 2014

Author Block:

X. Fan, M. Xiao, H. Wang, Y-C. Xu; Peking Union Med. Coll. Hosp., Beijing, China

Abstract Body:

Background: Worldwide, *C. tropicalis* has become the first to fourth leading cause of invasive candidiasis (IC). Here we report a notable and continuous increase in azole non-susceptibility among *C. tropicalis* causing IC in China in the past half-decade.**Methods:** Between August 2009 and July 2014, 585 *C. tropicalis* isolates were collected from 10 hospitals from the China Hospital Invasive Fungal Surveillance Net (CHIF-NET) study. The *in vitro* susceptibility of isolates to nine antifungal drugs - fluconazole, voriconazole, itraconazole, posaconazole, caspofungin, micafungin, anidulafungin, amphotericin B and 5-flucytosine - was determined by Sensititre YeastOne YO10 methodology. Current available species-specific clinical breakpoint or epidemiological cut-off values were used for interpretation of results.**Results:** Overall, 22.1% and 19.5% of isolates were non-susceptible to fluconazole and voriconazole, respectively, with 10.4% of the isolates showing cross-resistance to both. Over five years, there was a significant decrease in azole susceptibilities, particularly during the last two years. As shown in the Figure, the non-susceptible rate of *C. tropicalis* isolates to fluconazole and voriconazole continuously increased from 10.4% to 42.6% for fluconazole, and from 10.4% to 39.1% for voriconazole. The prevalence of fluconazole-voriconazole cross-resistant isolates also increased from 6.6% to 21.7%. Moreover, although all isolates remained of wild-type phenotype to itraconazole and posaconazole, the GM MIC and MIC_{50} values for these two drugs also rose by over two fold, and the MIC_{90} values had a 4-fold increase in the study period. In comparison, all *C. tropicalis* isolates included in the present study were of wild-type to amphotericin B, and only 0.7% of isolates were of non-wild type phenotype to 5-flucytosine. Over 99% of the isolates remained susceptible to all three echinocandin agents tested. In addition, during the five years of surveillance, there were no significant changes (within ±1 dilution) in MIC_{50}, MIC_{90}, and GM MIC values for these drugs.**Conclusions:** Our findings show an unusual high-level of fluconazole and voriconazole resistance, and a significant trend of decreasing azole susceptibility. Further study is needed to identify the contributing factors.

Seroepidemiologic Study of Canine Leptospirosis in Northern Taiwan During 2008-2015

Author Block:

C-H. Hsu, C-S. Lin; Natl. Taiwan Univ., Taipei, Taiwan

Abstract Body:

Background: Leptospirosis is an important infectious disease in dogs and humans with worldwide distribution. In Taiwan, canine leptospirosis is easily ignored and underreported because of its variable clinical manifestations and difficulty of diagnosis. The microscopic agglutination test (MAT) is the most common diagnosis method for this disease. Our aim is to investigate the serovars of canine leptospirosis in northern Taiwan from 2008-2015 and to compare the characteristics of different MAT titers.**Methods:** Data were extracted and analyzed from medical records at the National Taiwan University Veterinary Hospital.**Results:** Among 159 suspected cases, 78 serum positive cases (MAT titer≧100) and 81 serum negative cases were identified. The positive rate of MAT titer≧400, which was considered as acute infection, was 24.4% (19/78). Twelve pathogenic serovars of serum positive cases were identified, including Canicola, Icterohaemorrhagiae, Shermani, Lyme, Pyogenes, Australis, Bataviae, Inadai, Javanica, Pomona, Tarassovi, and Grippotyphosa; besides, 21 cases were multiple serovars infection. The most common serovars among these were Icterohaemorrhagiae (23.6%), Shermani (20.0%) and Canicola(18.2%). The mean value of serum concentrations of liver enzymes (ALKP, ALT and AST), total bilirubin, blood urea nitrogen (BUN), creatinine and white blood cell count were elevated in most serum positive cases. Among serum positive cases, there was also no statistically significant difference in age, breed, gender, location and serum biochemistry parameters between titer ≧400 and titer <400 while the mean value of platelet count was lower than normal range in titer≧400.**Conclusions:** We concluded that serovar Shermani should be the candidate for vaccine because of its high seroprevalence in northern Taiwan. Since the clinical features and the severity of the disease showed a similar pattern in the two positive titer groups, it is suggested not to underestimate the care and treatments for the patients with titer <400. Moreover, dogs can used as sentinels or indicators for human pathogenic Leptospira spp. , knowing the seroprevalence, risk factors, CBC and biochemical data may improve the prevention of canine leptospirosis and public health.

Polio Legacy on Epidemiology of Polio Case Based Surveillance in Ethiopia, from 2007-2014

Author Block:

F. HAILEMARIAM, **F. HAILEMARIAM**, A. ADEM; WHO, ADDIS ABABA, Ethiopia

Abstract Body:

Background: Polio was one of the most dreaded childhood disease mainly affecting under five years of age, one in 200 infection leads to irreversible paralysis among those paralyzed, 5%-10% die when their respiratory muscles become paralyzed. Since the global polio eradication initiative was launched in 1988 the number of cases was fallen by 99% (from 350,000 to 359 cases) only two counties in the world remain epidemic Pakistan & Afghanistan. The disease is targeted to eliminate by 2018. This study was conducted to determine the prevalence, age distribution, seasonal variation and regional distribution of Polio Cases in Ethiopia, 2007-2014. **Method:** Any person with acute flaccid paralysis was suspected Polio case. Stool sample for each suspected AFP case and demographic information was collected from suspected cases throughout the country, 2007-2014 onset of paralysis. Stool samples were tested for the presence of poliomyelitis by PCR to confirm. Demographic data and results were entered to data base and analysed by Epi Info software. **Results:** Among a total of 17359 stool samples collected and tested for Polio Suspected, 676 were suspected positive. The highest positivity rate 173 was seen in 2013, and the lowest 46 in 2011 From the Suspected Polio case 98% are all Sabin type and 2%(15) Wild type 1 Polio have been found Mostly in 2013 (9 Cases) and last case been in January 2014 and NEPNT rate highest in 2007 11.4% and lowest 4.5% in 2012. **Conclusion:** Ethiopia is Free from Polio for the past 2 years. To maintain zero Polio Improved routine and campaign Polio immunization and cross border vaccination and strong ongoing active case surveillance are recommended for communicable diseases. And Document this Polio Legacy so as it will be also helpful for other vaccine preventable disease like Measles which is endemic in Ethiopia.

Surveillance for West Nile Virus in Southwestern Nigeria

Author Block:

W. F. Sule[1], D. Oluwayelu[2], R. Adedokun[2], N. Rufai[3], L. Hernandez-Triana[4], K. Mansfield[4], L. Thorne[4], F. McCracken[4], N. Johnson[4]; [1]Osun State Univ., Osogbo, Nigeria, [2]Univ. of Ibadan, Ibadan, Nigeria, [3]Lagos Polo Club, lagos, Nigeria, [4]Animal and Plant Hlth. Agency, Surrey, United Kingdom

Abstract Body:

Background: To investigate role of West Nile virus in undifferentiated fevers (UF) in Southwestern Nigeria we undertook surveillance for the virus in humans, horses and mosquitoes.**Methods:** Blood samples were collected from consecutively selected unvaccinated horses (159) and humans, including horse grooms (213), at polo clubs and health care facilities, respectively in Lagos and Ibadan, southwest Nigeria. Mosquitoes were collected from around stables within polo clubs. Seroprevalence was assessed in horse and human sera by WNV IgG/IgM using ELISA and PRNT while human blood samples were screened for malaria and typhoid fever. Mosquitoes were sorted and analyzed by pan-flavivirus real-time RT-PCR (qRT-PCR).**Results:** WNV IgM was not detected in any horse sera. However, 143 (89.9% [95% CI: 85.3-94.6]) had WNV IgG. Group-specific seroprevalence rates were high and associated with study location (p=0.02) and horse breed (p=0.001). A similar situation was observed for human sera with 156 (73.2% [95% CI: 67.3-79.2]) being positive for WNV antibody. Being clinically ill was a covariate (p=0.001) of WNV seropositivity. "Active" and "non-active" participants had comparable (p=0.21) prevalence of 74.6% and 62.5%, respectively. Forty-five percent (18/40) of febrile participants had antibodies to only WNV suggesting an association with UF. Participants aged 18-66 years had higher (p=0.008) prevalence (75.8%) than those ≤ 17 years (47.4%). Participants showed an increased frequency of being WNV positive (75.5%) than *Plasmodium* (33.5%) and *S. typhi/paratyphi* (39.9%). PRNT confirmed that 50.0% and 10.5% of tested horses and humans respectively had neutralizing antibody. A total of 4,112 female mosquitoes (*Culex,* 98.98% and *Aedes,* 1.02%) were tested but no WNV RNA was detected in any sample.**Conclusions:** There is evidence for WNV in southwestern Nigeria with high seroprevalence observed in horses and humans. Seroprotection was higher among horses than humans with evidence that WNV infection contributed to UF in the study area. No evidence of WNV infection in tested mosquitoes, predominance of a competent vector - *Culex quinquefasciatus* - suggests a source of West Nile virus transmission.

Risk Factors for Long-Term Central Venous Catheter Infection Failure among Cancer Patients

Author Block:

M. P. Freire[1], P. Figueiredo[2], A. Zerati[1], K. Ibrahim[1], D. Peixoto[1], P. Bonazzi[1], A. Kono[1], M. Vieira[1], L. Souza[1], P. Hoff[1], E. Abdala[1], L. C. Pierrotti[1]; [1]Inst. do Câncer do Estado de São Paulo, São Paulo, Brazil, [2]São Paulo Univ., São Paulo, Brazil

Abstract Body:

Infections related to long-term central venous catheter (LTCVCI) have a great impact on cancer patients' survival.The goal of this study is to analyze the risk factors for failure in treatment of LTCVCI in an oncology population. **Methods:** We analyzed all LTCVCI episodes identified through active surveillance from January/2009 to December/2014. Patients who did not receive 24 hours of effective treatment or who lost follow up before the end of LTCRI treatment were excluded. Failure was defined as persistence of positive culture or persistence of clinical signs of infection after 7 days of effective therapy, evolution to complications (embolization or endocarditis), death during therapy or recurrence of LTCVCI by the same microorganism. Independent variables analyzed were: type of tumor, gender, age, totally implantable or semi-implantable catheter, site of insertion, presence of neutropenia, type of infection, infection by multidrug resistant (MDR) bacteria, agent of infection, time lapsed before the start of effective therapy, outpatient treatment, catheter removed, lock-therapy, and catheter thrombosis. Univariate statistical analysis was performed by Chi-square or Mann-Whitney, while logistic regression was used for multivariate analysis. **Results:** A total of 268 LTCVCI were identified, 9 were excluded. The types of infections were: incisional in 26 cases (10.0%), pocket in 45 (17.4%) and bloodstream infection in 188 (72.5%). Failure of initial treatment occurred in 64 (24.7%) cases and recurrence in 17 (6.6%); deaths related to LTCVCIs occurred in 40 (15.4%) patients. Multivariate analysis for failure treatment of all types of LTCVCI identified infections by *P. aeruginosa (PA)* or *A. baumannii (AB)* (*P* 0.02, OR 2.41 (1.12-5.18)) as risk, and incisional infection as protective factor (*P* 0.05, OR 0.30 (0.09-0.89)). Multivariate analysis for failure of catheter related bloodstream infection identified infection by *PA* or *AB* (P 0.06, OR 2.27 (0.96-5.41)) as risk and lock-therapy (P 0.01, OR 0.39 (0.18-0.83)) as protective factor.**Conclusions:** The use of lock-therapy has a positive impact on outcome of LTCVCI. Not only *PA* but also *AB* as agent of LTCRI may lead to a worse outcome of cancer patients with LTCVCI.

Clinical Scoring System to Differentiate *Pneumocystis pneumonia* versus Rituximab-Induced Interstitial Lung Disease in Lymphoma Patients Receiving Rituximab-Containing Chemotherapy

Author Block:

S. Park, M. Kim, W. Choi, Y. Jang, T. Kim, S. Hong, J. Jung, Y. Chong, D. Yoon, H. Sung, S-O. Lee, S-H. Choi, Y. Kim, C. Suh, J. Woo, S-H. Kim; Asan Med. Ctr., Seoul, Korea, Republic of

Abstract Body:

Background: It is difficult to differentiate *P. jirovecii* pneumonia (PCP) from rituximab-induced interstitial lung disease (RILD) in lymphoma patients with diffuse pulmonary infiltrates who are receiving rituximab-containing chemotherapy. Invasive diagnostic work-up often permits definite diagnosis, but this is not always feasible or without risk in critically ill patients. **Methods:** We reviewed the medical records of lymphoma patients who had received rituximab-containing chemotherapy between 2012 and 2015 in a tertiary hospital. PCP was diagnosed from a positive result in an immunohistochemical antibody assay for *P. jirovecii* in BAL fluid from patients with respiratory symptoms and radiologic findings compatible with PCP. Patients were classified as having RILD if (1) diffuse bilateral pulmonary infiltrates were seen on CT scan, (2) there was no evidence of other respiratory infection, and (3) if they experienced clinical improvement without receiving any drug active against *P. jirovecii*.**Results:** Among 613 lymphoma patients receiving rituximab-containing chemotherapy, 97 (16%) had diffuse pulmonary infiltrates. Of these, 16 (16%) with an alternative diagnosis and 22 (23%) with an indeterminate diagnosis were excluded. Finally, 21 (22%) patients were classified as having PCP and the remaining 38 (39%) as having RILD. Fever, short duration of symptoms (≤5 days), systemic inflammatory response syndrome (SIRS), and severe extent of disease on CT scan (>75%) were more common in patients with PCP than in those with RILD. Clinical scores were determined using the following system: SIRS=score 1, symptom duration ≤5 days = score 1, extent of disease on CT >75% = score 4. A score of ≥2 differentiated PCP from RILD with 91% sensitivity (95% CI, 70-99) and 71% specificity (95% CI, 54-84).**Conclusions:** A clinical scoring system based on presence of SIRS, short duration of symptoms, and severe extent of disease on CT scan appears to be useful in differentiation of PCP from RILD.

***Pneumocystis jirovecii* Pneumonia at Major Risk of Death in Chronic Obstructive Pulmonary Disease: A Retrospective Analysis on 113 Cases**

Author Block:

E. Gentilotti, **A. Ricciardi**, L. Coppola, G. Maffongelli, C. Cerva, V. Malagnino, A. Di Veroli, A. Mari, F. Berrilli, F. Apice, D. Di Cave, M. Andreoni, L. Sarmati; Tor Vergata Univ., Rome, Italy

Abstract Body:

Background: *Pneumocystis jirovecii* is an opportunistic fungus causing PCP, a severe lung infection mostly affecting immunocompromised patients. Adverse outcome and more acute and severe course of PCP has been reported in non-HIV compared to HIV-infected. We present a retrospective analysis of 113 patients diagnosed with PCP at "Tor Vergata" University Hospital of Rome.**Methods:** Data on 113 PCP inpatients from different units (Infectious Diseases, Hematology, Transplant, Respiratory Diseases) were retrospectively collected from 2011 to 2015. Demographic, clinical, radiological and genotype characteristics were considered. Statistical analysis was performed using IBM SPSS. **Results:** Sixty-seven out of 113 patients (59.3%) were male aged >50 years old (mean 54.3 years old, range 20-87); 36 (31.9%) were onco-hematologic patients (receiving chemotherapy or haematological stem cell transplantation); 23 (20.3%) had COPD; 22 (19.5%) were HIV-positive; 6 (5.3%) had solid cancer; 4 (3.5%) underwent a solid organ transplant; and the remaining 22 (19.5%) had other immunocompromising conditions. At univariate analysis, a negative PCP outcome statistically correlated with age>50 (p=0.04), pneumonia severity at the onset (p=0.01) and type of pathology (p=0.01). The outcome was available in 100 out of 113 patients: 19 out of 100 (19%) died due to PCP related respiratory failure. Of these, 9 (47.4%) were affected by COPD, while 5 (26,3%) by immunodeficiency illnesses, 3 (15,8%) by onco-hematologic neoplasms, 2 (10, 5%) by solid cancer. A significant higher number of patients with COPD died compared to the other groups (p=0.003). No adverse PCP outcome was observed in HIV-positive and solid organ transplanted subjects.**Conclusions:** A number of published data demonstrated an increase in *Pneumocystis* colonization in COPD which is linked to small airways dysfunction in this category of patients. The higher risk of death for PCP in COPD demonstrated by our retrospective study, leads to carefully consider PCP in the differential diagnosis of worsening lung function in patients with COPD. More study is needed in order to move towards a change of current clinical procedures regarding prophylaxis among patients affected by COPD.

Publishing Title:

Beta-D-Glucan as an Early Marker of Clinical Response in Patients with Candidemia

Author Block:

K. Nakajima, Y. Takesue, T. Ueda, K. Ichiki, Y. Wada, A. Doita, T. Tsuchida; Hyogo Coll. of Med., Nishinomiya, Japan

Abstract Body:

Background: beta-D-glucan (BG) is used as a standard of the empiric treatment of invasive candidiasis. Recently it is reported that the change of BG between initial and end of treatment.In this study, we investigated the corelation of the curative effect with the change of BG between initiation and early after treatment start.**Methods:** BG (WAKO) values >=11 pg/ml were interpreted as being positive. The change of BG at 7 days after the start of treatment of candidemia was assessed in patients with positive for initial BG was measured before treatment. Treatment response was evaluated at 7th days after start of treatment.**Results:** 44 episodes of candidemia (echinocandins 60.9%, azoles 32.6%, liposomal amphotericin B + flucytosine 6.5%) were evaluated. Treatment success was obtained in 78.3%. 28 days mortality rate was 4.5 %. BG decreased significantly at 7 days of therapy in patients with success (baseline 187.0±207.4 vs. 142.6±152.1, P<0.015). In contrast, there was no significant change in clinical failure/indeterminate (249.7±257.8 vs.244.1±258.4, p=0.47). BG remained positive at the end of treatment in 25 of 29 evaluable patients (86.2%) with successful treatment. Cutoff point of declining rate of BG to detect success was determined by receiver operating characteristic (ROC) curve. The area under ROC curve was 0.61, and best cutoff point of BG reduction rate to predict clinical success was 11.9%. Based on this definition, BG reduction was achieved in 66.7% of patients with success, and there was a significant difference when compared to clinical failure/indeterminate case (30.0%, p=0.037). A sensitivity, specificity, positive predictive value, and negative predictive value were 36.8%, 88.9%, 70.0% and 66.7%, respectively. In univariate analysis serum albumin (<=2.5g/dl), APACHIIscore (>=20) and BG reduction were associated with treatment success. In multivariate analysis, however, the change of BG was not independent factor associated with treatment success. **Conclusions:** In this study, we could not confirm that the early BDG change is a marker to clinical efficacy of in candidemia. The measurement of BG after start of treatment in patients with candidemia might be supportive manner.

Publishing Title:

Spectrum of Candidemia in Icus at a Tertiary Referral Center

Author Block:

R. K. Shields, C. J. Clancy, M. H. Nguyen; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: Early antifungal (AF) treatment reduces mortality for candidemia. Optimal strategies for identifying ICU populations that benefit from empiric or pre-emptive AFs are not defined. Incorporating prediction scores or non-culture diagnostics into rational strategies will require better understanding of invasive candidiasis (IC) in specific ICU settings. The objective of this study was to describe the spectrum of candidemia in ICUs at our center. **Methods:** Retrospective review of patients (pts) in medical (MICU), surgical (SICU), or transplant (TICU) ICUs at the onset of candidemia from 2009 - 2015. **Results:** 53 MICU, 49 TICU and 32 SICU pts were included. Pts were admitted from outside hospitals (45%), medical wards (26%), emergency dept. (17%), or long-term care facilities (12%). Median time from ICU admission to candidemia was 4d (range: 0 - 175). 44% developed candidemia within 48 hours of ICU admission. Mean age was 61 yrs; 58% of pts were men. Charlson Comorbidity Index (median = 3 [0 - 14]) and Pitt Bacteremia Scores (median = 6 [0 - 14]) did not vary by ICU location. Median SOFA scores ranged from 7.5 in the SICU to 13 in the TICU (P=0.006). Septic shock was present at the time of candidemia in 58%, 59%, and 37% of pts in the MICU, TICU, and SICU, respectively (P=0.06). 17% died prior to AFs; among the remaining pts, median time to AFs was 55 hours (1 - 205) and 55% received AFs >48 hours after blood cultures. 34% and 54% died within 7 and 30 days, respectively. Common risk factors included vascular catheters (96%), receipt of antibiotics (85%), and mechanical ventilation (82%). Less common factors varied by ICU, including ICU admission > 4 days (33-51%; P=0.07), hemodialysis (17-42%; P=0.03), recent surgery (9-67%; P<0.01), solid-organ transplant (3-24%; P=0.01), and hepatic insufficiency (10-41%; P<0.01). Using criteria from recent trials for empiric AFs, only 26% and 27% of pts met eligibility for MSG-01 and EMPIRICUS, respectively. **Conclusions:** Published criteria based on one-size-fits-all strategies are too insensitive to be useful in guiding empiric AFs against candidemia in ICUs. Strategies that incorporate non-culture diagnostics should be devised and tailored to pt populations, risk factors and types of IC within specific ICUs. In MICUs, strategies should be directed against candidemia. In SICUs and TICUs, however, strategies must also target intra-abdominal and necrotizing pancreatitis.

Microbiological & Clinical Characteristics of Blood Versus Abdominal *Candida* Infections

Author Block:

J. Teo, S. Lee, H. Leck, J. Aw, C-A. Chua, H. Neo, K. Leow, A-L. Tan, Y. Cai, T-P. Lim, W. Lee, A-L. Kwa; Singapore Gen. Hosp., Sg, Singapore

Abstract Body:

Background: In our previous Candidemia surveillance, we detected the emergence of echinocandin resistance. Abdominal (ABD) candidiasis has been suggested to be a hidden reservoir for echinocandin resistance. This study aimed to describe the microbiological & clinical characteristics of blood (BLD) & ABD candida infections. **Methods:** Non-duplicate BLD & ABD *Candida* isolates from a large tertiary Singapore hospital obtained between Oct 2014 - Nov 2015 were included. MICs were tested by the Sensititre YeastOne method. **Results:** 272 isolates (163 ABD, 109 BLD) from 200 cases were included. *C. albicans* (32%) were commonest, followed by *C. glabrata* (27%), *C. tropicalis* (22%) & *C. parapsilosis* (9%). *C. albicans* (40%) is predominant in ABD cultures, while *C. glabrata* (29%) was commonest in BLD. 15 cases involved both ABD & BLD cultures - only 2 had the same species type(s) with similar susceptibilities in both ABD & BLD cultures. Typically, only 1 species was isolated from BLD, while >1 species may be isolated from ABD. MICs are shown in Figure 1. Susceptibilities were similar among BLD & ABD isolates. More than 30% of *C. tropicalis* were azole non-susceptible. Echinocandin resistance was detected in 2 *C. glabrata* (1 ABD, 1 BLD). Median (range) age of patients were 68 years (22 - 101), with 24% from ICU. Most were surgical patients (62%). 30-day mortality rate was 30%. **Conclusions:** Species distribution differs between culture sites, even in cultures isolated from the same patients. High azole resistance in *C. tropicalis* & emerging echinocandin resistance in *C. glabrata* is a concern. Susceptibility patterns may no longer be sufficiently predicted by speciation in our institution. Relying on blood culture alone may not be enough in treatment of abdominal candidiasis.

Publishing Title:

The Presence of *Candida* in Bronchoalveolar Lavage Specimens in Immunocompromised Patients

Author Block:

K. Trevino, T. Davis; Indiana Univ., Indianapolis, IN

Abstract Body:

The presence of *Candida* in bronchoalveolar lavage (BAL) specimens is both common and commonly ignored due to its association with oral contamination. Invasive candiasis has an incidence of 10-14 per 100,000 individuals and an even higher incidence in immunocompromised patients. Whether the presence of *Candida* in a BAL specimen is significant in an immunocompromised patient population is unknown, leaving clinicians to interpret this reported finding based on the clinical scenario.Infectious disease pathology consults performed at Indiana University were reviewed from 2013-2015. 139 cases had yeast consistent with *Candida* in their BAL specimens. 124 of the cases underwent chart review, and culture, antigen testing, treatment, and outcomes data were collected for the 4 weeks surrounding the consult. The cases were sorted based on the presence or lack of treatment with an antifungal and the reason for treatment. Data was analyzed using chi square to assess the significance of outcome differences among those treated and those not treated for candidiasis.5 of 124 cases reviewed demonstrated invasive candidiasis by blood culture. None of these cases had corresponding antigen testing performed. 8 other cases had positive antigen testing but blood cultures remained negative. Overall, 61 of the 124 patients received treatment with an antifungal. 51 of the 124 patients had a poor outcome (death or discharged to hospice). There was no significant difference in outcome between patients who were treated with an antifungal and those who were not (poor outcomes in 28/61 and 23/63 patients respectively). There was also no significant difference in outcomes between groups based on the reason for treatment.Incidence of invasive candiasis in this population was higher than the general population (4% vs. 0.014%). However, we did not compare this rate to an immunocompromised population that did not demonstrate *Candida* in their BAL specimens. This further study is needed to assess whether this incidence is higher than a similarly immunocompromised population without the presence of *Candida* in their BAL. Nearly 50% of patients were treated with an antifungal during their hospitalization, with 12% treated solely based on their BAL result. However, no difference was seen in the overall outcome of the patients based on this treatment.

Abstract Body:

Background: An echinocandin is recommended as initial therapy for candidemia, but it is not active against Cryptococcus. Both mycosis cause significant mortality in SOT recipients, and it is critical to distinguish the two mycosis to optimize the empirical treatment. The present study aimed to characterize the differences between the two mycosis in SOT recipients. **Methods:** From Jan 2001 to Dec 2014 at National Taiwan University Hospital, a total of 37 SOT recipients with *Candida* species and 7 SOT recipients with *Cryptococcus neoformans* isolated from the blood were included for analysis to identify factors to distinguish these two mycosis in SOT recipients. The date of fungemia onset and diagnosis was the date of blood sampling. No anti-fungal prophylaxis was given post-transplant. **Results:** Candidemia developed in 10 heart, 14 liver, 9 kidney, and 4 lung transplant recipients while cryptococcocemia in 5 heart, 2 liver transplant recipients. The mortality within 2 weeks of fungemia onset was 32% and 29%, respectively. Fungemia developed within 3 months post-transplant in 21.6% of SOT recipients with candidemia and 42.9% of SOT recipients with cryptococcocemia (p=0.341). Patients with cryptococcocemia were more likely to presented with meningitis (28.6% vs. 0%) and was diagnosed sooner after admission than those with candidemia (median duration after admission 14 vs. 24 days) while candidemia developed more frequently in intensive care unit (ICU) than cryptococcemia (72.2% vs. 28.6%) (all P<0.05).**Conclusions:** In SOT recipients, cryptococcemia was community onset and presented frequently with meningitis while candidemia developed after prolonged hospital stay and in ICU setting.

***Scopulariopsis brevicaulis*: A Case of Mistaken Takayasu Arteritis**

Author Block:

T. B. Walls, R. F. Relich, T. E. Davis, B. H. Schmitt; Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Background: *Scopulariopsis brevicaulis*, a hyaline mold, is generally associated with onychomycosis, but in rare instances, it can cause deep tissue infections, otomycosis, and infections of the brain, lungs, and bone. This report describes a case of *Scopulariopsis* endocarditis secondary to iatrogenic immunosuppression. **Case:** A 37-year-old Japanese woman with a past medical history of aortic valve replacement secondary to a congenital aortic aneurysm and presumed Takayasu arteritis treated with prednisone presented to the hospital with left-sided back and lower abdominal pain. The patient had a 9-month recent history of repeated emboli with fevers. A CTA of the chest was obtained and showed a moderately-sized pseudoaneurysm from the ascending aortic graft and filling defects concerning for thrombi in the distal ascending aorta/proximal aortic arch near the graph anastomosis. Portions of thrombus from the thrombectomy were sent for histopathology and culture. **Results:** Histopathologic examination of the left iliac artery thrombus revealed branching, septate hyphae; however, blood cultures were negative. Subsequently, voriconazole was added to the patient's empiric antimicrobial regimen to cover suspected aspergillosis. The diagnosis of Takayasu arteritis was dismissed as the etiology of the patient's aneurysm and the patient's regimen of prednisone was discontinued. Fungal cultures of the tissue grew *S. brevicaulis* and amphotericin B was added to the antifungal regimen pending susceptibility data. **Discussion:** The isolate was later determined to be susceptible to posaconazole and micafungin, which prompted treatment with these drugs exclusively. After a 78-day hospital stay, the patient was discharged on long-term antifungal therapy with posaconazole. *Scopulariopsis* species are a rare cause of infective endocarditis. Less than 50% of cases of fungal endocarditis yield positive blood cultures, rendering this diagnostic method suboptimal. A combination of culture and histopathology are necessary to effectively detect this organism, and susceptibility testing of isolates is necessary to optimize therapy.

Detection of the Dimorphic Phases of *Mucor circinelloides* in a Blood Specimen

Author Block:

M. A. Arroyo, B. Schmitt, T. E. Davis, R. F. Relich; Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Background: *Mucor circinelloides* is a dimorphic zygomycete that exhibits hyphal growth in aerobic conditions and multi-budded yeast growth under anaerobic or high-CO_2 conditions. To date, very few cases of fungemia associated with *M. circinelloides* have been reported. Here, we describe a case of fungemia caused by *M. circinelloides* that demonstrated both dimorphic phases during Gram-stain examination of two sets of blood cultures.**Case:** A 38-year-old female presented to the Emergency Department with shortness of breath and cough, sinus congestion, fever of 103 °F, nasal drainage, sore throat, and yellow-green sputum production. The patient's medical history included sarcoidosis, IgG deficiency, and sinus infection for which she completed treatment with cefdinir 1 week before admission. As part of the initial diagnostic workup, blood specimens were obtained for culture and other laboratory testing.**Results:** Peripheral blood specimens obtained at the time of initial presentation demonstrated leukocytosis and low glucose, potassium, CO_2, total protein, and magnesium. An X-ray of her chest was unremarkable. The aerobic bottles from both sets of blood cultures turned positive within 24 hours of incubation. Gram stains revealed pleomorphic yeast forms and wide hyphae with right-angle branching. The isolate recovered from the blood-broth was a fast-growing mold that was initially identified as a *Mucor* species. The identity of the isolate as *M. circinelloides* was supported by its microscopic morphology and its ability to convert into yeast forms under anaerobic conditions.**Discussion**: Following diagnosis of fungemia based on initial blood culture results, the patient was started on therapy with liposomal amphotericin B. Subsequent blood and sinus cultures were negative. In addition, surgical pathology sinus biopsy results and CAT scan of the chest and sinuses did not show any clear evidence of fungal involvement. As a consequence, antifungal treatment was discontinued after 6 days and the patient was discharged home without further complications. At a follow-up assessment 1 week after discharge, the patient had no signs of *Mucor* infection. In conclusion, based on our patient's disease course and clinical outcome, this organism is presumably of low virulence.

Prognosis and Predictors of Death in Cryptococcal Meningitis - A Portuguese Cohort

Author Block:

A. Silva-Pinto, R. Serrão, A. Sarmento, L. Santos; Centro Hosp.ar São João, Porto, Portugal

Abstract Body:

Background: Cryptococcal meningitis usually occurs in people with immunodeficiency problems and has a considerably high mortality rate. The aim of this study is to evaluate the prognosis and outcome' predictors of patients with cryptococcal meningitis.**Methods:** We performed a retrospective study of cryptococcal meningitis patients admitted to our Infectious Diseases Unit between 2000 and 2014. We used the most appropriate measure of central tendency, of distribution and statistic test. The significance level used was 0.05.**Results:** We included 61 patients (55 men; age: median 37 and interquartile range (IQR) 15). The median symptoms time until hospitalization was 7 days (IQR 12.5). The most common symptoms reported were headache (n=53), fever (n=39), nausea (n=31), dizziness (n=27) and behavioral impairment (n=21). Only one aged patient had no known immunosuppression; the immunosuppression reported was HIV infection (n=55; median CD4 count 29/mm^3, IQR 42), hematologic neoplasia (n=2), chronic corticotherapy (n=1), tacrolimus (n=1) and hyper IgM symdrome (n=1). The serum cryptococcal antigen was positive in 44 patients (median 1/512). The cerebrospinal fluid (CSF) revealed in median 41 cells/mm^3, with hyperproteinorrhachia (median 56 mg/dL) and hypoglycorrhachia (mean 33% of the serum value). The CSF India ink was positive in 38 (62%) patients and the CSF cryptococcal antigen in 52 (median 1/1024). Fifty (82%) patients had a positive CSF culture and 24 positive blood culture. The quickest symptom to improve was fever (median 4 days IQR 3), followed by headache (median 6 days IQR 2,5) and behavioral impairment (median 7 days IQR 7). Nine patients died (15%) due to the cryptococcosis and nine patients had a relapse. The majority (n=31) cured the infection without sequel and 8 patients had significant morbidity. Predictors of death were as follows: hypoglycorrhachia (independent t test, p=0.040), higher CSF cryptococcal antigen (Mann Whitney U, p=0.037) and higher neutrophil count at admission (Mann Whitney U, p=0.050).**Conclusions:** Cryptococcosis is still a frequent disease specially associated with immunosuppression. Death rate is not negligible. This study addresses hypoglycorrhachia, high CSF cryptococcal antigen and higher neutrophil count at admission as predictors of death.

Laryngeal Cryptococcus Infection

Author Block:

O. A. M. Saeed[1], T. Walls[1], G. Ward[1], D-J. Summerlin[1], T. E. Davis[1], T. C. Huntley[2]; [1]Indiana Univ. Sch. of Med., Indianapolis, IN, [2]Ctr. for Ear Nose Throat & Allergy, Carmel, IN

Abstract Body:

Background: Laryngeal Cryptococcosis is a rare disease that mimics laryngeal carcinoma. There are only 18 cases reported in the literature. In this case report we describe the findings of a 61-year-old male who had laryngeal Cryptococcus Infection. **Methods:** case report and review of relevant English language literature**Results:** The usage of inhaled and oral steroids was described on 31.5 % and 26.3 % of the laryngeal cryptococcosis cases respectively. The gross description of the laryngeal lesion in the reported cases varied from as mild as congestion and redness to an irregular mass suspicious of laryngeal carcinoma. Over half of the cases were described as having granulomatous inflammation in the histological examination. Our patient was found to have a laryngeal mass on induction of general anesthesia. He was on prolonged long-term oral steroid. Direct laryngoscopy revealed a mass extending from the anterior aspect of the right arytenoid to the right false vocal fold. H & E histopathological examination showed diffuse granulomatous inflammation with fungal elements. GMS, PAS and Mucicarmine stain revealed Cryptococcus microorganisms. Blood Cryptococcus antigen test was positive. HIV screening was negative. The patient was treated with fluconazole 400 mg daily for 6 months.**Conclusion:** Prolonged usage of oral steroids is an important risk factor for laryngeal Cryptococcus infection. The laryngoscopic findings of the lesion can mimic laryngeal neoplasms. The use of fungal stains can usually confirm the diagnosis. Oral fluconazole is the most commonly used treatment modality.

Osteoarticular Mycoses - Comparative Analysis of the Epidemiology, Pathogenesis, Clinical, Diagnostic, and Therapeutic Characteristics of 1011 Cases

Author Block:

M. Gamaletsou, B. Rammaert, M. Bueno, B. Brause, D. Denning, M. Henry, D. M. Kontoyiannis, A. Miller, R. Petraitiene, V. Petraitis, E. Roilides, N. V. Sipsas, S. Taj-Aldeen, V. Zeller, O. Lortholary, T. Walsh; Intl. Consortium for Study of Osteoarticular Mycoses, New York, NY

Abstract Body:

Background: Osteoarticular mycoses (OM) are chronic debilitating infections that require extended courses of antifungal therapy and may warrant expert surgical intervention. To our knowledge, there is no systematic analysis of the different forms of osteoarticular mycoses. **Methods:** Using a database of 1011 cases fulfilling prespecified criteria, we studied the comparative epidemiology, pathogenesis, clinical manifestations, inflammatory biomarkers, treatment and outcome of six major groups of OM: *Candida* osteomyelitis (CO), *Aspergillus* osteomyelitis (AO), *Candida* arthritis (CA), *Aspergillus* arthritis (AA), dimorphic fungal osteomyelitis (DFO), and non-Aspergillus mould osteomyelitis (NAMO).**Results:** The age range extended from neonates to older adults most widely in CO and CA. For all OM, M:F ratio= 2.1. CO and CA, were associated with significantly greater events of hematogenous dissemination in 67% and 81%, respectively, than that of AO (45%) and than that of NAMO (39%) ($P<0.001$). There were significantly more immunocompromised patients with CO, CA, AO, AA, and NAMO than with DFO ($p<0.001$). Traumatic inoculation was more commonly associated with AO, AA, and NAMO ($p<0.01$). Values of inflammatory biomarkers overlapped considerably among groups. Synovial fluid cultures were highly sensitive in detection of CA and AA. Relapsed infection, possibly related to inadequate duration of therapy, developed among 32% with CA, significantly exceeding that of AO, AA, and CA ($p<0.05$). Overall mortality was greater for *Penicillium (Talaromyces) marneffei* (38.5%) osteomyelitis ($p<0.05$).**Conclusions:** OM constitute distinct clinical entities with a high representation of males, greater hematogenous infection in CA and CO, significantly more traumatic inoculation in AO, AA, and NAMO, and a high propensity for relapse in CO.

Dandruff Aetiology and the Effects of Edible Lipids on the Growth of Isolates from Lesions in Calabar, Nigeria

Author Block:

O. M. Ogba, L. N. Abia-Bassey, N. Biobelemoye; Univ. of Calabar, Calabar, Nigeria

Abstract Body:

Background: Dandruff is caused by *Malassezia* species, a lipophilic fungus.Information on the aetiology of the fungi associated with this condition and profile of affected persons are sparse in our locality. This prospective study was designed to determine the aetiology of dandruff causing fungi and to assess the effects of some edible lipids on the growth of predominant isolates in our locality.**Materials and methods:** A total of 245 subjects were enrolled for the study; 145 with dandruff-like lesions and 100 without lesions (controls). Ethical approval was obtained. Questionnaires were administered for biodata. Scalp scrapings were obtained from subjects visiting hair and beauty salons into sterile paper envelopes and transported to the Microbiology Laboratory, UCTH, for analysis. Samples were subjected to culture, microscopy and physiological tests. The effect of lipids on the growth of *Malassezia* species was assessed using common edible oils including groundnut oil.**Results:** Out of the 145 subjects with dandruff-like lesions, 90.3% were positive for different *Malassezia* species. The most prevalent *Malassezia* species among subjects with dandruff lesions was *M. furfur* (70.2%) while *M. globosa* (51.9%) was the most prevalent among the controls. *Malassezia pachydermatis* was the least prevalent species among the two groups. *M. furfur* grew exceptionally on SDA overlaid with groundnut oil.**Conclusion:** Groundnut oil could be used as an alternative for the cultivation of *M. furfur* especially in a resource poor setting like ours and should not be used in the preparation of hair ointment or creams.

***Candida parapsilosis* (*cp*) Intra-abdominal Candidiasis (Iac) May Stem From Endogenous Gastrointestinal (Gi) Sources**

Author Block:

P. Vergidis, M. H. Nguyen, C. J. Clancy; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: IAC is at least as common as candidemia, but it is less well studied. *Cp,* generally considered an exogenous pathogen that is introduced via indwelling catheters, has been a rare cause of IAC. We reviewed *Cp* IAC at our center in an era of increased use of intra-abdominal drains and stents. **Methods:** We performed a retrospective study of adult patients in 2012-13. IAC was defined by clinical evidence of intra-abdominal infection and isolation of *Candida* from an intra-abdominal sample collected under sterile conditions. We excluded patients whose samples were collected from drains that were in place >24 hours. In univariable analysis, we compared patients with mono-infections caused by *Cp* and other *Candida* species. The log-rank test was used for survival analysis.**Results:** A total of 180 isolates were recovered from 163 patients with IAC (*C. albicans* 57%, C. *glabrata* 25%, *Cp* 10%). *Cp* was isolated in 18 patients. In 5 patients, co-infection with another *Candida* species occurred. Mean age was 58 years, 67% were men. Infection was caused by GI tract perforation (8), enteric wall inflammation (2), complicated pancreatitis (4), liver/pancreas allograft infection (2), cholecystectomy complication (1), and peritoneal dialysis catheter infection (1). Intra-abdominal abscesses developed in half of the cases. Infection due to *Cp* more commonly resulted in septic shock compared to other *Candida* species (46% *vs* 15%, p=0.02). Among subjects who underwent prior surgery, IAC occurred at a mean time of 11 days post-operatively for *Cp* compared to 53 days for other *Candida* species (p=0.01). Infection was controlled with percutaneous drainage in 22% and surgery in 78%. Antifungal treatment was administered in 78%. 100-day mortality was similar between patients with IAC due to *Cp* and other *Candida* spp. (15% *vs* 29%, p= 0.35).**Conclusion:** In this cohort, *Cp* was the third leading cause of IAC. Most cases were not associated with intra-abdominal drains or stents, but rather disruption to GI tract mucosal integrity. Therefore, *Cp* may be an endogenous pathogen within the abdominal cavity, consistent with emerging microbiome data that the species can be found as part of GI flora. Outcomes of *Cp* IAC were comparable to other *Candida* species and septic shock was more common; this experience is in contrast to *Cp* candidemia, for which outcomes are better than with other species.

***Candida albicans* and *Klebsiella pneumoniae* Interact Synergistically During Intra-Abdominal Infection (IAI)**

Author Block:

P. Vergidis, C. J. Clancy, S. Cheng, M. H. Nguyen; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Background: *C. albicans* and *K. pneumoniae* are human gastrointestinal tract commensals, and leading causes of IAIs. We hypothesized that *C. albicans* and *K. pneumoniae* interact synergistically during IAI.**Methods:** Interactions between *C. albicans* SC5314 and a *K. pneumoniae* clinical isolate were studied *in vitro* and during mouse infections. Non-immunosuppressed, 6-8 wk old ICR mice were injected intraperitoneally with *C. albicans*, *K. pneumoniae*, or both organisms (10 mice/group; inocula of $5 \bullet 10^7$ and $5 \bullet 10^6$ CFU for survival and tissue burden studies, respectively). RT-PCR for select *C. albicans* genes was performed on liver homogenates (SYBR Green).**Results:** *C. albicans* growth was decreased by 1.2 $\log_{10}$ in YPD medium at 72h in the presence of *K. pneumoniae*. *K. pneumoniae* growth was not affected when the organisms were co-incubated. In survival studies, 7-day mortality rates among mice with *C. albicans* and *K. pneumoniae* mono-infections were 60% and 0%, respectively. Mortality during *C. albicans*-*K. pneumoniae* co-infections was 90% (p=0.06 compared to *C. albicans* mono-infection). In tissue burden studies, *C. albicans* concentrations were higher for co-infections than mono-infections in peritoneal fluid (median, 4.1 *vs* 2.0 $\log_{10}$ CFU/ml, p<0.001) and liver (5.5 *vs* 4.9, p=0.02) at 24h. At 72h, there was no significant difference in peritoneal fluid during co-infections (p=0.35), but there was a trend toward higher *C. albicans* burdens in liver (4.7 *vs* 3.3, p=0.09). At 24h *K. pneumoniae* burdens were higher in peritoneal fluid (6.1 *vs* 4.5, p<0.001) and liver (6.5 *vs* 3.3, p=0.02) during co-infections. Similarly, at 72h *K. pneumoniae* burdens were higher in peritoneal fluid (3.0 *vs* 1.5, p<0.001) and liver (6.2 *vs* 1.9, p<0.001) during co-infections. Expression of hyphal-specific *C. albicans* genes *RBT1*, *ECE1* and *HWP1* was 9-, 3- and 2-fold higher, respectively, in liver during co-infections than mono-infections at 24h. *RBT1*, *NRG1* and *HWP1* expression was 3-, 3- and 4-fold higher at 72h, respectively.**Conclusion:** *C. albicans* and *K. pneumoniae* exhibit synergistic interactions during IAI, which are not observed *in vitro*. Induction of hyphal-specific genes during co-infections suggests that *C. albicans* filamentation may facilitate *K. pneumoniae* invasion and persistence at sites of IAI.

Publishing Title:

A Comparative Study of Mixed Microbial Biofilms of *Aspergillus fumigatus, Scedosporium apiospermum* and *Lomentospora prolificans* Formed with *Pseudomonas aeruginosa*

Author Block:

E. Manavathu, S. Wakade, J. Vazquez; Med. Coll. of Georgia/Augusta Univ., Augusta, GA

Abstract Body:

Background: *Aspergillus fumigatus* (*Af*), *Scedosporium apiospermum* (*Sa*) and *Lomentospora prolificans* (*Lp*) are the most commonly isolated filamentous fungi from the airways of cystic fibrosis (CF) patients either alone or with *Pseudomonas aeruginosa* (*Pa*). In the CF airways *Pa* interacts with fungi to form polymicrobial (PM) biofilm highly tolerant/resistant to antimicrobial drugs. The primary objective of this study was to research the structure, development and antimicrobial susceptibility of *Af-Pa*, *Sa-Pa* and *Lp-Pa* PM biofilms. **Methods:** *Pa* PA01, 27853, MJK8, CF39wt, CF39s, *Sa*3634, *Lp*201214, *Af*43004 and *Af*43135 were used. Structure and development of PM biofilm were examined by SEM. Mixed microbial interaction was studied by coculture experiments and agar plate inhibition assays. Antimicrobial susceptibility was studied by exposing biofilms to various concentrations of the drug(s) individually and in combination. The effectiveness of the drug treatment was determined by CFU or MTT assays. **Results:** *Pa* formed PM biofilm with *Af, Sa* and *Lp*. The structure and development of *Pa-Af*, *Pa-Sa* and *Pa-Lp* biofilms were similar. The *Pa* cells were firmly attached to the fungal hyphae by surface appendages exploiting the extracellular matrix (ECM). In mature PM biofilm the bacterial cells were fully encased or trapped in the ECM made up of bacterial and fungal cellular components. The interaction of *Pa* and *Af* cells in mixed microbial cultures resulted in the growth inhibition and death of *Af* cells. In contrast, *Sa* and *Lp* cells were tolerant to the killing effect of *Pa* in cocultures, although growth was substantially inhibited. The antimicrobial drug susceptibility of the fungal cells in PM and monomicrobial (MM) biofilms was similar. In contrast, the *Pa* cells in PM showed tolerance/resistance to cefepime and imipenem (0.5-1.5 logs CFU reduction at 64µg/ml) compared to that in MM biofilm (2-3 logs CFU reduction at 64µg/ml). The susceptibility to ciprofloxacin and tobramycin was similar (4-5 logs CFU reduction at 64 µg/ml) for both MM and PM biofilms. **Conclusions:** The structure, development and antimicrobial drug susceptibility of *Pa-Af, Pa-Sa* and *Pa-Lp* biofilms are similar. However, the interaction of *Pa* with *Af* leads to the death of the fungal cells, whereas the fungicidal effect of *Pa* against *Sa* and *Lp* was minimal.

Publishing Title:

Mixed Microbial Biofilms of *Aspergillus fumigatus* with Methicillin-Susceptible and Methicillin-Resistant *Staphylococcus aureus*: Structure, Development and Antimicrobial Drug Susceptibility

Author Block:

E. Manavathu, J. Vazquez; Med. Coll. of Georgia/Augusta Univ., Augusta, GA

Abstract Body:

Background: *Staphylococcus aureus* (*Sa*) and *Aspergillus fumigatus* (*Af*) are commonly isolated pathogens from the airways of cystic fibrosis (CF) patients. For CF patients, with methicillin-resistant *Sa* (MRSA) the outcome is poor compared to those patients with methicillin-susceptible *Sa* (MSSA). In chronically infected CF airways, the interaction of *Af* and *Sa* may lead to the formation of *Af-Sa* biofilm showing high level tolerance to antimicrobial therapy. The objective of this work was to study the structure, development and antimicrobial drug susceptibility of monomicrobial (MM) and polymicrobial (PM) biofilms of MSSA and MRSA.**Methods:** *Sa*25923, *Sa*59395 (MSSA), *Sa*43300, *Sa*56694 (MRSA), *Af*43004 and *Af*43135 were used. Biofilms were grown in brain heart infusion (BHI) broth in 24-well cell culture dishes. The *Af-Sa* biofilm structure and development were studied by SEM. The antibiosis activity of *S*a on *Af* was examined by coculturing the organisms followed by CFU assay. Biofilm susceptibility to cephalexin (CPH), ceftaroline (CFT) ciprofloxacin (CIP) and linezolid (LIN) was studied by using various concentrations followed by a CFU assay.**Results:** The development of *Af-Sa* biofilm was dependent on fetal calf serum (FCS) in the growth medium. The rank order of *Af-Sa* biofilm production in BHI with and without FCS was BHI+10% FCS >100% FCS >BHI alone. SEM images showed that the *Sa* cells were firmly adhered to *Af* hyphae and encased by the extracellular matrix. Without FCS few *Sa* cells were adhered to *Af* hyphae. Coculture experiments showed no *Sa* antibiosis activity against *Af* cells. The MM and PM biofilms of MSSA and MRSA were approximately 300-1000 fold more tolerant to antibacterial drugs than the planktonic cells (5-7 logs CFU reduction). The MM and PM biofilms of MSSA were more susceptible to CPH (4-5 logs CFU reduction at 64µg/ml). The biofilms with MRSA were susceptible to CFT (2.5-3 logs CFU reduction at 64µg/ml). In contrast, the MM and PM of MSSA and MRSA showed similar susceptibility (1.5-3 logs CFU reduction at 64µg/ml) to CIP and LIN.**Conclusions:** *Af-Sa* biofilm formation is dependent on serum proteins. *Sa* in cocultures showed no antibiosis against *Af*. The *Sa* cells in MM and PM biofilms of MSSA and MRSA showed antibiotic dependent variation in drug susceptibility.

The Tolerability of Low-Dose Pentamidine as the 2nd-Line Treatment for HIV-Related Pneumocystis Pneumonia Patients

Author Block:

Y. Mutoh, S. Shibata, T. Aoki, K. Teruya, Y. Kikuchi, H. Gatanaga, S. Oka; Natl. Ctr. for Global Hlth.and Med., Tokyo, Japan

Abstract Body:

Background: The current understanding is that 1st choice of treatment for Pneumocystis pneumonia (PCP) among HIV-1 patients is Sulfamethoxazole-trimethoprim (SMX-TMP). However, several cases have to change treatment to another agent, such as pentamidine or atovaquone, because of their adverse events.In several cases, physicians treating with pentamidine (4 mg/kg/day IV daily) for PCP experience some adverse events such as neutropenia, kidney injury, angialgia, or hypoglycemia. Hence, some experts recommend using reduced-dose pentamidine (3 mg/kg/day IV daily) in order to avoid adverse events. However, its tolerability is not well known. Here, we assessed the tolerability of reduced-dose pentamidine for HIV-related PCP.**Methods:** In this single center, retrospective cohort study, 108 patients who were clinically diagnosed HIV-related PCP and admitted to the National Center of Global Health and Medicine, Japan, between January 2004 and December 2015 were included. All of their treatments were initiated with SMX-TMP, and intravenous reduced-dose pentamidine was used as the 2nd-line regimens. The primary outcome is the tolerability of reduced-dose pentamidine.**Results:**In total 108 patients received 2nd-line reduced-dose pentamidine treatment, male were 103 of 108 (95.4%), median age was 37 years old (IQR: 31.8-44.3), median CD4 count on admission was 35.5cells/mm^3 (IQR: 18.5-67.0). The median duration of reduced-dose pentamidine use was 7days (IQR: 5.0-10.0). Adjuvant glucocorticoids were used for 75 patients (69.4%). The number of patients who were able to complete the treatment with 2nd line reduced-dose pentamidine was 62 patients (57.4%). No patient discontinued pentamidine due to treatment failure. The three month mortality rate was 2.8% (3/108); however, the causes of death for all three patients were not PCP. The reasons of discontinuing treatment were fever (n=18, 16.7%), kidney injury (n=11, 10.2%), elevated liver enzyme (n=9, 8.3%), angialgia (n=8, 7.4%), neutropenia, (n=5, 4.6%), and hypoglycemia (n=1, 0.9%).**Conclusions:**Reduced-dose pentamidine is as much tolerable as conventional dose of pentamidine treatment for HIV-related PCP as the 2nd-line treatment. These results provide new insight into our understanding for 2nd line treatment of HIV-related PCP.

The Novel Species *Paenibacillus* sp. VT-400 as a Potentially Pathogenic Spore-Forming Bacteria in the Oral Cavity of Patients with Hematological Malignancies

Author Block:

V. Tetz, G. Tetz; Inst. of Human Microbiol., New York, NY

Abstract Body:

Background: Acute leukemia accounts more than 10,000 deaths annually. The major cause of morbidity in patients with leukemia, is opportunistic infection due to immunosuppression. In this study, we describe *Paenibacillus* sp. VT-400, a novel spore-forming bacterium (complete genome is deposited in GenBank No. LELF01000000), which has never been detected in humans before, isolated from the saliva of children with lymphoblastic leukemia, and investigate its potential to cause pneumonia. **Methods:** We used a mouse model of pneumonia to study virulence *in vivo*. C57BL/6 mice aspirated 50 µL *Paenibacillus* sp. VT-400, for a total dose of 5.0×10^7 - 5×10^9 CFU/mouse. Bacterial load was measured in the lungs and spleen of surviving mice 48 h post infection. Susceptibility to antibiotics was determined by the disc diffusion method. Whole-genome analysis was annotated using RAST and the NCBI Pipelines.**Results:** Analysis revealed a large number of virulence genes like proteases, ureases, chitinases, hemolysin D, superantigen CD4+ T-cell-stimulating antigen. Mice intranasally challenged with *Paenibacillus* sp. VT-400 exhibited typical signs of acute pneumonia within 24 h with direct correlation between severity of symptoms and dose. The isolate caused mortality in mice infected with 5.0×10^8 or more CFU due to acute pneumonia. Genome analysis revealed that *Paenibacillus* sp. VT 400 harbors antibiotic resistance genes: MFS, ABC, MATE transporters, SMR proteins *vanZ*, fosmidomycin, *TetA*, β-lactamases; genes encoding resistance to chemotherapeutics like tunicamycin and bleomycin. Expression of these genes revealed the resistance to erythromycin and azithromycin, chloramphenicol and trimethoprim.**Conclusions:** Detection, of a novel spore-forming *Paenibacillus* sp. VT 400 that harbors virulence factors and genes that confer resistance to antibiotics and to chemotherapeutic drugs in patients with acute leukemia is a critical result, especially in light of *in vivo* studies in which mice challenged with isolate died from pneumonia, with dissemination of the infection. The presence of identified pathogenic spore-forming bacteria with numerous antibioticresistance genes that may trigger a life-treatening respiratory infection of immunocompromised patients warrants special attention.

Sepsis Biomarkers in the Initial Assessment of Fever in Children with Cancer and Neutropenia

Author Block:

F. Carlesse[1], O. Araujo[2], D. C. B. Silva[1], M. Brunialti[3], A. Senerchia[1], A. Petrilli[1], R. Salomão[3]; [1]Pediatric Oncology Inst.(IOP/GRAACC) Univ.e Federal de Sao Paulo, Sao Paulo, Brazil, SAo Paulo, Brazil, [2]Pediatric Oncology Inst. (IOP/GRAACC), Univ.e Federal de Sao Paulo, Sao Paulo, Brazil, SAo Paulo, Brazil, [3]Univ.e Federal de Sao Paulo, Sao Paulo, Brazil, SAo Paulo, Brazil

Abstract Body:

Background: Biomarkers are potentially useful to discriminate between febrile neutropenic (FN) children with cancer that will develop a favorable clinical outcome from those that will develop sepsis and need more aggressive management.**Methods:** We tested 10 cytokines by Citometric Bead Array (interleukins 8, 6, 17, 21, 10, 1β, TNF-α, IL-12/23p40, G-CSF and GM-CSF), C-reactive protein (immunoturbidimetry) and procalcitonin (PCT ELISA) in the first 24 hours of fever in 35 patients with FN (median age 4 y-o), as potential discriminators of sepsis.**Results:** Thirteen Patients (37%) developed sepsis, with 10 severe sepsis (4 with shock) within 72 h of diagnosis of FN. Out of the 13 sepsis, 10 had bacteria isolated in cultures (8 in blood cultures: 3 coagulase-negative Staphylococci, 1 Enterococcus raffinosus, 2 E. coli, 1 Enterobacter sp., 1 Pseudomonas oryzihabitans; and 2 K. pneumoniae in urine cultures). IL-6, IL-8, IL-10 and TNF-α showed significant differences between septic and non-septic by Mann-Whitney test. For discrimination of sepsis, IL-8 showed an area under the ROC curve (AUC) of 0.86 (95% CI 0.72 - 1, P <0.0001); AUC was 0.87 for IL-6 (95% CI 0.75-0.99; P <0.0001) and 0.89 (95% CI 0.78 to 0.99; P <0.0001) for PCT. The optimal cutoff points were 240, 170 and 190 pg/mL for IL-8, IL-6 and PCT, according to Youden's J statistic. The C-reactive protein showed no power of discrimination. **Conclusions:** IL-6, IL-8 and PCT on the first day of fever may be useful markers to identify neutropenic patients who will develop sepsis in up to 72 h. The combination of two markers (IL-6 or IL-8 + PCT), with lower cutoffs, can improve the performance of the tests.

Microevolution of *Campylobacter* and *Helicobacter* Species within Two Chronically Infected Patients with X-Linked Agammaglobulinemia

Author Block:

R. A. Weingarten[1], S. Conlan[2], I. Fuss[3], W. Strober[3], S. K. Datta[3], S. M. Holland[3], R. Agarwala[4], J. A. Segre[2], K. M. Frank[1]; [1]Clinical Ctr., NIH, Bethesda, MD, [2]Natl. Human Genome Res. Inst., NIH, Bethesda, MD, [3]Natl. Inst. of Allergy and Infectious Diseases, NIH, Bethesda, MD, [4]Natl. Library of Med., NIH, Bethesda, MD

Abstract Body:

Patients with the primary immune disorder X-linked agammaglobulinemia (XLA) have abnormal development of B-cells and are prone to frequent, persistent viral and bacterial infections beginning at a young age. Despite immunoglobulin (Ig) replacement therapy, there are many case reports that document recurrent infections caused by bacteria including *Campylobacter* and *Helicobacter* species. We present a retrospective study to track the genomic evolution of *C. jejuni* and *H. bilis* isolated from blood and stool samples of two patients with XLA while undergoing long-term antibiotic treatment and Ig therapies. DNA was extracted from 17 *C. jejuni* isolates cultured between 2008 and 2015 in Patient 1 and five *H. bilis* isolates cultured between 1998 and 2013 from Patient 2. Illumina sequencing analysis was used to track single nucleotide variants (SNVs) and insertions/deletions of the genomes. Sequence analysis is consistent with chronic infections, rather than reinfection with new organisms, for both patients. There was limited *in vivo* evolution of the bacteria despite the long infection timeline. A number of SNVs were identified in both *C. jejuni* and *H. bilis* isolates and were mapped to efflux and transport systems, flagellin, and chemotaxis genes. *C. jejuni* iron-associated genes including FUR also contained SNVs. *C. jejuni* isolates developed high tinidazole resistance within months of tinidazole therapy initiation for Patient 1. *In vitro* experiments are currently underway to further examine specific SNVs identified *in silico*. Significantly altered genes identified by sequence analysis may offer insight into the role that *C. jejuni* and *H. bilis* play in maintaining these long-term bacteremic infections in patients with XLA.

Concordance of Pathology and Microbiology Testing in Identifying Pathogens in Immunosuppressed Individuals: A Case Report Series

Author Block:

E. McDonald[1], R. Relich[2], B. Schmitt[2], T. Davis[2]; [1]St. Vincent Hosp., Indianapolis, IN, [2]Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Immunocompromised patients are susceptible to infection from a wide variety of pathogens and identification of the causative organism(s) is crucial to choosing appropriate antimicrobial treatment. To meet the challenges these cases often present, our institution has established an infectious disease pathology (IDP) protocol. The IDP combines a battery of STAT DiffQuick, Giemsa, Gram, GMS, Calcofluor, and Modified Acid Fast stains and examination by pathologists with a panel of traditional microbiological tests. It is uncertain whether the microbiology test results generally confirm the STAT pathology findings or whether the two laboratory modalities provide discrete information. We wanted to determine 1) the overall positivity of pathological versus microbiological testing 2) the concordance rates of the two testing modalities and 3) do discordant results provide any significant clinical value. 513 IDP reports from specimens sent to IU Health in 2013 were compiled. Cases with equivocal pathological interpretations and with inaccessible microbiological results were excluded, reducing the number of cases analyzed to 442. Based upon pathological interpretation, 20.8% of cases were positive. Microbiology testing produced 25.8% positive cases by bacterial culture, 8.8% by fungal culture, and 4.8% by AFB culture. The overall concordance rate between the results was 70.4%. When the initial pathology result was negative, the concordance with microbiological testing increased to 75.4%. However, when the initial pathology result was positive, the concordance rate decreased significantly to 51.1%. Analyzing the discordant results with a positive pathology interpretation showed 55.6% of cases identified a fungal pathogen, most commonly Pneumocystis jirovecii, which cannot be identified by fungal culture. Discordant results with a negative pathology interpretation revealed 70.5% of cases grew a bacterial pathogen by culture, most commonly Pseudomonas aeruginosa and Staphylococcus aureus. Thus, the two testing modalities should be viewed as complimentary rather than confirmatory, as both the pathological results and microbiological results provide distinct information that will directly influence clinical treatment decisions.

Evaluation of a Specific *Nocardia* Genus Pcr on Clinical Samples for the Diagnosis of Nocardiosis

Author Block:

C. Rouzaud[1], V. Rodriguez-Nava[2], E. Catherinot[3], F. Mechaï[4], E. Bergeron[2], E. Farfour[5], A. Scemla[6], F. Suarez[7], O. Lortholary[1], D. Lebeaux[1]; [1]Ctr. d'Infectiologie Necker Pasteur, Paris, France, [2]Université Lyon 1, UMR CNRS 5557 Ecologie microbienne, Laboratoire de Mycologie Microbiologie, Lyon, France, [3]Hôpital Foch, Pneumologie, Suresnes, France, [4]Hôpital Avicenne, Maladies Infectieuses et Tropicales, Bobigny, France, [5]Hôpital Foch, Bactériologie, Suresnes, France, [6]Hôpital Necker Enfants Malades, Transplantation Rénale, Paris, France, [7]Hôpital Necker Enfants Malades, Hématologie, Paris, France

Abstract Body:

Background: The diagnosis of nocardiosis, a severe opportunistic infection, is challenging. This study aimed to: i) assess the sensibility and specificity of a specific 16S-based *Nocardia* PCR performed on clinical samples ii) describe cases of nocardiosis diagnosed with PCR. **Methods:** French prospective study conducted between January 2014 and April 2015. Inclusion criteria were: i) underlying condition favoring nocardiosis; ii) clinical and/or radiological signs compatible with nocardiosis. Patients were retrospectively classified as:Negative control (NC): negative culture for *Nocardia* and proven alternate diagnosis or improvement at 6 months without any anti-*Nocardia* treatment Positive control (PC): positive culture for *Nocardia* Probable nocardiosis (PN): positive *Nocardia* PCR from clinical samples and negative culture for *Nocardia* and no alternative diagnosis.**Results:** 67 patients were included. At the end of the follow up period, 47 were classified as NC, 9 as PC, 11 as NC. Mean age was 51(+/-19) years. Patients had a mean of 2 nocardiosis risk factors, most frequent being: immunosuppressive treatment (n=51), pulmonary disease (n=27), organ (n=14) or hematopoietic stem cell transplantation (n=17). Among the 47 NC, PCR was negative in 74% (35/47) of the cases. All patients with a false-positive PCR had respiratory tract samples. Moreover, patients with a false-positive PCR more frequently had chronic pulmonary disease: 67% (8/12) VS 31% (11/35), p=0.044. PCR was positive for 8/9 PC (88%). We also describe 11 cases of PN: 5 disseminated, 7 pulmonary and 7 extrapulmonary diseases.**Conclusions:** In our study, specific *Nocardia* PCR had a specificity and sensibility of 74% and 88%. Nocardiosis might be underestimated but the interpretation of PCR on respiratory samples is difficult, due to the possible detection of colonization.

Dona Estefania, Lisbon, Portugal, [4]Univ. of Texas Southwestern Med. Ctr., Dallas, TX, [5]Clinical Ctr., Bethesda, MD

Abstract Body:

Frequent life-threatening infections associated with Chronic Granulomatous Disease (CGD) occur due to deleterious mutations in genes encoding the reactive oxygen species-generating phagocyte NADPH oxidase (NOX2). Commonly, *Staphylococcus*, *Burkholderia*, and *Aspergillus* cause infections in CGD, however, over the past decade ≥9 CGD patients had serious infections (2 being fatal) caused by *G. bethesdensis*, a facultative methylotroph and member of the *Acetobacteraceae*. Serology of NIH CGD patients suggests that exposure is even more common and, in some cases, long-term sub-clinical infections may occur. Previous studies utilizing the type strain demonstrated NOX2-dependent killing by human myeloid cells as well as dramatic transcriptional adaptation of *G. bethesdensis* to its intracellular niche. To better understand why some cases were lethal and others were relatively mild, we compared the genotypes and phenotypes of 7 NIH isolates to a lethal Portuguese isolate. Total genome sequencing of these strains demonstrates that despite ≥99.7% identity in the 16s rRNA gene, unique genetic material accounts for up to 11% of each isolate's genome indicating promiscuous gene exchange in this genus. Phenotypically, the Portuguese isolate grew faster than NIH isolates *in vitro*, was a significantly less potent activator of human neutrophils and bound less complement but had intermediate sensitivity to normal neutrophils. On the other hand, it resisted killing by normal monocytes. Challenge of CGD mice demonstrated that the Portuguese isolate is significantly more virulent than 2 different NIH isolates. Further studies are underway to identify specific genetic determinants of virulence in the Portuguese and NIH isolates to better understand microbial pathogenesis by this emerging and sometimes lethal CGD pathogen.

Comparison of Clinical Characteristics and Outcomes of Spontaneous Bacterial Peritonitis and Culture Negative Neutrocytic Ascites in Patients with Liver Cirrhosis

Author Block:

S. Na, N. Kim, K-H. Song, P. Choe, W. Park, J-H. Bang, E. Kim, S-W. Park, H. Kim, M-d. Oh; Seoul Natl. Univ. Coll. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: Ascitic fluid infection (AFI) in cirrhotic patients can be classified into two groups: spontaneous bacterial peritonitis (SBP) and culture-negative neutrocytic ascites (CNNA). The aim of this study is to compare the clinical characteristics and prognosis of patients with SBP or CNNA. **Methods:** We retrospectively reviewed the medical records of cirrhotic patients with AFI. We evaluated demographic data, clinical presentation, laboratory findings, including ascites and/or blood culture, liver function defined by Child-Pugh score, Model for End-stage Liver Disease (MELD) score, and mortality rates.**Results:** Between January, 2006, and December, 2014, 565 patients with AFI were evaluated; 249 (44.1%) of those patients had SBP while 316 (55.9%) had CNNA. *Escherichia coli* (35.7%) was the most common isolated pathogen, followed by *Klebsiella pneumoniae* (17.7%), and Viridans streptococci (8.0%). Although the prevalence of fever (57.8% in SBP vs. 56.6% in CNNA, p=0.777), portal systemic encephalopathy (20.9% vs. 18.0%, p=0.395) and gastrointestinal variceal bleeding (10.0% vs. 10.4%, p=0.876) did not differ between the two groups, abdominal pain was significantly more frequently observed in patients in the SBP group (69.5% vs. 46.8%, p<0.001). Ascites neutrophil counts (4,378/mm3 vs. 1,091/mm3, p<0.001) and blood culture positive rate (37.3% vs. 20.3%, p<0.001) were significantly higher in the SBP group. The SBP group had a significantly worse MELD score with a mean value of 24.26 ± 8.84, compared with the CNNA group (21.67 ± 9.12) (p=0.001). The 7-day mortality rate was significantly higher in the SBP group (10.2% vs. 4.5%, p=0.010), but the 30-day mortality rate (24.3% vs. 18.0%, p=0.085) and 90-day mortality rate (40.1% vs. 36.1%, p=0.382) showed no significant difference.**Conclusions:** Patients in the SBP group had a higher MELD score, ascites neutrophil counts, and positive blood culture rate. Although 7-day mortality was significantly higher in the SBP group, 30-day and 90-day mortality rates were similar between the two groups.

Impact of Antibacterial Prophylaxis in Refractor or Relapse Acute Myeloid Leukemia

Author Block:

B. Ganti, B. Marini, **J. Nagel**, A. Perissinnotti; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Antibacterial prophylaxis with fluoroqinolones or trimethoprim/sulfamethoxazole in neutropenic patients is associated with decreased rates of infection. However, several publications report increasing rates of infection with nosocomial pathogens and antibiotic resistant pathogens. Significant heterogeneity in both the degree of immunosuppression and incidence of infection exists among all neutropenic patients. There are minimal published data evaluating the impact of antibacterial prophylaxis in profoundly immunosuppressed patients with relapsed or refractory acute myeloid leukemia (AML). **Methods:** This retrospective, single-center cohort study evaluated the impact of levofloxacin prophylaxis in neutropenic patients with relapsed or refractory AML from November 2006 to December 2015. A formal institutional protocol recommending antibacterial prophylaxis for relapsed or refractory AML was implemented in December 2013. The primary and secondary outcomes evaluated include incidence of bacteremia, incidence of overall infections, and clinical outcomes for patients receiving levofloxacin prophylaxis versus those not receiving prophylaxis. **Results:** A total of 145 patients were included; 97 in the control group and 48 in the prophylaxis group. Antibacterial prophylaxis significantly reduced the incidence of gram-negative bacteremia (21.6% vs. 2.1%, p=0.001) and the incidence of gram-negative infections from all sites (32.0% vs. 14.6%, p=0.028). Antibacterial prophylaxis was associated with a non-significant reduction in bacteremia from any pathogen (53.6% vs. 37.5%, p=0.079), a reduction in overall infections from any cultured pathogen (69.1% vs. 47.9%, p=0.081), and a numeric reduction in all-cause mortality during admission (14.4% vs. 10.4%, p=0.61). Antibacterial prophylaxis did not increase the incidence of *C. difficle* infection (13.4% vs. 10.4%, p=0.79). **Conclusion:** Bacteremia and other bacterial infections are common in relapsed or refractory AML patients. Antibacterial prophylaxis was associated with a reduction in gram-negative bacteremia, and gram-negative infections from all sites. A numeric, non-significant reduction in all-cause mortality and infection from any pathogen was also noted in patients receiving antibacterial prophylaxis.

Use of the Filmarray Respiratory Panel as Part of a Rapid Diagnostic Protocol for Critically Ill, Immunosuppressed Patients

Author Block:

B. H. Schmitt, T. E. Davis, R. F. Relich; Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Background: Our institution serves a very large immunosuppressed patient population. To help guide their therapy, our practice offers a rapid microscopic analysis of bronchoalveolar lavage fluid (BALF) and other specimen types using a customized protocol. The infectious disease pathology (IDP) protocol includes a battery of six stains that permit detection of bacterial, fungal, and some parasitic pathogens, as well as visualization of host cell populations and detection of viral cytopathology. In a previous case series, we identified that up to 26.3% of IDP cases provided clinically-useful information based on rapid microscopic examination alone. Traditional staining, however, does not permit detection of many viral and atypical bacterial respiratory pathogens. As a result, we used a relatively lengthy PCR method that provided results sometimes 24 hours following specimen collection. In an effort to provide information more rapidly, we recently implemented the FilmArray Respiratory Panel (RP) as part of the IDP. This study analyzes the types and frequency of additional pathogens rapidly identified from critically ill, immunosuppressed patients using the RP as an adjunct to microscopy.**Methods:** Between implementation of the assay and time of this data analysis, 302 patients received IDP's with the RP as a component. The data was assessed for types of and frequency of pathogens identified.**Results:** In total, 60/302 (19.9%) patient specimens yielded pathogens detected by the RP that were otherwise missed by microscopy, with 65 pathogens identified in total. These included: rhino/enterovirus (33); adenovirus (6); respiratory syncytial virus (6); parainfluenza virus type 1 (3), type 3 (9), and type 4 (1); coronavirus NL63 (1); human metapneumovirus (1); *Bordetella pertussis* (1); and *Mycoplasma pneumoniae* (1). In 5 patients, 2 pathogens were detected.**Conclusions:** The RP allowed for detection of non-microscopically identifiable pathogens in nearly 20% of additional patients. Coupled with the microscopic component of the IDP, approximately 45% of cases examined during this timeframe would likely provide an actionable result. The RP panel can potentially provide a useful adjunct rapid diagnostic method in the critically ill, immunosuppressed population.

***Cryptococcus neoformans* Infections in Patients with Lymphoproliferative Disorders**

Author Block:

M. V. Dioverti, S. A. Parikh, A. J. Tande, D. R. Osmon; Mayo Clinic, Rochester, MN

Abstract Body:

Background: Cryptococcosis is an opportunistic infection reported with increasing frequency in those with hematologic malignancies. While several cases of cryptococcosis in patients with lymphoproliferative disorders (LPD) have been reported, the clinical course and outcomes remain undefined. We performed a retrospective review to describe cryptococcosis in these patients.**Methods:** Adult patients with LPD and cryptococcosis from 1/2000 to 7/2015 were identified from an existing database. Data was obtained via retrospective chart review and descriptive statistics were used for analysis.**Results:** We identified 34 patients. The median age was 69 years (62 - 75) and patients were predominantly male (n= 29, 85%). The hematologic diagnosis was chronic lymphocytic leukemia (CLL) in 56% (n=19) while the rest had other LPD. There were 9 patients (26%) who had not received chemotherapy prior to infection. Infectious syndromes included disseminated infection 38% (n=13), pneumonia 29% (n=10), central nervous system (CNS) infection 15% (n=5), asymptomatic antigenemia 9% (n=3) or pulmonary colonization 9 % (n=3). Based on EORTC/MSG definition, 82% of patients had proven infection and 18% had probable infection, excluding asymptomatic antigenemia or colonization. Diagnosis was made via both culture and antigen in 59% (n=20), culture alone in 26% (n=9) and antigen alone in 12% (n=4). None were receiving antifungal prophylaxis. There was 1 death due to cryptococcal infection. Mortality at 30-days and 1 year was 18% and 46% respectively. We also stratified those with disseminated/CNS infection (DCI) (n=18, 53%) versus other (n=16, 47%). The diagnosis of malignancy preceded the infection by a median of 57 months (0-202 months) in the first group versus 18 months (0 - 131 months) in the latter (p=0.07). There were 16 patients (89%) with DCI and 8 patients (50%) without who received prior chemotherapy. 30 day mortality was 17% in the DCI group versus 19% in other.**Conclusions:** Cryptococcal infection in LPD patients is associated with poor outcomes, with 30 day mortality of 18% in our cohort. Further research to identify those at highest risk of infection is warranted, to define whether targeted antifungal prophylaxis would be beneficial.

Publishing Title:

Multiple Sclerosis and Infection: Microorganisms and Resistance Patterns

Author Block:

A. Silva-Pinto, A. Costa, M. Sá, P. Abreu, R. Serrão, A. Sarmento; Centro Hosp.ar São João, Porto, Portugal

Abstract Body:

Background: Infections requiring hospital admission and microorganisms' resistance patterns are poorly characterized in Multiple Sclerosis (MS). Our aim was to identify the most frequent site of infections, which microorganisms often cause infection in MS patients and relate resistance patterns with severity of infection, Intermediate/Intensive care Units (ICU) admission and death.**Methods:** We performed a retrospective study of MS patients admitted to our hospital between 2006 and 2014 due to infections. We used the most appropriate measure of central tendency, of distribution and statistic test. The significance level used was 0.05.**Results:** From the 608 MS patients's admissions, 60 hospital admissions occurred due to infections (34 patients). The patients had a median age of 56.5 and 18 were female. Most common locations of infections were higher (n=21) and lower urinary tract infections (n=11) and pneumonia (n=11).Other less frequent sites of infections were higher airway (n=5) and gastrointestinal infections (n=2). Thirty-six patients had sepsis; 3 severe sepsis and 8 septic shock. Eleven patients were admitted to ICU. Cultural isolation was obtained in 34 hospital admissions: *K. pneumoniae* (n=13) and *E. coli* (n=7) were the most frequently isolated microorganisms. Eleven had multiple susceptible organisms, 18 multidrug resistant (MDR) and 5 extensively drug-resistant (XDR). Patients infected with MDR/XDR microorganisms were more often admitted to the hospital (Mann-Whitney U, p=0.015). We found a statistically significant association between the presence of XDR microorganism and death (χ^2, p=0.05). Full recovery was obtained in most patients (n=57), 1 patient partially recovered and 2 patients died due to devastating infections.**Conclusions:** Urinary tract infections are the most common location of infection requiring hospitalization in MS patients. The majority of isolated microorganisms had antibiotic resistance and five were extensively-drug resistant. Drug resistance was associated with more hospital admissions and death.

Clinical Significance of Identifying *Corynebacterium* Species and Other Coryneform Gram-positive Bacilli in Blood Bb Maldi-Tof Mass Spectrometry - A Retrospective Chart Review

Author Block:

A. Mushtaq, D. J. Chen, B. L. Dylla, N. C. Cole, G. J. Strand, J. Mandrekar, R. Patel; Mayo Clinic, Rochester, MN

Abstract Body:

Background: With the advent of matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS), most Gram-positive bacilli (GPB) are readily identified, but their clinical relevance in blood cultures may be unclear. Herein, we assessed the clinical significance of identifying coryneform GPB in blood cultures by MALDI-TOF MS.**Methods:** A retrospective chart review of patients who presented to the Mayo Clinic, Rochester, MN from January 1, 2013 to October 13, 2015 was performed. We included all instances of blood cultures positive for *Corynebacterium* species or coryneform GPB. We assessed the number of bottle sets positive for a given isolate, time to positivity of blood cultures, patient age, medical history, interpretation of culture results by the healthcare team and whether an infectious diseases consultation was performed.**Results:** During the study period, 181 patients had a total of 246 GPBs isolates from blood cultures. 55.8% (n=101) of positive patient cultures were determined to be contaminants by the healthcare team and were not treated; 32.6% (n=59) were clinically determined to represent true bacteremia and were treated; 7.7% (n=14) were considered to be of uncertain significance, with patients prescribed treatment regardless; and, 3.9% (n=7) of patients had been discharged, were deceased or were transferred to another facility at culture positivity. Patient characteristics associated with an isolate being treated included younger age ($p=0.019$), identification to the species level ($p=0.02$), higher number of positive blood culture sets ($p<0.0001$), shorter time to positivity ($p<0.0001$), immunosuppression ($p=0.02$), and recommendation made by an infectious disease specialist ($p=0.0005$).**Conclusions:** This study highlights the role of MALDI-TOF MS in identification of GPB in blood and its implication on patient management, as well as the role of patient age, full species identification, number of positive blood culture sets, time-to-positivity of culture, immunosuppression, and infectious diseases consultation in healthcare teams' decisions to treat.

Outcomes and Safety of De-Escalation Therapy in Cancer Patients Receiving Empiric Meropenem

Author Block:

K. Shah[1], E. Fay[2], M. Kleinberg[1], E. Heil[2], J. T. Bork[3]; [1]Univ. of Maryland Sch. of Med., Baltimore, MD, [2]Univ. of Maryland Med. Ctr., Baltimore, MD, [3]Johns Hopkins Univ., Baltimore, MD

Abstract Body:

Background: Meropenem is frequently used for suspected infections in febrile cancer patients, and is standard empiric treatment in patients receiving fluoroquinolone (FQ) prophylaxis at our institution. Carbapenem-sparing regimens may prevent development of resistance and preserve broad-spectrum antibiotics. The purpose of this study is to analyze outcomes of meropenem de-escalation in febrile cancer patients. **Methods:** This is a retrospective study performed at the University of Maryland Greenebaum Cancer Center. Patients were identified from an existing antimicrobial prescription database from June 2014 to August 2015. Inclusion criteria were age ≥18 y and first febrile episode for which meropenem was given within 48 h of admission. Descriptive and outcome data were collected. A comparison was performed between: Group 1) de-escalated from meropenem, and Group 2) maintained on meropenem. **Results:** Eighty-seven patients met inclusion criteria. Mean age was 59 y, 64% had acute leukemia, and 95% had received chemotherapy. The main indication for meropenem was use of FQ prophylaxis (60%). 22% of patients had positive cultures, of which 37% were GN, and none had ceftriaxone or meropenem resistance. Fifty-four patients (62%) were de-escalated from meropenem an average of 66.2 h after first dose, mostly to cefepime or piperacillin-tazobactam (TZP). In Group 1, 26% of patients had positive cultures (vs. 15% in Group 2), and of these 36% were GN (vs. 20% in Group 2). Only three resistant GNs were isolated, two in Group 1 (FQ and TZP), and one in Group 2 (FQ). There was no breakthrough bacteremia in either group. Patients in Group 1 had fewer multidrug-resistant (MDR) GNs after admission (7% vs. 9%), and were also more likely to be discharged home (82% vs. 76%). Group 1 had a higher mortality than Group 2 (9% vs 6%), however, none of these deaths were attributed to untreated infection. **Conclusions:** De-escalated patients were more likely to have positive cultures and less likely to have MDR GNs isolated after hospitalization. No breakthrough MDR GN bacteremia was observed. This study suggests that febrile cancer patients with negative cultures can be safely de-escalated to narrow-spectrum antibiotics. Larger scale studies are needed.

Publishing Title:

Evolving Linezolid Resistance Mechanisms in a Worldwide Collection of Enterococcal Clinical Isolates: Results from the Sentry Antimicrobial Surveillance Program

Author Block:

R. E. Mendes, L. M. Deshpande, M. Castanheira, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: Linezolid (LZD) has been in clinical use for several years and large surveillance studies have reported low and stable resistance rates among Gram-positive clinical pathogens. The LZD resistance mechanisms are well known and mostly comprised of G2576T alterations. However, a new transferable determinant (*optrA*) was recently reported in enterococcal isolates from human and animal origins in China. This study evaluated the LZD resistance mechanisms among a global collection of enterococcal clinical isolates.**Methods:** Isolates from the SENTRY Antimicrobial Surveillance Program (2008-2015) were selected. Identification and MIC testing were performed by MALDI-TOF and broth microdilution (CLSI), respectively. Isolates with LZD MICs at ≥4 μg/ml were screened for *cfr*, *optrA* and mutations in the 23S rRNA-, L3 and L4-encoding genes. *optrA*-carrying isolates were submitted to whole genome sequencing for characterization of genetic context.**Results:** A total of 26 *E. faecalis* (EF) and 60 *E. faecium* (EFM) had LZD MICs at ≥4 μg/ml (0.35% of surveillance isolates received). EF had a LZD MIC range of 2 - 16 μg/ml ($MIC_{50/90}$, 8/16 μg/ml), while EFM displayed higher values (4 - 64 μg/ml; $MIC_{50/90}$, 8/32 μg/ml). *optrA* was detected in 13 (50.0%) EF and nine (33.3%) isolates had G2576T mutations in the 23S rRNA. The remaining EF isolates had *cfr* (1 isolate) or L4 alterations (2) alone. Most (53.8%) *optrA*-carrying EF were from the Asia-Pacific region (China [5], Malaysia [1] and Thailand [1]), but other isolates originated from the USA (2), Ireland (2), Panama (1) and Ecuador (1). Two *optrA*-carrying EF (Thailand and Panama) also produced Cfr. All EFM had G2576T mutations, while two isolates each had 23S rRNA alternations with concomitant presence of *cfr* (USA) or *cfr*(B) (USA). *optrA*-carrying enterococci (13 EF) exhibited high MICs for chloramphenicol, retapamulin and tiamulin. *optrA* was plasmid-located in most isolates and genetic context varied greatly.**Conclusions**: LZD resistance mechanisms differ between EF and EFM isolates. 23S rRNA alterations remain the main resistance mechanism in EFM, while the ABC transporter *optrA* prevails in EF. Plasmid-borne *optrA* was detected in isolates from countries other than China and showed a diverse genetic context.

Tigecycline Activity against Multi-Drug Resistant (MDR) *Acinetobacter baumannii* Collected from the Test Program: A Global Perspective 2012-2015

Author Block:

D. Hoban[1], **D. Biedenbach**[1], D. Sahm[1], H. Leister-Tebbe[2]; [1]IHMA, Inc., Schaumburg, IL, [2]Pfizer, Inc, Collegeville, PA

Abstract Body:

Background: *Acinetobacter baumannii* (ACB) causes infections including wound, lower respiratory tract, intra-abdominal and bacteremia among seriously ill hospitalized patients and is associated with high levels of resistance to multiple antimicrobial classes including carbapenems. Resistance patterns for this species can vary geographically. In this study analysis of global data from the Tigecycline Evaluation Surveillance Trial (TEST) was done to evaluate regional differences in ACB resistance patterns.**Methods:** Hospitals in Asia, Africa, Europe (EU), North America (NA), Latin America (LA) and Middle East (ME) contributed 4674 ACB isolates from multiple specimen sources in 2012-2015. Susceptibility testing was performed at each site by broth microdilution following CLSI guidelines and MIC results were interpreted using current CLSI and FDA (tigecycline) breakpoints. For this study MDR was defined as resistance to three or more drug classes.**Results:** The activity of seven agents against ACB are shown in the table.

Antibiotics	**% Susceptible/MIC$_{90}$ (mcg/ml)**

Tigecycline	NB[a]/2	NB/2	NB/2	NB/1	NB/2	NB/2	NB/1	NB/2

[a]NB, no breakpoint criteriaAmong the 4674 ACB isolates collected 63.0% were MDR in all regions combined. MDR rates were higher in ME, Asia, Africa and LA (85-92%) compared to

EU (63.3%) and NA (47.7%).**Conclusions:** The percent susceptibility to each drug tested dropped substantially with the MDR phenotype. Tigecycline was the only drug, based on MIC_{90} data, that maintained a potent level of in vitro activity against ACB overall, and this level of activity did not appear to be affected by the MDR phenotype. Although tigecycline is not indicated for the treatment of infections caused by ACB, it was the only drug to maintain good in vitro activity and this activity should continue to be monitored over time and on a regional basis.

***In vitro* Activity of Tigecycline and Comparators against a North American Collection of *Enterobacteriaceae* - Update of the Test Program**

Author Block:

D. Biedenbach[1], H. Leister-Tebbe[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Pfizer, Inc, Collegeville, PA

Abstract Body:

Background: Several species of Enterobacteriaceae are problematic to treat empirically due to intrinsic and/or acquired resistance mechanisms that are in a steady state of flux. MIC data collected from the Tigecycline Evaluation Surveillance Trial (TEST) were analyzed to provide updated susceptibility results for five commonly prescribed empiric agents used to treat infections caused by five common Enterobacteriaceae species or species groups. **Methods:** Isolates were identified and susceptibility tested using broth microdilution according to CLSI guidelines at each participating institution in North America during The TEST program 2011-2015. CLSI breakpoint criteria were applied to define susceptibility rates. FDA breakpoints were used for tigecycline. **Results:** Susceptibility to agents by organism are provided in the following table.

	Organism (n)/ MIC_{90}/%S					
Drug	***Citrobacter* spp. (52)**	***Enterobacter* spp. (4134)**	***E. coli* (4772)**	***Klebsiella* spp. (4670)**	***Serratia* spp. (1751)**	
Cefepime	4/86.5	4/89.9	4/89.1	2/90.5	≤0.5/96.3	
Levofloxacin	8/86.5	0.5/95.4	>8/67.8	4/89.0	1/95.1	
Meropenem	0.25/92.5	0.25/98.9	≤0.06/99.5	0.12/96.5	0.25/97.9	
Piperacillin-tazobactam	64/76.9	64/84.2	8/95.4	16/90.5	8/95.8	
Tigecycline	1/100	1/96.0	0.25/99.9	1/96.1	2/96.9	

ESBL rates were 9.8%, 8.6%, and 3.7% for *E. coli*, *K. pneumoniae*, and *K. oxytoca*, respectively.**Conclusions:** Tigecycline and meropenem were the only agents that provided >90% susceptibility against the five organism groups examined in this study. Variability among drug activity against certain species was observed, including lower levofloxacin susceptibility among *E. coli* and reduced activity of piperacillin-tazobactam activity against intrinsic AmpC-producing

Citrobacter spp. and *Enterobacter* spp. The TEST program will continue to monitor changes in the activity of these agents against Enterobacteriaceae.

Publishing Title:

Activity of Telavancin against a Global Collection of *Staphylococcus aureus* Causing Bacteremia (2011-2014)

Author Block:

R. E. Mendes[1], H. S. Sader[1], D. J. Farrell[1], J. I. Smart[2], R. K. Flamm[1], R. N. Jones[1]; [1]JMI Lab., North Liberty, IA, [2]Theravance Biopharma US, Inc, South San Francisco, CA

Abstract Body:

Background: Telavancin (TLV) vs standard intravenous therapy is under investigation for the treatment of subjects with *S. aureus* (SA) bacteremia, including endocarditis in a Phase 3 trial. TLV activity was assessed against a global collection of SA bacteremia isolates, including those responsible for endocarditis.**Methods:** 4,191 SA bacteremia isolates from a global network of hospitals were included. Isolates were submitted to a central laboratory as part of a surveillance program (2011-2014). Identification was confirmed and susceptibility (S) testing performed by CLSI methods. MIC interpretation of TLV results used the USA FDA, CLSI and EUCAST approved criteria.**Results:** Overall, SA isolates (100.0% TLV-S) had TLV MIC_{50}, MIC_{90} and MIC_{100} results of 0.03, 0.06 and 0.12 µg/ml, respectively. Equivalent MICs ($MIC_{50/90}$, 0.03/0.06 µg/ml) were obtained for methicillin-susceptible (MSSA) and -resistant (MRSA) isolates, as well as MRSA from community and nosocomial origins. TLV ($MIC_{50/90}$, 0.03/0.06 µg/ml) had similar potency against MRSA from North America and Europe, while isolates from the Asia-Pacific (APAC) and Latin America regions had slightly higher MIC_{50} values ($MIC_{50/90}$, 0.06/0.06 µg/ml). MRSA with vancomycin MICs of 2-4 µg/ml had TLV MICs ($MIC_{50/90}$, 0.06/0.12 µg/ml) 2-fold higher than those with vancomycin MICs at ≤1 µg/ml ($MIC_{50/90}$, 0.03/0.06 µg/ml), but TLV still inhibited all isolates at the S breakpoint of ≤0.12 µg/ml. SA causing endocarditis were inhibited by TLV ($MIC_{50/90}$, 0.03/0.06 µg/ml) at ≤0.12 µg/ml (100.0% S). Overall, TLV was 8-fold more potent than daptomycin ($MIC_{50/90}$, 0.25/0.5 µg/ml) and 16- to 32-fold more potent than linezolid ($MIC_{50/90}$, 1/1 µg/ml) and vancomycin ($MIC_{50/90}$, 1/1 µg/ml) against MRSA.**Conclusions:** TLV (100.0% S) demonstrated potent activity against this global and contemporary collection of SA causing bacteremia, including endocarditis. These *in vitro* results support the investigation of TLV for the treatment of SA bacteremia.

Organism (No. tested)[a]	MIC (µg/ml)							
	Telavancin		Daptomycin		Vancomycin		Linezolid	
	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}	MIC_{50}	MIC_{90}
S. aureus (4,191)	0.03	0.06	0.25	0.5	1	1	1	2
MSSA (2,701)	0.03	0.06	0.25	0.5	1	1	1	2

MRSA (1,490)	0.03	0.06	0.25	0.5	1	1	1	1
MDR (569)	0.06	0.06	0.25	0.5	1	1	1	1
VAN MIC = 2-4 μg/ml (51)	0.06	0.12	0.5	1	2	2	1	2

[a] MSSA = methicillin (oxacillin)-susceptible S. aureus; MRSA = methicillin-resistant S. aureus; MDR = multidrug-resistant (MRSA resistant to three or more drug classes); VAN = vancomycin.

Publishing Title:

***In Vitro* Activity of Piperacillin-Tazobactam and Comparators against *Pseudomonas aeruginosa* in North America and Latin America: Test 2011-2015**

Author Block:

D. Hoban[1], **D. Biedenbach**[1], H. Leister-Tebbe[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Pfizer, Inc, Collegeville, PA

Abstract Body:

Background: *P. aeruginosa* infections are common among debilitated, immunocompromised and seriously ill patients and can be difficult to treat due to the emergence of resistance mechanisms that this pathogen can produce or acquire. Regional variations in antimicrobial susceptibility to multiple classes of antimicrobials also provide additional challenges with selecting appropriate antimicrobial therapy. Piperacillin-tazobactam has remained a common treatment option for infections caused by *P. aeruginosa* for many years and this surveillance study provides current susceptibility data for this agent and comparators in both Latin and North America. **Methods:** *P. aeruginosa* isolates were identified and susceptibility tested using broth microdilution according to CLSI guidelines at each participating institution in North America (3605 isolates) and Latin America (934 isolates) during The Tigecycline Evaluation Surveillance Trial (TEST) program 2011-2015. CLSI breakpoint criteria were applied to define susceptibility rates. **Results:** Susceptibility to key anti-pseudomonal agents by region are provided in the following table.

	Region (n)/MIC_{90}/%S	
Drug	**North America (3605)**	**Latin America (934)**
Piperacillin-tazobactam	64/82.2	>128/60.2
Ceftazidime	16/84.7	32/59.7
Cefepime	16/80.1	>32/62.9
Meropenem	16/77.0	>16/54.3
Levofloxacin	>8/70.7	>8/54.3
Amikacin	8/97.3	>64/77.8

Conclusions: In both regions, based on percent susceptible, piperacillin-tazobactam was among the three most active agents. However, for all drugs studied the percent susceptibility was notably lower in Latin America relative to North America. As *P. aeruginosa* continues to be a

problematic pathogen associated with patient infections and resistance to several antimicrobial classes continued surveillance monitoring on a geographic basis is warranted.

Activity of Imipenem-Relebactam (MK-7655) against *Enterobacteriaceae* and *Pseudomonas aeruginosa* from Europe - SMART 2015

Author Block:

M. Hackel[1], K. Young[2], M. Motyl[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]MRL Merck & Co., Inc., Kenilworth, NJ

Abstract Body:

Objectives: Relebactam (formerly MK7655) (REL) is a newly developed beta-lactamase inhibitor of class A and class C carbapenemases. REL restores the *in vitro* activity of imipenem (IMI) against *Enterobacteriaceae,* including those producing KPC, and *Pseudomonas aeruginosa* (PA). In this study we evaluated the ability of REL to restore IMI susceptibility to a collection of Gram-negative isolates from European countries participating in the 2015 SMART surveillance program.**Methods:** 50 hospitals in 21 countries collected up to 100 consecutive Gram-negative pathogens from intra-abdominal, 50 from urinary tract and 100 from lower respiratory infections. MICs were determined for 775 PA and 3,835 non-*Proteae Enterobacteriaceae* (NPE) using CLSI broth microdilution. *Proteae* were excluded due to intrinsic non-susceptibility to IMI. REL was tested at a fixed concentration of 4 µg/mL in combination with IMI. The percent susceptible (S) was assessed using EUCAST breakpoints. IMI S breakpoints of ≤2 µg/mL (NPE) and ≤4 µg/mL (PA) were applied to IMI/REL.**Results:** The cumulative percent of isolates at each IMI and IMI/REL MIC is shown in the table.

Organism	N	Drug	MIC (µg/mL)							
			≤0.5	1	2	4	8	16	32	>32
P. aeruginosa	775	IMI	20.1	63.5	69.5	72.8	83.5	**94.7**	97.7	100
P. aeruginosa		IMI/REL	73.8	84.5	**92.8**	95.1	96.8	97.3	98.2	100
P. aeruginosa, IMI NS	211	IMI					39.3	80.6	**91.5**	100
P. aeruginosa, IMI NS		IMI/REL	9.5	44.1	73.5	82.0	88.2	**90.0**	93.4	100
NPE	3378	IMI	89.3	**96.2**	98.4	98.9	99.2	99.5	99.5	100
NPE		IMI/REL	**95.1**	98.7	99.1	99.3	99.5	99.6		100
NPE, IMI NS	55	IMI				30.9	49.1	67.3	70.9	**100**
NPE, IMI NS		IMI/REL	36.4	43.6	47.3	56.4	69.1	74.5		**100**

Shaded area indicates susceptible by EUCAST 2015 imipenem breakpoint; MIC$_{50}$ bolded; NPE, non-*Proteae Enterobacteriaceae*; IMI, imipenem; REL, relebactam; NS, non-susceptible

Among 775 PA, 73% (564) were S to IMI; of the 210 non-susceptible (NS) isolates, 173 (82%) were rendered S by the addition of REL, for a final 95% S. Among 3,835 NPE, 98% (3,758) were S to IMI; of the 77 NS isolates, 43 (56%) were rendered S by the addition of REL, for a final 99% S.**Conclusions**: Relebactam exhibited strong potential for restoring the *in vitro* activity of IMI against many pathogens otherwise NS to carbapenems. Further development of this compound could provide a valuable therapeutic option for treating infections caused by resistant Gram-negative bacilli.

Activity of Ceftaroline against *Staphylococcus aureus* from Pediatric, Adult, and Elderly Patients

Author Block:

D. Biedenbach[1], J. Iaconis[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Background: Ceftaroline (CPT), the active metabolite of CPT-fosamil, is a cephalosporin with in vitro activity against *S. aureus*, including methicillin resistant *S. aureus* (MRSA). This analysis evaluated the in vitro activity of CPT against *S. aureus* isolates from four geographic regions, stratified by patient age. **Methods:** *S. aureus* isolates were collected from all sources of infections in Europe, Latin America, Africa/Middle East and Asia-Pacific as part of the AWARE Surveillance Program during 2012-2014. Species were identified by a reference laboratory (IHMA, Inc., Schaumburg, IL) and susceptibility tested by broth microdilution according to CLSI guidelines. CLSI breakpoint criteria were applied to define susceptibility to CPT as follows: susceptible (S) ≤1 µg/mL, intermediate (I) 2 µg/mL, resistant (R) ≥4 µg/mL**.** Age was defined as pediatric ≤1-17, adult 18-65, and elderly >65 years old. **Results:** The table provides CPT activity by patient age and geographic region.

Region (n)[a]	MIC_{90}, µg/mL/%S					
	Pediatric (n)		**Adult (n)**		**Elderly (n)**	
	MSSA (1,790)	**MRSA (1,499)**	**MSSA (6,395)**	**MRSA (7,639)**	**MSSA (3,448)**	**MRSA (6,360)**

[a] Includes all age groups and MSSA and MRSA combined.MSSA=methicillin-susceptible *S. aureus*; n=number of isolatesCPT non-susceptible isolates (MIC ≥ 2 µg/mL) were primarily only observed among MRSA, regardless of region or age group. CPT susceptibility among MRSA was highest among isolates from pediatric populations. Overall, CPT non-susceptibility

was predominantly due to isolates with I MICs (7.3%) compared to those with R MICs (0.4%).**Conclusions:** Regardless of patient age or geographic region CPT maintained potent and consistent *in vitro* activity against MSSA. CPT activity against MRSA did vary by region and age group, but in the majority of instances non-susceptibility was associated with the intermediate category and not frank resistance. Continued monitoring of CPT activity by regional and age parameters is needed to monitor any changes in the drug's *in vitro* activity.

Activity of Ceftazidime-Avibactam against *Pseudomonas aeruginosa* Isolated from Patients in Latin America, Asia/Pacific and Middle-East/Africa 2012-2014

Author Block:

M. Hackel[1], G. Stone[2], B. de Jonge[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Background: Avibactam (AVI) inhibits Ambler class A β-lactamases, including extended-spectrum enzymes and KPCs, class C and some class D enzymes, but has no activity against metallo-β-lactamases (MBLs). AVI is able to restore the activity of ceftazidime (CAZ) against many CAZ-resistant *Pseudomonas aeruginosa* (PA). This study reports CAZ-AVI susceptibility data for recent clinical PA isolates from Latin America (LA), Asia/Pacific (AP), and Middle East/Africa (MEA) collected through the INFORM Surveillance initiative. **Methods:** 3,169 PA isolates were collected through 2012-2014 in LA (1,088), AP (1,392) and MEA (689). MICs were determined by CLSI broth microdilution and interpreted following CLSI 2015 or FDA (CAZ-AVI ≤8 μg/mL susceptible) guidelines.**Results**: CAZ-AVI exhibited potent *in vitro* activity against PA with 91.3% of all isolates susceptible, compared to 76.4% for CAZ alone. In the MBL-negative subset, 95.7% were susceptible to CAZ-AVI. Minor differences in activity were observed in different regions (88.7-93.2% susceptible), with higher activity against isolates with no MBLs (93.2-97.4% susceptible).

***In Vitro* Activity of Imipenem-Relebactam (MK-7655) against *Enterobacteriaceae* and *Pseudomonas aeruginosa* from the United States - SMART 2015**

Author Block:

M. Hackel[1], K. Young[2], M. Motyl[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]MRL Merck & Co., Inc., Kenilworth, NJ

Abstract Body:

Objectives: Relebactam (formerly MK7655) (REL) is a newly developed beta-lactamase inhibitor of class A and class C carbapenemases, including KPCs. REL restores the *in vitro* activity of imipenem (IMI) against *Enterobacteriaceae* and *Pseudomonas aeruginosa* (PA). In this study we evaluated the *in vitro* activity of IMI/REL against a collection of Gram-negative isolates from the 2015 SMART surveillance program in United States.**Methods:** 21 hospitals in the US each collected up to 100 consecutive Gram-negative pathogens from intra-abdominal, 50 from urinary tract and 100 from lower respiratory infections. MICs were determined for 351 PA and 1,373 non-*Proteae Enterobacteriaceae* (NPE) using CLSI broth microdilution. *Proteae* were excluded due to intrinsic non-susceptibility to IMI. REL was tested at a fixed concentration of 4 µg/mL in combination with IMI. The percent susceptible (S) was assessed using CLSI breakpoints. IMI S breakpoints of 1 µg/mL (NPE) and 2 µg/mL (PA) were applied to IMI/REL.**Results:** The cumulative percent of isolates at each IMI and IMI/REL MIC is shown in the table.

Organism	N	Drug	MIC (µg/mL)							
			≤0.5	1	2	4	8	16	32	>32
P. aeruginosa	351	IMI	17.7	62.7	70.7	75.8	86.6	**95.7**	99.4	100
		IMI/REL	71.5	82.9	**93.4**	96.3	99.1	99.7		100
P. aeruginosa, IMI NS	103	IMI				17.5	54.4	85.4	**98.1**	100
		IMI/REL	8.7	42.7	77.7	87.4	**97.1**	99.0		100
NPE	1,373	IMI	89.4	**96.0**	98.3	98.7	99.3	99.6	99.9	100
		IMI/REL	**96.1**	99.1	99.9	100				
NPE, IMI NS	43	IMI			46.5	58.1	76.7	86.0	**95.3**	100
		IMI/REL	37.2	69.8	**95.3**	100				

Shaded area indicates susceptible by CLSI 2015 imipenem breakpoint; MIC_{90} bolded; NPE, non-*Proteae* Enterobacteriaceae; IMI, imipenem; REL, relebactam; NS, non-susceptible

Among 351 PA, 71% (248) were S to IMI; of the 103 non-susceptible (NS) isolates, 80 (78%) were rendered S by the addition of REL, for a final 93% S. Among 1,373 NPE, 97% (1,330) were S to IMI; of the 43 NS isolates, 30 (70%) were rendered S by the addition of REL, for a final 96% S.**Conclusions:** Relebactam exhibited strong potential for restoring the *in vitro* activity of IMI against many pathogens otherwise NS to carbapenems. Further development of this compound could provide a valuable therapeutic option for treating infections caused by resistant Gram-negative bacilli.

***In Vitro* Activity of Tigecycline and Comparators against Genotypically Characterized β-Lactam-Resistant *Enterobacteriaceae* Isolates from the United States and Canada**

Author Block:

K. Kazmierczak[1], B. Johnson[1], H. Leister-Tebbe[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Pfizer, Inc., Collegeville, PA

Abstract Body:

Background: The Tigecycline Evaluation Surveillance Trial (TEST) monitors the *in vitro* activity of the glycylcycline tigecycline (TGC) against clinical isolates collected globally. This study reports the *in vitro* activity of TGC and comparators against *Enterobacteriaceae* (*Ebac*) collected in the United States (US) and Canada (CAN) in 2012-2014. **Methods:** Non-duplicate clinical isolates were collected from 60 participating sites. Susceptibility testing was performed by broth microdilution by the local laboratory using supplied panels and interpreted using CLSI breakpoints. Confirmation of extended-spectrum β-lactamase (ESBL) activity and meropenem (MEM) non-susceptibility (NS) was performed at a central laboratory.A subset of *Ebac* that were MEM-NS and/ or phenotypically ESBL positive (ESBLp+) were screened for β-lactamase (BL) genes by PCR, followed by sequencing.**Results:** TGC demonstrated good *in vitro* activity against *Ebac* collected in the US and CAN, with 97% of overall isolates inhibited by ≤2 µg/mL TGC. A total of 605 isolates (293 *Escherichia coli*, 256 *Klebsiella pneumoniae*, and 56 other *Ebac*) were molecularly characterized for BL genes. MIC_{90}s of TGC against ESBLp+, MEM-susceptible (S) subsets from both countries were 1 µg/mL, and were 1-2 µg/mL against MEM-NS subsets, including isolates carrying carbapenemases (KPC, OXA-48-like, NDM) and those producing ESBLs or AmpC BL that are assumed to also harbor changes in permeability.

Activity of Ceftaroline and Comparators against *Staphylococcus* spp. and *Streptococcus* spp. from Patients with Blood Stream Infections (BSI): Aware 2014 Surveillance Program

Author Block:

D. Biedenbach[1], J. Iaconis[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Background: Ceftaroline (CPT), the active metabolite of CPT-fosamil, is a cephalosporin developed for treating infections caused by *S. aureus* (MSSA and MRSA), *S. pneumoniae* (SPN), β-hemolytic streptococci (BHS), and some Gram-negative pathogens. The analysis evaluated the *in vitro* activity of CPT against Gram-positive isolates collected from BSI's in four geographic regions. **Methods:** Isolates (2018 total) were collected from patients in 37 countries in Europe, Latin America, Africa/Middle East and Asia-Pacific as part of the AWARE Surveillance Program during 2014. 13.4% of the isolates were collected from pediatric patients. Species were identified using MALDI-TOF by a reference laboratory and tested by broth microdilution according to CLSI guidelines. CLSI and EUCAST breakpoint criteria were applied to define susceptibility where applicable**. Results:** The table provides the activity of CPT and comparators against MSSA, MRSA, coagulase-negative staphylococci (CoNS), SPN, viridans group streptococci (VGS), and BHS.

	MIC_{90}, µg/mL [%S CLSI/EUCAST] [a]

LZD	2 [100/100]	2 [100/100]	2 [99.4/99.4]	**LZD**	2 [100/100]	2 [100/NA]	2 [100/100]

[a] Susceptibility was determined using CLSI M100-S25 (2015) and EUCAST version 5.0 (2015) breakpoint criteria.[b] Drug abbreviations: CPT (ceftaroline), VAN (vancomycin), TEC (teicoplanin), DAP (daptomycin), LZD (linezolid), CRO (ceftriaxone), PEN (penicillin), ERY (erythromycin).[c] *S. aureus* breakpoints were applied for CoNS and SPN breakpoints were applied for VGS and BHS for nterpretations of susceptibility.[d] NA=no applicable breakpoints recommended **Conclusions:** The findings demonstrate that CPT has potent *in vitro* activity against staphylococcal (including MRSA) and streptococcal isolates collected from BSIs. Given the propensity of these organisms, especially staphylococci, to develop resistance ongoing monitoring of CPT activity as the drug's use increases is warranted.

***In Vitro* Activity of Aztreonam-Avibactam (ATM-AVI) against Gram-Negative Pathogens from Latin America (LA) Collected in 2014**

Author Block:

K. Kazmierczak[1], M. Hackel[1], B. de Jonge[2], P. A. Bradford[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Background: AVI inhibits serine β-lactamases (BL), including class A ESBLs and KPC, class C, and some class D BL. The combination of ATM, which is refractory to hydrolysis by metallo-β-lactamases (MBL), and AVI is active against carbapenem-resistant *Enterobacteriaceae* (CRE) producing MBL in combination with serine BL. This study evaluated the *in vitro* activity of ATM-AVI and comparators against *Enterobacteriaceae* (*Ebac*) and *P. aeruginosa* (*Paer*) collected in LA in 2014. **Methods:** Non-duplicate clinical isolates were collected from 23 centers in Argentina, Brazil, Chile, Colombia, Mexico, and Venezuela. Susceptibility testing was performed using CLSI broth microdilution. ATM-AVI was tested at a fixed concentration of 4 µg/mL AVI. Isolates that were non-susceptible (NS) to carbapenems, resistant to ceftazidime, or phenotypically positive for ESBL were characterized for the presence of BL genes by PCR and sequencing.**Results:**MICs of ATM-AVI were ≤8 µg/mL against 2167 of 2168 (99.9%) collected *Ebac*, and were ≤4 µg/mL against meropenem-NS isolates. The addition of AVI to ATM reduced MIC_{90} values ≥128-fold, to 0.12-1 µg/mL, against all groups of *Ebac*, including those that produced MBLs co-carried with one or more plasmid- or chromosomally-mediated serine BL (Table). Only VIM- and NDM-type MBLs were found in *Ebac* from LA (Mexico, n=3; Venezuela, n=1). ATM-AVI showed only modest activity against *Paer*.

Mechanisms and Molecular Epidemiology of Ampicillin-Sulbactam-Nonsusceptible *Escherichia coli*

Author Block:

T. Noguchi, Y. Matsumura, M. Yamamoto, M. Nagao, S. Takakura, S. Ichiyama; Kyoto Univ. Graduate Sch. of Med., Kyoto, Japan

Abstract Body:

Background: A recent increase in the prevalence of ampicillin-sulbactam-nonsusceptible *Escherichia coli* has challenged an appropriate therapy for various infections such as bacteremia. However, data on resistance mechanisms, especially about outer membrane proteins (OMPs), and molecular epidemiology are limited. We performed a detailed analysis on clinical ampicillin-sulbactam-nonsusceptible *E. coli* isolates that caused bloodstream infections. **Methods:** We included 41 non-duplicate ampicillin-sulbactam-nonsusceptible *E. coli* isolates that were collected at a Japanese university hospital between 2010 and 2013. We performed PCR and sesquecing of β-lactamases genes, real-time PCR expression assay of $bla_{\text{TEM-1}}$, and phenotypic AmpC detection using cefoxitin-cloxacillin disk. OMPs were characterized by gene sequencing, SDS-PAGE, and matrix-assisted laser desorption ionization time-of-flight/time-of-flight mass spectrometry. Multilocus sequence typing was performed to determine prevalent clones. **Results:** Phenotypic and genotypic characterization of the 41 ampicillin-sulbactam-nonsusceptible *E. coli* isolates showed that β-lactamases were mainly responsible for the resistance (TEM-1 hyperproduction, n=14 [34%]; chromosomal AmpC hyperproduction [cAmpC], n=9 [22%]; plasmid-mediated AmpC [pAmpC], n=7 [17%]; OXA, n=2). All of the other 11 isolates had $bla_{\text{TEM-1}}$; 5 of them had deficient/decreased OmpF and wild-type OmpC and 2 had $bla_{\text{CTX-M}}$ in addition to $bla_{\text{TEM-1}}$. A total of 13 different sequence types (STs) were found; only ST131 was the dominant ST (32%, n=13). High-level expression of $bla_{\text{TEM-1}}$ was the most frequent mechanism in ST131 isolates (n=8) followed by cAmpC hyperproduction (n=3). Isolates with altered OMPs in ST131 were rare (n=1) while 10 non-ST131 isolates had altered OMPs. **Conclusion:** Hyperproduction of TEM-1 was the most common cause that was associated with ampicillin-sulbactam-nonsusceptible *E. coli*. Mutations in OmpF or cAmpC and acquisition of pAmpC were also associated with the nonsusceptibility. Clonal expansion of the ST131 clone hyperproducing TEM-1 might contribute to the increase of ampicillin-sulbactam-nonsuscpetible *E. coli*.

Publishing Title:

Oritavancin Longitudinal *In Vitro* Activity against Gram-Positive Organisms from USA Medical Centers: Results from the Sentry Antimicrobial Surveillance Program for 2010 - 2014

Author Block:

R. E. Mendes, R. K. Flamm, H. S. Sader, M. Castanheira, D. J. Farrell, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: Oritavancin (ORI) is approved in the USA and European Union for the treatment of acute bacterial skin and skin structure infections caused by gram-positive (GP) pathogens. This study evaluated ORI activity over time against GP isolates collected from USA hospitals in 2010-2014.**Methods:** A total of 16,340 *S. aureus* (SA), 1,313 coagulase-negative staphylococci (CoNS), 1,861 *E. faecalis* (EF), 1,037 *E. faecium* (EFM), 2,505 beta-hemolytic streptococci (BHS) and 1,067 viridans group streptococci (VGS) were included. Bacteria were identified by standard algorithms and/or MALDI-TOF. Susceptibility (S) testing was performed by CLSI methods; interpretation of MICs used FDA (ORI), CLSI (2015) and/or EUCAST (2015) criteria.**Results:** ORI had MIC_{50} and MIC_{90} values of 0.03 and 0.06 µg/ml, respectively, against SA (99.5 - 100.0% S), the methicillin-resistant (MR) subset (99.8 - 100.0% S) and CoNS during the study period (Table). The only exception was noted in the 2011 sampling year that showed a slightly higher MIC_{50} and MIC_{90} values ($MIC_{50/90}$, 0.06/0.12 µg/ml) against SA and MRSA. Daptomycin (DAP; $MIC_{50/90}$, 0.25/0.5 µg/ml), linezolid (LZD; $MIC_{50/90}$, 1/1 µg/ml) and vancomycin (VAN; $MIC_{50/90}$, 1/1 µg/ml) also had consistent MICs against SA or MRSA over the study period. Similar (±1 doubling dilution) ORI MICs were obtained against EF and EFM over time. Ampicillin, DAP, LZD and VAN showed consistent MIC_{50} values ($MIC_{50/90}$, 1/1-2 µg/ml) against EF, while DAP ($MIC_{50/90}$, 2/2-4 µg/ml) and LZD ($MIC_{50/90}$, 1/1-2 µg/ml) had consistent MICs against EFM (80.1% VAN-resistant) over the period. VGS were highly S to ORI (100.0% S) with consistent MICs between 2010 and 2014. Similar MICs were obtained for ORI against BHS (99.1 - 99.8% S) over the study period.**Conclusions**: ORI was highly active against an extensive longitudinal USA collection of clinically important GP pathogens. No significant year-to-year variations were noted in ORI activity against these clinical isolates.

Publishing Title:

Characterization of Fosfomycin Resistance Gene, *fosB,* in Methicillin-Resistant *Staphylococcus aureus* Isolates

Author Block:

Z. Fu, Y. Guo, F. Hu, **X. Xu**, M. Wang; Inst. of Antibiotics, Huashan Hosp., Fudan Univ., Shanghai, China

Abstract Body:

Background: In China, fosfomycin alone or in combination with other antibiotics is commonly used in the treatment of infections caused by Gram-positive bacteria, including methicillin-resistant *Staphylococcus aureus* (MRSA). Although fosfomycin-resistant *S. aureus* strains have continued to emerge and increase, the research on them is rare. In order to determine prevalence, location and flanking sequences of fosfomycin-resistance (*fos*) genes in MRSA clinical isolates, this study was carried out. **Methods:** A total of 67 non-duplicate fosfomycin resistant MRSA isolates were collected from blood and cerebrospinal fluid samples at Huashan Hospital in Shanghai between 2004 and 2014. By PCR and sequencing, 9 *fosB* gene positive strains was found. The locations of *fosB* genes were determined by Southern blotting and genetic environments were analyzed by primer walking sequencing. Multiple locus sequence typing (MLST) was used to characterize genetic diversity. Conjugation of *S. aureus* ATCC25923 with *fosB* genes was performed to evaluate the genes' transferability.**Results:** Among 67 fosfomycin-resistant MRSA strains, nine high level fosfomycin resistant strains (≥128 μg/ml) were *fosB*-positive. Three new subtypes of *fosB*, designated as *fosB4*(KR870311), *fosB5*(KT032253), and *fosB6*(KR870314), were identified. Seven out of nine strains that contained the *fosB1*, *fosB4* or *fosB6* genes, which were located on small plasmids (ca. 2.5 kb) and flanked by an analogous replication gene (*rep*). The *fosB5* gene located in a unique genetic environment and was surrounded by a shorter *rep* gene and two copies of a transposon gene (*tnp*) that shared high identity with the IS*257*-like transposon. Four MLST types were found among the nine *fosB*-positive strains. Conjugants with the *fosB* genes were resistant to fosfomycin with MIC 64 or 128 μg/ml.**Conclusions:** All 3 new subtypes of *fosB* gene found in MRSA can mediate fosfomycin resistance. These different subtypes and genetic environments of *fosB* indicate that *fosB* genes have different sources.

Publishing Title:

Activity of ceftazidime-avibactam (CAZ-AVI) against OXA-48- carrying *Enterobacteriaceae* isolated from a global surveillance program, 2012-2014

Author Block:

K. Kazmierczak[1], M. Hackel[1], G. Stone[2], B. de Jonge[2], P. A. Bradford[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Background: CAZ-AVI was developed for use against *Enterobacteriaceae* (*Ebac*) producing serine β-lactamases (BL), including carbapenemases. The AVI component of the combination is a novel non-β-lactam BL inhibitor that protects CAZ from inactivation by class A, class C, and some class D BL, including OXA-48. This study evaluated the *in vitro* activity of CAZ-AVI and comparators against OXA-48-producing isolates collected in 2012-2014 through the INFORM surveillance program. **Methods:** Isolates were collected globally in 176 sites from 39 countries. Susceptibility testing was performed by broth microdilution and interpreted using CLSI (CAZ, meropenem) or FDA guidelines (CAZ-AVI, ≤8 μg/mL susceptible). CAZ-AVI was tested at a fixed concentration of 4 μg/mL AVI. Isolates were screened for the presence of BL genes using PCR, microarray and sequencing. **Results:** Genes encoding OXA-48 enzymes were detected in 163 isolates across 10 species of *Ebac* (*K. pneumoniae*, *Enterobacter* spp., *E. coli*, *M. morganii*, *S. marcescens*, *Citrobacter* spp., *P. mirabilis*) collected in 15 countries, with 83% of isolates collected in Russia, Turkey, Romania, and Kuwait. The majority of isolates co-carried additional BL. CAZ and MEM showed poor activity against the OXA-48-containing isolates, but 95.1% of *Ebac* carrying OXA-48 were inhibited by ≤8 μg/mL of CAZ-AVI (Table). CAZ-AVI showed good *in vitro* activity against *Ebac* carrying OXA-48, including isolates that co-produce an ESBL or AmpC enzyme.

	Drug (MIC$_{90}$ [μg/mL], % Susceptible)

***In Vitro* Activity of Aztreonam-Avibactam (ATM-AVI) qgainst Gram-Negative Pathogens from Asia/Pacific (AP) Collected in 2014**

Author Block:

K. Kazmierczak[1], M. Hackel[1], B. de Jonge[2], P. A. Bradford[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Background: ATM-AVI is a β-lactam/ β-lactamase inhibitor combination being developed for use against carbapenem-resistant *Enterobacteriaceae* (CRE), especially those carrying metallo-β-lactamases (MBL) in combination with serine β-lactamases (BL) such as KPC, OXA-48, extended-spectrum enzymes (ESBL), and AmpC. This study evaluated the *in vitro* activity of ATM-AVI and comparators against *Enterobacteriaceae* (*Ebac*) and *P. aeruginosa* (*Paer*) collected in AP in 2014.**Methods:** Non-duplicate isolates were collected from 22 centers in 8 AP countries. Susceptibility testing was performed by broth microdilution. ATM-AVI was tested at a fixed concentration of 4 µg/mL AVI. PCR and sequencing of *bla* genes was performed on isolates non-susceptible to carbapenems, phenotypically positive for ESBL, and those with ceftazidime MICs ≥16 µg/mL.**Results:**ATM-AVI was very active against *Ebac*, testing with an MIC_{90} value of 0.12 µg/mL, with 99.9% inhibited by ≤8 µg/mL. Activity was retained against resistant subsets of *Ebac,* including MBL-producing isolates. MBLs were found in 10 *K. pneumoniae*, 3 *E. cloacae*, 2 *C. freundii*, and 1 *E. asburiae* collected in the Philippines (n=14), Japan and Thailand (n=1 each), and included five variants of IMP- and NDM-type MBLs. No VIM-type MBLs were found in *Ebac* from AP. All of these MBL-producing *Ebac* co-carried serine BL, with 11 isolates carrying 1-2 SHV- and/or CTX-M-type ESBLs. ATM-AVI showed moderate activity against *Paer*.

Publishing Title:

Activity of Ceftazidime-Avibactam against Carbapenem-Non-Susceptible *Enterobacteriaceae* from Latin America, Asia/Pacific and the Middle East/Africa, 2012-2014

Author Block:

M. Hackel[1], K. Kazmierczak[1], G. Stone[2], B. de Jonge[2], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]AstraZeneca Pharmaceuticals, Waltham, MA

Abstract Body:

Objectives: Avibactam (AVI) restores the *in vitro* activity of ceftazidime (CAZ) against *Enterobacteriaceae* that produce class A (including KPC), class C, and some class D β-lactamases (BLs). In this study we evaluated the *in vitro* activity of CAZ-AVI against carbapenem-non-susceptible *Enterobacteriaceae* isolated from Latin America (LA), Asia/Pacific (AP) and the Middle East/Africa (MEA) from the INFORM 2012-2014 surveillance program.**Methods:** MICs were determined using CLSI guidelines. Susceptibility (S) was assessed using FDA (CAZ-AVI, tigecycline), CLSI (CAZ, meropenem [MEM]) or EUCAST (colistin) breakpoints. Carbapenem-non-susceptible *Enterobacteriaceae* were defined as non-susceptible (NS) to MEM using CLSI breakpoints.**Results**: The %S for CAZ-AVI and comparators are shown in the table. 448 of 15,865 *Enterobacteriaceae* (2.8%) were MEM-NS. CAZ-AVI was active against 99.3% of all *Enterobacteriaceae*. Regional differences were apparent in activity against MEM-NS isolates, with lower activity in regions where carbapenem resistance was mainly due to the presence of isolates with metallo-β-lactamases (MBLs).

	% Susceptible			
Organism (N)	All	LA	AP	MEA
Enterobacteriaceae	N=15,685	N=5,317	N=7,087	N=3,281
Ceftazidime-avibactam	99.3	99.8	99.1	99.2
Ceftazidime	72.7	69.2	75.3	72.7
Colistin	83.0	82.2	83.5	83.5
Meropenem	97.1	94.9	98.5	98.0
Tigecycline	93.6	93.2	93.7	94.0
Enterobacteriaceae, MEM-NS	N=448	N=273	N=108	N=67
Ceftazidime-avibactam	80.1	97.8	48.2	59.7
Ceftazidime	5.8	5.5	3.7	10.5

Colistin	77.9	75.0	80.8	87.9
Tigecycline	93.1	95.2	87.0	94.0
Enterobacteriaceae, MEM-NS, MBL negative	N=366	N=269	N=61	N=36
Ceftazidime-avibactam	97.0	99.3	85.3	100
Ceftazidime	6.3	5.6	6.6	11.1
Colistin	75.6	74.3	70.0	88.9
Tigecycline	93.7	95.2	85.3	97.2

Conclusions: CAZ-AVI demonstrated good *in vitro* potency against *Enterobacteriaceae* isolates from LA, AP and MEA, including MEM-NS isolates, unless MEM-NS was caused by the presence of MBLs. The incidence of MBL-producing isolates amongst different regions explains to a large degree the different %S observed against MEM-NS *Enterobacteriaceae*.

***In Vitro* Activity of Fosfomycin against Bacterial Pathogens Isolated from Urine Specimens of Outpatients Attending Emergency Departments in Canada from 2007 to 2014**

Author Block:

J. A. Karlowsky[1], H. Adam[1], M. Baxter[2], N. Laing[2], B. Weshnoweski[1], R. Vashisht[2], G. G. ZHANEL[2]; [1]Diagnostic Services Manitoba, Winnipeg, MB, Canada, [2]Univ. of Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: In North America, fosfomycin (FOS) tromethamine is indicated for the treatment of uncomplicated urinary tract infections in women caused by *Escherichia coli* and *Enterococcus faecalis*. FOS has been shown to inactivate the enzyme UDP-*N*-acetylglucosamine-3-enolpyruvyltransferase (MurA) which ligates phosphoenolpyruvate (PEP) to the 3'-hydroxyl group of UDP-*N*-acetylglucosamine in peptidoglycan synthesis. FOS reference MIC antimicrobial susceptibility testing (AST) is rarely performed in clinical laboratories because the CLSI agar dilution method must be used. MIC data documenting the activity of FOS against outpatient urinary pathogens other than *E. coli* and *E. faecalis* are limited.**Methods:** FOS AST was performed using CLSI agar dilution testing (MHA supplemented with 25 µg/ml of glucose-6-phosphate; M100-S24 [2014]); all other antibacterial agents were tested using CLSI broth microdilution panels. MICs were interpreted using M100-S24 (2014) criteria. FOS susceptible, intermediate, and resistant breakpoints are ≤64, 128, and ≥256 µg/ml, respectively. The isolates tested were cultured from urine specimens of outpatients attending emergency departments (EDs) and submitted to the annual CANWARD surveillance study from 2007 to 2014.**Results:** The table shows MIC_{90} (µg/ml) and % susceptible data for oral antimicrobial agents.

	MIC_{90} (µg/ml) / % Susceptible				
Isolate Phenotype (n)	FOS	SXT	NIT	CIP	AMC
E. coli (877)	4 / 99.7	>8 / 78.2	32 / 97.9	>16 / 85.4	16 / 88.8
K. pneumoniae (106)	128 / 89.6	0.25 / 96.2	128 / 33.7	≤0.06 / 98.1	8 / 96.7

Proteus mirabilis (40)	128 / 85.0	>8 / 87.5	128 / 0	2 / 87.5	16 / 90.0
Staphylococcus aureus (26)	32 / NA	≤0.12 / 100	16 / 100	>16 / 50.0	NA / 66.7**
Pseudomonas aeruginosa (27)	256 / NA	NA	NA	>16 / 66.7	NA
Klebsiella oxytoca (22)	64 / 90.9	≤0.12 / 100	32 / 95.5	≤0.06 / 100	16 / 89.5

Enterobacter cloacae (14)	128 / 85.7	≤0.12 / 92.9	128 / 35.7	2 / 85.7	>32 / 21.4
Abbreviations: SXT, trimethoprim-sulfamethoxazole; NIT, nitrofurantoin; CIP, ciprofloxacin; AMC, amoxicillin-clavulanate; NA, not applicable. *AMC activity predicted by testing ampicillin for *E. faecalis*. **AMC activity predicted by testing cefoxitin for *S. aureus*.					

Conclusion: The in vitro activities of SXT (78%) and CIP (85%), two frequently prescribed empiric agents for urinary tract infections, were compromised against recent urinary isolates of *E. coli* when compared to FOS (>99%). 84% of *E. faecalis* isolates were susceptible to FOS. FOS demonstrated broad spectrum activity against facultative gram-negative (Enterobacteriaceae) and gram-positive (enterococci, staphylococci) pathogens frequently isolated from urinary tract infections of Canadian outpatients attending EDs.

Proteomic Profiles of Antibiotic Resistance Plasmid and Chromosome in *Escherichia coli*

Author Block:

N. Nolan, **F. Walsh**; Maynooth Univ., Maynooth, Ireland

Abstract Body:

This study investigated how different antibiotics treatments affect the protein abundances produced from a multi-drug resistant plasmid (pEK499) and *Escherichia coli* host chromosome. The proteomic profiles of a multi-drug resistance plasmid (pEK499) and chromosome of *Escherichia coli* under antibiotic stress were investigated using the Q-Exactive mass spectrometer. The bacteria were exposed to antibiotics, for which a resistance gene was present on the plasmid (ampicillin and cefotaxime) at high concentrations or sub-MIC concentrations for those, which the bacteria were susceptible (imipenem and ciprofloxacin). The plasmid contains the *aac(6')Ib-cr* quinolone helper resistance gene and had a ciprofloxacin MIC ≤0.125 m/L. The plasmid proteomes and chromosome proteomes of these bacteria under stress were compared to the same *E. coli* grown under the same conditions with no antibiotic stress.The results indicated that the presence of antibiotic resistance proteins from the plasmid was not dependent on the presence of the corresponding antibiotic. The quantities of bla_{TEM} and $bla_{CTX\text{-}M\text{-}15}$ proteins were similar under antibiotic stress or no antibiotic stress. The relative abundances of chromosomal proteins varied in comparison to the control from increases in 27 proteins (ampicillin) to increases in 98 proteins (ciprofloxacin) and decreases in protein abundances of 28 proteins (imipenem) to 80 proteins (ciprofloxacin). There were no common proteins to all antibiotic exposed or control bacteria. Proteins involved in gene expression were the most frequently identified metabolic pathway or process. In conclusion the variations between the relative abundances of chromosomal proteins in different samples, appears to be antibiotic specific but not antibiotic class specific and thus could indicate specific antibiotic-induction pathways or metabolic processes.

Epidemiology Of Transmissible 16s Rrna Methyltransferases In *enterobacteriaceae* Using Whole Genome Sequencing

Author Block:

L. Appalla, E. Snesrud, R. Maybank, K. Ong, R. Clifford, M. Hinkle, E. Lesho, P. Mc Gann; Walter Reed Army Inst. of Res., silver spring, MD

Abstract Body:

In the past decade, transmissible 16S rRNA methyltransferases (16S RMTase) have emerged as a new and worrisome source of aminoglycoside resistance. Increasingly, strains carrying these genes are co-producing carbapenemases, and understanding their epidemiology is essential for effective surveillance. 27 clinical isolates, representing 7 species of *Enterobacteriaceae*, had phenotypes indicative of 16S rRNA methyltransferase activity by arbekacin disk diffusion. All isolates were sequenced using a combination of long and short read sequencing using the Illumina Miseq and PacBio RSII platforms, respectively. Six genes encoding 16S RMTases were identified, with *armA* and *rmtH* being the most common (6 isolates each), followed by *rmtB* (N=5), *rmtC* (N=4), *rmtF* (N=3), and *rmtE* (N=1). 16S rRNA methyltransferases were most commonly found in *Klebsiella pneumoniae*, accounting for 19 of the 27 isolates tested (70.4%). Notably, all *K. pneumoniae* isolates carrying *armA* belonged to multi-locus sequence type (MLST) 231, whereas the six isolates carrying *rmtH* were assigned to five different ST types, including one novel ST. Three different 16S RMTases were identified among the 3 *Escherichia coli* isolates, including *rmtC* in an ST-131 strain, a globally distributed pathogenic lineage. 16S RMTase genes were also found in a single isolate of *Enterobacter cloacae* (*rmtC*), *Morganella morganii* (*rmtB*), *Proteus mirabilis* (*armA*), *Providencia sturatii* (*armA*), and *Serratia marcesens* (*armA*). All 16S RMTase genes were carried on plasmids, with those belonging to incompatibility group (Inc) FII being the most common. However, 16S RMTase genes were also carried on Inc A/C2, F1A, F1B, H1B, and L/M plasmids. Of particular concern was the observation that eight isolates also carried the carbapenemases bla_{NDM} (N=5) and bla_{KPC} (N=3). We demonstrate that transmissible 16S RMTases are carried on a wide variety of plasmids and are distributed among diverse members of the *Enterobacteriaceae*. The increasing association between carbapenemases and 16S RMTases is particularly ominous, as just two enzymes can now render the two most widely used antibiotic classes ineffective.

Involvement of Two Efflux Pumps in Tigecycline Resistant *S. aureus* Mutants

Author Block:

M. Herrera[1], **S. Di Gregorio**[2], S. Fernandez[2], G. Posse[1], M. Mollerach[2], J. Di Conza[2]; [1]UAP, ER, Argentina, [2]UBA, BA, Argentina

Abstract Body:

Background: *Staphylococcus aureus* has an extraordinary ability to develop antimicrobial resistance. Previously, we reported the in vitro selection of tigecycline resistant mutants (TRM) which showed an increase in tigecycline (TIG) MICs of 128-fold. The efflux phenotype was predicted by ethidium bromide MIC determination (64-128 μg/ml). Additionally, we demonstrated that MIC for both compounds showed a decrease greater or equal than 4 dilutions in the presence of 20 μg /ml reserpine (an efflux pump inhibitor). The aim of this study was to analyze the involvement of two efflux pumps implied in glycylcicline and tetracyclines extrusion (*mep*A and *nor*B) in two TRM strains analyzed previously (94159m and 2028m). **Methods:** Efflux pump genes were amplified by PCR and sequencing. Reverse transcription-Quantitative real-time-PCR (RT-qPCR) was performed to evaluate the expression of *mep*A and *nor*B genes. Data was expressed as normalized relative quantities (NRQ) using *gyr*B and *pta* as reference genes. All experiments were performed by triplicate. Statistical analysis of the data was performed using Student t test (*alfa*=0.05).**Results:** The nucleotide sequence of *mep*A gene (1700 bp) in the parental strains 94159p and 2028p showed 100 % of identity with the corresponding reference sequences (*S. aureus* Accession number HE579073.1 and CPO12119.1). By contrast, for both mutant strains (94159m and 2028m) a transition (C to T) was observed in the position 211 of the sequence, displaying the Thr29Ile mutation in the translated amino acid sequence. In addition 2028m harbored the transition A to G in the position 985 generating the Glu287Gly mutation.NRQ values of *mep*A gene were significantly higher in both mutant strains (94159m and 2028m) when compared to parental strains ($p<0.0001$ and $p=0.0009$ respectively). On the other hand, NRQ values of *nor*B gene were significantly decreased in mutant strain 2028m when compared to parental strain 2028p ($p=0.0007$), and no difference was detected for the pair 94159p-94159m ($p=0.1093$).**Conclusions:** This study demonstrates the involvement of efflux pumps in TRM. We identified a derived, charge-changing amino acid mutation in MepA and an increase in *mep*A gene expression which would be related to the development of TIG resistance in these mutants. The decrease in *nor*B expression observed might alter the extrusion of other compounds.

Resistance Mechanism and Clinical Characteristic of Linezolid-Resistant *Staphylococcus capitis* Isolated from Blood Cultures

Author Block:

Y. Yang, D. Lin, **X. Xu**; Inst. of Antibiotics, Huashan Hosp., Fudan Univ., Shanghai, China

Abstract Body:

Background: Linezolid resistant *Staphylococcus* spp. have caused nosocomial infection in several countries, including China. Recent years, Linezolid resistant *Staphylococcus capitis* have continued to emerge in a teaching hospital, Shanghai, China. This study was carried out to understand the resistance mechanism and clinical characteristic of linezolid-resistant *S. capitis* isolates. **Methods:** Five linezolid resistant *S. capitis* strains were isolated from blood samples in 2012. Antimicrobial susceptibility tests were carried out to determine the antimicrobial resistance in clinical strain. By PCR and sequencing, the *cfr* genes and 23S rRNA mutations related to linezolid resistance were detected. Analysis of Pulsed-field gel electrophoresis (PFGE) and clinical data were performed to understand the characteristics of the clinical isolates. **Results:** Five strains were not only resistant to linezolid, but also resistant to most common antimicrobial agents, except vancomycin, rifampin, tigecycline and SMZco. The G2576T mutation in the domain V region of 23S rRNA was identified in all 5 strains. Four of them carried *cfr* gene. All 5 isolates were belong to one PFGE type (Table 1). The deep vein indwelling catheters were applied in 3 patients, and 2 of them had treated with linezolid. **Conclusions:** Linezolid-resistant *S. capitis* isolates have multiple-drug resistant phenotype. The linezolid resistance of *S. capitis* is mediated by *cfr* gene and 23S rRNA mutations. The application of deep vein indwelling catheter and linezolid could increase the risk of linezolid resistant *S. capitis* infection.

Table 1. Characteristics of five clinical isolates of *S. capitis*

Strains	*cfr* gene	23S rRNA mutation	PFGE type	MICs (mg/L)

Clarithromycin Resistance in *Helicobacter pylori* Strains from Antrum and Body from Symptomatic Colombian Adults

Author Block:

B. V. Arévalo Jaimes[1], B. Mendoza[2], C. Jaramillo[1], J. F. Vera-Chamoro[2], D. F. Rojas[1], L. F. Jiménez-Soto[3], P. Rodriguez[2], R. Haas[3], J. Álvarez[2], M. P. Delgado[1]; [1]Univ. de los Andes, Bogotá, Colombia, [2]The Univ. Hosp. Fundación Santa Fe de Bogotá, Bogotá, Colombia, [3]Max von Pettenkofer-Inst. für Hygiene und Medizinische Mikrobiologie, München, Germany

Abstract Body:

Background: *Helicobacter pylori* is a bacterium associated with gastric pathologies. Unfortunately, the effectiveness of first line of treatment decreases drastically with the raise of *H. pylori* strains resistant to clarithromycin due to point mutations within the 23S rDNA gene . Infections by *H. pylori* strains with dissimilar antimicrobial susceptibilities in diverse parts of the stomach could affect the therapy success making necessary biopsies from different stomach locations to assess clarithromycin resistance. The present study aimed to know the prevalence of *H. pylori* clarithromycin-resistant in samples from two stomach sites. **Methods:** Therefore, 42 cultures from the bank of strains of Molecular Diagnostics and Bioinformatics Laboratory, Universidad de los Andes, were isolated from biopsies taken by gastroenterologists in the Fundación Santa Fe de Bogotá, Colombia from body and antrum of 21 adult symptomatic Colombian patients. DNA was extracted and used in conventional PCR according to Álvarez et al. (2009) and followed by electrophoresis. PCR products were purified, sequenced, and compared with the *H. pylori* susceptible strain (GenBank U27270). **Results:** Twenty-seven samples had a susceptible genotype (64.3%), in the remaining fifteen (35.7%), ten strains (66.7%) showed the A2143G and five (33.3%) the A2142G mutation. In total, seven patients (33.3%) had a single resistant infection (same mutation in body and antrum strains) of which five patients had the A2143G and two the A2142G mutation; one with mixed infection where a resistant strain (A2142G mutation) was isolated from antrum and a susceptible strain from body (4.8%) and, thirteen with susceptible infection (61.9%). **Conclusions:** The resistance prevalence obtained suggest the quadruple therapy as a better eradication regimen for *H. pylori* in Bogotá according to the IV Maastricht Florence Consensus Conference (2010). Due to the heteroresistance presence, prevalence studies should be completed with at least two biopsies from different stomach locations for a more reliable result.

Track the Cefoperazone-Sulbactam Resistance Development by Whole-Genome Comparison of Two *A. baumannii* Isolates from a Single Patient

Author Block:

X. Liu[1], W. Zhang[2], M. Zhao[1], L. Sun[1], Y. Li[3], J. Shi[3], P-y. Qian[2], J. Zhang[1]; [1]Huashan Hosp. affiliated to Fudan Univ., Shanghai, China, [2]The Hong Kong Univ. of Sci. and Technology, Hong Kong, China, [3]Roche R&D Ctr. (China) Ltd., Shanghai, China

Abstract Body:

Background: The whole genomes of two *A. baumannii* isolates were sequenced to reveal the cefoperazone-sulbactam resistance development. The two isolates were isolated from sputum of a hospital-acquired pneumonia patient who received therapy of cefoperazone-sulbactam (3g with a 45 min infusion, q8h) for 20 days and the therapy was failed. AB1845 and AB2092 were isolated before and after the therapy, and the MIC of cefoperazone-sulbactam was 16 and 128 μg/mL, respectively.**Methods:** The Molecular typing of both isolates was conducted by PFGE of *Apa*I-digested genomic and antibiotic resistance was tested by MIC following CLSI. The Genomic DNA was extracted and sequenced by Illumina Hi-seq 2000 platform. Assembly was also performed by SPAdes Genome Assembler 3.6.1. Genome annotation was searching against Kyoto Encyclopedia of Genes and Genomes (KEGG) databases. Phylogenetic analysis was performed by Mega6.06.**Results:** The PFGE patterns showed the isolates were from the same clone. MIC tests revealed both isolates were resistant to meropenem, imipenem, cefepime, amikacin, ciprofloxacin etc, and susceptible to colistin. Automated gene prediction detected 3872 and 3857 Open Reading Frames (ORFs) for AB1845 and AB2092, respectively. The G+C content was 38.9% for both strains. Comparative genomics revealed 99% similarity between the two isolates, whereas certain genes, such as a phage related protein was only present in AB1845. *A. baumannii Ab04-mff* was phylogenetically close to both isolates, which is a clinical isolate collected in Edmonton, Canada. This strain will be used as a reference to compare the resistance and virulence profiles.**Conclusions:** The whole genome shows differences between the two isolates. Further analysis will focus on comparing the resistant genes and SNPs with these two isolates to elucidate the resistant development mechanism which could lead to the treatment failure.

Identification of a Novel Plasmid-Borne Multidrug-Resistance Gene, *cfr(C)*, in *Campylobacter coli*

Author Block:

Y. Tang, L. Dai, O. Sahin, Q. Zhang; Iowa State Univ., Ames, IA

Abstract Body:

The *cfr* gene, encoding an rRNA methyltransferase, confers resistance to five chemically unrelated antimicrobial classes including phenicols, lincosamides, oxazolidinones, pleuromutilins, and streptograminA (known as the $PhLOPS_A$ phenotype). Although *cfr* has been identified in both Gram-positive and Gram-negative organisms, it has not been reported in *Campylobacter*, a major foodborne pathogen. In this study, we report the identification of a novel *cfr* variant in a multidrug resistant *C. coli* isolate from cattle feces. This *C. coli* isolate was highly resistant to florfenicol (MIC= 32 ug/ml), but PCR amplification did not detect any known genes mediating resistance to phenicols. Whole genome sequence analysis revealed a gene encoding a protein that share 55.1% and 54.9% amino acid homologies to Cfr and Cfr(B), respectively. This *cfr*-like gene is named *cfr(C*) in this study and was located on a conjugative plasmid of ~48kb. Cloning of *cfr(C*) into a susceptible *C. jejuni* isolate and transfer of the *cfr(C*)-containing plasmid by conjugation confirmed its role in antimicrobial resistance. The results indicates the *cfr(C*) conferred resistance to multiple antibiotics including phenicols, lincosamides, pleuromutilins, and oxazolidinones, and resulted in 8- to 256-fold increase in their MICs in both *C. jejuni* and *C. coli*. This finding identifies a new *cfr* variant and represents the first report of *cfr*-like gene in *Campylobacter*. The localization of *cfr(C)* on a conjugative and multi-resistant plasmid will facilitate its dissemination, warranting enhanced efforts to monitor its spread in *Campylobacter* and other foodborne pathogens.

Management of Vancomycin (VAN) Mic Creep in Adult MRSA Infections

Author Block:

N. Banniettis[1], S. E. Beekmann[2], P. Polgreen[2], S. Kaushik[1], S. Kohlhoff[1], D. N. Gilbert[3], J. E. Bennett[4], M. R. Hammerschlag[1]; [1]SUNY Downstate Med. Ctr., Brooklyn, NY, [2]Univ. of Iowa, Iowa City, IA, [3]Providence Portland Med. Ctr., Portland, OR, [4]NIAID, Bethesda, MD

Abstract Body:

Background: MRSA is a significant cause of both health-care associated and community-associated infections. VAN has been the mainstay of parenteral therapy for MRSA infections. However, its efficacy has come into question, with concerns over its poor tissue penetration, slow bactericidal activity, and possible "MIC creep" among susceptible strains. We sought to assess national trends in management of adult infections due to MRSA and reports of both MRSA VAN MIC creep and clinical failures with VAN use. **Methods:** Electronic 12 question survey of adult ID physician members of the IDSA Emerging Infections Network was conducted from 11/18/2015 to 12/18/2015.**Results:** 652 (53%) physicians responded, of which 617 treat *S. aureus* infections. Of these, 95% reported their clinical micro lab used a breakpoint of ≤ 2 g/mL as indicative of MRSA susceptibility to VAN; 91% reported routine inclusion of the MIC in the susceptibility report. VAN MICs were determined via E-test by 18%, broth microdilution 3%, Vitek 38%, Microscan 25%, BD Phoenix 6%; 14% were unsure of method used. 21% reported vancomycin treatment failure with MRSA bacteremia despite adequate troughs and source-control at least once over the last year; 50% reported ≥2 times. 37% of these reported initial MIC <2 g/mL and 22% MIC=2 in their most recent treatment failure. VAN was the empiric treatment of choice for persons who inject drugs and right-side IE in 89% (509/572) followed by daptomycin, 5% (29/572); 53% would switch from VAN to alternate therapy if MIC=2 g/mL; 6% would continue treatment with VAN at same dose despite 4 d of persistent bacteremia.**Conclusions:** 59% of respondents reported initial VAN MICs ≤ 2 g/mL with persistent MRSA bacteremia, while VISA and VRSA were rarely encountered (MIC>2 g/mL, 2%), reflecting poor response to therapy at the higher end of the CSLI susceptibility-range. This may partially be due to resistance-undercall of certain testing methods. Nonetheless, VAN's poor therapeutic efficacy at MIC ≤ 2 g/mL across a wide geographic distribution renders "MIC creep" more probable than clonal spread or testing artifact. Elevated MRSA VAN MICs have been associated with elevated daptomycin MICs, rendering the latter potentially problematic as alternate therapy.

***Enterobacter cloacae* Producing Ges-6 in a University Hospital in Northern Spain**

Author Block:

J. Calvo, M. E. Cano, I. Angulo, L. Martínez-Martínez; Hosp. Marqués de Valdecilla, Santander, Spain

Abstract Body:

Background: Detection of carbapenemase-producing bacteria (especially when resistance level is low) is critical. In our center, there is an ongoing outbreak of ESBL-producing *E. cloacae* complex (Eclo), with a clonal group producing CTX-M-15 coexisting with a polyclonal distribution of CTX-M-9, and other ESBL. The aim of this study was to detect the presence of carbapenemase in a collection of Eclo isolates recovered during Jan.2005-Sep.2011.**Methods:** A total of 118 (one per patient) ESBL(+)-Eclo isolates were evaluated: 72 isolates of the main group produce CTX-M-15 (n=67), CTX-M-9 (1), CTX-M-15+CTX-M-9 (1), or undefined ESBL (3); 46 isolates from other 28 clonal groups carry: CTX-M-9 (n=28), SHV-12 (11), CTX-M-3 (4), CTX-M-15 (1), SHV-12+CTX-M-9 (1) or TEM-12 (1).MICs of ertapenem (ETP), imipenem (IMP), meropenem (MPM), and other beta-lactams were determined by standardized broth microdilution. PCR multiplex to detect genes encoding IMP, VIM, NDM, SPM, AIM, DIM, GIM, SIM, KPC, BIC, OXA-48 and GES was carried out. The performance of AST-243 Vitek-2 cards [with ETP (0.5-8 mg/l) and IPM (0.25-16 mg/l)] for detection of carbapenemase-producing organisms was evaluated, considering EUCAST screening criteria (ETP or MPM >=0.12, IPM >=1).**Results:** GES-6 was detected in 28 isolates of the main clonal group. MICs of ETP and MPM above EUCAST screening criteria were observed in 28 and 4 Eclo producing GES-6, respectively. MICs (mg/l) of cefotaxime and cefepime for 3 isolates with GES-6 and lacking CTX-M-15 ranged 2-4 and 0.5-2, respectively, while these values for 44 isolates from the same clonal group with only CTX-M-15 were 64->128 and 4->16. The main clonal group was present since 2007, and isolates with GES-6 appeared in June 2010. With AST-243 cards, only 8 out of the 28 (28,6%) GES-6 (+) isolates showed ETP or IPM MICs above EUCAST screening criteria.**Conclusions:** Strains producing GES-6 were detected within the main clonal group producing CTX-M-15 using a PCR approach. Vitek2 cards should be designed in order to improve their reliability for low-level carbapenem resistance detection.

		main clonal group producing GES-6 (n=28)	main clonal group not producing GES-6 (n=44)	others clones not producing GES-6 (n=46)

Genotypic Diversity and Pathogenic Potential of *Campylobacter jejuni* Strains Isolated from Animal, Human and Food in Brazil

Author Block:

M. R. Frazao[1], S. S. Duque[2], M. I. C. Medeiros[3], J. P. Falcão[1]; [1]Sch. of Pharmaceutical Sci. of Ribeirão Preto - Univ. of São Paulo, Ribeirao Preto, Brazil, [2]Oswaldo Cruz Inst. (Fiocruz-RJ), Rio de Janeiro, Brazil, [3]Adolfo Lutz Inst. of Ribeirão Preto (IAL-RP), Ribeirao Preto, Brazil

Abstract Body:

Background: *Campylobacter jejuni* is an important causative agent of human diarrheal diseases worldwide. Specifically, in Brazil *C. jejuni* has been underdiagnosed and understudied. Therefore, studies that molecularly characterize strains of this species isolated in the country are of great importance. The aims of this study were to genotype and investigate the presence of some virulence-associated genes of *C. jejuni* strains isolated in Brazil. **Methods:** A total of 90 *C. jejuni* strains isolated from humans (36), animals (28) and food (26) between 1996 and 2012 in Brazil were genotyped by PFGE and *flaA*-SVR sequencing. Additionally, the presence of 16 virulence-associated genes was searched by PCR. **Results:** The dendrogram of genetic similarity of PFGE grouped the strains in three clusters with more than 43.7% of similarity. Cluster PFGE-A comprised 18 strains isolated from animals, humans and food. Cluster PFGE-B comprised 35 strains isolated from animals, humans and food. Cluster PFGE-C comprised 36 strains isolated from animals, humans and food. In the three PFGE clusters, 76 (84.4%) strains of clinical and non-clinical sources were grouped in subclusters with a similarity of ≥ 80%. The dendrogram of genetic similarity of *flaA*-SVR sequencing grouped the strains in two clusters with more than 81.5% of similarity. Cluster SVR-A comprised 8 strains isolated from animals and humans. Cluster SVR-B comprised 82 strains isolated from animals, humans and food. All the 90 strains studied presented the genes *flaA*, *flhA*, *cadF*, *docA*, *cdtA*, *cdtB*, *cdtC*, *iamA*, *ciaB*, *racR*, *crsA*, *pldA*, *dnaJ* and *sodB*. The gene *wlaN* was found in 9 (10.0%) strains and the gene *virB11* was found in only one (1.11%) strain. **Conclusions:** The results obtained by PFGE and *flaA*-SVR sequencing showed a high genomic similarity among some *C. jejuni* strains which may suggest that a possible contamination may have occurred among clinical and non-clinical sources during 16 years in Brazil. Furthermore, the high frequency of the majority of the virulence-associated genes searched highlighted the pathogenic potential of those strains.

Publishing Title:

Comparison of Ribotyping and MLST for Genotyping *Bordetella bronchiseptica*

Author Block:

K. B. Register, T. L. Nicholson, B. W. Brunelle; USDA/ARS/Natl. Animal Disease Ctr., Ames, IA

Abstract Body:

Bordetella bronchiseptica is a widespread bacterial pathogen that infects a variety of domesticated and wild animals. Multilocus sequence typing (MLST) and *PvuII* ribotyping have proven useful to distinguish among strains of *B. bronchiseptica*. Both are highly discriminatory and have been used to infer relationships among isolates and identify likely sources of exposure. It is unclear which of these methods is most discriminatory since they have not been directly compared using a single set of isolates and relatively few isolates have been typed by both methods. The purpose of this study was to compare the discriminatory power of these methods using a single set of geographically and genetically diverse strains. A total of 122 isolates was analyzed, including representatives of the 22 *PvuII* ribotypes so far recognized and 25 of the 61 MLST sequence types currently associated with *B. bronchiseptica* isolates in the *Bordetella* PubMLST database. Isolates were sourced from the United States, Europe, Israel and Australia and include 24 from humans, 20 from seals, 17 from pigs, 13 from turkeys, 12 from rabbits, 10 from dogs, 8 from guinea pigs, 7 from horses, 6 from cats, 3 from koalas, 1 from a leopard and 1 of unknown origin. A total of 32 ribotype patterns was identified based on various combinations of 35 restriction fragments ranging in size from ~1.8 Kb to 5.9 Kb. DNA from one isolate could not be digested completely with *PvuII* such that a ribotype could not be assigned. In comparison, all isolates were typeable by MLST and a total of 30 sequence types was identified. The discrimination indices for ribotyping and MLST are nearly identical, 0.920 and 0.919, respectively. Nonetheless, for 10 ribotypes and 10 MLST sequence types, the alternative method discriminates among isolates that otherwise type identically. These data indicate *Pvu*II ribotyping and MLST are complementary but equally discriminatory methods. Because MLST offers practical advantages over ribotyping, including ease of standardization, scalability, portability and the ability to type all isolates, it is the preferred primary typing tool for *B. bronchiseptica*. *PvuII* ribotyping provides a secondary method that may be applied to further discriminate isolates not distinguishable by MLST.

Molecular Epidemiological Analysis of *Burkholderia* Isolates from Cystic Fibrosis Patients Attended at Two Reference Centers in Brazil

Author Block:

C. P. C. Capizzani[1], N. C. Caçador[1], L. A. G. M. Torres[2], C. E. Levy[3], P. Vandamme[4], A. C. Darini[1]; [1]Sch. of Pharmaceutical Sci. of Ribeirão Preto - Univ. of São Paulo, Ribeirão Preto - SP, Brazil, [2]Clinic Hosp. of the Ribeirão Preto Med. Sch. - Univ. of Sao Paulo, Ribeirão Preto - SP, Brazil, [3]Sch. of Med. Sci. - State Univ. of Campinas, Campinas - SP, Brazil, [4]Lab. of Microbiol. - Ghent Univ., Ghent, Belgium

Abstract Body:

Many species of *Burkholderia cepacia* complex (Bcc) from cystic fibrosis (CF) patients are highly resistant to antibiotics and transmissible. MLST has been recently used as a powerful tool for species identification and genetic typing in this group of bacteria. The aim of this study was to perform molecular epidemiological analysis of Bcc species of CF patients from two Centers in Brazil by PFGE and MLST and analyze the antibiotics sensitivity. About 66 Bcc isolates were obtained from 48 CF patients. Species were identified by *recA* gene sequencing analysis. Isolates were typed by (i) MLST according to Bcc MLST Databases and (ii) *Spe*I-PFGE, and the results were analyzed by BioNumerics. Antibiotics sensitivity was performed according to CLSI. *B. vietnamiensis* was the most prevalent specie in both centers, which is very unusual since normally the most common species in CF patients are *B. multivorans* and *B. cenocepacia.* PFGE analysis showed a slightly higher molecular diversity (6%) among the isolates than MLST. In total, 17 different STs were typed by MLST. No new species of Bcc was identified; however, 14 novel STs were obtained and 3 STs (ST911, ST17 and ST369) have presented intercontinental distribution. *B. cenocepacia* seems to be more commonly spread among CF patients and associated with outbreaks. Nevertheless, *B. vietnamiensis* reached the largest number of patients with the same ST (27 patients). In most cases, the first and last isolates from each patient belonged to the same sequence type. It could explain the strong ability of Bcc strains to persist in CF patients lungs. Different results in relation to antibiotics sensitivity were obtained between the centers, which were also showed by other studies. It demonstrates the importance in perform susceptibility test looking for the best therapeutic option and to avoid treatment failure.This study contributed to update the Bcc MLST database providing more data for global epidemiological investigations, besides correlating these results with bacteria resistance.

***Aacinetobacter baumannii* and the Conflict in Iraq: New Insights from Whole Genome Sequencing**

Author Block:

E. C. Snesrud, P. Mc Gann, **A. C. Ong**, R. Maybank, L. Appalla, F. Onmus-Leone, R. Clifford, M. K. Hinkle, E. Lesho; Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

Background: Acinetobacter baumannii emerged as a significant source of infection during the conflict in Iraq. Over the course of the war, carbapenem resistant A. baumannii (CRAB) increased exponentially, primarily via the introduction of Class D carbapenemases. Chronicling the emergence CRAB using conventional typing methods, such as PFGE and MLST, is difficult due to resolution limitations, but whole genome sequencing (WGS) offers the prospect of changing this paradigm. **Methods:** In this study, WGS was employed to sequence every de-duplicated A. baumannii clinical isolate archived at the Walter Reed Army Medical Center (WRAMC) from 2003-2011 (n= 1,024). WGS was performed using a combination of short-read and long-read sequencing on the NextSeq 500 and PacBio RSII, respectively. A comprehensive analysis was subsequently performed to unravel the epidemiology of these isolates.**Results:** 970 (94.7%) of isolates were identified as A. baumannii, with Acinetobacter non-baumannii accounted for the remaining 54 isolates. In silico multi-locus sequence typing (MLST) revealed 73 ST's, including nine novel ST's. Despite the large number of ST's, >85% of isolates were assigned to just 6 ST's: ST-1, 2, 20, 25, 81 and 94. Single Nucleotide polymorphism (SNP)-based analysis revealed that ST-1 was composed of 4 different clonal clusters that were temporally separated. In contrast, isolates of ST-2, 20, 25, 81, and 94 were all caused by a single clone that persisted and spread throughout the healthcare facility over 1 to 6 years. 387 (38.5%) isolates carried blaOXA, with blaOXA-23 identified in 312 (80.6%). WGS indicated that OXA-negative strains were gradually replaced by new strains carrying Class D carbapenemases.**Conclusions:** Despite being responsible for hundreds of infections during the course of the conflict, WGS revealed that the majority of infections by CRAB were caused by just 9 different strains. Overall, the majority of CRAB represented the emergence of new strains that supplanted previously carbapenem-sensitive populations.

Characterisation Of Multi Resistant *pseudomonas Aeruginosa* From Clinical Isolates From Animals

Author Block:

J. Hordijk, E. M. Broens, V. Scheele, J. A. Wagenaar, B. Duim; Utrecht Univ., Utrecht, Netherlands

Abstract Body:

Background: *Pseudomonas aeruginosa* can cause opportunistic infections in both humans and animals. It is intrinsically resistant to multiple classes of antibiotics. Resistant *P. aeruginosa* is often isolated from clinical animal samples. Little is known about both phenotypic and genotypic characteristics of veterinary isolates. The purpose of this study was to determine susceptibility profiles and genetic diversity of *P. aeruginosa* isolates from animals. **Methods:** 113 presumptive *P. aeruginosa* isolates, obtained from clinical samples from the Veterinary Microbiological Diagnostics Center (VMDC), were included. These were isolated from dogs (99), cats (6), horses (6) and rabbits (2) between January and September 2015. Species determination was confirmed by MALDI-TOF, susceptibility testing was performed by broth microdilution. A ChromID agar was used for detection of carbapenemase activity. Presence of common beta-lactamase genes was screened by PCR. Multi Locus Sequence Typing was performed to determine the sequence types (ST).**Results:** In total, 109 isolates were confirmed to be *P. aeruginosa* by MALDI-TOF. The remaining four isolates were excluded for further analysis. Based on Minimal Inhibitory Concentration data, all isolates were resistant to more than three antimicrobial classes and therefore multi resistant. 33 unique resistance profiles and five recurring profiles were identified. The recurring profiles consisted of 5, 7, 10, 14 and 16 isolates respectively. 58.7% of the isolates were phenotypically positive for carbapenemase activity, but all tested negative for the most common beta-lactamase genes by PCR. In total 36 known sequence types (ST) and 41 novel STs were identified by MLST. Comparison with the PubMLST isolate database, showed that several previously described high risk clones in human, were also identified (ST244, ST274 and ST277) among the veterinary isolates. Interestingly, 6 isolates from cats were screened, of which 4 belonged to ST1320 and all 4 showed the same resistance pattern, whereas the strains were epidemiologically unrelated.**Conclusions:** 1: The diversity in STs of animal isolates of *P. aeruginosa* correlated with the diversity observed among STs of human isolates.2: No common beta-lactamase genes were identified.

Molecular Epidemiology of Betalactamase Resistance in *Neisseria gonorrhoeae* Isolates in France

Author Block:

H. Jacquier[1], M. Micaelo[1], A. Goubard[2], G. La Ruche[3], E. Denamur[4], O. Tenaillon[4], E. Cambau[1], B. Bercot[1]; [1]Hôpital Lariboisière, IAME, Univ Paris Diderot, PARIS, France, [2]Inst. Fournier, PARIS, France, [3]French Inst. for Publ. Heath Surveillance, Depart. Infect. Dis.,, PARIS, France, [4]Univ. Paris Diderot, IAME, UMR 1137, Sorbonne Paris Cité,, PARIS, France

Abstract Body:

Background: In France, the resistance of *Neisseria gonorrhoeae* to penicillin by beta-lactamase production (PPNG) is increasing (18% in 2014). This resistance is related to the presence of the $bla_{\text{TEM-1}}$ gene which is carried by small plasmids pJD4, pJD5 and pJD7. We recently reported the emergence of the betalactamase TEM-135 and new TEM-1 variants. The aim of this new study was to investigate the distribution of these strains by looking at their genetic materials and their clonality.**Methods:** Our collection included 176 isolates collected between 2010 and 2012 in various French regions producing TEM-1 (n=155), TEM-135 (n=14) and TEM variants defined by mutations P14S/P14L (n=8), G228S (n=2) and Q269K (n=1). Plasmids were characterized by PCR or complete sequence. Genotyping of the strains was carried out by the NG-MAST technique.**Results:** The 176 PPNG isolates were divided into 106 Sequence Type. We highlighted four main clusters of PPNG circulating in France: cluster A, related to the ST1479 (10.2%), cluster B, related to the ST1582 (8.5%), ST8922 (5.7%) and ST1285 (5.1%). The pJD5 plasmid was predominant (89.2%) whereas pJD7 and pJD4 were found in respectively 7.4% and 3.4% of the isolates. All the pJD7 and 61% of pJD4 harbored the $bla_{\text{TEM-135}}$ gene, while 94% of pDJ5 harbored $bla_{\text{TEM-1}}$ and 6% the other bla_{TEM} variants.All the PPNG isolates included in the cluster B, ST1285 or ST8922 harbored the pDJ5 plasmid and produced the TEM-1 protein. Conversely, the two plasmids pDJ4 and pDJ5 were highlighted among the isolates comprised in the cluster A. Isolates producing the TEM variants G228S and Q269K were identified in the cluster A, suggesting an emergence *de novo* of these new mutations.**Conclusion:** This work highlights the wide dissemination of $bla_{\text{TEM-1}}$ gene in France in different isolates and different genetic materials and circulation of clonal isolates producing variants of ß lactamase TEM-1.

Genotype Diversity of Cefixime-resistant *Neisseria gonorrhoeae* Isolated in France 2014-2015

Author Block:

P. Gaspar[1], S. Kumanski[2], A. Goubard[3], N. Ndeikoundam[4], H. Jacquier[2], F. Meunier[2], E. Cambau[2], **B. Bercot**[2]; [1]Brazilian Ministry of Hlth., Brasilia, Brazil, [2]GH St Louis-Lariboisière–FW, APHP, Assoc. Lab. for the Natl. Reference Ctr. for gonococci,, PARIS, France, [3]Inst. Fournier, PARIS, France, [4]IFrench Inst. for Publ. Heath Surveillance, Depart. Infect. Dis, Saint-Maurice, France

Abstract Body:

Background: Sexually transmitted infections due to *Neisseria gonorrhoeae* (NG) are a recurrent public health problem, with worldwide increasing incidence. The recent emergence of NG isolates resistant to cephalosporin critically complicates the treatment guidelines and requires resistance surveillance. This study investigates NG isolates with decrease ssusceptibility or resistance to cefixime.**Methods:** Twenty-six NG isolated in France during 2014-2015 showing decrease susceptibility (Etest MIC= 0.125 µg/ml, EUCAST breakpoint) or resistance (MIC>0.125 µg/ml) to cefixime were submitted to molecular epidemiology typing by the reference method NG-MAST. Sequence types were assigned *via* the on line NG-MAST data base. A maximum-likelihood phylogenetic tree was constructed with PHYML program using concatenated *porB* and *tbpB* alleles.**Results:** Among the 26 strains, there were 13 with MIC of 0.125, 11 with MIC of 0.19 and 2 with MIC of 0.25 µg/ml. All isolates were susceptible to ceftriaxone. The NG isolates distributed into 14 different Sequence Type (ST) with 3 major clusters: ST6778 (n=6; 23%), one related to ST11018 (n=6; 23%), and the Genogroup G1407 (n=5; 19%). Among the resistant isolates, there were 5 ST11018, 3 G1407, 2 ST 6778 and 3 others. The phylogenetic study showed that ST11018 and ST6778 have probably a common ancestor although they are not closely related. Among the 6 isolates of ST 6778, 4 were diagnosed in the Paris area in 2015 and may be epidemiologically related.**Conclusions:** Although the well-known Genogroup 1407 is still observed among the strains with decreased susceptibility or resistance to cefixime resistance, we described two new STs, which were prevalent among the resistant strains and which require surveillance.

St-11 Clonal Complex Causing Invasive Meningococcal Infection in the Basque Country, Northern Spain, in the Last 28 Years

Author Block:

J. M. Marimón[1], C. Mojica[2], D. Vicente[1], M. Alkorta[2], G. Cilla[1], E. Perez-Trallero[3]; [1]CIBERES & H.U.Donostia-IIS Biodonostia, San Sebastián-Donostia, Spain, [2]H.U.Donostia-IIS Biodonostia, San Sebastián-Donostia, Spain, [3]EHU/UPV, CIBERES & H.U.Donostia-IIS Biodonostia, San Sebastián-Donostia, Spain

Abstract Body:

Background: Meningococcal disease is related to some serogroups but also to some genotypes, as the hypervirulent ST-11 clone, responsible of epidemic outbreaks in the past decades. The main objective of this work was to analyze the epidemiology of ST-11 clonal complex (cc11) in our area in the last 3 decades. **Methods:** From June 1987 to June 2015, 887 non-duplicated invasive meningococcal isolates from the Basque Country, Northern Spain, were analyzed. Capsular serogroup were identified by latex agglutination (Murex Biotech Ltd., Dartford, England) and/or by PCR of the *siaD* and *orfA* genes. The genosubtype was determined after amplification and sequencing of variable regions (VR1/VR2) of the *PorA* gene. Genotyping was performed by MLST and PFGE after *Spe*I restriction. Antibiotic susceptibility was determined by the E-test. Meningococcal C conjugated vaccine was introduced in our region for infants in 2000 and for adolescents in 2005. **Results:** Of 887 invasive episodes, 165 (18.6%) were caused by cc11 isolates: 63 (38.2%) serogroup B and 102 (61.8%) serogroup C. MLST: 155 (93.4%) isolates were ST11 (99 serogroup C, 56 serogroup B), being the others ST3419 (n=3), ST6648 (n=2), ST67 (n=2), ST761, ST4091 and ST4706. PFGE: Two main cc11 clones: SPE-1 was prevalent between 1987-1994 representing 94.4% (34/36) of cc11 isolates obtained before 1995. SPE-2 clone was mainly isolated during 2000-2010: 121 among total 124 cc11 isolates. Genosubtype: the most frequent porA type (VR1/VR2) within SPE-1 and SPE 2 isolates were: 5/2-1 and 5-1/10-8, respectively. The *fHbp* B1 gene was present in all 17 SPE-2 isolates studied but in none 19 SPE-1. However, 12/19 SPE-1 isolates studied had the *NadA* variant 2/3. All isolates were susceptible to cefotaxime but 58 (35.2%) were penicillin non-susceptible. The mortality rate related to ST-11 clonal complex was 13.6%. **Conclusions:** Most ST-11 clonal complex strains belonged to the hypervirulent ST11 ET-37 complex, 62.5% of them being serogroup C. The 4CMenB vaccine would have covered most cc11 isolates.

Molecular Epidemiological Analysis of *Bordetella pertussis* Isolates from Nuevo LeóN, MéXico

Author Block:

J. Gutiérrez Ferman[1], J. Ramírez-Aranda[1], A. Camacho Ortíz[1], R. Ballesteros-Elizondo[2], M. Moreno-Juárez[3], E. Garza-González[1]; [1]Univ. Autónoma de Nuevo León, San Nicolás, Mexico, [2]Secretaría de salud of Nuevo Leon, Guadalupe, Mexico, [3]Secretaría de salud of Nuevo Leon, San Nicolás, Mexico

Abstract Body:

Background: *Bordetella pertussis* is the major agent of whooping cough, a highly contagious disease of the respiratory tract. Despite the vaccination, the disease remains as a public health problem in México. The aim of this study was to determine the genetic diversity and temporal distribution of *B. pertussis* isolates in Nuevo León, México.**Methods:** Isolates were recovered from patients with clinical presentation of pertussis, from 2006 to 2014. The isolates were identified by phenotypic and genotypic tests. A total of 119 *B. pertussis* isolates (α=0.005, CI=10) were selected to determine the clonal diversity by Pulsed-Field Gel Eelectrophoresis (PFGE). Epidemiological and demographic data were collected included.**Results:** Of the 356 isolates collected, 98% were identified as *B. pertussis*, 1.7% as *Bordetella parapertussis* and 0.3% as *Bordetella bronchiseptica*. A total of 25 different genotypes with profiles comprising 11 to 16 restriction fragments and a similarity of 75 to 100% were obtained by PFGE. Three predominant clones were detected, clone A (52.9%), A1 (6.7%) and A2 (5%). The years with the highest number of *B. pertussis* isolates were 2009, 2012 and 2014 with 72, 74 and 64 isolates collected, respectively. The age group most affected was the younger than 2 months with 156 cases reported. From the infant population the 85.9% who should have received at least one dose of acellular vaccine, did not have any doses.**Conclusion:** The results suggest that the clone A is an endemic strain of Nuevo Leon and persisted for seven consecutive years, from 2008 to 2014. Further analysis is necessary to determinate if the persistence and spread of the endemic clone are a result a particularly virulent strain rather than the immune status of the study population.

Risk Factors for Mortality in Patients with Extended-spectrum Beta-Lactamase-Producing Enterobacteriaceae Bloodstream Infections: A Multi-Centre, Cohort Study

Author Block:

N. F. Dewhurst[1], S. M. Poutanen[2], B. Hamandi[3], L. W. Goneau[4], L. Dresser[3], M. Pitre[3], A. Y. C. Lin[5], M. D. Mistry[6], L. Graham[3], D. O. Lowe[3]; [1]St. Michael's Hosp., Toronto, ON, Canada, [2]Mount Sinai Hosp., Toronto, Ontario, Canada, Toronto, ON, Canada, [3]Univ. Hlth.Network, Toronto, ON, Canada, [4]Univ. of Toronto, Toronto, ON, Canada, [5]London Hlth.Sci. Ctr., London, ON, Canada, [6]Kingston Gen. Hosp., Kingston, ON, Canada

Abstract Body:

Background: While controversy exists whether extended-spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae increase mortality among hospitalized patients with bloodstream infections (BSIs), limited data exist regarding predictors of mortality. We examined predictors of mortality and 7- and 30-day mortality rates among patients with ESBL-producing Enterobacteriaceae BSIs.**Methods:** Retrospective cohort study of 4 tertiary care hospitals in Toronto, Canada from Nov. 2005 to Nov. 2012. All adult inpatients with ESBL-producing Enterobacteriaceae BSIs during the study period were included (n=220). The primary outcome measures were 7- and 30-day mortality rates. Cox regression analyses were conducted to determine associations between survival and potential risk factors.**Results:** Mortality rate at 30-days among patients with ESBL-producing Enterobacteriaceae BSIs was 50/209 (23.9%). Univariate analysis revealed that 30-day mortality rates for adequately and inadequately treated patients were 37/184 (20.1%) and 13/25 (52.0%), respectively; for patients with non-nosocomial and nosocomial-associated ESBL BSIs were 20/112 (17.9%) and 30/97 (30.9%), respectively; and for patients with Charlson co-morbidity indexes of 0-4 (reference), 5-6 and ≥ 7 were 33/162 (20.4%), 9/28 (32.1%), and 8/19 (42.1%), respectively. A Cox proportional hazards model revealed that inadequate therapy [hazard ratio (HR)=4.0; p<0.001], nosocomial-associated infections (HR=2.6; p=0.002) and a Charlson co-morbidity index ≥7 (HR=3.1; p=0.007) demonstrated a significant mortality risk at 30-days.**Conclusions:** Among patients with ESBL-producing Enterobacteriaceae BSIs, inadequate therapy, nosocomial-associated infection and Charlson co-morbidity index ≥7 are associated with an increased risk of death. These clinical factors should be taken into consideration when assessing mortality risk in patients with ESBL-producing Enterobacteriaceae BSIs.

Extended-spectrum Beta-Lactamase-Producing *Enterobacteriaceae* are Not Associated with Decreased Survival in Patients with Bloodstream Infections

Author Block:

N. F. Dewhurst[1], S. M. Poutanen[2], B. Hamandi[3], L. W. Goneau[4], L. Dresser[3], M. Pitre[3], A. Y. C. Lin[5], M. D. Mistry[6], E. Chung[7], L. Graham[3], D. O. Lowe[3]; [1]St. Michael's Hosp., Toronto, ON, Canada, [2]Mount Sinai Hosp., Toronto, Ontario, Canada, Toronto, ON, Canada, [3]Univ. Hlth.Network, Toronto, ON, Canada, [4]Univ. of Toronto, Toronto, ON, Canada, [5]London Hlth.Sci. Ctr., London, ON, Canada, [6]Kingston Gen. Hosp., Toronto, ON, Canada, [7]The Hosp. for Sick Children, Toronto, ON, Canada

Abstract Body:

Background: Factors impacting mortality among patients with Enterobacteriaceae bloodstream infections (BSIs) are not well defined. Controversy exists whether extended-spectrum beta-lactamase (ESBL)-producing Enterobacteriaceae are independently associated with increased mortality compared to non-ESBL-producing Enterobacteriaceae among patients with BSIs. We examined 7- and 30-day mortality rates along with mortality risk in patients with ESBL compared to non-ESBL-producing Enterobacteriaceae BSIs.**Methods:** Retrospective matched cohort study of 4 tertiary care hospitals in Toronto, Canada from Nov. 2005 to Nov. 2012. All adult inpatients with ESBL-producing Enterobacteriaceae BSIs during the study period (n=162) were matched (1:1) to those with non-ESBL-producing Enterobacteriaceae BSIs (n=162). Seven and 30-day mortality rates were determined. Mortality risk was assessed using time to death, censored at 30 days, for the Cox regression analysis.**Results:** Seven-day mortality rates for the ESBL and non-ESBL groups were 21/161 (13.0%) and 19/160 (11.9%), respectively [odds ratio (OR), 1.1, 95% confidence interval (CI)= 0.6-2.2, p=0.73]; 30-day mortality rates were 35/152 (23.0%) and 32/153 (20.9%), respectively (OR=1.3, 95% CI: 0.7-2.3, p=0.38). Using Cox regression analysis, controlling for inadequate therapy, nosocomial-association and Charlson comorbidity index, 30-day mortality was not statistically different between patients with ESBL or non-ESBL-producing Enterobacteriaceae BSIs (HR=1.1; p=0.61).**Conclusions:** Patients with ESBL-producing Enterobacteriaceae BSIs do not have an independent increased mortality risk compared to those with non-ESBL-producing Enterobacteriaceae BSIs. When assessing mortality risk in patients with Enterobacteriaceae BSIs, emphasis should be placed on clinical factors such as adequate therapy, nosocomial-association and comorbidities.

***Acinetobacter* Infections and Outcomes in Critically Ill Patients at an Academic Medical Center**

Author Block:

N. Law, C. Emery, K. Raible, S. Joshi, T. Bias; Hahnemann Hosp., Philadelphia, PA

Abstract Body:

Background: *Acinetobacter baumanni* has emerged as a major cause of healthcare-associated infections, posing an important challenge to clinicians as conventional therapy often fails. This study aims to describe the epidemiological characteristics, microbial resistance patterns and clinical outcomes associated with acquisition of *Acinetobacter* infections in critically ill patients. **Methods**: A retrospective, observational study was conducted to evaluate adult patients (age ≥ 18 years) admitted to the intensive care unit who had a documented *Acinetobacter* infection between June 2013 and October 2015. Demographics and disease specific information were collected. The following clinical outcomes were assessed: 30-day mortality, infection-related mortality, microbiological cure, length of stay, and intensive care unit (ICU) length of stay.**Results:** Fifty-three patients met criteria for inclusion with a total of 111 clinical isolates of *Acinetobacter* identified. Patients with *Acinetobacter* infections were frequently admitted from healthcare facilities (38%), required mechanical ventilation (83%), had 2 or more invasive devices (66%) and antibiotic exposure within 30 days of acquisition (49%). The most common source of infection was lung (66%), followed by blood (21%), skin (9%) and urine (4%). Carbapenem resistance was identified in 62% of isolates, with colistin being most susceptible (100%) and subsequently tobramycin (65%). Despite primary source control, the overall infection related mortality and all cause 30 day mortality rates were 36% and 38% respectively. Patients who received inappropriate therapy based on Vitek 2 susceptibilities had higher rates of infection related mortality (42% vs. 25%, p=0.2). Overall, hospital length of stay (33 days [interquartile range (IQR), 13-59]) and ICU related length of stay (19 days [8-39]) was prolonged in our cohort. **Conclusions:** *Acinetobacter* infections have a high attributable mortality and remain a serious public health concern. New strategies aimed at promptly recognizing infections, selecting effective antimicrobial treatment options, preventing transmission through infection control measures and implementing stewardship initiatives for high risk patients.

Multidrug-Resistant Clones of *Acinetobacter baumannii* from a Tertiary Care Hospital in MéXico Are Highly Biofilm Producers, Resistant to Human Serum and Potent Inflammatory Immune Response Inducers

Author Block:

R. Rosales-Reyes[1], D. Calderón-Campos[1], C. Rivera-Benítez[2], J. I. Santos-Preciado[1], D. Alcántar-Curiel[1]; [1]UNAM, Mexico, Mexico, [2]Hosp. Gen. de México, Mexico, Mexico

Abstract Body:

Background: During the period from January to December of 2014, we identified 113 isolates of *A. baumannii* causing nosocomial infections in the Hospital General de Mexico. The great majority (97%) was resistant to carbapenem associated with the production of metallo-beta-lactamases (89%) and 84.6% carried the $bla_{\text{OXA-type}}$ gene. The aim of this study was to determine the ability of these 113 clinical isolates to form biofilm over abiotic surfaces, resistance to human serum and their ability to induce an inflammatory immune response. **Methods:** The biofilm production was assessed over polystyrene surfaces. The resistance to serum was assessed on *in vitro* assays using normal human serum (NHS). The TNFa released into supernatants from infected macrophages with *A. baumannii* were quantified by ELISA. Cell death was determined by quantification of the Lactate Dehydrogenase (LDH) activity.**Results:** Virtually all (98.41%) of clinical isolates of *A. baumannii* were biofilm producers. The 82.5% of were resistant to 40% of normal human serum (NHS) and only 12.5 % of all the clinical isolates were highly susceptible to NHS (>98% of susceptibility). All isolates tested were high inducers of TNFα release by infected macrophages with a variable cell death induction.**Conclusions:** The high prevalence of *A. baumannii* in the Hospital General de México could be due to their high ability to form biofilm over abiotic surfaces. Based on these results, we propose that the ability of these *A baumannii* isolates to form biofilm coupled to their high resistance to human serum (82.5%) and their ability to induce TNFa may explain in part their pathogenicity and their persistence in the hospital environment.

Evaluation of *in vitro* Combination Effects of Trimethoprim-Sulfamethoxazole Combined with Levofloxacin, Ticarcillin/Clavulanate, or Minocycline Against *Stenotrophomonas maltophilia*

Author Block:

H. Araoka, M. Baba, C. Okada, M. Abe, M. Kimura, A. Yoneyama; Toranomon Hosp., Tokyo, Japan

Abstract Body:

Background: *Stenotrophomonas maltophilia* is an important cause of hospital-acquired infection including bacteremia and pneumonia, particularly in severely immunocompromised patients. The aim of this study was to evaluate the *in vitro* combination effects of trimethoprim-sulfamethoxazole (TMP-SMX) with other antimicrobial agents against *S. maltophilia* strains.**Methods:** Eighty-nine *S. maltophilia* strains isolated from blood (29) and the respiratory tract (60) between June 2012 and October 2014 were investigated. Levofloxacin (LVFX), ticarcillin/clavulanate (T/C), and minocycline (MINO) were selected to examine their effects, when combined with TMP-SMX, by the checkerboard method. Synergy is defined in checkerboard tests when the fractional inhibitory concentration (FIC) index is ≤0.5. Antagonism is defined by an FIC of >4.0.**Results:** The results of TMP-SMX + LVFX showed synergy in 21, no interaction in 61, and antagonism in 7. The results of TMP-SMX + T/C showed synergy in 71, no interaction in 18, and antagonism in 0. The results of TMP-SMX + MINO showed synergy in 10, no interaction in 79, and antagonism in 0. There were no significant differences between the combination effects of strains from blood and those from the respiratory tract.**Conclusions:** These *in vitro* data suggest that TMP-SMX + T/C was microbiologically beneficial and not antagonistic. Antagonism was observed only with the TMP-SMX + LVFX combination.

Relationship between Daptomycin (DAP) Minimum Inhibitory Concentration (MIC) and Patient Outcomes in Vancomycin-Resistant Enterococci (VRE) Bacteremia

Author Block:

J. T. Babic[1], K. W. Garey[2], H. R. Russo[1]; [1]CHI St. Luke's Hlth.Baylor St. Luke's Med. Ctr., Houston, TX, [2]Univ. of Houston, Houston, TX

Abstract Body:

Background: Patients with increased DAP MICs may have poorer outcomes compared to those with lower MICs. To optimize therapy, a dosing policy of daptomycin ≥ 8 mg/kg was implemented for non-urinary VRE infections. The purpose of this study was to assess the effectiveness of this policy on outcomes of patients stratified by low versus high DAP MICs.**Methods:** A retrospective cohort study was performed on hospitalized patients with VRE bacteremia (2010-2014). Adult patients who received at least 72 hours of DAP were included. Area under the curve (AUC)/MIC ratios were calculated for each patient based on mean population pharmacokinetics (AAC, 2004). Clinical and microbiological outcomes were compared based on MIC (≤ 2 and >2 mcg/mL) and AUC/MIC ratios.**Results:** Sixty-nine patients (59% male, 38% Caucasian) aged 61 ± 15 years were identified. Average DAP dose was 8.9 mg/kg ± 1.31 (range 4.6 – 13.2) with 81% of patients receiving ≥ 8 mg/kg. Forty-three of 69 (62%) patients had DAP MICs > 2 mcg/mL. No difference was found in clinical cure rate between groups with low MIC [18/26 (69%)] vs high MIC [27/43 (63%); p=0.612]. Microbiological cure occurred more frequently in patients with low MICs [26/26 (100%) vs high MICs [37/43 (86%);p=0.046]. Average AUC/MIC was 491 ± 365 (range 143-1736). No significant difference in clinical or microbiological outcomes was seen in patients with low versus high AUC/MIC ratios.**Conclusions:** In this retrospective study, there was no significant difference in clinical cure rates of VRE bacteremia between patients with low and high DAP MICs, however patients with low DAP MICs had a higher rate of microbiological cure. Our institution’s dosing strategy appears to be effective clinically in treating VRE bacteremia with DAP MICs up to 4 mcg/mL, but higher doses or alternative antibiotics may be needed for microbiologic cure.

Five-Year Decreased Incidence of Surgical Site Infections Following Gastrectomy and Prosthetic Joint Replacement Surgery Through Active Surveillance by Konis

Author Block:

H. Choi[1], L. Adiyani[2], J. Sung[2], J. Choi[3], H. Kim[4], S. Han[5]; [1]Ewha Womans Univ. Sch. of Med., Seoul, Korea, Republic of, [2]Seoul Natl. Univ., Seoul, Korea, Republic of, [3]Yonsei Univ. Coll. of Med., Seoul, Korea, Republic of, [4]Seoul Natl. Univ. Coll. of Med., Seoul, Korea, Republic of, [5]Soonchunhyang Univ. Bucheon Hosp., Seoul, Korea, Republic of

Abstract Body:

Background: Surveillance of health care-associated infection has been associated with a reduction in surgical site infection (SSI). The Korean Nosocomial Infection Surveillance system (KONIS) was evaluated to assess its effects on SSI since it was introduced. **Methods:** SSI data after gastrectomy, total hip arthroplasty (THA), and total knee arthroplasty (TKA) between 2008 and 2012 were analysed in an evaluation of the KONIS. The pooled incidence of SSI was calculated for each year; the same analyses were also conducted from hospitals that had participated in KONIS for at least three consecutive years. Standardized SSI rates for each year were calculated by adjusting for SSI risk factors. SSI trends were analysed using the Cochran-Armitage test. **Results:** The SSI rate following gastrectomy was 3.12% (522/16,918). There was a significant trend of decreased crude SSI rates over five years. This trend was also evident in analysis of hospitals that had participated for more than three years. The SSI rate of THA was 2.05% (157/7,656) and it significantly decreased from 2008 to 2012. The risk factors for SSI after THA included the National Nosocomial Infections Surveillance risk index, trauma, re-operation, and age (60-69 years). The SSI rate of TKA was 1.67% (165/9,862), and it also decreased significantly over five years. However, the risk-adjusted analysis of SSI did not significantly show a decrease in all surgeries. **Conclusions:** The SSI incidence of gastrectomy and prosthetic joint replacement declined over five years as a result of active surveillance by the KONIS.

Clinical and Economic Impact of Delaying Catheter Removal before Preliminary Microbiological Reports in Catheter-Related Bloodstream Infections

Author Block:

K-H. Park, M. Jung, S-y. Moon, J. Son, M. Lee; Kyung Hee Univ. Sch. of Med., Seoul, Korea, Republic of

Abstract Body:

Background: Central venous catheter (CVC) removal is recommended in most patients with catheter-related bloodstream infection (CRBSI). However, it remains unclear whether delaying of CVC removal before preliminary microbiological reports influence length of hospital stay and hospital charge, compared with early CVC removal. The objective of this study was to quantify the impact of delayed catheter removal on outcomes in these patients.**Methods:** This study was performed at two tertiary care hospitals, Seoul, Republic of Korea. Patients with early CVC removal were defined as those who had the CVC removed within 2 days after onset of CRBSI. Outcomes were evaluated using the following measures: in-hospital mortality, length of hospital stay after onset of CRBSI, and hospital charge after onset of CRBSI**Results:** During the study period, 187 episodes of CRBSI were identified. Of the 187 episodes of CRBSI, 118 (63.1%) were early removal group and 69 (36.9%) were delayed removal group. Delayed removal group was more likely to be associated with absence of fever, long-term catheter, and community-onset infection. After multivariate analysis, compared with early catheter removal, delayed catheter removal was independently associated with increased length of hospital stay (hazard ratio 1.79, 95% CI, 1.23-2.61; $P = 0.03$) and hospital charges (1.74 odds ratio, 95% CI, 1.25-2.41; $P = 0.001$). There was a trend towards an increased in-hospital mortality among delayed catheter removal group, this was not statistically significant (2.02 odds ratio, 95% CI, 0.91-4.45; $P = 0.08$).**Conclusions:** Our data suggest that an initial delay of 1-2 days in CVC removal before the preliminary microbiological reports was not associated with in-hospital mortality, but it was associated with significant increases in the length of hospital stay and hospital charges.

An Under-Diagnosed Cause Of Morbidity And Mortality In Hospitalized Patients: Healthcare-Acquired Viral Infections

Author Block:

A. K. Skrzynski, V. Russo, B. Boyanton, M. D. Sims, J. D. Band; Beaumont Hlth.- Royal Oak, Royal Oak, MI

Abstract Body:

Background: Healthcare-associated infections are a major issue in healthcare today and lead to significant morbidity and mortality. Though respiratory viral infections are among the most common infections in the general population, very little research has been conducted on the epidemiology and clinical implications of healthcare-acquired respiratory viral infections (HA-RVIs).**Methods:** We conducted a retrospective analysis of all patients with a positive respiratory virus panel (RVP) PCR from September 2011 through May 2015, aged ≥ 18 years and admitted to the hospital >5 days with symptoms of respiratory illness (utilizing the CDC concept of "influenza-like illness" as our case definition). Medical records of patients meeting criteria were reviewed for relevant clinical data and mortality.**Results:** A total of 4065 positive RVPs were noted during our study period with 44 patients (1.1%) developing a viral-associated respiratory illness after >5 days of hospitalization including *influenza* (13), *parainfluenza* (10), *rhinovirus* (9), *respiratory syncytial virus* (6), *human metapneumovirus* (4) and *coronovirus* (3) (one patient was co-infected with both *coronavirus and respiratory syncytial virus*). The average age of infected patients was 73.8 years. Cases peaked during two seasons with *parainfluenza* predominating in spring and *influenza* predominating in winter. Our cohort had significant respiratory symptoms: cough, sputum production and hypoxic respiratory failure being the most common and significant. The mortality rate for our cohort was 42%.**Conclusions:** Though under-appreciated, HA-RVIs appear to target the sickest patients in the hospital and lead to significant morbidity and mortality. Careful attention to infection control measures is paramount. Encouraging awareness among healthcare workers of the dangers transmissible respiratory viral illnesses pose for their patients and enforcement of policies to prevent acutely ill healthcare workers from caring for patients should be implemented. Likewise, ill family members should be restricted from visiting during their illness. Immunization of healthcare personnel against *influenza* should be made mandatory.

Patterns of Antimicrobial Resistance among Nosocomial Infections in Peru from 2011-2015

Author Block:

M. P. Simons[1], M. Lopez[1], E. Canal[1], M. Bernal[1], B. Pizango[1], R. Abadie[1], W. Prudencio[2], V. Changano[2], J. Celis[3], E. Zamora[3], C. Coral[4], H. Rodriguez[4], E. Linares[5], M. Calisto[5], J. Guevara[6], N. Reynolds[1], D. Tilley[7], C. Rocha[1]; [1]Naval Med. Res. Unit No. 6 Peru, Washington, DC, [2]Hosp. de la Fuerza Aerea del Peru, Lima, Peru, [3]Hosp. Regional de Loreto, Punchana, Peru, [4]Hosp. Apoyo Iquitos, Iquitos, Peru, [5]Hosp. Edgardo Rebagliati Martins, Lima, Peru, [6]Hosp. Daniel Alcides Carrion, Callao, Peru, [7]Naval Med. Ctr., San Diego, San Diego, CA

Abstract Body:

Enhanced surveillance is critical to control the spread of antimicrobial-resistant (AMR) strains, especially in underreported regions. From 2011 to 2015, we established an AMR surveillance network with 3 hospitals in Lima and 2 hospitals in Iquitos, Peru we collected 1,690 isolates from 2,665 patients and paired environmental samples classified as nosocomial infections. These isolates were retested in our laboratory for identification and susceptibility versus 37 antibiotics by disk diffusion. Epidemiological data was paired with the laboratory results on all isolates (220 variables in total). Of the 1,143 isolates collected from Lima, the most common isolates were coagulase-negative *Staphylococcus* (CONS) (26.7%), *Pseudomonas aeruginosa* (15.8%), *Klebsiella pneumoniae* (13.7%), *S. aureus* (10.4%), *E. coli* (8.7%), *Acinetobacter baumanii/calcoaceticus* complex (8.3%), and *Stenotrophomonas maltophila* (3.9%). From the 547 isolates collected in Iquitos, the most prevalent were *E.coli* (21.8%), *P.aeruginosa* (14.8%), *K.pneumoniae* (13.5%), CONS (13.4%), *Acinetobacter* spp. (12.1%), *S. aureus* (7.9%), and *Klebsiella* spp. (4.8%). Of the *S. aureus* isolates, 124/162 (76.5%) were resistant to oxacillin. Among Gram-negatives, 555/733 (75.7%) resistant to ceftriaxone and 277/1036 (26.7%) resistant to imipenem. Imipenem resistance (IMP-R) was most commonly found among *A. baumanii* (72/92, 78.3%) and *P. aeruginosa* (125/258, 48.5%). Among the IMP-R isolates, 200/277 (72.2%) were resistant to ciprofloxacin, 182/277 (65.7%) were resistant to aztreonam, and 166/277 (59.9%) resistant to amikacin, indicating high rates of MDR. Infection with an IMP-R isolate was associated with an increased hospital stay of 7.6 days (p=0.0746). Collectively, these data provide insight into causes of HAI and antibiotic resistance trends in an under-reported region of the world.

***Legionella indianapolisensis sp.* Nov., Isolated from a Patient with Pulmonary Disease**

Author Block:

R. F. Relich[1], B. H. Schmitt[1], H. Raposo[2], L. Barker[2], S. J. Blosser[3], M. May[2]; [1]IU Hlth.Pathology Lab., Indianapolis, IN, [2]Univ. of New England, Biddeford, ME, [3]Indiana State Dept. of Hlth.Lab., Indianapolis, IN

Abstract Body:

Background: To date, at least 50 species of *Legionella* have been described. These organisms are ubiquitous in nature and have been isolated from diverse ecological environments, including man-made structures such as cooling towers and spas. Legionellae have also been isolated from human and veterinary clinical specimens, and their roles in disease are well-established. In this report, we describe the isolation of a novel *Legionella* species from a respiratory specimen from a patient with influenza and suspected pulmonary embolus.**Case:** A 68-year-old male presented to an Indianapolis-area hospital with pulmonary disease and, upon workup, was found to have influenza. However, the bronchoalveolar lavage fluid was also submitted for conventional bacterial culture and *Legionella* culture. The patient was prescribed broad-spectrum and recovered.**Results:** A *Legionella*-like microorganism was isolated on buffered charcoal yeast extract agar, and it was determined not to be *Legionella pneumophila* by immunofluorescence. Subsequently, the isolate was referred to the IU Health Pathology Laboratory and the state health department for identification. Mass spectrometry and comparative 16S rRNA gene sequencing inconclusively identified the isolate as *Legionella* sp. Further analysis of the 16S rRNA gene and multilocus sequence typing confirmed the strain to be a new species, related to *Legionella jamestownensis.* Physiochemical and morphologic testing were used to confirm the discovery of a novel species, *Legionella indianapolisensis* sp. nov.; type strain KT361191.

Publishing Title:

Predictors Of Multidrug Resistant (Mdr) *Pseudomonas Aeruginosa* Nosocomial Pneumonia (Pa-Np) In The Intensive Care Unit (Icu)

Author Block:

T. D. Trinh, E. J. Zasowski, K. C. Claeys, A. Lagnf, S. L. Davis, M. J. Rybak; Wayne State Univ., Detroit, MI

Abstract Body:

Background: PA-NP in the ICU has high morbidity/mortality. MDR PA makes appropriate empiric antibiotic selection difficult, warranting clinical decision tools to better predict MDR PA-NP in this population. Risks associated with MDR PA-NP in critically ill patients require further exploration. We sought to determine independent predictors of MDR PA-NP in ICU patients. **Methods:** Retrospective cohort study at two centers from 2013 - 2015. Inclusion: age ≥18 years, PA-NP culture obtained in ICU. Exclusions: PA colonization, cystic fibrosis, death ≤24 hours of empiric antibiotic administration for NP. Primary objective: to determine risk factors for MDR PA-NP in ICU patients. MDR PA isolates defined as non-susceptible to ≥3 antipseudomonal classes. Clinical characteristics of patients with and without MDR PA-NP were compared using χ^2/Fisher's exact test and Student's t-test/Mann-Whitney U test. Variables associated with MDR PA-NP at a p-value <0.20 were entered into a multivariable logistic regression model to determine predictors of MDR PA-NP.**Results:** Included 178 PA-NP episodes; 22.5% MDR. Mean (SD) age 64.3 (15.2) years; 65.2% male; 60.7% African-American; median (IQR) sequential organ failure assessment score 9 (7,12); 61.2% medical ICU; 24.7% surgical/trauma ICU; 54.5% clinically-defined NP; 30.3% ventilator-associated pneumonia (VAP); 51 (28.7%) experienced 30-day mortality. In bivariate analysis, diabetes mellitus (DM), solid organ transplant, prior hospitalization ≤60 days of PA-NP episode, admission from nursing home/skilled nursing facility (SNF), and VAP were candidates for entry into the multivariable model. The final model results are shown below.

Variable	MDR (N=40) n (%)	Non-MDR (N=138) n (%)	OR (95% CI)	aOR (95% CI)
DM	27 (67.5)	66 (47.8)	2.27 (1.08 - 4.75)	2.28 (1.05 - 4.96)
Prior hospitalization ≤60 days of PA-NP episode	17 (42.5)	33 (23.9)	2.35 (1.12 - 4.92)	2.25 (1.01 - 5.04)

Admission from SNF	13 (32.5)	17 (12.3)	3.43 (1.49 - 7.89)	2.80 (1.15 - 6.81)

Conclusions: History of DM, prior hospitalization ≤60 days of PA-NP episode, and admission from SNF were independently associated with MDR PA-NP. Patients transferred to the ICU with clinical signs of NP should be assessed for MDR PA risk via history of DM, recent hospitalizations, and nursing home residency.

Impact of Clinical Underestimated in Phenotypic ESBLs by Co-Harboring ESBL and pAmpC

Author Block:

F. Nishimura, Y. Morinaga, N. Kaku, K. Takeda, N. Uno, K. Kosai, H. Hasegawa, K. Yanagihara; Nagasaki Univ., Nagasaki, Japan

Abstract Body:

Background: ESBL and plasmid-mediated AmpC (pAmpC) have been known as plasmid-mediated cephalosporinases, but the AmpCs are not routinely identified. When isolates have both ESBLs and AmpCs, there is some possibility of misidentifying ESBLs for AmpCs in the clinical laboratory. In this study, we studied the prevalence of pAmpCs and the impact of pAmpCs on laboratory detection of ESBLs in potential ESBL-producers with cefepime (FEP) sensitive. **Methods:** Clinical isolates of *Escherichia coli*, *Klebsiella* spp., and *Proteus* spp. were analyzed. We defined the potential ESBL-producers with FEP sensitive as the isolate with MIC for ceftazidime ≥2μg/mL and FEP ≤8μg/mL. The phenotypic ESBLs were detected by automated microbiology system (AMS), and the isolates were analyzed for ESBL genotyping and pAmpC types by in-house PCR. **Results:** Potential ESBL-producers with FEP sensitive were observed in 528 of all 8299 isolates. Of the 528 isolates, the prevalence of pAmpCs, ph-ESBLs and genotypic ESBLs (g-ESBLs) were 27.5%, 43.6% and 57.6%, respectively. Of the ph-ESBL, 19 were in pAmpC group, and 211 were in non-pAmpC group (Table). The isolates, which were not detected ESBL by AMS but detected ESBL genes by in-house PCR (non-ph-ESBL/g-ESBL), were more frequently observed in pAmpC isolates, compared with non-pAmpC isolates (42.8% vs. 16.7%, p< 0.01) (Table).**Conclusions:** Since non-ph-ESBL/g-ESBL was observed frequently observed in pAmpC in comparison with non-pAmpC, the co-harbouring ESBL and pAmpC might mask the ESBL-phenotype in the laboratory testing.

Characteristic of ESBL between pAmpC and non-pAmpC group

ESBL phenotype/genotype	pAmpC group, n, (%)	non-pAmpC group, n, (%)	P values
ph-ESBL/g-ESBL	12 (8.3)	166 (43.3)	< 0.01
non-ph-ESBL/g-ESBL	62 (42.8)	64 (16.7)	< 0.01
ph-ESBL/non-g-ESBL	7 (4.8)	45 (11.7)	< 0.01
non-ph-ESBL/non-g-ESBL	64 (44.1)	108 (28.1)	< 0.01
Total	145 (100.0)	383 (100.0)

Rapid and Efficient Approach to Urine Culture Screening Using CHROMagar Orientation/ESBL Medium

Author Block:

A. Nakayama[1], A. Niwa[1], H. Ohta[1], N. Furuta[1], H. Ito[2], N. Murakami[1], K. Ohkusu[3], M. Seishima[2]; [1]Gifu Univ. Hosp., Gifu, Japan, [2]Gifu Univ. Graduate Sch. of Med., Gifu, Japan, [3]Tokyo Med. Univ., Tokyo, Japan

Abstract Body:

Background: CHROMagar Orientation(CHO)/ESBL (Kanto Chemical, Japan) is a bi-plate consisting of CHO medium and CHROMagar ESBL for the differentiation and presumptive identification of clinically important gram-negative bacteria and detection of ESBL-producers. We report a rapid and efficient approach to urine cultures using CHO/ESBL medium. **Methods:** A total of 1995 urine culture results generated during the months of February, April, July and October of 2012 (1073 reports) and 2015 (922 reports), were selected at random for comparison of time to result between conventional urine culture and improved method. In the conventional method, 10 μl of urine was streaked on a sheep blood agar plate. A sample of the urine was also prepared for gram-staining. In the improved method, in addition to plating, the urine sample was centrifuged at 1,500 g for 10 min after which the supernatant was discarded and the pellet was smeared onto a glass slide for gram staining. If gram-negative organisms were observed, a CHO/ESBL plate was added.**Results:** The mean time to reporting was 4.1 days for the conventional method compared to 3.9 days with the improved method. When ESBL-producing organisms were present in the urine specimen, the mean time to reporting was 4.6 days compared to 3.5 days with the improved method. With respect to negative urine cultures, the mean time to reporting was 3.2 days compared to 2.4 days with the improved method.**Conclusions:** The use of CHO/ESBL bi-plates allow differentiation of bacteria the day after plating and providing information on the presence or absence of ESBL-producing organisms. As this medium allows confirmatory testing of resistant organisms to be setup at the same time as antimicrobial susceptibility testing, CHO/ESBL allows reporting of resistant organisms 1 day earlier compared to conventional methodology. Furthermore, the staining of centrifuged urine sediments has reduced false negative microscopies, allowing release of final negative culture reports on the next day as well as workup of cultures with a cutoff of 10^3cfu/ml for specimens showing >5 WBC/hpf. The improved efficiency contributes to rapid reporting of clinically useful information.

Development of Simplified Assay for Detection of *van*-Gene Harbored Enterococci Using Automated BD MAX Platform

Author Block:

Y. Yamagishi, D. Sakanashi, H. Suematsu, H. Mikamo; Aichi Med. Univ., Aichi, Japan

Abstract Body:

Backgound: Molecular technologies have largely replaced culture in the clinical laboratory. The BD Max system (BD Diagnostics, Sparks, MD) is an automated molecular platform that combines specimen extraction and real-time PCR with a number of FDA-cleared assays. In addition, their generic extraction and PCR reagents for the "open platform" allow users to design their own assays using their own primers and probes. Since nosocomial spread of vancomycin-resistant enterococci (VRE) is serious problem in each hospital, rapid detection of VRE would be very important. **Methods:** We developed and evaluated of multiplex real-time PCR assay for detection of vancomycin-resistant genes (*vanA, vanB, vanC1* and *vanC2/C3*) using the new, fully automated BD MAX platform.**Results:** Cycle threshold value analyses of real-time PCR simultaneous repeatability test have showed the usefulness; coefficient of variation: CV (%) were determined 2.09%, 1.72%, 1.41% and 1.52% with *vanA*, *vanB, vanC1* and *vanC2/C3*, respectively. We also evaluated with 43 strains of enterococci were characterized by conventional PCR method; 4/4 for *vanA*-positive, 14/14 for *vanB*-positive, 1/1 for *vanB* plus *vanC1*-positive, 6/6 for *vanC1*-positive, 4/4 for *vanC2/C3*-positive and 14/14 for all-van gene-negative strains were identified correctly. This assay was automatically performing before and after PCR operations previously done manually by operator, such as DNA extraction, sample dispensing and gel electrophoresis or the ethidium bromide dyeing. As a result, work burden and the risk of the contamination were largely reduced and were shortened to about half for measurement time.**Conclusions:** We conclude that our newly developed assay might be able to greatly contribute to efficient and rapid detection of vancomycin-resistant genes.

Improved EPI-CRE Test for Rapid Carbapenemase Detection

Author Block:

A. J. Slesar, P. C. Schreckenberger; Loyola Univ. Med. Ctr., Maywood, IL

Abstract Body:

Background: The Modified Hodge Test (MHT) is used to confirm the presence of KPCs but requires 24 h and has limited ability to detect other non-KPC CREs. The Carba-NP test is rapid and has been endorsed by CLSI, but is tedious to make. As an alternative, we evaluated the improved EPI-CRE® test (Pilots Point LLC, Sarasota FL) to detect carbapenemases directly from bacterial colonies. EPI-CRE is a colorimetric test that measures fermentation of a proprietary substrate present in a solution containing meropenem and bromocresol purple. This causes the solution to change from purple to yellow, indicating the presence of a CRE.**Methods**: EPI-CRE was prepared by adding 40 ml dH_2O to the powdered test reagent. The pH was adjusted to 7.5 (±0.1) using 1 M NaOH. 1 ml aliquots of the solution were added to test tubes. The tubes were inoculated with a 1 µl loopful of an overnight bacterial subculture from a blood agar plate. The tubes were incubated at 37°C and monitored for color change from purple to yellow at 1 h intervals. KPC isolates tested included: *K.pneumoniae* (2), *E.coli* (1), *E.cloacae* (1). OXA-48 isolates tested included: *E.coli* (1), *E. cloacae* (1), *K.pneumoniae* (1). MBL isolates tested included: *E.coli* (4), *K.pneumoniae* (1). ESBL isolates tested included: *E.coli* (1), *E.cloacae* (1), *K.oxytoca* (1), *K.pneumoniae* (1). AmpC isolates tested included: *E.aerogenes* (2), *S.marcesens* (2), *E.cloacae* (1). The Xpert CARBA-R RUO cartridge (Cepheid, Sunnyvale, CA), the MHT, and the EDTA Etest (BioMeriéux) were tested on all isolates. ESBL isolates were confirmed using the combination disk diffusion method. AmpC isolates were identified as bacteria belonging to the MYSPACE group of chromosomal AmpC producers.**Results:** The EPI-CRE test detected 12 out of 12 CREs in 6 h or less, including 6 isolates that were negative by the MHT. See Table.**Conclusion**: EPI-CRE is a simple, inexpensive assay that requires no sophisticated equipment or lengthy setup. Due to its ease of use, EPI-CRE has the potential to be an effective tool in screening for CREs at the bench, especially as confirmation for a questionable MHT, or as an alternative to the Carba-NP test, or molecular assays.

	MHT	MBL Etest	EPI-CRE	Xpert CARBA-R (RUO)
KPC	4 / 4	0 / 4	4 / 4	4 / 4
OXA-48	2 / 3	0 / 3	3 / 3	3 / 3
MBL	0 / 5	5 / 5	5 / 5	5 / 5

ESBL	0 / 4	0 / 4	3 / 4	0 / 4
AmpC	0 / 5	0 / 5	0 / 5	0 / 5
Sensitivity	6 / 12 = 50.0%	5 / 12 = 41.7%	12 / 12 = 100%	12 / 12 = 100%
Specificity	9 / 9 = 100%	9 / 9 = 100%	6 / 9 = 66.7%	9 / 9 = 100%

Publishing Title:

A Real Time Multiplex PCR Assay Using Rapid Amplification Technology for the Simultaneous Detection of 6 OXA Carbapenemases

Author Block:

S. Morrow[1], R. Fowler[2], N. D. Hanson[1]; [1]Creighton Univ., Omaha, NE, [2]Univ. of NE Med Ctr, Omaha, NE

Abstract Body:

Background: The emergence of OXA carbapenemases in *Acinetobacter spp* and members of *Enterobacteriaceae* threatens the clinical efficacy of carbapenems. The purpose of this study was to design a real time multiplex PCR assay that detects six important OXA carbapenemases in two real time PCR reactions. **Methods:** Purified DNA was prepared using the DNeasy Blood and Tissue Kit®. Primers and hydrolysis probes were designed for *bla*$_{\text{OXA-48}}$, *bla*$_{\text{OXA-143}}$, *bla*$_{\text{OXA-58}}$, *bla*$_{\text{OXA-23}}$, *bla*$_{\text{OXA-24/40}}$, and *bla*$_{\text{OXA-51}}$. Degenerate primers specific for the 16S-rRNA gene were used as an internal control (IC). Primer set sensitivity was evaluated by singleplex endpoint PCR. PhilisaFAST® DNA polymerase was used to optimize the real time assays, which were validated using the 7500 Fast Real-Time PCR System. Individual positive controls were synthesized for each target. 122 clinical isolates representing 32 negative and 90 positive isolates for the target genes were used to validate the multiplex assay and included *E. coli, Klebsiella spp, Enterobacter spp, Morganella spp, S. marcescens, P. aeruginosa,* and *Acinetobacter spp*. Two master mixes were optimized to identify the six OXA carbapenemases with the IC included in both mixes. PCR reactions for both master mixes consisted of primer and probe concentrations optimized to simultaneously amplify all targets using the same PCR conditions. **Results:** This assay detected multiple OXA targets within characterized clinical isolates. The sensitivity and specificity of this assay was 97% (115/119) and 100% (32/32), respectively. The IC product was detected in all 122 isolates. The total time required for DNA extraction, PCR set-up, amplification, and analysis was ~2.5 hrs. **Conclusions:** This real time OXA-multiplex assay is a rapid molecular diagnostic tool for the detection of important OXA carbapenemase genes. With the increasing prevalence of microorganisms carrying one or more OXA carbapenemases, this assay offers fast and reliable detection of six clinically important OXA carbapenemases. Implementation of such a rapid assay can have a positive impact for infection control and patient care.

Commercial Multiplex PCR Kit for the Detection of Gram Negative β-Lactamase Genes: Adapting Procedures for Improved Workflow

Author Block:

K. M. Riederer, J. T. Fishbain, S. M. Szpunar; St. John Hosp. and Med. Ctr., Detroit, MI

Abstract Body:

Background: Multiplex PCR detection of resistance genes among *Enterobacteriaceae* can provide useful epidemiologic information and confirmation of phenotypic results. Commercial kits are available for use but are validated using specific assay conditions and equipment. We investigated the utility of the ARM-D™ for Beta-Lactamase ID kit (Streck) using a rapid DNA extraction method and standard thermocycler. **Methods:** DNA was extracted in parallel for 50 organisms using the validated QIAGEN® DNeasy® Blood and Tissue kit (Q) and a rapid boil method (R). Briefly, a 10µl loop of organism was suspended in 200µl water, heated at 99ºC for 15 minutes then centrifuged at 16,000 x g for 2 minutes. DNA yield and purity of supernatant (R) and eluate (Q) was assessed by spectrophotometry. DNA template from each method was amplified in parallel with internal kit controls on the Eppendorf Mastercycler® Nexus thermocycler, following kit manufacturer conditions. Gels were stained in EtBr and molecular weight of resulting bands compared. ATCC strains #25922, 700603 and BAA-1705 were included.**Results:** Selected isolates included *E. coli* (11), *Klebsiella* (16), *Enterobacter* (13), *Acinetobacter* (4), *Serratia* (2), *Proteus* (2), *Pseudomonas* (1) and *Citrobacter* (1). DNA yield was significantly higher ($p<0.0001$) with the R method (mean 57.2 µg/ml ± 52.30) compared to Q extraction (mean 13.9 µg/ml ± 8.86). Purity (A_{260}/A_{280} ratio) was also better ($p=0.013$): mean 1.72 ± 0.10 and mean 1.67 ± 0.12 for R and Q extraction, respectively. Extraction time was faster for R (20 minutes) compared to Q (1.5 hours). Positive bands for CTX-M (10), KPC (19) and NDM (1) genes were concordant using both extraction methods; 2 *K. pneumoniae* had CTX-M and KPC genes. Negative samples (22) were also concordant. Presence of non-specific bands was observed in both R (50%) and Q (34%) samples, most often with *Klebsiella* and *Enterobacter*. Non-specific bands did not correlate with DNA yield or purity.**Conclusions:** Rapid DNA extraction is a suitable option for detection of Gram negative resistance genes with the ARM-D™ for Beta-Lactamase ID kit. Optimization of amplification conditions for alternate thermocyclers may reduce or eliminate non-specific bands. The ability to use rapid DNA extraction with existing thermocyclers may facilitate use of this assay and improve workflow.

High-Plex UTI Panel for the Detection of Bacterial Resistance Genes in Infected Urines

Author Block:

K. Schmidt[1], K. Stanley[2], D. M. Livermore[1]; [1]Univ. of East Anglia, Norwich, United Kingdom, [2]AusDiagnostics, Sydney, Australia

Abstract Body:

Introduction: Increasing resistance drives wider empirical use of previously-reserved antibiotics, including in complicated urinary tract infections (UTIs). Rapid resistance profiling, without culture, might better guide early therapy in deteriorating UTI patients and we explored the potential of the AusDiagnostics High-Plex PCR UTI Panel to deliver this.***Methods***: The High-Plex UTI panel was designed to identify 16 resistance genes by multiplexed tandem PCR; amplification is tracked in real time, with the product melting temperature determined to confirm identity. Assays were performed on 74 infected urines and 35 pure cultures. Human cells were removed from urines at 300*g*; bacterial pellets were then resuspended in water and denaturated by heat, with the lysate used as template for the High-Plex PCR. Depending on the resistance, results were compared with sequencing, real-time SybrGreen PCR, or phenotypic susceptibility.***Results*:** Performance was similar regardless of whether urines or cultured bacteria were used; time from specimen to results was *c.* 3.5h. The assay detected extended-spectrum β-lactamase (41 bla$_{CTX\text{-}M\ Gp1}$, 17 bla$_{CTX\text{-}M\ Gp9}$), *ampC* (16 bla$_{CMY}$), penicillinase (55 bla$_{TEM}$, 22 bla$_{SHV}$, 27 bla$_{OXA\text{-}1}$) and carbapenemase(7 bla$_{OXA\text{-}48}$, 5 bla$_{KPC}$, 10 bla$_{NDM}$, 1 bla$_{VIM}$) genes with 100% sensitivity and 96-100% specificity compared with reference molecular methods. *dfrA1/A5/A7/A12* genes were found in 77 of the 82 urines or isolates with phenotypic trimethoprim resistance, with sensitivity 93.9%, and specificity 100%. *aac(6')-1b* was reliably identified and consistently associated with tobramycin resistance (sensitivity 100%, and specificity 93.3%); other tobramycin and gentamicin modifying enzymes were not sought. Fluoroquinolone -susceptible and -resistant *E. coli* (only) were distinguished by the melting temperatures of their *gyrA* products.***Conclusion***: The assay rapidly identified resistance genes from Gram-negative bacteria in infected urines, potentially guiding early therapy. Limitations were (i) a narrow range of aminoglycoside targets;(ii) detection of fluoroquinolone resistance only in *E. coli*, (iii) inability to detect rarer resistance determinants e.g. to trimethoprim.

Publishing Title:

Standard Detection and Reporting of pAmpC Helps Limiting Its Spread in the Hospital Setting

Author Block:

Z. Daoud, E. Najem, E. Ragheb, R. Taoutel, M. Bousaab, I. Dandachi; Univ. of Balamand, Beirut, Lebanon

Abstract Body:

Background: Chromosomal and plasmidic AmpC enzymes (pAmpC) have received relatively little attention in comparison to Extended-spectrum beta lactamases (ESBLs). An increasing prevalence of pAmpCs has been reported recently in different areas of the world. While many infection control activities addressed ESBLs in the hospitals, pAmpCs remain inappropriately detected in most of the clinical labs what contributes to its spread. Our aim is to evaluate the importance of detection and reporting of pAmpC on its prevalence in the hospital setting. **Methods:** Between 31/12/2010 and 31/12/2015, *E.coli* and *K. pneumonia* isolates were screened for AmpC using a combination of reduced susceptibility to 3rd generation cephalosporins and cefoxitin as a screening strategy. As a confirmation test, we used the combination disk consisting of cefoxitin and ceftazidime combined with boronic acid or cloxacillin as inhibitors. ESBL was also detected using the Double Disc Synergy test. Prior to 1/1/2015, no infection control measures were taken concerning pAmpC patients. Between 1/1/2015 and 31/12/2015, isolates that gave positive confirmatory test were reported to the infection control department and isolation of the patient was performed accordingly and percentage of pAmpC was determined yearly for comparison. Statistical analyses were performed using SPSS V 20.0**Results:** While *E.coli* isolates showed an ESBL rate increase from 2011- 2012 from 25% to 29% and then reached 30% and stabilized between 2012 -2015; a progressive increase at the level of AmpC production from 2011 -2014 (5 to 9%) was noted when isolation of the patient was not performed. In 2015, an abrupt decrease from 9 to 4% (p<0.05) was noted in parallel to the implementation of patient isolation. A similar but less significant pattern was observed with *Klebsiella* most probably due to the lower incidence of pAmpC in this genus.**Conclusions:** Our data show that the appropriate detection of pAmpC and its subsequent standard reporting as a Multi-Drug-Resistant organism that can spread in the hospital, decreases the incidence of this type of resistance. Therefore, clinical microbiology labs should adopt a phenotypic technique to detect pAmpC and differentiate it from ESBL and report it to the infection control department for follow up. This will help containing the spread of this enzyme with high potential of transmission.

Publishing Title:

Rapid Identification of *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$ by Multiplex Arms PCR

Author Block:

A. Nakano[1], R. Nakano[1], F. Mizuno[1], S. Endo[2], K. Kasahara[1], H. Yano[1]; [1]Nara Med. Univ., Nara, Japan, [2]Tohoku Univ. Graduate Sch. of Med., Miyagi, Japan

Abstract Body:

Background: Carbapenem-resistant Enterobacteriaceae have been globally reported because of the acquisition of carbapenemase genes. Transferable carbapenem resistance genes, IMP (*bla*$_{IMP-1}$ and *bla*$_{IMP-6}$), are most commonly identified in clinical settings in Japan. They have different substrate specificity; IMP-1 producers were more resistant to imipenem than to meropenem, while IMP-6 (IMP-1 variant differs only a single nucleotide) producers were more resistant to meropenem than to imipenem. In this study, we developed a rapid multiplex amplification refractory mutation system (ARMS) PCR assay to discriminate between *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$ by using allele-specific PCR primers. **Methods:** Multiplex ARMS PCR primers, including two primers sets, were designed based on the nucleotide sequence of *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$. Two primers (forward and reverse) were designed to recognize conserved sequences of *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$, and two other primers were designed to recognize specific nucleotide sequences of *bla*$_{IMP-1}$ (forward) and *bla*$_{IMP-6}$ (reverse), respectively. PCR products of *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$ were confirmed by electrophoretic analysis. The specificity of the assay was evaluated using 40 IMP (10 IMP-1 or 30 IMP-6)-producing clinical isolates of Enterobacteriaceae (*Escherichia coli*, *Klebsiella pneumoniae*, and *Enterobacter cloacae*). **Results:** The multiplex ARMS PCR assay conducted amplification within 60 min. *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$ PCR products had the expected size of *ca*. 400 and 150 bp and *ca*. 400 and 300 bp, respectively. Moreover, PCR amplification for 40 IMP-producing Enterobacteriaceae strains was successful with expected product sizes. Cross-reactivity was not observed for other types of carbapenemase producers (NDM, VIM, KPC, and OXA-48), and false positive or false negative results were not observed. **Conclusions:** The developed multiplex ARMS PCR assay successfully discriminates between *bla*$_{IMP-1}$ and *bla*$_{IMP-6}$. This method could serve as a specific, rapid, and easier alternative for the detection of IMP-1 or IMP-6 producers in clinical settings. Therefore, this method might guide the appropriate choice of antimicrobial therapy and facilitate epidemiological studies.

Volatile Metabolites for Rapid Diagnosis of Carbapenem Resistance in *Klebsiella pneumoniae*

Author Block:

C. A. Rees[1], A. Smolinska[2], M. Nasir[1], P. C. Zucchi[3], E. B. Hirsch[3], J. E. Hill[1]; [1]Dartmouth Coll., Hanover, NH, [2]Maastricht Univ., Maastricht, Netherlands, [3]Northeastern Univ., Boston, MA

Abstract Body:

Background: Infections caused by carbapenem-resistant *Enterobacteriaceae* are a growing global public health threat, resulting in high mortality. More rapid diagnosis could reduce mortality and length of hospitalization by expediting appropriate antimicrobial therapy. Here, we show that the volatile metabolites produced by *Klebsiella pneumoniae* can be used to reliably predict carbapenem resistance. **Methods:** Sixty-two clinical isolates of *K. pneumoniae* (30 carbapenem-resistant [C-R] and 32 carbapenem-susceptible [C-S], 3 replicates per strain) were grown in Mueller-Hinton broth to early stationary phase. C-R isolates were positive for bla_{KPC} by PCR and sequencing and resistant to meropenem (MEM), while C-S isolates were neither. Culture supernatants were collected in air-tight vials, and volatile metabolites were analyzed using GCxGC-TOFMS. The Mann-Whitney U test with Benjamini-Hochberg correction was used to identify volatiles that differed in abundance between the two groups. Random Forest (RF) analysis was used to identify volatiles that most accurately predicted MEM susceptibility (one-third of the data was used as an independent validation set). The receiver operating characteristic (ROC) curve was used to assess accuracy of the classification model.**Results:** 212 volatile metabolites differed significantly ($p < 0.05$) in relative abundance between the C-R and C-S groups. RF identified a set of 25 volatiles predicting the MEM susceptibility with accuracy of 94.4% in our training set and 95.1% in the validation set. ROC analysis showed a sensitivity of 1, a specificity of 0.91, and an area under the curve of 0.96 (95% C.I. of 0.91-1.0) for the detection of C-R isolates in the validation set. Sixty of 64 C-S and 57/60 C-R isolates in the training set, and 29/32 C-S and 30/30 C-R isolates in the validation set classified correctly.**Conclusion:** Amongst the 62 strains analyzed, volatile metabolite suites could distinguish C-R from C-S isolates with approximately 95% accuracy. The identification of predictive volatile biomarkers linked to carbapenem susceptibility could inform the development of a rapid, minimally-invasive breath-based diagnostic for lung infections, and could also serve in the analysis of patient blood and/or urine samples.

Evaluation of Alere^{tm} Pbp2a Assay for Detection of Methicillin-resistance in *Staphylococcus* Isolates

Author Block:

N. KANWAR, A. Nguyen, R. Selvarangan; Children's Mercy Hosp. and Clinics, kansas City, MO

Abstract Body:

Objective: Penicillin binding protein 2a (PBP2a), encoded by mecA gene, is responsible for beta-lactam resistance in *Staphylococcus spp*. The aim of this study was to evaluate the performance of Alere^{TM} PBP2a assay, a rapid immunochromatographic assay, for the detection of PBP2a in *Staphylococcus* isolates. **Methods:** Retrospectively collected 150 *S. aureus* and 377 coagulase-negative staphylococcus (CoNS) isolates as identified by Staphaurex® latex agglutination assay were utilized for this study. CoNS isolates were speciated with Microscan Automated ID system. Isolates were grown on columbia agar with 5% sheep blood (CA), tryptic soy agar with 5% sheep blood (TSA) or Mueller-Hinton agar (MHA). Isolates from different plate types were tested by the Alere^{TM} PBP2a assay and results compared to the cefoxitin disk diffusion test.**Results:** Methicillin-resistance was detected in 63/150 *S. aureus* isolates and 140/377 CoNS isolates by cefoxitin disk diffusion testing. The most common CoNS species detected in the study was *S. epidermidis* (n=238). See table 1 for Alere^{TM} PBP2a assay performance on different media types.**Conclusion:** The Alere^{TM} PBP2a assay had high sensitivity and high specificity for rapid detection of methicillin-resistance in *S. aureus* isolates. For CoNS isolates, the sensitivity and specificity was 95% or above for all plate types. Alere^{TM} PBP2a assay was found to be quick, easy to use, highly sensitive and specific method to detect methicllin-resistance in Staphylococcus isolates.Table 1: Performance characteristics of Alere^{TM} PBP2 assay

Evaluation of a Rapid Immunochromatographic Test for Detection of Distinct Variants of Kpc Carbapenemase Among *Enterobacteriaceae*

Author Block:

A. Ramos[1], A. Gales[1], J. Monteiro[1], S. Suzane[2], A. Machado[1], C. Carvalhaes[1]; [1]Univ.e Federal de São Paulo - UNIFESP, São Paulo, Brazil, [2]Tampa Gen. Hosp., Tampa, FL

Abstract Body:

Background: The prevalence of carbapenemase-producing *Enterobacteriaceae* isolates is raising worldwide. Therefore, rapid and feasible tests for their detection are highly desirable. Media used to bacteria growth is known as a potentially confounder for carbapenemase detection by CARBA-NP and MALDI-TOF, mainly MacConkey agar. KPC is one of the most prevalent carbapenemase described among *Enterobacteriaceae*. To date 23 KPC variants were reported. This study evaluated the performance of a rapid immunochromatographic test for detection of different variants of KPC carbapenemase directly from a single bacterial colony. The influence of distinct growth media was also studied. **Methods:** A total of 26 Gram-negative isolates were studied, including 17 KPC-producing enterobacteria (7 distinct variants of KPC: KPC-2; -3; -4; -6; -7; -8; -11), 4 carbapenemase-producing isolates other than KPC (BKC-1-; NDM-1-; OXA-48-producing *K. pneumoniae* and OXA-23-producing *A. baumannii*) and 4 non-carbapenemase-producing *K. pneumoniae* (ESBL-producing isolates possessing porin losses). The isolates were subcultured onto Müeller-Hinton (MHA), MacConkey (MAC) and ChromID CPS® agar (CPS). Briefly, a bacterial colony was resuspended and homogenized in 10 drops of LY-LA buffer (TRIS, NAN_3, detergent; pH 7.5) from KPC *K*-SeT® kit (CORIS BioConcept). Three drops of this solution were applied into the cassette sample spot and read up to 15 minutes. A positive result was observed when two visible red lines were detected. **Results:** None of the non-KPC-producing isolates recorded positive results by KPC *K*-SeT (100% specificity). However, the isolates harboring the variants KPC-6 and KPC-8 could not be detected (sensitivity 88%). All the positive results were observed within 1-3 minutes. The distinct growth medium did not influence the results, independently of the KPC variant tested. **Conclusions:** The KPC *K*-SeT immunochromatographic kit showed to be a feasible and rapid test for detection of the main variants of KPC. The test was able to detect all tested KPC variants but KPC-6- and KPC-8, without influence of distinct culture media.

Publishing Title:

Rapid Identification of Oxa-48, Oxa-163 Subfamily and Kpc in Carbapenemase-producing *Enterobacteriaceae*

Author Block:

L. Denorme[1], I. Ote[1], F. Pasteran[2], S. Gomez[2], A. Corso[2], **P. Y. M. G. Mertens**[1];
[1]CorisBioconcept, Gembloux, Belgium, [2]INEI-ANLIS "Dr. C. Malbrán", Ciudad Autónoma de Buenos Aires, Argentina

Abstract Body:

Background: CPE are a leading cause of antibiotic resistance worldwide. OXA-48 and KPC are two carbapenemases expressed in CPE and their identification present a serious challenge for laboratories. Noteworthy, some allelic variants of OXA-48, such as OXA-163 which is highly prevalent in Argentina, show weak carbapenemase activity while it hydrolyses broad-spectrum cephalosporins. Definitive confirmation of OXA-48 variants currently relies on molecular assays and gene sequencing. We developed the OXA-163/48 Duo *K*-SeT test, a new lateral flow assay that identifies OXA-48 and OXA-163-like carbapenemases, and we combined this test with the KPC identification in the OXA-163/48 and KPC Trio *K*-SeT test.**Methods:** Immunochromatographic sandwich tests were developed by using monoclonal antibodies in both capture (coating on membrane) and detection (coupling to colloidal gold). Tests are performed on bacterial colonies grown on solid medium after suspension in a specific buffer.**Results:**Two anti-OXA-48 antibodies were selected as specific capture reagents on two lines for the Duo test: (1) a first antibody directed against OXA-48 (but not OXA-163) and (2) another antibody directed against another epitope of OXA-48 and other variants (including OXA-163). A third antibody directed against all OXA-48 variants (including the OXA-163 subfamily) was chosen as a detection reagent. If the sample contains OXA-48, it will remain bound to the first capture antibody (anti-OXA-48). If the sample contains the OXA-163, it will not react with the first antibody and will bind to the second capture antibody (anti-OXA-163+48). This OXA-163/48 Duo *K*-SeT test allowed to accurately and rapidly identify (i) OXA-163 and other related variants (OXA-247 and -438) and (ii) OXA-48 and -181 from a panel of 40 positive clinical strains with 100% sensitivity. All 30 non-OXA-48 strains remained negative. The OXA-163/48 and KPC Trio *K*-SeT test allowed to detect KPC in all tested KPC positive strains. **Conclusions:**We developed the OXA-163/48 Duo and OXA-163/48 and KPC Trio *K*-SeT tests for the rapid identification of carbapenemases from the OXA-48 family, OXA-163 subfamily and KPC. The 100% performance of the tests will be further assessed on a larger panel of clinical bacterial isolates

Publishing Title:

Effectiveness of the Immunochromatographic Method for the Rapid Identification of Oxa-48 Carbapenemase

Author Block:

S. Aksaray[1], E. Sanmak[2], I. Davarci[2], S. Akcay[2], A. Kuskucu[2]; [1]Haydarpasa Numune Hosp., istanbul, Turkey, [2]haydarpasa numune Hosp., istanbul, Turkey

Abstract Body:

Hospital infections due to carbapenemase producing enteric gram negative bacterias cause high morbidity and mortality as a result of multiple drug resistance. This is why it is vital to detect carbapenemase existence correctly and rapidly. While some part of carbapenemase can be detected using phenotyping methods, D group carbapenemase can be detected with molecular methods. In this study, we aimed to determine the efficacy of immunochromatographic method to show OXA-48 carbapenemase existence at Klebsiella pneumoniae strains. We have included 39 *Klebsiella pneumoniae* strains, isolated from several clinical samples from inpatients during one year, that are detected as carbapenem resistant or lower sensitivity using standard disc diffusion method and Vitek-2 system (BioMerieux-France). We have tested OXA-48 by Real-time PCR (Corbett research,Australia) and OXA-48 K SeT (Coris Bio, Belgium) at all strains. OXA-48 was found positive at 27 *Klebsiella pneumoniae* strains with both methods. The sensitivity and specificity of immunochromatographic method was found as 100%. Enteric bacteria infections that cause carbapenemase, present a serious problem in our country as worldwide. However, OXA-48 has been reported from Turkey for the first time in world. Molecular methods are time consuming and expensive and this causes difficulties in diagnosis. According to our preliminary results; altough the number of strains in our study is low (we are planning to continue our study with more samples); we have come to a conclusion that the OXA-48 K SeT will be a vary good alternative at rapid diagnosis, giving results in a very short time, having high sensitivity and specificity along with its easy procedure.

A Molecular Multidrug Resistance Gene Panel as an Innovative and Accurate Alternative to Antibiotic Susceptibility Testing

Author Block:

P. Dawson, M. Stonebraker, D. Stalons, L. Malone, E. Grigorenko; Diatherix Lab., LLC, Huntsville, AL

Abstract Body:

Background: Antibiotic susceptibility testing (AST) is one of the most important tests in a clinical microbiology laboratory. Accurate and rapid detection of antibiotic resistance patterns is crucial for all aspects of antimicrobial stewardship, including resistance surveillance and effective patient treatment. Existing traditional culture-based ASTs are time-consuming and often lack specificity for new generations of antimicrobials. In this study, we compare the performance of a rapid molecular multidrug resistance gene (MDRG) panel to gold-standard Kirby-Bauer AST methodology. **Methods:** Twenty-six isolates were obtained from IHMA, Inc., with all information about them withheld. Isolates were cultured on a non-selective medium, followed by nucleic acid extraction and testing on custom OpenArray® qPCR plates with seventeen MDRG targets. Simultaneously, an antibiotic resistance profile (ARP) was determined using the Kirby-Bauer method of AST. Corresponding resistance phenotypes of detected genes were assigned from published literature and compared with the Kirby-Bauer method's ARPs.**Results:** The MDRG Panel was 100% accurate in detecting the correct resistance gene(s) in the blinded isolates. There was excellent agreement between the ARPs generated through the Kirby-Bauer method and those generated from the detected antibiotic resistance genes. There was a 92% correlation in detection for resistance to carbapenems; 100% to cephalosporins, fluoroquinolones, and macrolides; and 53% to the monobactam, aztreonam. Expected carbapenem resistance was observed in all but one strain which had a zone of inhibition just beyond that of the resistant phenotype, indicating intermediate susceptibility and a possible evolution into the resistant phenotype. The low agreement of monobactam resistance between the two methods seemed largely due to the presence of CTX-M genes in the strains. This can be explained from the variability in antibiotic resistance expression among the different CTX-M gene classes reported in published literature.**Conclusions:** Our findings indicate that the accuracy of the MDRG Panel is comparable to the Kirby-Bauer method in predicting antibiotic class resistance phenotypes and is an innovative and rapid alternative to conventional AST methods.

Detection of Esbls, Mbls, Kpcs, and Plasmid-Mediated *amp*c β-Lactamase Genes by Multiplex Real-Time Pcr

Author Block:

M. P. Torres[1], S. Morrow[2], J. Lechner[1], L. Porter[1], C. Connelly[1], N. D. Hanson[2]; [1]Streck, Omaha, NE, [2]Creighton Univ., Omaha, NE

Abstract Body:

Background: The production of extended-spectrum β-lactamases (ESBLs) by Gram-negative bacteria has emerged as a major resistance mechanism that threatens healthcare facilities. Current phenotypic tests do not differentiate clinically important β-lactamases and may not identify several co-existing resistance mechanisms. Novel diagnostic tests that lead to the accurate identification of these resistance mechanisms can improve antibiotic stewardship and infection control. This study describes two multiplex Real-Time PCR assays for the detection of 9 different β-Lactamase gene families and 6 different plasmid-mediated *amp*C β-Lactamase genes.**Methods:**Streck's ARM-D® for β-Lactamase ID and *amp*C ID Real-Time PCR Kits (Streck, Omaha, NE) were used to detect the following β-Lactamases: IMP-1, NDM, OXA-48, CTX-M-14, CTX-M-15, CMY-2, DHA, VIM, and KPC; and plasmid-mediated *amp*Cs: MOX, DHA, ACC, EBC, FOX, and CMY-2. An internal control (IC) that targets a conserved region in Gram-negative bacteria was included in each mix to discriminate false negative results. PCR amplification was monitored using hydrolysis probe chemistries. DNA samples extracted from characterized clinical isolates were used to validate gene identification. Data for both Multiplex assays was generated using the ABI QuantStudio™7 Flex and Bio-Rad CFX96 Touch™ real-time PCR instruments. However, each kit has been developed as an endpoint real-time detection assay compatible with multiple real-time PCR instrument platforms using Philisa*FAST*® DNA polymerase.**Results:**The ARM-D® for β-Lactamase ID and the Philisa® *amp*C ID Real-Time PCR kits have been validated with previously characterized clinical isolates. Specificity and sensitivity for both assays was 100%. β-Lactamase positive isolates amplified within the first 20 cycles of the PCR.**Conclusions:**These assays provide a rapid detection strategy for monitoring β-Lactamase-based antibiotic resistance in Gram-negative bacteria. Given the broad range of β-Lactamase families identified by these kits, these assays represent a valuable tool to improve antibiotic stewardship practices and active surveillance of resistance mechanisms.

Screening and Detection of Antimicrobial Agents Production Bioprospects in Metagenomic Libraries from Aquatic Bodies in Puerto Rico

Author Block:

B. M. Soriano, L. M. Del Valle Perez, C. Rios Velazquez; Univ. of Puerto Rico at Mayaguez, Mayaguez, PR

Abstract Body:

Background: Antimicrobials have revolutionized human health care, but in recent years, their effectiveness has been diminishing. Antimicrobial resistance is a global public health concern causing nearly 19,000 deaths annually in United States and around $20 billion in care related costs each year. Being aware of the enormous repercussions of this problem, it is imperative to do more research in order to reduce the impact of this issue. Knowing the scarce discovery of novel antibiotics by culture-dependent methods, it is necessary to implement culture-independent methods such as Metagenomics as an alternative solution for the increasing antimicrobial resistance issue. **Methods:** For this, an antimicrobial agent production functional analysis methods were performed to four high molecular weight aquatic bodies metagenomic libraries (AML) generated from samples of Guajataca water reservoir (GWR- G1 and G2), Rio Grande de Añasco (RGA), Playuela Beach (PB). The functional screening was done using two assays: (1) overlay inhibition test and (2) Kirby Bauer assay (KBA). In the first test, 500 clones of the respective AML were spreaded on Petri plates with Luria Bertani (LB) and after 24 hrs of incubation, an overlay of *Klebsiella pneumoniae* as target was done on top of the AML clones. A total of 1% of the clones per AML was screened for antimicrobial agents production. In the KBA, supernatants of the AML, one after centrifuging the un-lysed AML culture (S1) and the other one after lysing the AML culture (S2). After spreading *K. pneumoniae* on LB plates, 5mm individual disks impregnated with S1 and S2 were placed on top and incubated for 24 hrs.**Results:** While no antibiosis halos were detected for S1, halos with variable inhibition zones were found in the S2 tested. For PB no inhibition halos were found, however for G1 43% of the disk demonstrated inhibition halos, for G2 thebinhibition ratio was 21% and 36% inhinition ratio for RGA.**Conclusions:** These results demonstrated the reliability of Metagenomics in the discovery of antimicrobial products in these environments, representing an opportunity and a new alternative in solving the antibiotic resistant issue.

The Isolation of Ocean Microbes That Produce Antibiotics Against *Pseudomonas aeruginosa* Strains from Cystic Fibrosis Patients

Author Block:

D. M. Walsh; MassBay Community Coll., Wellesley Hills, MA

Abstract Body:

Microbes are the source of antibiotics. It is necessary to find new antibiotics against the bacterium *Pseudomonas aeruginosa*. This is the causative agent of infection in cystic fibrosis patients and it can develop antibiotic resistance.Water samples were taken from various marine environments. With aseptic technique, 100 µl of marine water was added to each of the following microbial media; *Streptomyces* agar, R2A agar, Sabourauds Dextrose agar (SAB), and R2A and SAB both supplemented with sea water. The marine water was streaked for isolation, and incubated at 25ºC-35°C for 3-5 days.The cross streak method was used with all of the isolated colonies against *Pseudomonas aeruginosa* ATCC 39324 (PAcf), a strain isolated from a cystic fibrosis patient. If a potential antibiotic is produced by the isolated water microbe, there would be growth inhibition of PAcf near the streaked area.Of the many tests performed only 1 isolate proved to inhibit PAcf. The microbe was identified by Gas Chromatography (GC) as *Pseudoalteromonas nigrifaciens*. The potential antibiotics produced were acetone extracted, and identified by GC-Mass Spectrometry (GC-MS) as benzophenone, 1, 2-butanediol, and cetene. These molecules could perhaps be used in clinical phase I trials in cystic fibrosis patients. This could lead to a possible cure for this terrible disorder.

Isolation and Identification of Antibiotic Producing Bacteria from Soil

Author Block:

M. Bailey, J. Pifer, E. Hardin; Lewis Univ., Romeoville, IL

Abstract Body:

Most antibiotics currently prescribed to treat infections are derivatives of natural compounds produced by bacteria and fungi. Unfortunately, most antibiotics will not remain clinically effective long-term due to the increasing frequency of antibiotic resistance. Increasing instances of multidrug resistance coupled with a decrease in the discovery and development of novel antibiotics is setting the stage for a global healthcare crisis. To combat this increasing public health threat, the idea of "crowdsourcing" to isolate and identify new antibiotic producers and new drugs is growing in prominence. This work represents the results of implementation, in our undergraduate microbiology laboratory, of the Small World Initiative crowdsourcing for antimicrobial discovery. Suspensions of soil samples from thirty-two locations were plated to yield individual colonies. Diverse colonies and any colonies exhibiting clear zones of growth inhibition of neighboring cell growth were selected. Isolates were tested for antimicrobial activity against a panel of ESKAPE pathogen safe relatives. Isolates exhibiting greatest antimicrobial activity against the ESKAPE panel were identified using 16S rRNA sequencing followed by nucleotide BLAST sequence alignment. Additionally, isolates exhibiting the most significant antimicrobial activity against the ESKAPE tester strains were subjected to organic extraction with ethyl acetate. The organic extracts were dried, resuspended and spotted onto LB agar plates inoculated with the same ESKAPE strains to test for organic antimicrobial activity. Over 400 diverse colonies were tested against a panel of Gram positive and Gram negative ESKAPE pathogen safe relative strains. Sixteen examples that exhibited the most substantial growth inhibition of tester panel strains were sequenced and subjected to the organic extraction process. Sequencing identified species of the genera *Bacillus, Pseudomonas, Microbacterium, Staphylococcus, Streptomyces* and *Enterobacter*. One particular isolate, ELHA18b, identified as a strain of *Bacillus pumilus,* was found to actively grow and produce an active organic antimicrobial across a range of temperatures from -80C to 42C. The data support the concept that soil yields a diverse population of bacteria that produce active antimicrobial compounds and may harbor as yet unidentified antibiotic compounds.

Controlling Bacterial Weapons: Biosynthesis and Regulation of Antifungal, Antibacterial and Nematicidal Metabolites in *Serratia*

Author Block:

M. A. Matilla[1], J. E. E. U. Hellberg[2], G. P. C. Salmond[3], T. Krell[1]; [1]EEZ-CSIC, Granada, Spain, [2]Univ. of Cambridge, Cambridfe, United Kingdom, [3]Univ. of Cambridge, Cambridge, United Kingdom

Abstract Body:

The extended use of antibiotics and chemical pesticides has driven the emergency of multidrug resistance microorganisms. As a consequence, great efforts are being made to isolate and develop new broad-spectrum antibiotics. Soil bacteria are a promising source of secondary metabolites, which are mainly synthesized by large multifunctional enzymes known as polyketide synthases (PKSs) and non-ribosomal peptide synthetases (NRPSs). During the screening of a collection of soil and plant-associated bacteria, we found that one of them, the rhizobacterium, *Serratia plymuthica* A153, showed a broad spectrum of biological activities - including antifungal, anti-nematode, and antibacterial. Using genome sequencing, mutagenesis, chemical analyses and *in vivo* antagonistic and virulence assays, we identified three secondary metabolites as responsible for the observed bioactivities. Firstly, we isolated and characterized for the first time the PKS gene cluster responsible for the biosynthesis of the antifungal and anti-oomycete haterumalide, oocydin A. Secondly, we found that A153 produces the hybrid NRPS/PKS antibacterial acetyl-CoA carboxylase inhibitor, andrimid. Finally, we demonstrated that the observed nematicide properties are due to the production of the PKS/NRPS antibiotic, zeamine. Using the nematode worm, *Caenorhabditis elegans* as a model organism, we showed that early larvae are more sensitive to zeamine. We also investigated the genetic regulation of these three secondary metabolites. Our results showed that the expression of their respective gene clusters is highly controlled at both transcriptional and posttranscriptional levels - highlighting the complexity of the regulatory mechanisms controlling secondary metabolism in this enterobacterium.

Urinary *Lactobacillus crispatus* Produces a Molecule Which Kills Uropathogenic *E. coli*

Author Block:

K. A. Diebel, T. Price, A. J. Wolfe; Loyola Univ. Chicago, Chicago, IL

Abstract Body:

Background: As many as 1 in 2 women will have at least one urinary tract infection (UTI) in their lifetime. UTIs can cause complications in pregnancy and decrease quality of life, and their treatment and prevention are expensive. Uropathogenic *E. coli* (UPEC) is the primary cause of UTI. A vaginal suppository of the bacterium *Lactobacillus crispatus* has been shown to protect against recurrent UTIs caused by UPEC, and vaginal *Lactobacillus* isolates have been shown to produce by-products that inhibit the growth of UPEC. The probiotic and bactericidal capacities of gut and vaginal *Lactobacillus* isolates have been studied, but the same attention has not been paid to urinary strains. *L. crispatus* strains isolated from the bladders of women without lower urinary tract symptoms are significantly genetically different from vaginal and gut strains. These urinary isolates of *L. crispatus* appear to have a greater killing capacity against UPEC and this bactericidal activity does not depend on the cells themselves, consistent with the hypothesis that they secrete a molecule with anti-UPEC activity. In the future, this bacterium could be useful as a probiotic and molecules it produces could be used as antibacterial compounds.**Methods:** *L. crispatus* isolates were grown in de Man, Rogosa and Sharpe broth (MRS), at 37°C in CO_2, for 48 hours. The spent culture supernatant (SCS) was removed and filter-sterilized. NU14 was aerated in tryptic soy broth (TSB) at 37°C in O_2 for an average of 19 hours. Two mL each of NU14 and SCS were combined and aerated at 37°C in O_2. Aliquots of 100 µl were harvested at chosen time points, serially diluted and spread onto tryptic soy agar (TSA) plates, which are placed at 37°C in O_2 for 24 hours. Colonies were counted and the CFU/mL of NU14 were calculated.**Results:** The SCS of one urinary isolate of L. crispatus killed several logs of UPEC within 2 hours of exposure. This isolate creates a more acidic environment than isolates of other Lactobacillus species, but the killing of UPEC was not due to low pH alone, as buffered of the SCS delayed but did not eliminate the bactericidal effect. This effect became stronger after the SCS was left to sit for 24 hours. The molecule was not heat sensitive.**Conclusions:** A urinary L. crispatus isolate produces a unique soluble molecule that can kill up to 9 logs of UPEC within 24 hours. The molecule may be an antimicrobial peptide or bacteriocin. Further experiments are required.

Designing a Chronic Wound Anti-biofilm Strategy Using Probiotics

Author Block:

J. G. Thomas, L. listico, R. Kreft; Allegheny Hlth.Network, Pittsburgh, PA

Abstract Body:

Background: Since 2011, we have reported on the efficacy of silver dressings against a broad spectrum of wound isolates in planktonic (P/P) and biofilm phenotypes (P/BF), unmasking developing biofilm resistance and gauze colonization. Hence, we wanted to investigate a bi-phasic intervention, "Disruption: Reconstruction" with silver and probiotics, here, focusing on the selection of probiotics. **Methods:** Initial studies targeted Methicillin Resistant *Staph aureus* and gauze colonization using 3 probiotic challenges containing different combinations *of Lactobacillus sp., Bifidobacterium sp.,* and/or *Saccharomyces boulardi*i MRSA P/BF were grown in BHI for 24-72 hrs. in 25 mm petri dishes with 1 cm square gauzes evaluated using 1) FISH with species specific *Staph aureus* 16 S rRNA probe and 2) Live /Dead stain background quantifying 1) MRSA P/BF mass, 2) average thickness and 3) average roughness.Secondary studies targeted 7 clinical isolates measuring anti-planktonic activity *of Lactobacillus rhueteri* (LR), ATCC 53608, and *Bifidobacterium pseudocatenulatum (BP)*, ATCC 27919, using a disc diffusion/zone of inhibition(ZOI) assay at 24, 48 and 7 days. **Results:** Two probiotic pools containing 4 species, LB and SLB, showed inconsistent results via both CLSM and Live/Dead stains; studies with LR, *Lactobacillus rheuteri*, showed promising results highlighting a 30% reduction in biomass and 80% reduction in MRSA gauze biofilm thickness, stabilizing gauze integrity. Secondary studies showed varying anti-planktonic ZOI (7-10mm) of both LR and BP against 10^3 CFUs/ml of clinical isolates. **Conclusions:** CLSM data suggested that 1) *Lactobacillus rheuteri*, can disrupt/ reduce the 3-D biofilm architecture of MRSA while maintaining gauze integrity and 2) a combination of anti-planktonic probiotics may be necessary.

Ahl-Lactonases of *Bacillus cereus*, Characterization of Activities and Sequencing Encoding Genes

Author Block:

M. Sakr, M. Aboulwafa, K. Aboshanab, N. Hassouna; Faculty of Pharmacy, Ain Shams Univ., Cairo, Egypt

Abstract Body:

Background: N-Acyl homoserine-lactone-dependent quorum sensing plays a major role in the virulence of a number of pathogenic bacteria, therefore is considered a useful target for antimicrobial therapy. In this study, activities of crude AHL-lactonase enzymes from five *B. cereus* isolates were characterized followed by sequence analysis of the genes/enzymes involved. **Methods:** Total protein concentration was determined by Lowry's method. Thermal and pH stabilities were determined. Effect of some divalent metals (Ca++, Fe++, Mg++ Cu++, Zn++) and EDTA on activity was tested. Catalytic rates, effect of temperature (5-70°C) and pH (6-9) on activity were studied. Kinetic constants were determined and enzyme substrate specificity was measured using standard synthetic signals (C4, C6, C7 and C8-HSL). Lactonase genes were sequenced, analyzed, assembled, ORFs detected and the full nucleotide sequences were submitted to GenBank database. Domain analysis and prediction of putative tertiary structures were performed.**Results:** The enzymes displayed high thermal and pH stabilities. Maximum enzymes activities were obtained within the temperature range of 28-50°C and pH 6-9. Their activities were neither enhanced by any of the tested metals nor inhibited by EDTA. However, a concentration of 10 mM Fe^{+2} either completely or partially inhibited their activities. Enzymes proved to be constitutively produced. AHL lactonase activity ranged between 17.7-32.97 U/mg. Vmax values ranged between 59.9-113.6 $nM.min^{-1}$ per mg protein, and Km between 14.27-27.2 nM. All tested enzymes have a broad activity spectrum. DNA sequences were submitted to GenBank database (accession codes: KF254906, KF254908, KF254909, KF254907, KF254910). The protein sequences revealed conserved multi-histidine motif and position 194-tyrosine residue. Predicated structures showed them to be metalloenzymes with binding sites for 2 zinc atoms. **Conclusion:** Displaying high physical stability and relatively strong catalytic activity, the five studied lactonase enzymes proved to be potential candidates for development into antipathogenic drugs.

A Novel Natural Ramoplanin Analog Produced by an Actinomycete Strain

Author Block:

F. VICENTE, M. DE LA CRUZ; FUNDACION MEDINA, GRANADA, Spain

Abstract Body:

Ramoplanin is a glycolipodepsipeptide obtained of *Actinoplanes* sp. with activity against clinically multi-drug-resistant pathogens including vancomycin-resistant *Enterococcus*, methicillin-resistant *Staphylococcus aureus* and vancomycin-intermediate resistant *Clostridium difficile*. It disrupts bacterial cell wall through a novel and a unique mechanism of action by sequestering the peptidoglycan intermediate Lipid II and does not show cross-resistance. However, while demonstrating excellent antimicrobial activity in systemic use in infection animal models, ramoplanin presents low tolerability intravenously. Therefore, new derivatives are desirable to overcome this issue.A natural product program developed to discover compounds that inhibit peptidoglycan transglycosylation binding the intermediate Lipid II permitted the identification of a novel ramoplanin analog produced by an actinomycete fermentation. Minimum inhibitory concentration of the purified compound was measured against a panel of isolates. Cytotoxicity, cytochrome inhibition and kinetic aqueous solubility at different pH were also measured by MTT, LC-MS and turbidimetric assays.This new ramoplanin (2572 Da), exhibited specific activities against Gram-positive bacteria (methicillin-resistant *S. aureus*, *E. faecalis*, *E. faecium* and *C. difficile*). No relevant activity was observed when the compound was tested against Gram-negative bacteria. The compound displayed no significant toxicity (IC_{50} above 23.6 µM) against human hepatocyte cell line, and weak CYP450 inhibition with IC_{50} values above 36 µM. According to the kinetic solubility classification, the compound can be categorized into acceptable (>50 µM).We present here a novel natural ramoplanin analog whose favorable pharmacological profile and excellent antibacterial activities support further investigation. Data obtained in this study reinforce the fact that natural products are a source of potential drugs, in particular of antibiotics.

Abstract Body:

Background: Antibiotic-resistant infections are predicted to kill 10 million people worldwide per year by 2050. The majority of these infections are caused by biofilms, which demonstrate increased adaptive resistance to conventional antibiotics. Host defense systems have evolved to fight off infections, including the human innate immune system that produces small molecules such as cationic peptides and nitric oxide (NO), and the adaptive immune system CRISPR-Cas of bacteria that operates by cleaving invading phages and plasmids. Here, we leveraged these systems for the design and implementation of next-generation antimicrobials. **Methods:** For peptide work, microplate, flow cell assays, NMR and TLC were used. CRISPR phages were generated by programming the *S. pyogenes* Type II CRISPR-Cas9 system to recognize specific DNA targets and packaging this system using the M13 filamentous bacteriophage. The resultant phage particles were purified and used to deliver the CRISPR construct into recipient bacteria containing or lacking the target sequences.**Results:** We identified synthetic peptides that:i) are broad-spectrumii) interfere with the signalling nucleotide ppGppiii) synergize with antibioticsiv) protect *C. elegans* and *G. mellonella* from otherwise lethal *Pseudomonas aeruginosa* biofilm infectionsNO mimetics eradicated biofilms and synergized with fluoroquinolones.Finally, when CRISPR phages were used to target carbapenem-resistant *E. coli*, a highly discriminatory lethal activity was noted that depended on the presence of the pre-defined sequence within the recipient cells. Programmed phages were also used to selectively remove single *E. coli* strains from a three-strain consortium by targeting the different resistance genes contained within the strains. A CRISPR phage therapeutic targeting a virulence factor of enterohemorrhagic *E. coli* O157:H7 significantly improved *G. mellonella* survival.**Conclusions:** We have generated bioinspired therapeutics that effectively target drug-resistant infections both *in vitro* and *in vivo*.

The Antibiotic Actinorhodin: From Phenotypic Marker in Streptomycete Research to Potential Antibacterial Drug Candidate

Author Block:

N. M. Nass, C. P. Randall, R. F. Seipke, A. J. O'Neill; Univ. of Leeds, Leeds, United Kingdom

Abstract Body:

Background: New antibacterial drugs are urgently required to replace those whose therapeutic utility has become compromised by antibiotic resistance. One approach to identifying antibacterial drug candidates is to revisit known antibiotics that have not been clinically exploited. Actinorhodin (ACT) is a pigmented antibiotic produced by *Streptomyces coelicolor*, first discovered in the 1940's, and often employed as a phenotypic marker in streptomycete research. Here we report on the antibacterial properties of ACT, concluding that this compound may have potential as an antistaphylococcal agent.**Methods**: ACT was extracted from *S. coelicolor* L646 with ethyl acetate, and further purified by HPLC. Broth microdilution MICs and time-kill studies were performed according to CLSI guidelines. Cytotoxicity was evaluated by measuring lactate dehydrogenase release and ATP levels in human proximal tubular HK-2 cells. Antibacterial mode of action (MOA) was investigated by macromolecular synthesis (MMS) studies using radiolabeled precursors, and effects upon membrane potential/ integrity were assessed using $DiSC_3(5)$ and potassium (K^+) leakage assays, respectively.**Results**: ACT demonstrated bacteriostatic antibacterial activity (MIC of 8 µg/ml) against multi-drug resistant (MDR) *S. aureus*, but lacked activity against Gram-negatives. ACT exhibited an LC_{50} >100 µg/ml in mammalian cytotoxicity tests. ACT caused rapid, non-specific inhibition of MMS (≥ 87% inhibition at 10 min), a result typically observed for membrane perturbing compounds. However, assays detecting changes in membrane potential [$DiSC_3(5)$] and membrane integrity (K^+ leakage), revealed limited effects (<30% reduction) after 60 min, suggesting that the membrane may not be the primary target of ACT. No reduction in ACT susceptibility was selected upon serial passage of *S. aureus* in the presence of ACT for 5 days.**Conclusion**: ACT exhibits selective antibacterial activity against MDR staphylococci at concentrations in range of established antibacterial drugs, and demonstrates low resistance potential. Although further studies will be required to precisely elucidate the MOA of ACT, we consider that ACT represents a promising candidate for the treatment of staphylococcal infection.

Antibiofilm Activity of Bioactive Compound from *Pseudomonas stutzeri* AF3 Against Pathogenic Bacteria

Author Block:

D. E. Waturangi, L. Suteja, M. T. Suhatono; Atma Jaya Catholic Univ., Jakarta, Indonesia

Abstract Body:

Background: Biofilm is an assemblage of surface-attached microorganism embedded in exopolysaccharide (EPS) matrix. It is one of the key factor for microbial survival in adverse environment. In the recent years, various means have been explored in order to control biofilm formation and accumulation. Many recent studies suggest that antibiofilm compounds extracted from diverse microorganism have the ability to control biofilm without exhibiting biocidal activity (Kostakioti*et al.* 2015).From previous studies, endophytic bacteria AF3 (*Pseudomonas stutzeri*) had been isolated from *Anrederacordifolia* and had been shown antibiofilm activity against wide range of human pathogenic bacteria (Jessica 2011; Febri 2013).**Methods:** In this study we purified the compound from *Pseudomonas stutzeri* AF3 using ion exchange chromatography as well as desalting to concentrated the sample followed by antibiofilm assay using static biofilm assay to inhibit and destruct biofilm formation of *Pseudomonas aeruginosa* and *Staphylococcus aureus.* **Results:** The compound was purified using ion exchange chromatography showed single peak when eluted using linear gradient of NaCl 2 M. While desalting was done to obtain concentrated sample.. Significant increase in antibiofilm activity of purified samples was observed. The highest increase observed in inhibition and destruction antibiofilm of *P. aeruginosa* at 10% concentration of sample. Concentrated sample exhibited relatively high antibiofilm activity when compared with purified sample even after 10-fold dilution. There was an exception for biofilm inhibition against *S. aureus* where the antibiofilm activity of concentrated sample diluted 10-fold was much lower than purified sample. The highest increase in biofilm inhibition activity was showed against *P. aeruginosa* when 5% of compound was added whereas in destruction activity 10% of compound added to *P. aeruginosa* showed highest increase.**Conclusions:** Bioactive compound from *Pseudomonas stutzeri* showed antibiofilm activity agains *P. aeruginosa* and *S. aureus,* the activity increased after purification. This suggested that polysaccharide might have an important role in biofilm destruction activity of this compound.

Synergistic Antibacterial & Pharmaceutical Advantage of the Ciprofloxacin Multi-Component Forms

Author Block:

P. Singh, R. Chadha; Panjab Univ., Chandigarh, India

Abstract Body:

Background: Ciprofloxacin, the active ingredient of the antibacterial drug Cipro (in USA), is potent and active against both Gram-positive and Gram-negative bacteria; however, it is known to have poor solubility and absorption. Thus, to improve solubility and bioavailability characteristics, multi-components forms of the drug have been prepared and also been tested for synergistic antibacterial activity.**Methods:** Multi-components are formed with succinic acid (salt), adipic acid (salt), caffeine (eutectic), glycine (eutectic) and gentisic acid (cocrystal) using solvent assisted grinding technique.Antibacterial activity (MIC) was tested on *Pseudomonas aeruginosa, Staphylococcus aureus, Escherichia coli* and *Klebsiella pneumoniae* using broth dilution method.**Results:** The MIC value for these multi-component forms ranged between 0.05µg/mL and 0.8µg/mL. Moreover, the cocrystal and eutectics as multi-components exhibits improved solubility and dissolution compared to the salt forms in water. Pharmacokinetic studies on rats showed that the cocrystal and eutectic forms exhibits doubled plasma AUC values in a single dose.**Conclusions:** To conclude, the design, synthesis and characterization of these kinds of multi-components are essential in order to further expand the scope of the available pre-formulation options beyond pure API forms.

The Isolation and Characterization of Marine Antibiotic Producing Bacteria from Sarasota Bay, Florida

Author Block:

D. Christou-ader, E. Warrick; State Coll. of Florida, Bradenton, FL

Abstract Body:

The current emergence of a plethora of multi-drug resistance bacteria has left us with a dwindling variety of effective antibiotics to fight infections. The once elementary infection may now be of great concern as the cause of the infection may have developed the ability to combat one of our only outside defenses, antibiotics. This emerging crisis has stimulated the need for researchers to discover and develop new antibiotics to target these multi-drug resistance bacteria. In order to discover new antibiotics, samples should be taken from more unique environmental locations. To accomplish this, sediment and water samples taken from offshore and inshore sites along the Gulf of Mexico and Sarasota bay were collected and cultured on various media looking for antibiotic producing bacteria. Media recipes included potato dextrose agar, lysogeny broth, and actinomycetes isolation agar. All of the media were supplemented with 0.5M NaCl and 100µg/ml cycloheximide. Incubation conditions were designed to be optimal for the enrichment and isolation for marine Actinomycetes. All samples were plated at dilutions yielding plates that contained 30-300 colonies and then transferred to a gridded master plate for individual testing. Each colony was tested against several ESKAPE safe relatives; *Staphylococcus epidermidis, Bacillus subtilis, Enterobacter aerogenes, and Citrobacter freundii* as well as the non-pathogenic marine organism *Chromohalobacter salexigens* for the ability to produce a zone of inhibition. Colonies that showed inhibition of an ESKAPE safe relative were preliminarily identified using 16s rDNA gene. Initial testing resulted in *Streptomyces aurues, Bacillus amyloliqefaciens, Chromobacterium aquaticum* and an unknown species of *Microbacterium*. Many samples came back as known antibiotic producing bacterium. The unknowns will be used for continued research. Chemical analysis of the antibiotic compound(s) is ongoing and will be discussed.

Accurate Quantification of D-Ala-D-Lac Terminated Peptidoglycan Stem Structures in Cell Wall of Vancomycin-Resistant *Enterococcus faecalis*

Author Block:

J. Chang, E. Foster, S. Kim; Baylor Univ., Waco, TX

Abstract Body:

Background: Vancomycin-resistant *Enterococcus faecalis* (ATCC 51299) is VRE of *VanB* type which replaces D-Ala-D-Ala peptidoglycan (PG) stem with D-Ala-D-Lac in the presence of vancomycin. This substitution reduces the binding affinity of PG-stem to vancomycin by thousand fold and confers VRE vancomycin resistance. Although D-Ala-D-Lac terminated cytoplasmic PG precursors have been previously observed, evidence for the existence of D-Ala-D-Lac terminated PG resulting from these precursors has remained elusive. This has led to suggestions that D,D-carboxypeptidase completely cleaves all D-Lac away from PG in the cell wall. In this study, we investigate using LC-MS and solid-state NMR vancomycin induced changes to the chemical composition of the cell wall in VRE. **Methods:** VRE was grown with or without the presence of vancomycin (4 μg/ml) in defined media containing [2-^{13}C]pyruvate, or L-[1-^{13}C]Ala and L-[ε-^{15}N]Lys. Solid-state NMR was used to determine the extent of accumulated Park's Nucleotide in intact whole cells by monitoring the amount of D-[2-^{13}C]Lac and D,L-[2-^{13}C]Ala converted from [2-^{13}C]pyruvate. The effect of D-Ala-D-Lac substitution on PG bridge-linking efficiency was determined by ^{13}C{^{15}N} REDOR NMR. LC-MS was used to quantify the chemical composition of PG fragments resulting from mutanolysin digestion of the isolated cell wall. **Results:** Induction of vancomycin resistance shows excess accumulation of cytoplasmic D-Ala-D-Lac terminated Park's Nucleotide in VRE. Approximately 20% of PG pentapeptide in the cell wall during the exponential growth phase were composed of D-Ala-D-Lac, and this proportion increased to 60% once the stationary growth phase was reached. **Conclusion:** REDOR NMR confirmed that the bridge-linking efficiency was not affected by D-Ala-D-Lac substitution. D-Ala-D-Lac substituted PG fragments from the cell wall were observed and differentiated from D-Ala-D-Ala terminated PG fragments via LC-MS through m/z values and chromatographic retention time. D-Ala-D-Lac substituted fragments were only observed upon the induction of vancomycin resistance.

Murine Lung Infection Model Demonstrates Reduced *In Vivo* Resistance Emergence to Wall Teichoic Acid Inhibitors Compared to Observed *In Vitro* Resistance

Author Block:

L. Liang, C. Gill, S. Lee, J. Liu, P. Mann, H. Wang, J. Xiao, C. Tan, T. Roemer, A. Flattery; MERCK RESEARCH LABORATORIES, Kenilworth, NJ

Abstract Body:

Increasing multiple drug resistance to marketed antibacterials is limiting the effective options for treatment of infections by Methicillin Resistant *Staphylococcus aureus* (MRSA). There is emerging evidence that wall teichoic acid (WTA) synthesis plays an important role in the expression of ß-lactam resistance in MRSA. We have previously demonstrated that inhibition of WTA synthesis in MRSA via mutations or with WTA inhibitor compounds leads to reduced virulence and restored susceptibility to the β-lactam antibiotic imipenem in mouse infection models (Wang *et al* 2013). These in vivo studies demonstrated that inhibition of WTA synthesis is an attractive target for combination therapy with ß lactams to combat MRSA infections. In vitro studies however revealed a higher frequency of resistance (FoR) than acceptable over an extended 48 hr time period and had the potential to derail this program. In order to examine the significance of this drug resistance observed in vitro, we developed a novel in vivo infection model. Herein we describe studies in a murine MRSA lung infection model utilizing both MRSA COL and an isogenic strain deficient in WTA as the first gene involved in WTA synthesis, tarO, was deleted. The ΔTarO mutant serves as a genetic surrogate for WTA inhibition by a small molecule and simplifies FoR analysis as only the high frequency bypass mutants observed in vitro can be obtained. We compared the efficacy of 2 β-lactam antibiotics imipenem and dicloxacillin against both MRSA and its ΔTarO mutant in immune competent and neutropenic mice. Our results demonstrate that the MRSA ΔTarO mutant strain is more sensitive to the immune response and more susceptible to both imipenem and dicloxacillin treatment compared to MRSA COL in this lung infection model. Recovery of resistant mutants in our lung model was dramatically reduced compared to the in vitro FoR, suggesting that the likelihood of resistance emergence in the clinic would be lower than anticipated based on the in vitro data. Moreover, this innovative in vivo FoR model may be broadly applicable to other antibacterial programs.

Molecular Analysis of *Streptococcus pyogenes*, Macrolide Resistance, *emm* Types and Virulence Genes of Pediatric Isolates During a 7-Year Period

Author Block:

A. Michos[1], F. Koutouzi[1], A. Tsakris[1], P. Chatzichristou[1], E. Koutouzis[1], G. Daikos[1], A. Stathi[2], V. Syriopoulou[1]; [1]Natl. and Kapodistrian Univ. of Athens, Med. Sch., Athens, Greece, Greece, [2]Aghia Sophia Children's Hosp., Athens, Greece, Greece

Abstract Body:

Background: Increased macrolide resistant of Group *A streptococcus* (GAS) has been reported in many countries posing a significant problem in cases of β- lactam allergy. The aim of the study was the molecular characterization of pediatric GAS isolates regarding macrolide resistance, virulence genes and relevant *emm* types in Greece. **Methods:** Pharyngeal and non-pharyngeal GAS isolates were collected during a 7-year period (2007-2013) and examined for antibiotic susceptibility, macrolide-resistant genes (*mef*(A), *erm*(A), and *erm*(B)), *emm* typing and streptococcal pyrogenic exotoxins genes (*speA, speB, speC* and *ssa*).**Results:** The overall GAS macrolide resistance was 20.4% (270/1324); Macrolide resistance varied during the study period with maximum in 2008 (29.57%) and minimum in 2013 (10.95%) (*P*-value for trend=0.007). At the same period consumption of pediatric macrolide packages was gradually reduced by 55%. Regarding macrolide resistance genotypes, *mef*(A) was detected in 87(32.2%), *erm*(A) in 136 (50.37%), *erm*(B) in 44(16.29%) and both *mef*(A) and *erm*(A) in 3(1.1%) isolates. The most prevalent *emm* types among erythromycin-resistant isolates were *emm*77 (31.48%), *emm*4 (18.15%) and *emm*12 (10.74%). Ten *emm* types accounted for 90.3% of macrolide-resistant isolates. Among 415 randomly selected GAS isolates *spe*A was detected in 61(14.7%), *speB* in 280(67.5%), *speC* in 252(60.7%) and *ssa* in 82(19.7%) isolates. Increased prevalence of *speC* was found among macrolide-resistant isolates (72.6% vs 56.6%, respectively; *P*=0.01) and of *speB* among invasive isolates (79.48% vs 62.41%; *P*=0.0009). Distribution of virulence genes differed among GAS *emm* types with all virulence genes detected only in *emm* types 1, 3, 4, 12.**Conclusions:** GAS macrolide resistance remained significant in our area during the study period with a reduction in the last year of the study, that followed the reduced consumption of macrolides.

Publishing Title:

Combination Antibiotic Exposure Selectively Alters the Development of Vancomycin Intermediate Resistance in *Staphylococcus aureus*

Author Block:

X. Zheng[1], A. Berti[2], W. Rose[2]; [1]China Med. Univ., Shenyang, China, [2]Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Background: Heterogeneous vancomycin-intermediate *Staphylococcus aureus* (hVISA) is associated with high rates of vancomycin (VAN) and secondary treatment failure. Combination therapy with VAN is one strategy to prevent resistance, but comprehensive assessments of potential combinations are limited. This study identifies optimal combinations to prevent the emergence of vancomycin-intermediate *Staphylococcus aureus* (VISA). **Methods:** hVISA Mu3 (VAN MIC=1 mg/L) was exposed for 28 d *in vitro* to VAN alone, VAN with beta-lactams (BLs) (cefazolin (CFZ), piperacillin-tazobactam (TZP), meropenem (MEM)) and VAN with other antibiotics (gentamicin (GEN), trimethoprim-sulfamethoxazole (SXT), rifampin (RIF), and fosfomycin (FOS)). VAN was increased from 1-6 mg/L according to growth, while the secondary antibiotic was maintained at the serum free average concentration. VAN MIC was determined every 7 d. Antibiotic susceptibility, cell wall thickness (CWT), pigment, and membrane fluidity were determined prior to and following exposure. **Results:** Exposure to VAN alone or VAN+GEN, SXT, RIF, or FOS increased the Mu3 VAN MIC to 8-16 mg/L at day 28. Combinations with GEN, SXT, RIF or FOS prevented VAN resistance at day 7 but were not effective thereafter, while FOS combination was no different than VAN alone at any time point. VAN plus any BL limited the VAN MIC increase to 2-4 mg/L at day 28, with CFZ and TZP as the most effective agents (VAN MIC=2 mg/L). The combination of VAN and BLs exposure resulted in no significant change to DAP or TLV MIC, while other combinations increased the MIC of DAP and TLV. LZD MIC was unchanged with all treatments. No changes to the MIC of secondary antibiotic were observed in any combination except VAN and RIF which increased the RIF MIC 512-fold. No correlation was observed between pigment or fluidity and VAN MIC. VAN and BLs exposure decreased CWT significantly compared with VAN alone (mean 52.0-58.3 vs 60.1±6.7 nm, $p<0.05$) whereas VAN plus other antibiotics increased the CWT (mean 63.5-68.5 vs 60.1±6.7 nm, $p<0.05$). **Conclusions:** Only the combination exposures of VAN and BLs suppresses the development of VAN resistance and the transition from hVISA to VISA. This combination should be further explored as a long-term treatment of serious MRSA infections due to ability to suppress VAN resistance.

Molecular and Cellular Changes That Accompany the Development of Low-Level of Vancomycin Resistance in Methicillin-Resistant *Staphylococcus aureus* during *In Vitro* Therapy

Author Block:

C. VIDAILLAC[1], G. SAKOULAS[2], R. TEWHEY[3], T. KAOMA[4], F. BERNARDIN[4], A. MULLER[4], G. KAATZ[5], W. ROSE[6], L. VALLAR[4], M. J. RYBAK[1]; [1]Wayne State Univ., Detroit, MI, [2]Univ. of California, San Diego, CA, [3]Harvard Univ., Cambridge, MD, [4]Luxembourg Inst. of Hlth., Luxembourg, Luxembourg, [5]John D. Dingell VA Med. Ctr., Detroit, MI, [6]Univ. of Wisconsin, Madison, WI

Abstract Body:

Background: Sequential molecular and cellular alterations accompanying the development of low-level VAN resistance (LVR) in MRSA during therapy remain unclear. **Methods:** We used an *in-vitro* pharmacokinetic/pharmacodynamic model with simulated endocardial vegetations (SEV) to expose the VAN susceptible MRSA JH-1 to a standard VAN regimen (1g q12h) over 60 days. SEV samples were collected daily to further characterize the bacterial population and selected LVR mutants. Over the treatment course, 6 isolates (JH3R to JH8R) exhibiting increased VAN MICs (> 2 µg/mL) were recovered and evaluated for phenotypic and genotypic changes, using JH1 and its *in-vivo* derivative JH2 as comparators. Techniques used included imaging, genome sequencing and microarray data analysis. **Results:** Similar to the *in-vivo* derivative JH2, JH3R-8R isolates exhibited increased VAN and daptomycin MIC values (≥3 and 1 µg/mL, respectively). Consistent with VISA characteristics, JH3R-8R demonstrated reduced autolysis and hemolysis phenotypes, progressive increase in cell wall thickness (up to 68%), and reduced cell separation (increased cellular clumping). Altered virulence phenotypes included decreased staphyloxanthin pigment production (up to 89%) and increased biofilm formation. Consistent mutations supporting the cellular changes were identified in *yycF*, *yycG* and *rpoA*. Microarray data analysis revealed a significant downregulation of *pur* genes involved in the purine/pyrimidine biosynthesis in selected LVR mutants exposed to VAN (up to -3.02 $\log_2$ FC with a FDR ≤ 0.001). **Conclusions:** Our results lend additional support towards a significant role of *yycFG* and *rpo* associated genes in the initial steps of the emergence of LVR during VAN therapy, and highlight the complexity of this inducible resistance mechanism, with multiple and significant changes in the expression of genes associated with cell envelop biosynthesis, regulation, virulence and metabolism.

Emergence of a Mrsa Clone Harbouring a New Composite Scc*cad/Ars*-Scc*mec* Cassette in France

Author Block:

O. Barraud[1], P. Martins Simões[2], N. Hidri[1], M. Bes[2], C. Martin[1], M-C. Ploy[1], F. Garnier[1], F. Laurent[2]; [1]INSERM, Université de Limoges, CHU Limoges, Limoges, France, [2]CNR Staphylocoques, CIRI INSERM U1111, Hospices Civils de Lyon, Université de Lyon, Lyon, France

Abstract Body:

Background: MRSA are responsible for a wide range of infections, notably bacteraemia. In France, MRSA have been decreasing for several years with prevalence close to 20% in 2015. At the Limoges University Hospital Centre, we observed that, among the MRSA collected from blood cultures, the proportion of isolates susceptible to kanamycin (Kana-S) increased from 15% to 78% in the last decade (2005-2015). **Methods:** In 2014, a Kana-S MRSA isolate (LIM88), not detected as MRSA by the Xpert MRSA/SA BC kit (Cepheid) was characterized by *spa*-typing and WGS (IonProton™). WGS data allowed i) *in silico* MLST, ii) characterization of SCCmec cassette, iii) design of a multiplex PCR (*mecA*, *ccrA4B4*, *ccrC*) specific to the SCCmec of this isolate. All 2015 Kana-S MRSA isolates from bacteraemia in the Limoges Hospital were tested using the multiplex PCR.**Results:** LIM88 belonged to ST5 and harboured a t777 *spa*-type. WGS analysis revealed the presence of a novel composite 40 kb-long SCC*cad/ars*-SCC*mec* element including i) a SCC*cad/ars* domain harbouring genes related to detoxification of heavy metals, *cadA (cadmium) and arsCBAD (arsenic), associated to a ccr*C1 recombinase, ii) a SCC*mec* domain harbouring a *mec*A classD complex (IS*431-mec*A-delta*mec*R1), a *ccr*A4B4 complex, and a *cop*A gene coding for resistance to copper. Comparison with other SCC elements reveals a mosaic structure composed of i) the SCC*mec* domain related to the SCC*mec* element of the "new" Paediatric MRSA clone (ST5-MRSA-VI-t777), ii) the operon *ars*CBAD similar to the one found in *S. haemolyticus* JCSC1435, iii) *ccrC* domain almost identical to the one of the ZH43 MRSA isolate. Phylogenetic analysis using other published ST5 whole genomes confirmed that LIM88 represents a new ST5 MRSA lineage.Screening with the multiplex PCR revealed that 20% of the Kana-S bloodstream MRSA isolated in 2015 were positive for the 3 targeted genes. Further investigations are underway concerning the other Kana-S MRSA isolates.**Conclusion:** Here, we report the emergence of a new ST5-t777 MRSA clone with a novel, composite SCC*cad/ars-SCCmec* element in Limoges University Hospital Centre. Interestingly, this clone represents in 2015 20% of all bloodstream Kana-S MRSA in this hospital.

Characterization of Gene Expression Profile Associated with Daptomycin Nonsusceptibility in *Staphylococcus aureus*

Author Block:

G. L. Oliva[1], R. Shah[1], J. Lu[1], S. V. Catlett[1], M. P. Pai[1], W. E. Rose[2], G. Sakoulas[3], M. Malik[1]; [1]Albany Coll. of Pharmacy, Albany, NY, [2]Univ. of Wisconsin-Madison Sch. of Pharmacy, Madison, WI, [3]Univ. of California, San Diego, La Jolla, CA

Abstract Body:

Background: Extensive use of daptomycin for treating complex methicillin-resistant *Staphylococcus aureus* (MRSA) infections has led to the emergence of daptomycin-non-susceptible *Staphylococcus aureus* (DNSA) strains. An understanding of the molecular mechanisms underlying daptomycin non-susceptibility is required for early diagnosis and intervention with alternate combination therapies. While phenotypic changes associated with DNSA strains have been well established, the genotypic changes, especially, alteration in the kinetics of expression of genes responsible for daptomycin nonsusceptibilty are not well understood. In this study, we used a phenotypically well characterized DNSA strain along with its daptomycin-susceptible (DSSA) isogenic pair to study gene expression profile and genetic mutations associated with daptomycin nonsusceptibility.**Methods:** We determined expression profiles of genes involved in cell membrane charge (*mprF, dltABCD*), autolysis (*atl, lytM*), cell wall synthesis (*femA, femB, vraSR, walkR*), and penicillin binding proteins (*pbp2*, *pbp2a*, *pbp4, pbp1*) in D592 (DSSA) and D712 (DNSA) strains.**Results:** A characteristic signature of genes involved in cell surface charge (*mprF, dltABCD*), cell wall synthesis (*vraS, femB*) and penicillin binding protein gene *pbp2a* that were observed to be significantly upregulated in D712 strain. In contrast, the gene profile signature of D592 strain was an enhanced expression of the master controller of peptidoglycan metabolism gene *walkR*, the autolysis genes *atl* and *lyt*M; and *pbp1* and *4*. Together, these alterations in gene expression profiles provide a mechanistic explanation for the resultant phenotypic changes such as low membrane binding affinity for daptomycin and increased cell wall thickness of these strains. The *mprF* gene is the major target for genetic mutations and these mutations most likely contribute to daptomycin non-susceptibility.**Conclusions:** Differences in gene expression profiles in the DNSA strain result in phenotypic changes associated with daptomycin nonsusceptibility and that these expression profiles may serve as excellent surrogate for differentiation of DNSA and DSSA strains.

Exploring the Role of Two Abc Transporters Essential for Acquired Nisin Resistance in *Staphylococcus aureu*s

Author Block:

C. P. Randall, B. Utley, A. J. O'Neill; Univ. of Leeds, Leeds, United Kingdom

Abstract Body:

Background: Nisin (NIS) is a lantibiotic routinely used as a food preservative, and may have a role in the chemotherapy of bacterial infection. We demonstrated recently that spontaneous resistance to NIS can arise in *Staphylococcus aureus* through mutation in the sensor kinase NsaS, leading to constitutive phosphorylation of the response regulator NsaR and subsequent upregulation of BraDE and VraDE, two putative ABC transporters. However, the role of these transporters in NIS resistance is unclear. Here we report on studies to examine this issue. **Methods:** Markerless deletions of *braDE* and *vraDE* were created in NIS-resistant S. aureus (SH1000 [$NsaS_{A208E}$]) using plasmid pIMAY. Complementation analysis was achieved using the regulable expression vector pRMC2, and the effect of deletions/complementation on NIS susceptibility was assessed by MIC determination according to CLSI methods. The impact of *braDE* deletion on expression of *vraDE* was evaluated by qRT-PCR, whilst interaction between BraDE and NsaRS/VraDE was assessed using the BACTH two hybrid (2H) system.**Results:** Deletion of *braDE* or *vraDE* in SH1000 ($NsaS_{A208E}$)(NIS MIC 64 mg/L) resulted in strains displaying NIS susceptibility equivalent to that of NIS-susceptible, wild-type SH1000 (NIS MIC 4 mg/L), and complementation of the deletion *in trans* restored NIS resistance. Overexpression in SH1000 of *vraDE* alone, but not *braDE*, resulted in an increase in NIS resistance to a level comparable to that seen for SH1000 ($NsaS_{A208E}$). Whilst expression of *vraDE* in SH1000 ($NsaS_{A208E}$) was ~65-fold greater than that observed in SH1000, deletion of *braDE* in SH1000 ($NsaS_{A208E}$) returned expression of *vraDE* to wild-type levels. 2H analysis revealed that BraDE interacts directly with NsaRS *in vivo*, but not VraDE.**Conclusions:** The ability of VraDE alone, but not BraDE alone, to confer high-level NIS resistance when overexpressed *in trans* in SH1000 indicates that VraDE is solely responsible for NIS detoxification in acquired NIS resistance. The loss of VraDE expression in NIS-resistant strains deleted for *braDE*, and the direct interaction observed between BraDE and NsaRS *in vivo* implies that BraDE participates in transduction of the signal through NsaS that leads to VraDE overexpression.

Iron/Manganese Homeostasis Contribute to Mutagenesis during Acquisition of Hetero/Homo β-Lactam Resistance in Mrsa

Author Block:

M. Fatouuraei, L. Paz, R. R. Rosato, **A. E. ROSATO**; Houston Methodist Res. Inst., houston, TX

Abstract Body:

Background: Methicillin-resistant *Staphylococcus aureus* (MRSA) remains a major public health problem and a therapeutic challenge. The majority of MRSA strains display a Hetero-resistant (HeR) phenotype (mix of cells expressing low (HeR) or high (HoR) levels of resistance). We previously demonstrated that exposure of HeR-MRSA to β-lactams leads to important perturbations in cell wall/division machinery that require of metabolic adaptations that, as a by-product, stimulate intracellular production of reactive oxygen species (ROS). Furthermore, we found that oxidative damage and iron/manganese homeostasis are associated with ROS production which constitute major drivers of mutagenesis that, together with metabolic signal pathways and cell wall adaptations, favor the survival of HeR-MRSA in presence of β-lactams.**Methods:** The mechanistic role of Fe(II) and Mn(II) during oxidative stress induced by exposure to β-lactams were analyzed in cells grown in Fe-repleted conditions ± OXA. In the case of Mn, cells were supplemented with Mn(II). The role of Fur regulator in sensing iron during β-lactam-mediated HeR/HoR selection was determined using a *fur* mutant. Gene expression analysis was performed by RNA-Seq; ROS production was measured by fluorescence (dihydrorhodamine 123, DHR123). Mutation frequencies for resistance to rifampicin and β-lactams were determined by E-test. ROS-induced DNA damage was investigated by Comet assay. **Results:** Blockade of ROS with iron chelators determined important effects during acquisition of β-lactam-mediated HoR phenotype. Growth and phenotypic analysis of MRSA-*Δfur::tet* strain ± OXA (0.5 μg/ml) showed a significant delay in growth, persistent levels of ROS production and increased mutation rate due to continuous intake of Fe and reduced expression of detoxifying KatA, SodA and SodM enzymes, while GraSR, a two component regulator of CAMP in *S. aureus*, showed a marked upregulation in cells repleted with Mn +OXA, increased expression of enzymes and reduced formation of ROS. **Conclusions:** Oxidative damage regulated by GraSR and iron/manganese homeostasis associated with ROS production are major drivers of mutagenesis that, together with both metabolic signal pathways and cell wall adaptations, favor the survival of MRSA.

Beta-Lactams (Bl) Plus Vancomycin (Van) Prevent Emergence of Van Resistance in *Staphylococcus aureus* (*S. aureus*) *In Vitro*

Author Block:

N. B. Singh[1], J. Yim[1], G. Sakoulas[2], M. J. Rybak[1]; [1]Wayne State Univ., Detroit, MI, [2]Univ. of California San Diego Sch. of Med., San Diego, CA

Abstract Body:

Background: Vancomycin (VAN) is a widely used antibiotic for treatment of Methicillin-resistant *S. aureus* (MRSA) infections and Methicillin-susceptible *S. aureus* (MSSA) infections in patients allergic to penicillin. Development of heterogeneous VAN-intermediate *S. aureus* (*h*VISA) and VAN-intermediate *S. aureus* (VISA) during VAN therapy has been reported, especially at subtherapeutic(STh) VAN concentrations. Although synergy between β-lactams (BL) and lipopeptides /glycopeptides has been demonstrated, there is little to no data on whether BL, combinations with VAN could prevent the emergence of VISA. Our objective is to determine if BL+VAN could prevent the emergence of VAN resistance in *S. aureus* under STh VAN exposure. **Methods:** RN 9120, a MSSA isolate with dysfunctional accessory gene regulator group II (*agr- II)* that is susceptible to VAN (MIC = 1 mg/L), was evaluated in vitro. The organism was exposed to STh VAN concentrations in a 1-compartment pharmacokinetic/pharmacodynamic (PK/PD) model, simulating human PK of VAN 200 mg q 12h over 72 h to induce resistance. At 72h, organisms recovered from the model were re-exposed to the same VAN regimen for an additional 72-144 h exposure to generate VISA. The same experiment was repeated with continuous infusion of cefazolin (CFZ) at 0.5x MIC (MIC= 0.25 mg/L). Changes in MIC were evaluated at the end of each 72 h exposure. A population analysis profile (PAP) was performed to evaluate for shifts in population susceptibility.**Results:** VAN MIC of RN 9120 increased to 4 mg/L as soon as 144h under STh VAN exposure. When CFZ was concomitantly infused at 0.5x MIC, VAN MIC increased to 2 mg/L at 72h. However, no further increase in MIC was noted up to 216h of STh VAN administration. PAP revealed a shift in the overall population towards non-susceptibility.**Conclusions:** The addition of low concentration of CFZ appears to prevent emergence of VISA under STh exposure to VAN. Further investigations with MRSA isolates are warranted using various BL combinations.

A Novel *erm*(44) Gene Variant From a Human *Staphylococcus saprophyticus* Isolate Confers Resistance to Macrolides, Lincosamides but not Streptogramins

Author Block:

V. Perreten, C. Strauss; Univ. of Berne, Berne, Switzerland

Abstract Body:

Staphylococcus saprophyticus, widespread in the environment, in animals and in humans, is a major cause of urinary tract infection and cystitis. Although macrolides and lincosamides are not used for the treatment of urinary tract infections, their general use may contribute to the selection of resistant bacteria of the normal human flora, including staphylococci from the skin. Genes conferring resistance to macrolide, lincosamide and streptogramin B (MLS_B) antibiotics in staphylococci have been associated with erythromycin ribosome methylase (*erm*) genes.One *S. saprophyticus* isolated from the skin of a healthy person was found to exhibit resistance to erythromycin (MIC 64µg/ml) and clindamycin (MIC >256µg/ml). Whole genome sequence (Ion Torrent technology) analysis of the isolate revealed the presence of a 23S rRNA methylase gene which belonged to the Erm(44) determinant based on the nomenclature of the MLS_B resistance genes. It showed 81% amino acid identity to Erm(44) of *S. xylosus* from bovine milk and 77% amino acid identity with Erm(44) of *S. saprophyticus* from environmental origin. The novel *erm*(44) variant differed for the two other *erm*(44) genes by the absence of a streptogramin B phenotype as demonstrated by cloning in vector pTSSCm-Pcap and expression in *S. aureus* RN4220 and after measurement of the MIC of pristinamycin Ia and virginiamycin S1. The *erm* gene was located on a putative 19’400-bp genetic island, which is absent in the MLS_B-susceptible strain *S. saprophyticus* KACC16562. It was flanked by two unrelated integrases and integrated at a specific 19-bp integration site (*attC*).This study revealed the presence of a novel *erm*(44) variant which does not confer resistance to streptogramin B antibiotics thus differing from all the other *erm* determinants described to date. The discovery of this novel *erm* gene emphasizes once again the role of staphylococci as a large reservoir of MLS_B resistance genes and their particular ability to acquire new genes through multifaceted mechanisms.

Detection and Characterization of a Novel Integron Gene Cassette in the Human Oral Metagenomic DNA That Confers Resistance to D-Cycloserine

Author Block:

M. Rahman, F. Kaiser, P. Mullany, A. P. Roberts; Univ. Coll. London, London, United Kingdom

Abstract Body:

Background: A PCR-based metagenomic approach was used to investigate the presence of integrons carrying antibiotic resistance genes (ARGs) in the oral cavity of healthy human individuals from the UK and Bangladesh. Integrons are gene capture and expression system which are known for their role in dissemination of ARGs in clinically important pathogens. Although the oral cavity is a reservoir of ARGs, no study has been carried out using metagenomic DNA to detect if these genes are part of integrons.**Methods:** Saliva samples were collected from healthy volunteers and metagenomic DNA was prepared. PCR primers were used to target the integrons and associated gene cassettes and a library of amplicons was constructed. These libraries were analysed using bioinformatic tools to detect the presence of putative antibiotic resistance genes. The genes of interest were sub-cloned into pHCMC05 (*Bacillus subtilis- E coli* shuttle vector) and pET28a (expression vector) to determine the minimum inhibitory concentration (MIC) of antibiotics in *B. subtilis* and to express and purify proteins for *in vitro* analysis of biological activities, respectively. MICs of antibiotics were determined using agar dilution method.**Results:** We identified two novel variants of an integron located D-alanine-D-alanine ligase gene (*ddl*) in the oral metagenomic library among other putative ARGs such as virginiamycin acetyl transferase (*vat*) and bleomycin binding protein. We observed that both constitutive and induced expression of the *ddl* variants confer high level resistance to D-cycloserine (DCS; MIC=256 µg/mL) in *Escherichia coli* and *Bacillus subtilis*. Over-expression of these genes significantly increases the cell-wall thickness of *B. subtilis* which confirms their role in cell-wall synthesis. Using paper chromatography and an inorganic phosphate detection assay we further confirmed the formation of D-ala-D-ala dipeptide in the reactions catalyzed by purified 6xHis-tagged Ddl and showed this was D-alanine specific. The reactions catalyzed by Ddl were also found to be inhibited by DCS in a dose-dependent manner.**Conclusions:** These results represent the first time that *ddl* has been found on an integron. Enzymatic characterization of Ddl showed that it is biologically active, inhibited by DCS and plays an important role in cell-wall synthesis.

Publishing Title:

Strain Dependent Genetic Networks for Antibiotic-Sensitivity in a Bacterial Pathogen with a Pan-Genome

Author Block:

T. van Opijnen, S. Dedrick; Boston Coll., Chestnut Hill, MA

Abstract Body:

The interaction between an antibiotic and bacterium is not merely restricted to the drug and its direct-target, rather antibiotic induced stress resonates through the bacterium, creating selective pressures that drive the emergence of adaptive mutations not only in the direct-target, but in genes involved in many different (fundamental) processes as well. Surprisingly, it has been shown that adaptive mutations do not necessarily have the same effect in all species, indicating that the genetic background influences how phenotypes are manifested. However, to what extent the genetic background affects the manner in which a bacterium experiences antibiotic stress, and how this stress is processed is unclear. Here we employ the genome-wide tool Tn-seq to construct antibiotic-sensitivity profiles for different strains of the bacterial pathogen *Streptococcus pneumoniae*. Remarkably, over half of the genes that are important for dealing with antibiotic-induced stress in one strain are dispensable in another. By confirming hundreds of genotype-phenotype relationships, probing potassium-loss, employing genetic interaction mapping as well as temporal gene-expression experiments we reveal genome-wide conditionally important/essential genes (antibiotic-induced weakest-links), we discover roles for genes with unknown function, and uncover antibiotic mode-of-action. Moreover, by mapping the underlying genomic network we encounter little conservation in network connectivity between strains as well as profound differences in regulatory relationships. Our approach uniquely enables genome-wide fitness comparisons across strains, enabling the discovery that antibiotic responses are complex events that can vary widely between strains, which suggests that the emergence of resistance may be strain specific and at least for species with a pan-genome less predictable.

Vancomycin Intermediate *Staphylococcus aureus*- Visa: It's Everywhere You Don't Want to Be

Author Block:

A. R. McMullen, M. Wallace, A. Shupe, C-A. Burnham; Washinton Univ. Sch. of Med., St Louis, MO

Abstract Body:

Background: At Barnes-Jewish Hospital, approximately 5% of the *Staphylococcus aureus* strains isolated from clinical specimens have a vancomycin-intermediate phenotype (VISA). Few studies that have examined the antimicrobial susceptibility profile of a large collection of VISA isolates.**Methods:** We evaluated the minimum inhibitory concentration (MIC) of a panel of antibiotics against 100 VISA and 50 vancomycin susceptible *S. aureus* (VSSA) isolates using the TREK microbroth dilution panel GPALL3F and gradient diffusion (Etest) assays. Isolates were characterized using a multiplex PCR to detect and differentiate SCC*mec* types I-IV. Additionally, PCR assays to detect high level mupirocin resistance (*mupA*) and chlorhexidine tolerance (*qacA/B*) were performed. Chart reviews were performed for patient demographics and source of each isolate.**Results:** The demographics of the patients and specimen source from which the VSSA and VISA isolates were not significantly different. Antimicrobial susceptibility profiling of the isolates is shown in Table 1. For vancomycin (VAN), VISA isolates had a mean MIC of 2.35 µg/ml with a range of 1-4 µg/ml. The VAN MIC50 and MIC90 for VISAs was also elevated at 2 µg/ml and 4 µg/ml, respectively. VISA isolates demonstrated increased MICs to daptomycin (DAP) but similar MICs against other drugs including ceftaroline (CPT) and linezolid (LZD). About 60% of the VSSA and VISA isolates were susceptible to methicillin (MSSA). Few isolates were *mupA* positive, but nearly 1/3 carried *qacA/B*, the gene associated with chlorhexidine tolerance.**Conclusions:** Using *SCCmec* typing, we are able to demonstrate that the isolates in our study are not clonal. There were relatively few differences in the patient demographics, specimen source and antimicrobial profile between VSSA and VISA isolates with the exception that VISA isolates had elevated MICs to cell-wall active agents including VAN and DAP.

	VSSA (n=50)	**VISA (n=100)**

Antibiotic Resistance Profiling and Panton-Valentine Leukocidin Gene Detection among *Staphylococcus aureus* from Nasal Passage of Hospital Staff in Haripur and Abbottabad Cities of Pakistan

Author Block:

M. A. Syed, Sr.[1], M. Rukan[1], H. Jamil[1], S. Ali[1], M. Gul[1], A. Khan[2], H. A. Bokhari[2]; [1]Univ. of Haripur, Haripur, Pakistan, [2]COMSATS Inst. of Information Technology, Islamabad, Pakistan

Abstract Body:

Background: *Staphylococcus aureus* is one of the most common causes of nosocomial infections. Health care professionals may also be a source of infection for those receiving treatment in hospitals or health care settings. It was a cross-sectional study carried out on health care staff of different hospitals of Hazara division during the period January 2015 to June 2015 to determine the nasal carriage of Methicillin resistant *Staphylococcus aureus* by Operation Theater and ward staff of different hospitals in Haripur and Abbottabad cities of Pakistan. Panton Valentine Leukocidin gene was also detection in the isolated strains using PCR.**Methods:** The samples were collected from the participants who were working in hospital for one or more than one year of time duration and cultured in microbiology lab at University of Haripur. Microbiological and biochemical tests were performed for *Staphylococcus aureus* confirmation. In order to determine antibiotic resistance of *S. aureus* by disc diffusion test, eight antibiotics were used including methicillin. Furthermore, multiplex PCR was performed to detect *mecA* and *pvl* genes.**Results:** A total of 206 samples were collected, out of that 167 (81%) samples were found positive for *S. aureus.* Majority of the strains (54%) were methicillin resistant, whereas large number of isolates showed resistance against all tested antibiotics (Ofloxacin= 34% (n= 57), Erythromycin=77% (n= 128), Doxycycline=21% (n=36), Lincomycin=70% (n= 117), Augmentin = 59% (n= 99), Ciprofloxacin= 37% (n= 62), Ciprofloxacin = 53% (n=88)). *Pvl* gene was present in 29% of the strains.**Conclusions:**The results of this study show high level of resistance against antibiotics. This study concludes that due to exposure of different antibiotics the resistant strains are emerging. It might be possible that the staff members are transferring MRSA to the patients and causing nosocomial infections.

Design And Evaluation Of SER-262: A Fermentation-Derived Microbiome Therapeutic For The Prevention Of Relapse In Patients With Primary C*lostridium difficile* Infection

Author Block:

J. Lachey, J. R. Wortman, M. J. Lombardo, K. D. Litcofsky, J. E. Button, C. L. Morse, M. Vulic, S. Sykes, K. Halley, C. McChalicher, J. Winkler, J. G. Aunins, M. R. Henn, D. N. Cook, J. M. Otero; Seres Therapeutics, Cambridge, MA

Abstract Body:

Background: Approximately 25% of patients relapse after a primary episode of *Clostridium difficile* infection (CDI) in part because antibiotic treatments do not repair the underlying dysbiosis of the gut microbiome. SER-109, an ecology of spore-forming bacteria from healthy screened stool donors, was effective in preventing CDI recurrence in a Phase 1b/2 study of subjects with a history of multiply recurrent CDI. Here, we present development of a second-generation microbiome therapeutic, SER-262, produced by *in vitro* fermentation of bacterial strains for the prevention of CDI recurrence in subjects with a primary episode. **Methods:** Microbes were selected based on relatedness to clades identified in SER-109, prevalence in healthy humans, spore-forming potential, and safety. Compositions of up to 15 strains were formulated to mimic the phylogenetic and functional diversity of SER-109. Compositions were evaluated in the CDI mouse model for efficacy in preventing body weight loss, clinical symptoms and death. **Results:** The 100+ compositions tested exhibited variable efficacy; however, the composition selected for clinical development as SER-262 exhibited robust and reproducible protection from CDI across experiments.

Table 1. Select data demonstrating SER-262 efficacy in the mouse CDI model

Treatment	**Endpoint**		
	Mortality (%)	**Body weight loss (mean ± SEM)**	**Maximum Clinical Score (Range 0-4; mean ± SEM)**
PBS control	40%	18.7% ± 2.6	2.8 ± 0.3
SER-262	0%***	1.3% ± 0.4**	1.0 ± 0.0**
Naïve (no CDI)	0%***	0.6% ± 0.2**	0.0 ± 0.0**

Study details: C57Bl/6 mice, n=10/group.
Body weight loss is calculated as the percent change relative to Day -1.
Maximum clinical score is a composite score of lethargy, posture, grooming, wet tail/abdomen

(indicative of diarrhea) and hypothermia, with a higher score denoting worsening clinical symptoms.
***$p \leq 0.001$ using a Fisher's exact test.
**$p \leq 0.001$ compared to PBS group using 1-way ANOVA with Fisher's LSD.

Conclusions: SER-262 is a novel, defined composition of spores designed as an oral Ecobiotic™ drug to prevent recurrence in patients with primary CDI. The composition is fermentation-based making it more amenable to very large-scale manufacturing. SER-262 was highly efficacious in the mouse CDI model and has been extensively characterized and the preclinical data support continued development into a Phase 1b clinical study.

Characterization Of Aurone X As A Potential Drug Candidate Against *cryptococcus Neoformans*

Author Block:

Y. Mohammed, D. Araujo, E. McClelland; Middle Tennessee State Univ., Murfreesboro, TN

Abstract Body:

Background: *Cryptococcus neoformans* is an opportunistic, fungal pathogen that can spread from the lungs to the central nervous system and cause life-threatening meningitis, most commonly in immune depressed individuals. Amphotericin B and fluconazole are the standard treatment; however, this has resulted in renal toxicity and resistant strains. The lack of safe, effective medication for treating cryptococcal meningitis is the motivation for identifying if Aurone X is a potential drug candidate by characterizing the compound's inhibition.**Methods:** A previous screen of an aurone library using the A27-M2 CLSI standard micro-dilution method identified aurone X, which showed >90% inhibition to *C. neoformans*. Toxicity assays conducted on rat L6 fibroblasts and human THP1 macrophages showed minimal toxicity. Additional tests were performed to determine aurone x's potential as a drug candidate. We characterized the minimum inhibitory concentrations (MIC) of aurone X in different medias, at different cell concentrations, with different serotypes and strains, and tested for synergy with Fluconazole, Flucytosine, and Amphotericin B.**Results:** Thirty-six extracts showed >90% inhibition of *C. neoformans* at 100 µM. Aurone X was selected for further characterization based on its low MIC and its low toxicity to THP1 macrophages and fibroblasts (>100 µM). Aurone X was found to inhibit *C. neoformans* in RPMI+MOPS, asparagine media, and YPD at 25,100, and >200 µg/ml respectively. The MIC's at cell concentrations of 10^3, 10^4, and 10^5 cells/ml were 25, 50, and 100 µg/ml, respectively. Clinical serotype A strains B18 and B45 had an MIC of 25 µg/ml each, and B58 had an MIC of 50 µg/ml. Serotype D strains 24067 and JEC21 both had an MIC of 25 µg/ml, and B3501 had an MIC of 50 µg/ml. Both strains of *Cryptococcus gattii*, R265 and R272, had MIC's of 50 µg/ml. Preliminary results suggest that aurone X is synergistic with all three drugs tested.**Conclusions:** Preliminary data on the inhibition of *C. neoformans* by aurone X suggests that it may be a potential drug candidate. This cannot be confirmed unless further tests are done including more experiments on synergy and a mouse challenge study. Based on aurone x's low toxicity and potential effectiveness at low dosages, aurone X could be a possible drug candidate against *C. neoformans* infections.

Novel Broad-Spectrum Antibacterial Agents with Activity Against Mdr Gram-Negative Pathogens

Author Block:

P. Picconi[1], C. Hind[2], M. E. Wand[2], M. J. Sutton[2], K. M. Rahman[1]; [1]King's Coll. London, Univ. of London, London, United Kingdom, [2]Publ. Hlth. England, Salisbury, United Kingdom

Abstract Body:

Background: Bacterial resistance to antibiotics is becoming a major global issue and the development of novel antimicrobial agents, especially active against Gram-negative pathogens, is an urgent priority. We developed a new class of DNA minor groove binder with good efficacy against multi-drug resistant (MDR) Gram-negative pathogens through modification of an existing scaffold that showed excellent activity against Gram-positive pathogens.**Methods:** The newly designed chemical entities were synthesized, using solution phase chemistry through a consolidated synthetic route. The activity of various compounds was assessed against several Gram-negative pathogens to determine the MIC (minimum inhibitory concentration). Lead compounds were further evaluated against several MDR isolates to determine their bactericidal/bacteriostatic mode of action through time-kill assays and the effect of efflux on activity was analysed using efflux pump inhibitors in an adapted MIC method. Compounds were also examined for their potential synergy with existing antibiotics using standard chequerboard assays.**Results:** To date, 30 compounds presenting three distinct structural modifications have been synthesized, showing good efficacy against several MDR Gram-negative pathogens with MICs in the range of 0.25-4 µg/ml. Tested strains included isolates of MDR *Klebsiella pneumoniae*, *Acinetobacter baumannii* and strains from the *Burkholderia cepecia* complex. Existing drug-resistance mechanisms appeared to have no influence over the compounds efficacy with MDR strains showing similar MIC levels to more antibiotic susceptible isolates. The MIC of some of the compound was decreased by the addition of efflux pump inhibitor PaβN and by the addition of the membrane permeabilizing agent PMBN. The compounds did not show significant toxicity against eukaryotic cell lines at the highest concentration tested.**Conclusions:** A new class of broad spectrum antibacterial agents belonging to the class of DNA minor groove binder has been developed and presents a good activity against a range of MDR Gram-negative pathogens. The microbiological data set provides the basis for further med-chem modification and lead optimisation to develop a broad spectrum antibiotic as a pre-clinical candidate.

Newly Synthesized Quinolinium Derivatives and Their Antimicrobial Effect

Author Block:

E. Kim, S-H. Lee, O-P. O-Pil Kwon, H. Yoon; Ajou Univ., Suwon, Korea, Republic of

Abstract Body:

Antibiotic resistant pathogens become a serious and urgent concern in public health due to an increase incidence of failure with existing antibiotics and the abuse of antibiotics facilitates the occurrence of a variety of Multi Drug Resistant (MDR) pathogens. Quaternary Ammonium Compounds (QACs) have been widely used as antimicrobial agents against a broad range of microorganisms. In this study, we tested the antibacterial activities of rationally designed quinolinium derivatives to compete against resistance toward current QACs. Minimum Inhibitory Concentration (MIC) of quinolinium derivatives was determined on several species of Gram-positive and Gram-negative bacteria using Alamar Blue redox indicator that exhibits a colorimetric change in response to cellular metabolic activity. Among fifteen quinoliniums synthesized, six compounds had antibacterial effects against Gram-positive bacteria showing MICs of 4.7 ~ 37.5 μg/ml and two of these six showed inhibitory activities to Gram-negative bacteria as well. Bacterial susceptibility to the quinolinium compounds was further verified with Kirby-Bauer disc diffusion method. The synergistic effect was tested and analyzed using a Fractional Inhibitory Concentration Index (FICI) with ampicillin. Among four tested quinoliniums, one compound showed an additive effect against Gram-positive bacteria. For the case of Gram-negative bacteria, three compounds showed an additive effect against *Salmonella-enterica* subsp. and one compound against Enterohaemorrhagic *E. coli*. These results would provide a possible aspect for designing future quinolone derivatives having antimicrobial effect against pathogenic bacteria.

Discovery of Three New Compounds Series Targeting Bacteria Peptidoglycan Glycosyltransferases (Pgt)

Author Block:

P. Warn[1], D. Kahne[2], S. East[3], A. Parkes[3], D. Corbett[1], M. Whittaker[3], F. Krieger[4], S. Walker[5]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Harvard Univ., Cambridge, MA, [3]Evotec (UK) Ltd, Abingdon, United Kingdom, [4]Evotec Ltd, Hamburg, Germany, [5]Harvard Univ., Boston, MA

Abstract Body:

Background: There is an urgent need for new antimicrobials to treat MDR infections. Multiple antimicrobials are in the pipeline but most have targets that have been extensively exploited. Moenomycin (Moe) is a potent inhibitor of Gram positive (Gm pos) and negative (Gm neg) bacterial PGTs. We used a Moe-based probe to identify inhibitors of PGTs, apply hit expansion, structure-based and biology techniques to progress novel inhibitors**Methods:** A Moe-based probe was used in a displacement fluorescence polarization (FP) HTS of Evotec and Harvard chemical libraries in 2 campaigns to identify inhibitors that bind to the invariant amino acid residues in the PGT active site. Following hit confirmation, secondary screens were performed incl. nephelometry, secondary FP and SPR binding assays. Hit series were pursued using medicinal chemistry and structural biology approaches. Optimisation was driven by toxicity, solubility and *in vitro* potency. MICs were performed against Gm pos and Gm neg isolates (incl. *E. coli* BW25113, JW5503-1 (ΔtolC::kan) and JW0452-3 (ΔacrA::kan) to determine the contribution of the major multi-drug efflux pumps and *E. coli* MC4100 and MC4100*imp4213* to determine the contribution of outer membrane permeability).**Results:** HTS screens of >460K compounds resulted in ~700 hits. Following profiling and additional selection 61 were followed up, resulting in 3 series progressing to medicinal chemistry expansion. Series 1 compounds have potent activity v Gm pos bacteria (*S. aureus* MICs <0.5µg/mL) and active highly active against MC4100*imp421.* Series 2 compounds have potent activity v Gm pos bacteria (*S. aureus* MICs <0.25µg/mL) and are highly active against the efflux pump mutants. Series 3 compounds have potent activity v Gm pos bacteria (*S. aureus* MICs <0.125µg/mL) and are active against wild-type Enterobacteriaceae (MICs <0.25µg/mL) and highly active against the efflux pump and outer membrane mutants**Conclusions:** We identified 3 novel series of inhibitors of bacterial PGTs that have potent activity against Gm pos bacteria, one series has promising activity against Gm negs. These studies support continued development of PGT for the treatment of MDR infections

Mouse Tolerability, Pharmacokinetics (Pk) and *In Vivo* Efficacy of Novel Compounds Targeting Bacteria Peptidoglycan Glycosyltransferases (Pgt)

Author Block:

P. Warn[1], D. Kahne[2], A. Parkes[3], M. Whittaker[3], F. Nutter Howard[1], J. Smith[1], S. Walker[4]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Harvard Univ., Cambridge, MA, [3]Evotec (UK) Ltd, Abingdon, United Kingdom, [4]Harvard Univ., Boston, MA

Abstract Body:

Background: Peptidoglycan (PG) is an essential structural macromolecule in the bacterial cell wall, assembled by membrane-bound glycosyltransferases and transpeptidases. Inhibition of synthesis of PG leads to bacterial lysis and death making it an attractive antimicrobial target. We have developed 3 series of PGT inhibitors with potent *in vitro* activity against Gm posbacteria (one series effective against Gm neg). Examples from all series were assessed in murine models for tolerability and PK; an example of one series was assessed in a mouse model of *S. aureus* sepsis**Methods:** Naïve male ICR mice were used. Compounds were formulated in 5% DMSO/10% cremophor/85% saline and dosed at 5-20mg/kg IV, SC or IP at 10mL/kg. For tolerability studies mice were observed for 24h compared to vehicle controls. For PK studies mice were treated IV and blood sampled by tail vein stab (~40µL/sample) at 10, 30, 60 and 240 min post dose. Bioanalysis was by LSMS-MS & data analysed in a non-compartmental model. For the efficacy study, mice were infected IP using *S. aureus* EMRSA 16. Mice were treated 1 & 5h post infection (PI) with 7.5mg/kg IP and the burden determined in IP wash & blood 9h PI, vancomycin (VAN) 10mg/kg IP was administered at the same times as a control**Results:** All compounds were well tolerated at the max deliverable dose with no adverse effects. Series 1 compounds dosed at 5 or 20mg/kg IV had T½ and Vdss of 0.7-1.5h and 2.4-11L/kg respectively. Series 2 compounds dosed at 10mg/kg IV had T½ and Vdss of 0.4h and 0.3L/kg. Series 3 compounds were dosed at 5 - 20mg/kg IV, SC or IP had T½ and Vdss of 0.7-0.9h and 0.6-1.6L/kg. Infected mice developed a robust infection with vehicle burdens of 6.0 and 6.1$\log_{10}$cfu/mL in wash and blood respectively. Treatment with a series 3 compound resulted in a reduction of burden in wash and blood of 0.45 & 2.14$\log_{10}$cfu/mL respectively, similar to VAN (1.2 & 2.0$\log_{10}$cfu/mL)**Conclusions:** All 3 series of PGT inhibitors were well tolerated following IV, IP or SC dosing. All series demonstrated acceptable PK parameters. A series 3 compound was highly effective in a murine model of *S. aureus* sepsis. These studies support continued development of PGT for the treatment of MDR infections

Antiviral Activity of Novel Di-Dabco Molecules on Non-enveloped Viruses

Author Block:

K. A. MELKONIAN, L. Chrastecka, E. Stirling; LONG ISLAND Univ., Brookville, NY

Abstract Body:

We have previously engineered novel DABCO (1,4-diazabicyclo[2.2.2]octane)-hydrocarbon molecules that display numerous antimicrobial properties when covalently bound to carbohydrate- or protein-based surfaces. Using a prokaryotic system, we have shown that specific novel DABCO-hydrocarbon cloths have the ability to reduce (>90%) the number of T4 bacteriophage virus particles available for infection after incubation. Using a plaque assay, we have shown that the cloth removes virus from the solution, rendering it incapable of infecting bacteria.DABCO-hydrocarbon surfaces have also been shown to prolong the life of MDCK (Madin-Darby canine kidney) cells that have been exposed to the influenza H3N2 virus. However, DABCO-hydrocarbons have shown little to no anti-viral activity against certain non-enveloped viruses, such as adenovirus. Therefore, di-DABCO variants of the surface modifications were prepared. Using fluorescence microscopy, one specific di-DABCO molecule (when covalently bound to cotton cloth) was shown to inhibit GFP-adenovirus infection of HeLa cells. We have shown that the spacing between the DABCO molecules is critical to the surface's antiviral activity. In addition, by neutralizing the charges on the DABCO molecule, we have shown that a charge interaction is responsible for the inhibition of viral infection. Therefore, a combination of DABCO-hydrocarbon and di-DABCO modifications applied to a surface will provide anti-bacterial, anti-fungal and anti-viral activity against a wide range of microorganisms. These surfaces may prove to be an invaluable first line of defense for our medical workers (hospital linens, scrubs, etc.) and for our armed forces (protective uniforms, wound dressings, etc.) in the future.

Developing Safer Polymyxins (Pms): Structure-Activity (Sar) and Structure-Toxicity (Str) Relationships of Modifications to Positions 6 and 7

Author Block:

K. D. Roberts[1], J. Wang[1], H. Yu[1], L. Wang[1], O. Lomovskaya[2], D. Griffith[2], S. Hecker[2], M. Dudley[2], P. E. Thompson[1], R. L. Nation[1], T. Velkov[1], J. Li[1]; [1]Monash Univ., Melbourne, Australia, [2]The Med.s Company, San Diego, CA

Abstract Body:

Background: PM B and colistin (COL) are last-line antibiotics for the treatment of multidrug-resistant (MDR) Gram-negative pathogens; however, their use is hampered by their potential for nephrotoxicity. The *N*-terminal fatty acyl chain and Dab residues have been implicated in nephrotoxicity. Unfortunately, modification of these structural regions has yet to deliver safer PMs with comparable efficacy. Using a novel medicinal chemistry approach, we substituted the residues at positions 6 (D-Phe^6/Leu^6) and 7 (Leu^7) with less hydrophobic amino acids (Thr, Ala, Val, Ser, Abu) and examined the SAR and STR of these modifications using animal models.**Methods:** Peptides were synthesized using solid-phase peptide synthesis. MICs were determined against a panel of 17 PM-susceptible ATCC and clinical MDR Gram-negative isolates (*Pseudomonas aeruginosa* (Pa), *Acinetobacter baumannii* (Ab), *Klebsiella pneumoniae* (Kp), and *Enterobacter cloacae*) using broth microdilution. Nephrotoxicity was investigated (accumulated dose 60 mg/kg for 24 h) in a mouse model and kidney histological examination was conducted. *In vivo* efficacy was evaluated against *Pa* ATCC 27853, Ab ATCC 19606, Kp M320455 at 4 h following a single intravenous bolus dose (4 mg base/kg) in a neutropenic mouse blood infection model.**Results:** Substitution of either or both the D-Phe^6/Leu^6 and Leu^7 with Thr, Ala, Val, Ser or Abu resulted in no observable kidney damage, compared to PM B and COL (mild to severe nephrotoxicity) in mice. While changes at position 7 retained antimicrobial activity, a minimum level of hydrophobicity (D-Leu^6) is required at position 6 to maintain comparable *in vitro* (MIC <0.125-2 μg/mL) and *in vivo* ($\Delta\log_{10}$ >-1 to -3) antibacterial activity to PM B and COL. Further modification, changing the stereochemistry of position 3 to the D-configuration nullified the decrease in the nephrotoxicity achieved by modifications at positions 7.**Conclusions:** PM nephrotoxicity can be modulated through substitution of position 7 with less hydrophobic residues without compromising antibacterial potency. Our lead peptides show potential for obtaining safer PMs, and are undergoing further preclinical evaluation.

Novel Isolate, Novel Compound - Lipopeptide from *Paenibacillus tyrfis* Mst1, a Malaysian Tropical Peat Swamp Soil Isolate

Author Block:

Y. Aw, C. Yule, Y. Cheow, S. Lee; Monash Univ. Malaysia, Selangor, Malaysia

Abstract Body:

Rapid emergence of antimicrobial resistance limits therapeutic options for infections by antimicrobial resistant bacteria (ARB). New antimicrobial compounds are needed to combat ARB related infections and scientists have shifted their attention towards exploration of unique, understudied ecosystem for novel compounds. Tropical peat swamps are examples of such ecosystems, with unique characteristics such as acidic pH, phenolic rich blackwater and constantly waterlogged substrate. Screening peat for antimicrobial producing bacteria yielded a novel species of *Paenibacillus* known as *Paenibacillus tyrfis* that exhibits broad spectrum antimicrobial activity against bacteria, yeasts and fungi. This study focused on characterization of the antimicrobial compounds and prediction of the structure of the compounds based on genome sequence analysis of *P. tyrfis* MSt1. The antimicrobial compounds were subjected to partial purification using reverse phase column chromatography and active fraction exerted strong antimicrobial activity against *Escherichia coli* ATCC 25922 (MIC = 1.5 µg/mL), MRSA ATCC 700699 (MIC = 25 µg/mL) and *Candida albicans* IMR (Institute Medical Research, Malaysia) (MIC = 12.5 µg/mL). Active fraction caused membrane rupture on *E. coli* ATCC 25922 when viewed with SEM. LC-MS analysis showed mass fragments with *m/z* of 1091, 1105 and 1119 together with base peak of *m/z* 678 which highly suggested the presence of lipopeptide compounds in the active fraction. Analysis of the genome of *P. tyrfis* MSt1 also revealed a lipopeptide biosynthetic gene cluster that is closely related to the biosynthesis of pelgipeptin, a lipopeptide produced by *Paenibacillus elgii* B69. Using the adenylation domain in the non-ribosomal peptide synthetase (NRPS) modules, the nonapeptide sequence of the lipopeptide was predicted to possess the following amino acid sequence; DAB-Val-DAB-Phe-Phe-DAB-Val-Phe-Ser where DAB stands for 2,4-diaminobutyric acid. This is the first lipopeptide compound with this amino acid sequence and strongly highlights the novelty of the lipopeptide compound produced by *P. tyrfis* MSt1. Further purification and identification of the lipopeptide compound will be performed in the future to accurately identify and characterize the lipopeptide compound.

A Novel Approach for Identifying Molecules with Activity Against New Targets in Bacteria

Author Block:

C. E. PETERS, A. Lamsa, J. Durrant, J. L. Garrido, R. Amaro, J. Pogliano, K. Pogliano; Univ. of California San Diego, La Jolla, CA

Abstract Body:

The emergence of multi-drug resistant bacteria and the decline in the number of new antibiotics coming to market poses a major global health threat. There is an urgent need to discover antibiotics that act by novel mechanisms of action (MOA). We have developed a rapid and versatile platform for identifying drugs that act by novel MOAs called Bacterial Cytological Profiling (BCP). BCP utilizes fluorescence microscopy to observe changes in cytological parameters of bacteria exposed to lethal concentrations of antibiotics. Antibiotics that hit targets in different pathways generate different cytological profiles. For novel drug targets, those for which there are currently no antibiotics, we have developed Rapid Inhibition Profiling (RIP), in which we generate cytological profiles by degrading essential proteins, providing a visual screen for antibiotics hitting novel targets. We have utilized RIP to obtain profiles of targets within a number of essential pathways in *Bacillus subtilis* and selected several proteins with novel profiles as targets for virtual screens. Here we combine BCP with a novel virtual screening approach that utilizes snapshots of target proteins extracted from state-of-the-art molecular dynamics simulations. We used simulation-based virtual screening to identify candidate molecules active against our selected novel drug targets and then determined the MOA of these compounds using BCP. We show that combining these approaches provides a rapid and efficient platform identifying molecules with activity against new targets in bacteria.

Publishing Title:

Adjunctive Use of Clavulanic Acid Abolishes the Cefazolin Inoculum Effect of Methicillin-Sensitive *Staphylococcus aureus* (MSSA) *in vitro*

Author Block:

W. R. Miller, K. V. Singh, C. A. Arias, B. E. Murray; Univ. of Texas McGovern Med. Sch., Houston, TX

Abstract Body:

Background: The inoculum effect (InE) refers to an increase in minimum inhibitory concentration (MIC) of an antibiotic when large numbers of organisms are present. In MSSA, this effect has been linked to the production of a staphylococcal type A β-lactamase (β-lac) and is associated with clinical failures of cefazolin (CFZ), which appears to be efficiently hydrolyzed by the enzyme. We investigated the ability of clavulanate, a β-lac inhibitor, to reverse the InE *in vitro*.**Methods:** Three *S. aureus* strains were used in this study ***i)*** ATCC 25923, a β-lac negative strain, ***ii)*** ATCC 29213, previously shown to produce small amounts of β-lac and ***iii)*** TX0117, a β-lac producing clinical isolate known to show the CFZ InE. MICs by broth microdilution at both standard inoculum (SI, 5 x 10^5 CFU/mL) and high inoculum (HI, 5 x 10^7 CFU/mL) were performed using Mueller-Hinton II media. CFZ alone and combined with amoxicillin/ clavulanate (AM/CL) at 0.5/0.125 µg/mL (1/16 MIC) and 1/0.25 µg/mL (1/8 MIC) were tested in triplicate for all three strains. We tested AM/CL together as it is a common co-formulation. Time-kill curves (TKC) for strain TX0117 were performed with CFZ (64 µg/mL) alone at SI and HI or in combination with AM/CL (1/8 MIC) at HI. Samples were taken at 0, 4 and 24 hours, centrifuged and washed to remove antibiotics and dilutions were plated for colony counts.**Results:** At SI, both β-lac producing stains had CFZ MICs in the susceptible range. At HI, CFZ MICs for both ATCC 29213 and TX0117 increased from 0.5 to 4 µg/mL and 1 to 128 µg/mL, respectively. Using HI, the addition of AM/CL at 1/16 MIC to CFZ reverted the CFZ MIC to 1 µg/mL. This effect was not seen with CFZ plus ampicillin (to control for possible synergism between β-lactams). In TKCs, CZF alone at HI resulted in a 0.7 log10 reduction at 4 hours before regrowth to a level similar to the antibiotic free control at 24 hours. In contrast, CFZ plus sub-MIC AM/CL at HI achieved killing similar to CZF at SI (2.86 log10 decrease from T=0) and a 4.5 log10 decrease at 24 hr compared to CFZ alone at HI; growth in sub-MIC AM/CL alone did not differ from the control.**Conclusions:** The use of sub-MIC AM/CL with CFZ abolished the InE of MSSA observed *in vitro*. In select MSSA infections where a high inoculum may be present, the addition of oral AM/CL to CFZ may theoretically offer protection against the InE.

Response of USA300 to Sub-Concentrations of Antibiotics

Author Block:

E. Torres-Sangiao[1], B. Cillero-Pastor[2], **M. Cartelle-Gestal**[3], H. G. Wiker[4], C. G. Riestra[1]; [1]USC, LCG, Spain, [2]Maastricht Univ., MST, Netherlands, [3]Univ. of Georgia, Athens, GA, [4]UiB, BGO, Norway

Abstract Body:

Staphylococcus aureus is a magnificent example of evolving pathogen and one of the most common causes of infections. Over the past decades CA-MRSA has emerge as an important pathogen. USA300 clone has the ability to infect healthy individuals due to its highly virulence. The aim was clarify the response against antibiotic pressure of the USA300 strain**Method:**USA300 cells were grown under ¼ & ½ MIC of LNZ, TGC, OXA & VAN (TSB, 37ºC, 250 rpm). The peptide mix from SDS-PAGE followed by in-gel trypsin digestion, were analysed by nLC-MS/MS Orbitrap. MaxQuant (*v*1.5.3.28) was used for protein identifications & LFQ intensities calculation. Multivariate analysis was performed by Perseus (*v*1.5.2.6). Missing values were imputed before normalization. *Z*-scoring was performed on columns and substract components on the first 3 principal components (PC). PCA was performed by singular value decomposition**Results:**The PC1, PC2 & PC3 represented the 52.2, 35.2 & 12.6 % (100 %) of variance, resp. (**Figure a**). The bi-plot (**Figure b**) shows the first 2 PC and 86 significant proteins by ANOVA test (**Figure c**)Control cells showed an up-regulation of purine and serineproteases biosynthesis pathway, as well as SaeS two-component System & Esa System, both involve in the establishment of infection and dispensable for laboratory growth.TGC & OXA showed a response to stress by up-regulation of proteins involved in pathogenesis (Coa & Sak, resp.) or biofilm formation (FnbB & PsmA1, resp.)**Conclusion:**PCA identified 4 patterns. LNZ did not lead relevant changes. VAN showed similar patterns to control. The major variability was observed with TGC & OXA.The results show that sub-MICs can lead to a strong mechanism of protection by USA300 against the used antibiotics.

Protective Efficacies of Tedizolid Phosphate, Linezolid, and Vancomycin in Rabbit Model of Mrsa Necrotizing Pneumonia

Author Block:

H. Le, V. Le, M. Pinheiro, K. Hahn, M. Dinh, B. Diep; Univ. of California, San Francisco, San Francisco, CA

Abstract Body:

Background: Linezolid has previously been shown to be superior to vancomycin in a rabbit model of necrotizing pneumonia because it inhibits *Staphylococcus aureus* from producing two key lung-damaging toxins, alpha-toxin and Panton-Valentine leucocidin. Herein we compared the protective efficacy of tedizolid phosphate, a second-generation oxazolidinone that potently inhibits *S. aureus* protein synthesis, to those of linezolid, vancomycin, or saline in the same model. **Methods:** Using a well-characterized rabbit model of necrotizing pneumonia with the USA300/SF8300 strain, 48 infected rabbits were randomized into 1 of 4 groups that were administered the following treatment regimens at 1.5 h post infection: 1) 6 mg/kg tedizolid phosphate [TR-701 FA] intravenously twice daily, 2) 50 mg/kg linezolid subcutaneously three times daily; 3) 30 mg/kg vancomycin intravenously twice daily; and 4) 5 ml saline intravenously twice daily. Animals were monitored every 2 h for the first 30 h postinfection, and every 6 h thereafter until 48 hours for mortality. Animals with profound pulmonary dysfunction (respiration rate >75, cyanosis, and cough) were euthanized for humane reasons.**Results:** The rabbit dosing regimen of 6 mg/kg tedizolid phosphate IV BID, which yielded $AUC_{0\text{-}24h}$ values approximating those in humans, was used. Survival of rabbits treated with 6 mg/kg tedizolid phosphate BID was similar to those treated with 50 mg/kg linezolid TID (10/12 vs. 10/12, P=0.98), but was significantly improved compared to those treated with 30 mg/kg vancomycin BID (10/12 vs. 2/12, P=0.002) and saline (10/12 vs. 2/12, P=0.001) using two-sided log-rank (Mantel-Cox) test with Bonferroni correction for multiple comparisons. Bacterial count in lungs of rabbits treated with tedizolid phosphate was significantly decreased compared to those treated with saline (log_{10}CFU ± std dev of 6.3±1.3 vs. 8.1±1.1, P=0.010), although this was not significantly different from those treated with vancomycin (vs. 7.5±1.9, P=0.11) or linezolid (vs. 6.4±1.4, P=1.00) by nonparametric one-way ANOVA with Kruskal-Wallis test followed by Dunn's multiple comparisons test.**Conclusions:** Tedizolid phosphate, like linezolid, improves survival outcomes in a rabbit model of staphylococcal necrotizing pneumonia.

Evaluation of Vitamin D3 and Vitamin C in Cooperation with Doxycycline against *Borrelia burgdorferi* and *Borrelia garinii*

Author Block:

A. Goc, A. Niedzwiecki, M. Rath; Dr. Rath Res. Inst. BV, Santa Clara, CA

Abstract Body:

Background: Little is known about the anti-borrelieae activity of vitamins with commercially available agents against spirochetes of *Borrelia sp.* that cause Lyme disease. To better understand such cooperation, we studied the anti-bacterial efficacy of vitamin D3 and vitamin C (known for their antimicrobial activity) with doxycycline (one of the most frequently prescribed drugs for Lyme patients) against *Borrelia sp*. **Methods:** Doxycycline was tested in combination with vitamin D3, and with vitamin C for their *in vitro* effectiveness against vegetative (spirochetes) and dormant (rounded bodies, biofilm) forms of *Borrelia burgdorferi* and *Borrelia garinii* using dark field and fluorescence microscope. Synergistic antibacterial effect of these agents was evaluated at their MIC values and three dilutions above (2-6 X MIC) as well as three dilutions below their MICs (1/2-1/8 X MIC), according to checkerboard assays, and defined by fractional inhibitory concentration index. Additionally, a Student t-test statistical analysis was performed for further validation. All experiments were performed in triplicates. **Results:** The results showed that doxycycline in combination with vitamin D3 exhibits additive anti-spirochetal and amended anti-biofilm effects, whereas with vitamin C additive anti-spirochetal and amended anti-rounded bodies effect was observed. Although complete elimination of rounded forms and mature biofilm was not noted, tested combinations of agents greatly reduced viable organisms in term of qualitative effect. **Conclusions:** The data obtained from this *in vitro* study revealed that doxycycline in combination with vitamin D3 and vitamin C expresses compelling antibacterial action against examined species of *Borrelia*. This indicates that a commercially and widely used drug doxycycline may act with vitamins D3 and C and that these vitamins may serve as an important addition to treatment of Lyme disease bacteria.

Evaluation of the Antimicrobial Activity of Cetylpyridinium Chloride against Oral and Throat Flora

Author Block:

A. M. García[1], A. M. Aristizabal[2], I. P. Torres[2], O. M. Gómez[2], D. H. Cáceres[2], C. de Bedout[2], G. I. Mejía[2]; [1]Univ. de Antioquia, Medellín, Colombia, [2]Corporación para investigaciones Biologicas - CIB, Medellín, Colombia

Abstract Body:

Background: Quaternary ammonium salts such as cetylpyridinium chloride, act penetrating the cell membrane altering bacterial metabolism and inhibiting cell growth (Ozdemir 2013; Liu 2013). This compound has shown a beneficial effect in reducing dental plaque as it has a broad spectrum of antimicrobial activity against bacteria and fungi found in the oral cavity that produce odor. The objective of this study was to assess the minimum inhibitory concentration (MIC) of cetylpyridinium chloride as an antimicrobial agent against some pathogens from oral and throat, and some microorganism common skin flora, such as Candida albicans (Ca), Streptococcus mutans (Sm), Streptococcus pyogenes (Sp), Haemophilus influenzae (Hi), Porphyromonas gingivalis (Pg), Fusobacterium nucleatum (Fn), *Actinomyces* israelii (Ai) and Prevotella loescheii (Pi). All microorganism tested were ATCC strains. **Methods:** Agar disk diffusion technique was employed, preparing cetylpyridinium chloride sensidiscs at different concentrations (0.125, 0.5, 2, 8 and 32 ug). As inhibition control different antibiotics sensidiscs specific for each microorganism were used (25 ug fluconazole - Ca, 10 ug ampicillin - Sm, Sp, and Hi, 5 ug ampicillin - Pg, 2 ug ampicillin - Fn, ampicillin 15 ug - Ai and 5 ug ampicillin - Pi). The incubation time and the inhibition zone read were performed according to the recommendations of the CLSI. The data were analyzed with the program GraphPad Prism version 4. t Student test was performed to determine statistically significant differences, with $p < 0.05$.**Results:** The inhibitory activity of cetylpyridinium chloride activity was evidenced from 0.5 ug in Sm; for Ca, Sp, and Pi from 8 ug; for Hi and Pg from 2 ug. In all organisms the inhibition zone diameter rise with increasing concentration tested, except for Ai which showed inhibition only in the highest concentration (32 ug) and in Fn where the inhibition was not observed. **Conclusions:** In conclusion, cetylpyridinium chloride exerted its antimicrobial power at low levels in almost all organisms tested except for A. israelii who needs higher concentrations and in F. nucleatum where not effect was observed.

Aminoglycosides and Triclosan for the Kill: Drug Synergism That Eradicates *Pseudomonas aeruginosa* Biofilms

Author Block:

A. M. A. Hunt, J. A. Gibson, C. M. Waters; Michigan State Univ., East Lansing, MI

Abstract Body:

Chronic infections caused by *Pseudomonas aeruginosa* are difficult to eradicate. As biofilms form, microbial cells protected by an exopolysaccharide matrix, and cells within the biofilm in a reduced metabolic state become tolerant to conventional antimicrobials. As a result, patients suffering from diseases like cystic fibrosis and diabetic foot ulcers have recurrent infections without the prospect of biofilm elimination. The search for new drugs is a long and costly process. Therefore, the identification of known biologically active compounds that exhibit synergistic effects with clinically used antibiotics represents an attractive approach to treat biofilms. A screen of over 6000 biologically active molecules identified 26 hits that exhibited synergistic activity when combined with tobramycin to kill *P. aeruginosa* biofilms while exhibiting no activity themselves. From these compounds, triclosan, known to have little to no effect against *P. aeruginosa* was selected for further investigation. High throughput assays combined with luminescence cell viability were used to test the killing effect of different concentrations of the compounds. Associations with other aminoglycosides and classes of antibiotics were evaluated, as well as their activity against different microorganisms. *In vitro* results demonstrated that in combination the antimicrobials killed nearly 100% of all strains of *P. aeruginosa*, including 19 clinical isolates, at the highest concentrations of 250 µg/mL tobramycin and 100 µM triclosan. Moreover, even at a 5-fold dilution 87% of the biofilm was eradicated with one dose. Synergistic effects were confirmed with other aminoglycosides and treated biofilms of *Burkholderia* spp also exhibited reduced cell viability. *In vivo* testing with a *P. aeruginosa* alginate-producing isolate showed a 3 log killing improvement with the dual treatment. The combination eradicated *P. aeruginosa fabI* mutant biofilms, the known target of triclosan, demonstrating that the killing effect is not a consequence of triclosan's inhibition of fatty acid production. The striking antimicrobial properties of aminoglycosides-triclosan both *in vitro* and *in vivo* is a promising approach to manage recalcitrant biofilms.

Antimicrobial Activity and Synergistic Combinations of Methyl Gallate with Antibiotics against Multidrug-Resistant Bacteria

Author Block:

F. K. Zeeshan[1], M. Yousuf[2], S. Faizi[2], S. u. Kazmi[3]; [1]Dow Univ. of Hlth.Sci., karachi, Pakistan, [2]HEJ Res. Inst. of Chemistry, Intl. Ctr. for Chemical and Biological Sci. (ICCBS), Univ. of Karachi, Karachi, karachi, Pakistan, [3]Dada Bhoy Inst. of Higher education, karachi, Pakistan

Abstract Body:

Objective: The main purpose of study is to check antimicrobial activity of Methyl gallate and its synergistic combinations with antibiotics against MDR (multi drug resistant) Bacteria.**Background:** Antibiotic resistance has now become serious health problem. Alternative treatment regime are needed to fight against MDR pathogens. Plants are used in herbal medicine since ages. Methyl gallate is a phenolic compound isolated from plant *Caesalpinia pulcherrima*, known to have antimicrobial activities. Therefore, Methyl gallate was choosen in this study. **Methods:** Methanol extract of fresh pods of *Caesalpinia pulcherrima* was subjected to bi phasic liquid separation which gave Hexane, Ethyl acetate, Butanol and Aqueous phases separately. Ethyl acetate phase was further fractionated , led to the isolation of a Methyl gallate. Minimum Inhibitory Concentration (MIC) of Methyl gallate was performed by micro broth dilution and tube dilution method. Synergistic combinations of Methyl gallate with Amoxycillin and Ciprofloxacin were determined by Fractional Inhibitory concentration index. **Results:** MIC of Methyl gallate (125-250µg/ml) against Methicillin Resistant Staphylococcus aureus, MDR *E. coli, P. aeruginosa, S. typhi, P. mirabilis, Acinetobactor spp,* ATCC *E.coli* 25922, and ATCC *S. aureus* 29213 . Synergistic combination of Ciprofloxacin and Methyl gallate showed fall in MIC from 512 µg/ml to 0.0312 µg/ml and 250 µg/ml to 15.6 µg/ml, respectively against MDR *E.coli*. Synergistic combination of Amoxycillin and Methyl gallate from 256µg/ml to 0.0625µg/ml and 250 µg/ml to 31.25µg/ml, respectively against MRSA. .**Conclusion:** Methyl gallate showed remarkable antimicrobial activity and synergistic combinations against MDR bacteria. Detailed pharmacological studies are required in order to use Methyl gallate as therapeutic agent in future.

Activity of Telavancin Tested against Gram-Positive Pathogens Isolated from Bone and Joint Infections in European (EU), Latin American (LATAM), USA and Asia-Pacific (APAC) Nations

Author Block:

R. N. Jones[1], J. I. Smart[2], R. E. Mendes[1]; [1]JMI Lab., North Liberty, IA, [2]Theravance Biopharma US, Inc, South San Francisco, CA

Abstract Body:

Background: Telavancin (TLV), a lipoglycopeptide, has broad activity against *S. aureus* (SA; MIC_{90}, 0.06 µg/ml), coag-negative staphylococci (CoNS; 0.06 µg/ml), β-hemolytic (BHS) and viridans group (VGS) streptococci (≤0.06 µg/ml) and vancomycin-susceptible (VAN-S) enterococci (0.12 µg/ml). TLV, as a candidate for osteomyelitis therapy, was tested against a worldwide collection of pathogens (940) isolated from bone-joint infections (BJI).**Methods**: A SENTRY Program collection of BJI strains (2011-2014) was tested by reference broth microdilution susceptibility (S) methods for TLV and 12 other agents including VAN, oxacillin, daptomycin (DAP) and teicoplanin (TPN). Data were analyzed by region (EU, LATAM, USA, APAC), patient age (≤17 and ≥18 years) and resistant (R) subgroups. Organism numbers tested were: SA (693), CoNS (117), BHS (93), VGS (37) and enterococci (65).**Results**: The most common pathogen was SA (73.7%; range 51.2% [APAC] to 79.1% [USA]), having a 35.7% MRSA rate and TLV $MIC_{50/90}$ of 0.03/0.06 µg/ml (100% S by USA-FDA/EUCAST breakpoint criteria). CoNS (12.4% of BJI) had TLV MIC $_{50/90}$ at 0.06/0.06 µg/ml (100.0% S), but 64.1 and 13.7% were MR CoNS and TPN-R, respectively. Monitored streptococci were 100% S to TLV (MIC_{90}, 0.03-0.06 µg/ml). Most BJI isolates were from USA (52.8%) followed by EU (24.7%), LATAM (13.3%) and APAC (9.1%). Only 12.5% of SA were observed in patients ≤17 years and 31.2% were MRSA (36.6% in adults). DAP-R strains (0.3%) were noted in USA, all MRSA in adults and TLV-S (≤0.12 µg/ml). Enterococci overall had TLV MIC $_{50/90}$ at 0.12/0.25 µg/ml, but VAN-S strains had TLV MICs at ≤0.12 µg/ml. All VRE had a VanA-phenotypes.**Conclusion**: TLV was active against all SA strains regardless of phenotype. Only VRE (all VanA) were not S to TLV (MICs, 0.25-2 µg/ml). TLV appears to be a viable candidate for BJI/osteomyelitis treatment caused by gram-positive cocci in adults and children.

	TLV MIC 50/90 by age and region:						
BJI Pathogen (no.)	**All (% S)**	≤17 yrs	≥18 yrs	USA	EU	LATAM	APAC

In Vitro* Synergistic Activity of Antimicrobial Agents in Combination against Clinical Isolates of Colistin-Resistant *Acinetobacter baumannii

Author Block:

S. Bae, T. Kim, S. Park, S-H. Kim, H. Sung, S-O. Lee, M-N. Kim, S-H. Choi, Y. Kim, J. Woo, Y. Chong; Asan Med. center, Seoul, Korea, Republic of

Abstract Body:

Background: Emerging resistance to colistin in clinical isolates of *Acinetobacter baumannii* is of growing concern. As the treatment options are extremely limited, we investigated *in vitro* activities of various antimicrobial combinations against colistin-resistant *A. baumannii*.**Methods:** 9 clinical isolates of colistin-resistant *A. baumannii* were collected in Asan Med. Ctr., Seoul, Korea between Jan 2010 and Dec 2012. To screen synergy, combinations of every double antimicrobial among 12 agents were tested using the multiple-combination bactericidal test (MCBT). Checkerboard tests were then performed to validate the existence of synergism.**Results:** On the MCBT, the most effective combinations were colistin-rifampin and colistin-teicoplanin as in both of these combinations 8 of 9 strains were inhibited. Colistin combined with aztreonam, meropenem, and vancomycin showed inhibition of growth on 7 strains. Colistin was the most common component of the antimicrobial combinations which were active against *A. baumannii*. Further checkerboard tests were conducted in colistin-based combination regimens. Notably, colistin-rifampin was fully synergistic (FICI ≤ 0.5) against all the 9 strains (100%). Glycopeptide or β-lactam containing combinations showed fairly successfully effects and the remaining regimens revealed limited synergism.**Conclusions:** Using MCBT and the checkerboard test, we found that colistin-based combination regimens, particularly with rifampin, glycopeptides or β-lactams, can offer a therapeutic benefit for infection caused by colistin-resistant *A. baumannii*.Table 1. Results of the checkerboard test for colistin-resistant A. baumannii

Agent	Synergy (FIC ≤ 0.5)	Partial synergy (0.5 < FICI <1)	Additive/Indifferent (1 ≤ FICI < 4)
CST + SAM	h	b,d,f,g,i	a,c,e
CST + RFP	a,b,c,d,e,f,g,h,i	-	-

Evaluation of Outcome for Empiric Treatment of *Escherichia coli* Bacteraemia with Piperacillin-Tazobactam or Cefuroxime

Author Block:

J. Knudsen, F. Jansåker, S. Thønnings; Depart of Clin Microbiol, Hvidovre Hosp., Hvidovre, Denmark

Abstract Body:

Background: In one of six hospitals in Copenhagen, the empiric antimicrobial treatment was changed due to high prevalence of ESBL-producing *Klebsiella pneumoniae*, and cephalosporins were avoid after January 2010. We wanted to study the outcome after bacteremia with *E. coli*, two years before and after 2010, in six hospitals, when using piperacillin-tazobactam (PT) and cefuroxime (XM). **Methods:** We retrospectively identified *E. coli* bacteremia patients in the Copenhagen area, 2008 to 2011. The ESBL-rate in *E. coli* in this period was 4-9%. Data on the empiric treatment, patient demographics, Charlson co-morbidity index (CCI), and 30 and 90 days all-cause mortality were retrieved, for patients treated with either PT of XM. The study was approved by the Danish authorities.**Results:** 1207 episodes were found, 228 and 979 cases, were treated with PT and XM, respectively. Before 2010, the patients treated with PT compared to XM, had higher 30 and 90 day mortality, i.e. 53% and 58% for PT, and 14% and 22% for XM ($p<0.01$). After 2010, the same figures were for PT 15% and 22%, and for XM 16% and 23%, respectively ($p's>0.8$). Among patients with ESBL-producing isolates, treated with PT 16% died, and for XM 18% died within 30 days ($p=1.0$). In the multivariate analyze of the 30 day mortality, no difference were seen between the two treatments, and mortality could only be correlated to high age, high co-morbidity, and to be hospital-associated or acquired.**Conclusions:** The higher 30 and 90 days mortality rate for PT treatment of *E. coli* bacteremia seen before 2010 (53% and 58%), where not predictive for outcome when PT was used more often (14% and 22%). We saw no differences in outcome for PT and XM for patients with ESBL-producing *E. coli*. In an area with low prevalence of resistance, no difference in outcome after *E. coli* bacteremia could be seen for PT and XM. Our results highlight the importance on the phenomenon confounding by indication.

Ceftaroline Fosamil Use in a National Health Care System

Author Block:

C. R. FREI[1], G. C. Lee[1], K. R. Reveles[1], **N. K. Boyd**[1], K. M. Sorensen[1], X. Jones[2], M. Bollinger[2]; [1]The Univ. of Texas at Austin and The Univ. of Texas Hlth.Sci. Ctr. San Antonio, SAN ANTONIO, TX, [2]The Univ. of Texas Hlth.Sci. Ctr. San Antonio and the South Texas Veterans Hlth.Care System, SAN ANTONIO, TX

Abstract Body:

Background: The United States (U.S.) has approved ceftaroline fosamil for acute bacterial skin and skin structure infections and community acquired bacterial pneumonia, but it is unknown how ceftaroline is being used in real-world settings and how adverse effects and mortality compare to clinical trials. The study objective was to describe ceftaroline use, adverse effects, and mortality in patients admitted to U.S. Veterans Health Administration (VHA) hospitals. **Methods:** This was a phase 4, population based, epidemiologic study of patients at least 18 years of age who received at least one ceftaroline dose within 14 days of admission at 69 VHA hospitals in 41 U.S. states/territories from 10/1/10 to 9/30/14. Data from VHA repositories were linked using a unique patient identifier. ICD9CM codes were used to determine diagnoses and adverse effects. Descriptive statistics were used to summarize patient demographics, adverse effects after 14 days of therapy, and patient mortality. **Results:** A total of 824 patients met study criteria. Patients were 97% male, 55% white, 26% black, 15% Hispanic, and 4% other/missing race, 61 years of age (median), with a Charlson score of 4 (median). Diagnoses included skin (39%), sepsis (34%), osteomyelitis (28%), diabetic foot (21%), pneumonia (17%), bacteremia (14%), endocarditis (8%), meningitis (3%), and device (2%) infections. Ceftaroline use was 37% first-line and 56% second-line. The typical patient received ceftaroline 3 days (median) after their hospital admission and for 5 days (median) in the hospital. Rates of eosinophilia, leukopenia, leukocytosis, fibromyalgia, myalgia and myositis, and polymyalgia were less than 1%. Rates of 30/60/90-day mortality were: overall (4/6/9%), skin (2/3/6%), sepsis (5/8/11%), osteomyelitis (4/5/7%), diabetic foot (2/2/5%), pneumonia (8/14/16%), bacteremia (6/10/12%), endocarditis (6/11/11%), meningitis (0/4/8%), and device (0/0/0%). **Conclusions:** Ceftaroline is used in VHA hospitals for many types of infections. Adverse effects and patient mortality are low, and comparable with rates from clinical trials. Additional studies are needed to compare these ceftaroline results to other drugs used in similar situations.

A Polymyxin Based Triple Combination Combats ST258 KPC-2 Producing *Klebsiella pneumoniae*

Author Block:

Z. P. Bulman[1], M. J. Satlin[2], B. Kreiswirth[3], J. B. Bulitta[4], C. B. Landersdorfer[5], J. R. Lenhard[1], V. Petraitis[2], T. J. Walsh[2], P. N. Holden[1], A. Forrest[6], R. L. Nation[5], J. Li[5], B. T. Tsuji[1]; [1]SUNY Buffalo, Buffalo, NY, [2]Weill Cornell Med., New York, NY, [3]Publ. Hlth.Res. Inst. Ctr., Newark, NJ, [4]Univ. of Florida, Orlando, FL, [5]Monash Univ., Melbourne, Australia, [6]Univ. of North Carolina, Chapel Hill, NC

Abstract Body:

Background: High bacterial density KPC-producing *K. pneumoniae* cause severe infections with excessively high mortality rates. Our objective was to identify an antimicrobial regimen capable of achieving bactericidal activity against a variety of clinical KPC-2 producing *K. pneumoniae* isolates.**Methods:** Four clinical KPC-2 producing *K. pneumoniae* isolates were used (Isolate, PMB/MERO/RIF MICs: 9A, 0.5/16/64; 24A, 0.5/64/>64; 27A, 1/32/>64; 5A, 64/32/64 mg/L) and each contained other β-lactamases concurrently. Static 48h time-kill experiments with polymyxin B (PMB) (6 mg/L), meropenem (MERO) (100, 200 mg/L), and rifampin (RIF) (3.5 mg/L) were conducted at a starting inoculum of 10^8 CFU/mL. A 10-day hollow fiber infection model (HFIM) was utilized to simulate human pharmacokinetic profiles at traditional dosage regimens for the triple combination at an inoculum of 10^8 CFU/mL. **Results:** In time-kill studies, PMB alone caused >3 $\log_{10}$CFU/mL killing within 6h against 9A, 24A and 27A but regrowth approaching growth controls occurred by 24h. PMB alone showed no killing activity against 5A. PMB (6 mg/L), MERO (100 mg/L), and RIF (3.5 mg/L) in combination displayed sustained bactericidal activity from 6h through 48h against 9A, 24A and 27A (Strain, 6h log reduction: 9A, -4.6; 24A, -8.3; 27A, -4.7). Against 5A, a combination of PMB 6 mg/L, MERO 100 mg/L and RIF 3.5 mg/L achieved -2.2 and -1.6 log reductions at 24 and 48h, respectively. This triple combination with MERO 200 mg/L instead of 100 mg/L achieved maximal bacterial reduction at 48h with a -5.0 log reduction against 5A. Among our 4 clinical isolates in time-kill experiments, PMB MIC predicted bacterial killing well. Regrowth in the HFIM occurred more rapidly than in time-kill studies although the PMB, MERO, and RIF triple sustained bactericidal activity longer than any double combination. **Conclusion:** Triple drug combination therapy using polymyxin B, meropenem and rifampin was bactericidal *in vitro* and may be of clinical utility in the fight against KPC-producing *K. pneumoniae*.

Empiric Meropenem versus Ceftazidime for Severe Community Acquired Pneumonia (SCAP)

Author Block:

N. G. Chua, **W. LEE**, Y. X. Liew, S. Tang, Y. Zhou, K. Patel, M. P. Chlebicki, A. L. Kwa; SINGAPORE GENERAL Hosp., SG, Singapore

Abstract Body:

Background: SCAP is associated with 67% mortality in Singapore. Empiric β-lactam plus macrolide or fluoroquinolone is recommended for SCAP in many guidelines but the most optimal regimen is not established. Locally, ceftazidime (CEF) or meropenem (MER) is preferred for melioidosis cover. We compare the outcomes between these 2 regimens. **Methods:** A single center, retrospective cohort study was performed from Jan 11 to Apr 15 on patients (18 years & above) with SCAP, requiring intensive care unit (ICU) admission & mechanical ventilation within 48 hours of admission. Collected data included demographics, clinical data, microbiological data & antibiotic use data. Primary outcome was overall mortality (OM) within 30 days. Secondary outcomes were CAP-related mortality (CM) & clinical response. Chi-Square, Fisher's Exact, Mann Whitney U, log-rank tests & Kaplan-Meier survival analysis were employed. Multivariate Cox regression was used to adjust for confounders. **Results:**59 patients received CEF while 41 received MER; median age was 64 (interquartile range, IQR 56-75) & 62 years (IQR 54-74) respectively. Age, gender, Charlson comorbidity index, APACHE II score, CURB-65 score & pneumonia severity index were similar for both groups. CEF was mostly paired with antipneumococcal quinolones (88%) while MER was paired with azithromycin (73%). 30-day OM was 63% & 29% for CEF & MER groups respectively (p=0.001) while 30-day CM was 34% & 22% respectively (p=0.195). Median time to OM for CEF was 7 days vs >30 days for MER (p<0.001) while median time to CM was not significantly different (p=0.071). After adjusting for confounders, age & immunocompromised state, CEF use was associated with greater OM - hazards ratio, HR 3.0 (95% CI: 1.5-5.8). After adjusting for concurrent bacteremia, CEF use was associated with greater CM - HR 2.5 (95% CI: 1.1-5.7). More patients on MER had antibiotic de-escalation after a median of 3 days (68% vs 32%, p<0.001) & recovered at the end of therapy (59% vs 29%, p=0.003). 22% of patients on CEF required escalation to a carbapenem. Length of hospital & ICU stay was similar for survivors in both groups. **Conclusions:** Empiric MER plus macrolide may be more effective than CEF plus fluoroquinolone in reducing early mortality among patients with SCAP. Prompt antibiotic de-escalation can be considered after 3 days if patients have adequate response.

Patient Outcomes with Complicated Intra-Abdominal Infections (cIAI) Caused by Gram-Negative Pathogens from IGNITE1: A Phase 3 Study to Evaluate the Efficacy and Safety of Eravacycline (ERV) versus Ertapenem (ETP)

Author Block:

J. Sutcliffe[1], A. Marsh[1], S. Izmailyan[1], L. Tsai[1], M. Castanheira[2], J. Solomkin[3], P. Horn[1]; [1]Tetraphase Pharmaceuticals, Inc., Watertown, MA, [2]JMI Lab., North Liberty, MA, [3]Univ. of Cincinnati Coll. of Med., Cincinnati, OH

Abstract Body:

Background: Eravacycline (ERV) is a novel, fully synthetic fluorocycline antibiotic of the tetracycline class with broad-spectrum activity. It is being developed for the treatment of serious infections, including those caused by MDR pathogens. ERV was evaluated in a phase 3, randomized, double-blind, multicenter study where patients with cIAI received either ERV (1.0 mg/kg IV BID) or ETP (1g IV QD). ERV demonstrated non-inferiority to ertapenem in the primary analysis (1). This analysis evaluated patient outcomes based on the resistant phenotypes and genotypes present in baseline Gram-negative pathogens.**Methods:** Baseline blood and cIAI specimens were obtained from all randomized patients. Susceptibility to study antibiotics and relevant comparators was determined by CLSI broth microdilution methods. Isolates of the same bacterial species from a single subject were evaluated by pulsed-field gel electrophoresis (PFGE) to assess genetic relatedness. Gram-negative aerobes resistant to any $3^{rd}/4^{th}$ generation cephalosporin and/or carbapenem were screened using published PCR conditions for narrow- and extended-spectrum β-lactamases (ESBL) and carbapenemases. Overexpression of chromosomal AmpC β-lactamases (↑AmpC) was evaluated.**Results:** 541 patients were randomized; baseline isolates were cultured from 446 patients. Following PFGE testing of 708 isolates, 1353 unique isolates were identified among the 446 patients. 151 Gram-negative isolates were tested for β-lactamase resistance mechanisms. CTX-M enzymes were the most common ESBLs among Enterobacteriaceae. KPC, IMP, VIM and OXA carbapenemases were detected.**Conclusions:** ERV was efficacious in patients with cIAI including those infected with difficult-to-treat Gram-negative pathogens.

IGNITE 1: Favorable Outcomes[1] (Clinical Cure at TOC in the micro-ITT Population) for Patients with Gram-Negative Pathogens		
Pathogen	**ERV**	**ETP**

Understanding the Inhibition of Mexb and Adeb Efflux Pump Transporters by PaβN

Author Block:

S. Jamshidi[1], J. M. Sutton[2], K. M. Rahman[1]; [1]King's Coll. London, London, United Kingdom, [2]Publ. Hlth.England, Salisbury, United Kingdom

Abstract Body:

Background: Multi drug (MDR) efflux transporters play key roles in bacterial pathogenicity and resistance to antibiotics. Agents that can inhibit the tripartite efflux pump systems, MexB, AcrB and AdeB, can play an important role in reviving antibiotics that have become resistant in a variety of Gram-negative pathogens. Computational approaches provide useful insight into the binding of inhibitors to the MDR efflux pumps and designing new inhibitors. We studied the interaction of PAβN with MexB and AdeB transporters both from *Acinetobacter baumannii* to explore the interactions that play key roles in inhibiting these transporters.**Methods:** The interaction of PAβN with MexB and AdeB transporters was explored using computational methods. The structures of the transporters were generated by homology modelling. After molecular docking of PAβN to the transporters, 50s molecular dynamics (MD) simulations combined with MM-PBSA/MM-GBSA were performed to understand the molecular interactions of PAβN with the binding pockets of the transporters.**Results:** Our results showed that PAβN passes through the multisite binding pocket of AdeB and MexB. The Phe-loop of the binding monomer guides the ligand, by shifting through the narrow channel to pass the proximal binding pocket, towards the distal binding pocket. Ser134, Thr668, GLn42 and Glu665 of AdeB and Ser132, Ser133, Ser135, Thr44, Phe618 and Thr668 of MexB formed hydrogen bonds with PAβN during the course of the simulation. MD simulations further showed that PAβN behaves like a climber; it uses Phe residues of the Phe-cluster as hooks to go forward in the channel, then it climbs and goes upward in distal binding pockets along the intramolecular channel of transporters. The differences in amino acid sequences in the binding site of the pumps dictate in the way PAβN interacts and inhibits these transporters by generating hydrophobic microenvironments with diverse strength in the binding site of different complexes.**Conclusions:** Information obtained from this study provides detailed insight into the interaction of PAβN with AdeB and MexB transporters in *A. baumannii*. This molecular interaction with the key residues within the binding pocket will contribute to the design of new effective and selective efflux pump inhibitors that could play key roles in reversing antimicrobial resistance.

A Reducing Cell-free *In Vitro* Expression System to Generate High Quantities of Antibacterial Microcin S

Author Block:

C. Auerbach[1], K. Zimmermann[2], F. Gunzer[1]; [1]TU Dresden, Med. Faculty 'Carl Gustav Carus', Dresden, Germany, [2]SymbioPharm GmbH, Herborn-Hörbach, Germany

Abstract Body:

The number of infections caused by antibiotic resistant bacteria is vastly increasing. Often, conventional antibiotics don't make an impact anymore. Therefore, detection of so far unknown antimicrobial substances is required. The probiotic *Escherichia coli* G3/10, a component of the drug Symbioflor2, is producing such an antibacterial peptide, called microcin S (MccS). To investigate its antibacterial spectrum and mode of action in more detail quantitative amounts of biologically active MccS are needed. Since recombinant intrabacterial expression delivered no sufficient concentrations - due to its assumed toxicity - a bacteria based but cell-free *in vitro* expression system was set up and optimized. This system consists of a cell extract of *E. coli* BL21 Rosetta 2(DE3), a fructose-1,6-bisphosphate based energy buffer enriched with ATP and NAD, amino acids and template DNA encoding either a carboxy- or an amino-terminally 6 x His-tagged or an untagged microcin S (*mcsS*). Linear templates were generated by a new three round PCR technique with primers containing all up- and downstream elements required for efficient protein expression. Cloning of linear amplicons into pUC19 provided circular templates. To improve protein folding, any reducing substances were excluded from the reaction mixture. The impact on antimicrobial activity was analyzed after MccS samples were treated with oxidizing glutathione. Performance of MccS synthesis was measured by dot blot followed by immune detection. Activity of MccS was determined by performing an agar-diffusion assay against sensitive strains. Best *in vitro* expression rates could be achieved by using circular DNA templates in combination with a concentrated cell extract. However, antibacterial activity could only be detected when the C-terminus of MccS is tag-free. Presence of the MccS signal peptide didn't cause any influence on expression rate and activity. Biological activity was improved by treating the samples with glutathione. The results confirm that we were able to develop a system to produce high yields of active MccS *in vitro* under reducing conditions to improve formation of disulfide bonds necessary for proper folding. MccS concentrations reached with this system are sufficient to get better insight into its structure and mode of action.

Isolation of *Shigella* Cross-Reactive Environmental Bacteria as Potential Shigellosis Live Vaccine Candidate Strains

Author Block:

N. Azmuda[1], R. Bilkis[1], S. I. Khan[2], N-K. Birkeland[3]; [1]Jahangirnagar Univ., Dhaka, Bangladesh, [2]Univ. of Dhaka, Dhaka, Bangladesh, [3]Univ. of Bergen, Bergen, Norway

Abstract Body:

Background: Shigellosis is recognized as an endemic disease worldwide**,** including Bangladesh and one of the most common causes of morbidity and mortality among children. Approximately 125 million shigellosis cases and 14,000 related deaths occur annually in Asia. There is a strong need for a shigellosis vaccine, particularly because of the global emergence of antibiotic-resistant shigellae strains. Protective immunity against shigellosis is serotype specific and directed against the surface lipopolysaccharide antigens. At present, no effective vaccine against *Shigella* infection exists. Noninfectious bacterial genera sharing common surface antigens with *Shigella* spp. could be potential vaccine candidates for combating shigellosis. **Methods:** A number of serologically cross-reactive environmental bacteria were isolated by an immunocapturing technique using group specific polyvalent *Shigella*-antisera. The isolates were identified and characterized by cultural and biochemical properties, 16S rRNA gene sequencing and Western blot analysis.**Results:** Environmental isolates of *Aeromonas veronii*, *Enterobacter cloacae*, *Escherichia coli*, *Klebsiella pneumoniae*, *Stenotrophomonas maltophilia* and *Plesiomonas shigelloides* showed cross-reactivity with a number of group- and type-specific *Shigella* antisera due to sharing of common surface proteins and/or LPS. *Aeromonas veronii* and *Enterobacter cloacae* cross-reacted with *Shigella boydii* type 16 and 15 monovalent antisera, respectively, through reaction with O-antigens, thus revealing a type of inter-species cross-reaction not reported earlier. Many of the isolates showed cross-reactivity with more than one group of type-specific *Shigella*-antisera due to the presence of immunogenic proteins. However, *Plesiomonas shigelloides* were cross-reactive with *Shigella sonnei* phase I monovalent antisera only due to immunogenic LPS.**Conclusions:** This study revealed that important *Shigella* spp. surface antigens are shared by a number of environmental bacteria. Naturally occurring environmental bacteria expressing surface lipopolysaccharide antigens specific for certain types of *Shigella* could be a good choice for vaccine candidates against shigellosis.

***In Vitro* Activity of Wck 4873 (Nafithromycin) Against Resistant Subsets of *Streptococcus pneumoniae* from a Global Surveillance Program (2014)**

Author Block:

D. J. Farrell, H. S. Sader, P. R. Rhomberg, R. K. Flamm, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: WCK 4873 (INN: Nafithromycin) is a novel lactone ketolide, currently in clinical development for the treatment of community acquired bacterial pneumonia (CABP). WCK 4873 has completed SAD and MAD Phase 1 studies in Europe and an intra-pulmonary pharmacokinetic study in USA. WCK 4873 was awarded QIDP status in 2015. In this study, WCK 4873 was tested against contemporary *Streptococcus pneumoniae* (SPN) clinical isolates (including resistant subsets) collected in medical centers worldwide as part of the 2014 SENTRY Antimicrobial Surveillance Program.**Methods**: A total of 1,911 SPN, were tested for susceptibility (S) against WCK 4873 and multiple comparator agents by reference broth microdilution methods and interpretive criteria. Number of isolates by geography (country or region) were as follows: USA (712), Europe (698, 23 countries), Asia Pacific (251, 8 countries) and Latin America (250, 11 countries).**Results**: Against all 1,911 SPN, WCK 4873 was very active ($MIC_{50/90}$, 0.015/0.06 µg/mL) with all strains inhibited at MIC values ≤0.25 µg/mL (Table). Telithromycin (TEL) S (CLSI/EUCAST) rates were 99.9/89.3% and WCK 4783 was up to eight-fold more potent than TEL ($MIC_{50/90}$, 0.015/0.5 µg/mL). Using the EUCAST S breakpoint for TEL of ≤0.25 µg/mL, 204 strains were non-S to TEL and all 204 strains demonstrated WCK 4873 MIC values of ≤0.25 µg/mL ($MIC_{50/90}$, 0.06/0.12 µg/mL). WCK 4873 was four-fold less active against penicillin (PEN) -intermediate and -resistant (R) strains compared to PEN-S strains with WCK 4783 $MIC_{50/90}$ values of 0.06/0.12, 0.06/0.12 and 0.015/0.03 µg/mL, respectively. Ceftriaxone (CRO) non-S was 9.3% using CLSI non-meningitis breakpoints. Erythromycin (ERY) R was 37.9%, and 19.7% were R to clindamycin (CLI). WCK 4783 retained good activity against ERY-R/CLI-S strains ($MIC_{50/90}$, 0.03/0.06 µg/mL) and ERY-R/CLI-R strains ($MIC_{50/90}$, 0.03/0.12 µg/mL).**Conclusions**: WCK 4873 demonstrated potent activity against contemporary (2014) global SPN isolates and retained good activity against strains with lower activity to TEL (including 204 strains non-S by EUCAST breakpoints), PEN, CRO, ERY, and CLI.

WCK 4873 (Nafithromycin): *In Vitro* and *In Vivo* Activity of Novel Lactone-Ketolide, against Clinically Relevant *S. pneumoniae* (SPN) Resistotypes and Methicillin-Sensitive *S. aureus* (MSSA)

Author Block:

J. S. Satav, S. S. Takalkar, A. M. Kulkarni, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 4873 is a lactone-ketolide (Phase 1 studies completed in US, Europe) with a broad spectrum activity against respiratory-tract pathogens (RTI). WCK 4873 is characterized by its potent activity against macrolide and ketolide resistant SPN. Herein, we describe *in vitro* and *in vivo* activity of WCK 4873 against key RTI pathogens. **Methods:** WCK 4873 MICs were determined for six SPN strains (resistotypes: *ermB*, *mef*, *ermB+mef*, L4+L22) and two MSSA. MICs were determined employing agar dilution methods (Medium: MHA + 5% sheep blood). *In vivo* efficacy ($ED_{50/90}$) was determined through murine peritonitis model. Mice were intraperitoneally infected ($5x10^7$-$2x10^8$ CFU/mL) and oral treatment (twice-daily) was initiated 1h post-infection. $ED_{50/90}$ values were calculated by probit analysis. PK studies were carried at the corresponding efficacy doses. Mouse serum drug concentrations were estimated by LCMS-MS method.**Results:** WCK 4873 MICs for various RTI pathogens ranged from 0.007-0.5 µg/mL, while telithromycin MICs were 0.015-8 µg/mL. *In vivo*, ED_{50} for WCK 4873 ranged from 0.59-27.2 mg/kg while ED_{90} ranged from 0.79-35 mg/kg (table). ED_{90} values of telithromycin ranged from 3.3->150 mg/kg. Mouse 24h serum exposures ($fAUC_{0-24}$) at doses 50 and 100 mg/kg were 1.0 and 2.5 µg.h/mL respectively.

Organism (Resistance mechanism)	WCK 4873 MIC (µg/mL)	ED_{90} (mg/kg)
SPN ATCC 49619 (WT)	0.015	3.1
SPN 772 (*mef*)	0.06	31.1
SPN 3591 (*ermB*)	0.007	11.8
SPN 3773 (*ermB*)	0.5	35.0
SPN 1179 (*mef+ermB*)	0.12	8.32
SPN 6683 (Mutations in L4 and L22)	0.03	15.5
MSSA ATCC 25923	0.06	6.2

MSSA 5044	0.06	11.8

Conclusion: WCK 4873 (Nafithromycin) provided promising therapeutic effect against both SPN expressing diverse clinically relevant resistance mechanisms and MSSA at significantly low doses.

Publishing Title:

Activity of Novel Oxazolidinone Tedizolid against Clinical Gram-Positive Pathogens Collected from Canadian Hospitals: CANWARD 2013-15

Author Block:

A. R. Golden[1], H. J. Adam[2], M. Baxter[1], K. A. Nichol[2], B. Weshnoweski[2], R. Vashisht[1], S. Biju[1], J. A. Karlowsky[2], D. J. Hoban[2], G. G. Zhanel[1], The Canadian Antimicrobial Resistance Alliance (CARA); [1]Univ. of Manitoba, Winnipeg, MB, Canada, [2]Diagnostic Services Manitoba, Winnipeg, MB, Canada

Abstract Body:

Background: The novel oxazolidinone tedizolid (TZD) has been approved for the treatment of acute bacterial skin and skin structure infections. TZD demonstrates high antibacterial potency, and is active against Gram-positive pathogens including methicillin-susceptible and -resistant *Staphylococcus aureus* (MSSA/MRSA). TZD demonstrates numerous positive attributes, including 6-day short course therapy, once daily oral or intravenous dosing with no requirement for dose adjustment across a range of patient factors, a low potential for drug-drug interactions and a well-tolerated safety profile. Currently, TZD is being evaluated in Phase 3 trials for the treatment of hospital-acquired and ventilator-associated bacterial pneumonia.**Methods:** Beginning in January 2013, Canadian hospital laboratories (15 sites in 2013, 13 sites in 2014 and 2015) were asked to submit consecutive pathogens from blood, respiratory, urine and wound infections as part of the CANWARD 2013, 2014 and 2015 studies. Antimicrobial susceptibility testing was performed in accordance with CLSI guidelines.**Results:** The table below demonstrates the activity of TZD (MIC, μg/mL) and select comparators against Canadian clinical Gram-positive pathogens tested to date during CANWARD 2013, 2014 and 2015 studies:

Organism (n)	TZD Susceptibility*			TZD MIC_{50}/MIC_{90}	TZD Range	Comparators (MIC_{50}/MIC_{90})			Fold Reduction in TZD MIC_{50}/MIC_{90} vs. LZD MIC_{50}/MIC_{90}
	%S	%I	%R			LZD	VAN	DAP	
MRSA (417)	99.7	0.3	-	0.25/0.25	0.12-1	2/2	0.5/1	0.25/0.5	8/8
HA-MRSA (248)	99.4	0.6	-	0.25/0.5	0.12-1	2/2	1/1	0.25/0.5	8/4

CA-MRSA (169)	100	-	-	0.25/0.25	0.12-0.5	2/2	0.5/1	0.25/0.5	8/8
MSSA (1,857)	100	-	-	0.25/0.25	0.06-0.5	2/2	0.5/1	0.25/0.5	8/8
S. epidermidis (200)	NA	NA	NA	0.12/0.12	0.06-0.5	0.5/1	1/2	0.25/0.25	4/8
E. faecalis (309)	100	-	-	0.25/0.25	0.12-0.5	2/2	1/2	1/2	8/8
VAN-resistant *E. faecium* (25)	NA	NA	NA	0.25/0.5	0.12-2	2/4	>32/>32	2/2	8/8
VAN-susceptible *E. faecium* (107)	NA	NA	NA	0.25/0.5	0.12-0.5	2/2	0.5/1	2/2	8/4
S. agalactiae (178)	100	-	-	0.25/0.25	≤0.03-0.25	1/2	0.5/0.5	0.25/0.25	4/8
S. pneumoniae (481)	NA	NA	NA	0.12/0.25	≤0.03-0.5	1/2	0.25/0.25	0.12/0.12	8/8
S. pyogenes (137)	100	-	-	0.25/0.25	≤0.03-0.25	1/2	0.5/0.5	0.12/0.12	4/8
*, Interpretive breakpoints defined by FDA; S, susceptible; I, intermediate; R, resistant; NA, breakpoints not available; HA, healthcare-acquired; CA, community-acquired; LZD, linezolid; VAN, vancomycin; DAP, daptomycin.									

Conclusion: Based on MIC_{50} and MIC_{90} values, TZD demonstrated four- to eight-times greater activity than LZD and greater potency than VAN versus Gram-positive organisms isolated from Canadian hospitals in the surveillance period. TZD also demonstrated equal or greater potency than DAP against *Staphylococcus* and *Enterococcus* spp. The highest recorded MIC value for TZD was 2 μg/mL in a VAN-resistant *E. faecium*.

Comparison of *In Vitro* Susceptibility Testing of Tedizolid (Tzd) and Linezolid (Lzd) Against Isolates of Nontuberculous Mycobacteria (Ntm)

Author Block:

B. A. Brown-Elliott, J. V. Philley, D. E. Griffith, **R. J. Wallace, Jr.**; Univ. of Texas Hlth.Sci. Ctr. at Tyler, Tyler, TX

Abstract Body:

NTM are responsible for infections including respiratory, cutaneous, and disseminated disease. Most clinically relevant species of NTM are multidrug resistant, and there is a paucity of antimicrobials with efficacy against these organisms. Multiple species of NTM have been shown to be susceptible to LZD, the first commercially available oxazolidinone. TZD is a new oxazolidinone with improved *in vitro* and intracellular potency against *Mycobacterium tuberculosis,* including multidrug resistant strains, and some species of NTM compared with LZD. Using the current Clinical and Laboratory Standards Institute (CLSI) recommended method of broth microdilution, susceptibility testing of 170 isolates of rapidly growing mycobacteria (isolates of *M. fortuitum*, *M. smegmatis, M. mucogenicum, M. chelonae,* and *M. abscessus* complexes) showed equivalent or lower (1- to 8-fold MIC_{50} and/or MIC_{90} values) MIC_{90} values for TZD compared to LZD. The TZD MIC_{90} for *M. abscessus* subsp. *abscessus* (n=81 isolates) and *M. abscessus* subsp. *massiliense* (n=12) was 8 μg/mL and 4 μg/mL, respectively, compared to a LZD MIC_{90} of 32 μg/mL for both. The MIC_{90} for *M. fortuitum* (n=20) was 2 μg/mL for TZD and 4 μg/mL for LZD. *M. chelonae* (n=22) had TZD and LZD MIC_{90} values of 2 μg/mL and 16 μg/mL, respectively. Slowly growing NTM (n=148), including 7/7 *M. marinum*, 7/7 *M. kansasii*, and 128/128 of other less commonly isolated species had TZD MIC values ≤1 μg/mL and LZD MIC values ≤8 μg/mL. Less than 10% of *Mycobacterium avium* complex isolates (n=100) and *M. simiae* isolates (n=8) had TZD MIC values ≤1 μg/mL or LZD MIC values ≤8 μg/mL. *M. arupense* (n=9 isolates) had MIC_{50} values of 4 μg/mL and 16 μg/mL for TZD and LZD, respectively. These findings demonstrate greater *in vitro* potency of TZD than LZD against NTM and suggest that evaluation of TZD as a potential treatment agent for infections caused by selected NTM is warranted.

Publishing Title:

***In Vitro* Activity of Tedizolid Against Gram-positive Pathogens Isolated from Patients with Skin and Skin Structure Infections in the United States and Europe (2014-2015)**

Author Block:

D. J. Farrell, R. E. Mendes, R. K. Flamm, R. N. Jones; JMI Lab., North Liberty, IA

Abstract Body:

Background: Tedizolid (TZD) is approved for treatment of acute bacterial skin and skin structure infections (ABSSSI) in the United States (USA), European Union (EU), and Canada. The*in vitro* activity of TZD was tested against Gram-positive pathogens isolated from patients with SSSIs collected in 2014 and 2015 as part of an ongoing resistance surveillance program. **Methods:** Non-duplicate, single-patient SSSI clinical isolates (USA/EU) of *Staphylococcus aureus* (SA; 3019/1778), coagulase-negative staphylococci (CoNS; 159/283), β-hemolytic streptococci (BHS; 384/231), and enterococci (ENT; 233/328) were tested for antimicrobial susceptibility (S) as per CLSI guidelines. MIC values for TZD and linezolid (LZD) were read both at (1) the first well where trailing begins (80% read; TZD80 and LZD80) as per CLSI M07-A10 and (2) at no-growth endpoint (100% growth inhibition; TZD100 and LZD100). USA-FDA and EUCAST breakpoints were used to determine %S.**Results:** TZD activity ($MIC_{50/90}$/Range/%S) was similar for isolates obtained from USA or EU (Table). For SA, 100.0% of isolates were S to both LZD and TZD, and TZD was four- to eight-fold more potent than LZD. For 442 CoNS isolates, $MIC_{50/90}$ values for TZD80 and TZD100 were 0.06/0.12 µg/mL and 0.12/0.25 µg/mL, respectively, and for LZD80 (100.0% S) and LZD100 were 0.5/1 µg/mL and 1/1 µg/mL, respectively. All 615 isolates of BHS (TZD80/100 MIC_{90}, 0.12/0.25 µg/mL; LZD80/100 MIC_{90}, 1/2 µg/mL) were S to TZD and LZD according to both EUCAST and USA-FDA-approved breakpoints. For 561 ENT isolates, the $MIC_{50/90}$ values for TZD80 and TZD100 were 0.12/0.25 µg/mL and 0.25/0.5 µg/mL, respectively, and for LZD80 and LZD100 were 1/1 µg/mL and 2/2 µg/mL, respectively. **Conclusion**: TZD had very potent activity against recent USA and European SSSI isolates of SA, CoNS, BHS, and ENT. In general, TZD80 MIC values (read as per CLSI M07-A10, 2015) were one doubling dilution lower than those read at TZD100. Based on MIC_{90} values, TZD was 4- to 8-fold more potent than LZD, consistent with previous reports.

Wck 4873 (Nafithromycin): Safety Studies of a Novel Lactone-Ketolide in Rat and Dog

Author Block:

M. B. Nandanwar, A. J. Kansagara, M. I. Patel, S. R. Gupta, R. D. Yeole, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: Nafithromycin (WCK4873) is a novel non-fluoroketolide with differentiating characteristics of the "lactone-ketolide". Unlike other ketolides,WCK 4873 is a five membered lactone ring, to which the alkyl aryl side chain is attached via chiral carbon of lactoneBased on its unique structure it overcomes macrolide, telithromycin, penicillin and quinolone resistance in *S. pneumoniae*. Safety of WCK 4873 was studied in 28-day toxicity studies, both in Rat and Dog.**Method:**All studies were designed in accordance with the ICH guidelines. WCK 4873 was administered once-daily (oral) at doses of 0, 50, 100 and 200 mg/kg in Rat and at doses of 0, 25, 50 and 75 mg/kg in Dog. In both the studies, recovery group was maintained at the highest dose. For toxicokinetic profiling, blood was sampled at multiple time points (on 1, 14 and 28 days). Clinical signs, body weight, food consumption, ophthalmoscopy, clinical pathology, ECG, organ weight, gross and histopathology evaluations were performed.**Results:**Increased macrophages in lung and vacuolated histiocytes in lymphoid organs (suggestive of phospholipidosis - a class specific effect), were observed at 200 mg/kg in rats. In both the studies, unlike other macrolides/ketolides, WCK 4873 did not show any indications of liver toxicity even at the highest dose. Liver specific enzymes (ALT, AST and bilirubin) and liver histopathology were normal at the end of 28-day treatment. The increased pulmonary macrophages and vacuolated histiocytes in lymphoid organs were reversed to normal at the end of recovery period. ECG did not reveal any alterations. Based on the minor reversible changes in lungs and lymphoid organs, No Observable Adverse Effect Level (NOAEL) was established to be 100 mg/kg in rat and 50 mg/kg in dog. The average AUC at NOAEL dose in rat and dog was 105.7 µg.h/mL and 50.96 µg.h/mL, respectively.**Conclusions:**WCK 4873 (Nafithromycin) showed a promising safety profile including hepatic safety in both rat and dog.

Wck 4873 (Nafithromycin): Mouse and Dog Pharmacokinetic (Pk) Profile of a Novel Lactone-Ketolide

Author Block:

R. P. Chavan, A. M. Patel, V. S. Zope, J. U. Shaikh, A. D. Patil, R. D. Yeole, **M. V. Patel**; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: For macrolide/ketolide class of agents, gaining good oral bioavailability is a major challenge in view of they being hydrophilic molecules and substrate of both intestinal P-gp and CYP3A. WCK 4873 is a broad spectrum novel lactone ketolide antibacterial drug (Phase I studies recently completed in Europe and US) with a promising activity against macrolide and telithromycin-NS Pneumococci. We investigated Mouse and Dog pharmacokinetic profile of WCK 4873. **Method:** WCK 4873 (15 and 30 mg/kg) or telithromycin (TEL) was administered either oral or intravenous (i.v.) route to Swiss mice. Serum, lung and liver concentration of WCK 4873 and TEL were measured over 24h by LC-MS/MS method. PK parameters were determined by non-compartmental analysis using Win-Nonlin. **Results:** Following single oral dose administration (15, 30 mg/kg), the mean serum C_{max} of WCK 4873 and TEL were 1.83, 3.82 and 3.11, 4.73 µg/mL respectively. Similarly, the AUC of WCK 4873 and TEL (15, 30 mg/kg) were 8.8, 15.01 and 13.97, 29.43 µg.h/mL respectively. However, lung exposures of WCK 4873 were 4-6 times higher compared to TEL (15 mg/kg per oral: WCK 4873: 116.7 µg.h/mL and TEL: 20.51 µg.h/mL; 30 mg/kg: WCK 4873: 272.7and TEL: 68.94 µg.h/mL). In liver, the exposure of WCK 4873 was considerably lower compared to TEL (30 mg/kg per oral: WCK 4873: 200.3 µg.h/mL and TEL: 428.7µg.h/mL).The mean serum $t_{1/2}$ of WCK 4873 and TEL following i.v. administration was 1.8h and 1.3h, respectively. Dog AUCs at i.v doses of 15 and 30 mg/kg was 18.7 and 38.9 µg.h/mL, respectively. The mean serum $t_{1/2}$ of WCK 4873 was in the range of 3.9-4.5h. In Dog, the oral bioavailability at the dose of 30 mg/kg was 100%. **Conclusion:** WCK 4873 (Nafithromycin) showed good PK profile and favourable tissue distribution including higher lung penetration in Mouse. Dog PK profile was suggestive of once a day dosing potential in clinic.

Outpatient Treatment of Acute Bacterial Skin and Skin Structure Infections (Absssi) with Tedizolid Phosphate and Linezolid in Patients in the United States

Author Block:

C. De Anda, S. Anuskiewicz, P. Prokocimer, R. Kullar; Merck & Co., Inc., Kenilworth, NJ

Abstract Body:

ABSSSI are a frequent cause of hospital admissions in the United States (US). Tedizolid phosphate, the prodrug of the oxazolidinone tedizolid (TZD; 200 mg once daily for 6 d), demonstrated noninferior efficacy to linezolid (LZD; 600 mg twice daily for 10 d) for treatment of ABSSSI due to confirmed or suspected Gram-positive pathogens in two randomized, controlled, Phase 3 trials. The subpopulation of US-based outpatients from both trials combined was explored retrospectively. The pooled intent-to-treat population included 403 TZD and 410 LZD patients from the US who were not hospitalized during the study. Patient demographics and clinical characteristics were comparable between both treatment arms; however, systemic inflammatory response syndrome was about twice as common in the TZD arm (Table). Based on clinical characteristics, the outpatient population in both treatment groups was severely ill, with high rates of large lesions (>300 cm^3), lymphadenopathy, hepatitis C, and intravenous drug use. Early clinical response (≥20% reduction in lesion size at 48-72 h) and clinical success at end of therapy (EOT) and 7-14 d post-EOT were similar between TZD and LZD (Table). Overall incidence of treatment-emergent adverse events (AEs) was comparable between TZD and LZD (50.9% [204/401] vs 51.9% [210/405], respectively); however, gastrointestinal AEs were more common with LZD (21.4% [86/401] and 29.4% [119/405], respectively). These findings, observed in a study population in which comorbidities and fairly severe infections were frequent, suggest that ABSSSI due to confirmed or suspected Gram-positive pathogens can be successfully treated with short-course TZD in an outpatient setting.

Table. Patient Characteristics and Clinical Outcomes in US-Based Outpatients (ITT population)

Patient Characteristics, n (%)	**Tedizolid (N = 403)**	**Linezolid (N = 410)**
WBC count (≥10,000 or <4000 cells/mm^3)	182 (45.2)	156 (38.0)
Fever (≥38°C)	32 (7.9)	21 (5.1)
SIRS	55 (13.6)	29 (7.1)
Lymphadenopathy	366 (90.8)	375 (91.5)
Hepatitis C	152 (37.7)	173 (42.2)
IV drug use	178 (44.2)	200 (48.8)
Lesion surface area, cm^2, mean (range)	253.4 (22.5-2030.0)	259.8 (27.0-2490.0)
>300 cm^2	83 (20.6)	88 (21.5)
Early clinical response, n (%)	332 (82.4)	324 (79.0)
Clinical success, n (%)		
EOT	351 (87.1)	353 (86.1)
Post-EOT evaluation	335 (83.1)	343 (83.7)

EOT, end of therapy; ITT, intent-to-treat; IV, intravenous; SIRS, systemic inflammatory response syndrome; WBC, white blood cell.

Wck 4873 (Nafithromycin): Pk/Pd Analysis Against *S. pneumoniae* (Spn) Including Telithromycin-Non-Susceptible (Tel-Ns) Strains Through Murine-Lung Infection Model

Author Block:

S. S. Takalkar, R. P. Chavan, A. M. Patel, K. V. Umarkar, **S. S. Bhagwat**, M. V. Patel; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background: WCK 4873 is a lactone-ketolide with activity against typical and atypical respiratory pathogens including potent activity against TEL-NS Pneumococci. Recent surveillance studies show that WCK 4873 MIC_{90} for global SPN (n=1911) including macrolide and TEL-NS was 0.12 µg/mL. We employed 6 SPN strains (1 *ermB*$^-$, 5 *ermB*$^+$ including 2 TEL-NS) in murine lung infection studies to establish bactericidal exposures. PK/PD analyses aimed at identifying the efficacy driving PK/PD index and its magnitude employing mouse serum and ELF PK.**Methods:** PK data was obtained by administering single oral doses in mice ranging from 2.5-600 mg/kg. Serum and BALF were collected over 24h and assayed for WCK 4873 by LC-MS/MS method. Urea measurement (colorimetric assay) in serum and BALF were used to determine WCK 4873 concentrations in ELF. Neutropenic mice were infected intra-nasally (10^7-10^9 CFU), so that the bacterial burden at the initiation of treatment (2h post-infection) was in the range of 5.82–7.71 $\log_{10}$ CFU/lung. 27h post-infection, animals were sacrificed to enumerate the bacterial lung load. To arrive at the representative PK/PD index in SPN 49619, various doses and their fractionated regimens were employed (dose range 0.6-25 mg/kg, q6h, q12h and q24h). For *ermB*$^+$ strains, various doses (2.5-600 mg/kg, q24h) were administered to arrive at the magnitude of the PK/PD index. Exposure-response analysis to arrive at PK/PD index and its magnitude was undertaken using Graph Pad prism.**Results:** With SPN 49619 (WCK 4873 MIC 0.015 µg/mL) 24h *f*AUC/MIC best correlated with efficacy (r^2=0.934) followed by Time >MIC (r^2=0.853) and *f*C_{max}/MIC (r^2=0.777). For 6 SPN strains (WCK 4873 MIC: 0.015-0.5 µg/mL) *f*serum AUC_{0-24}: MIC and ELF AUC_{0-24}: MIC associated with 1 $\log_{10}$ CFU reduction from the baseline were in the range of 1.8–17.48 and 30.6–1984.2, respectively. Similar pooled analysis involving all the 6 strains showed that for 1 $\log_{10}$ CFU reduction, *f*serum AUC_{0-24}: MIC and ELF AUC_{0-24}: MIC requirement was 3.06 and 336.4, respectively.**Conclusions:** WCK 4873 PK/PD targets based on mouse unbound serum and ELF PK were identified. This data would form the basis of probability of target attainment analysis and clinical dose justification employing population PK and Monte Carlo Simulations.

WCK 4873 (Nafithromycin): Structure-Activity Relationship (SAR) Identifying a Lactone-Ketolide with Activity Against Telithromycin-Resistant (TEL^R) Pneumococci (SPN) and *S. pyogenes* (SPY)

Author Block:

P. K. Deshpande, S. B. Bhawsar, V. J. Patil, R. Tadiparthi, S. S. Pawar, L. S. Pavase, R. P. Kale, S. V. Gupta, V. V. Deshmukh, S. K. Dhabade, D. V. Dekhane, M. U. Shaikh, R. D. Yeole, K. R. Patil, V. P. Rane, B. K. Trivedi; Wockhardt Res. Ctr., Aurangabad, India

Abstract Body:

Background:SAR objectives were to identify the ketolide candidate with activity against TEL^R SPN, improved hepato-safety and good oral bioavailability with favorable tissue distribution profile.**Methods:**Various lactone-ketolides were synthesized via coupling appropriate side chains to amidoxime core followed by oxidation and deprotection. Agar dilution MICs were undertaken in MHA+5% sheep blood employing inoculum of 10^4 CFU/spot. In addition to macrolide-sensitive and *mef*-expressing pneumococci, TEL^R SPN 3773 and SPY 3530 were employed for SAR studies.**Results:**Several compounds were found to be superior in antibacterial activity over Telithromycin. This was attributed to unique amidoxime core having un-conventional chiral carbon in fused five member ring attached to macrocycle. Specific orientation and length shortening double bond geometry was critical. 1,3,4-thiadiazole and 2-pyridine moieties were found to be optimal as ring A and B, respectively. The specific orientation conferred by 'S' stereochemistry in the side chain rendered higher potency against SPN 3773 and SPY 3530. Expectedly, 2-fluoro ketolide versions were found to be 1 fold more potent than non-fluoro ketolides against SPN 3773.**Conclusion:**WCK 4873 (Nafithromycin)- a non-fluoro ketolide compound was identified as a candidate for further development.

Comparison of *In Vitro* Susceptibility Testing of Tedizolid (Tzd) and Linezolid (Lzd) Against Isolates of Nocardia

Author Block:

B. A. Brown-Elliott, **R. J. Wallace, Jr.**; Univ. of Texas Hlth.Sci. Ctr. at Tyler, Tyler, TX

Abstract Body:

Nocardia are responsible for various types of infections including respiratory, cutaneous and disseminated disease. Most clinically relevant species of *Nocardia* are multidrug resistant and there is a paucity of efficacious antimicrobials (especially oral) against these organisms. To date, all species of *Nocardia* have been shown to be susceptible to LZD, the first commercially available oxazolidinone. TZD is a new oxazolidinone with previously reported improved *in vitro* and *in vivo* (intracellular) potency against *Mycobacterium tuberculosis*, including multidrug resistant strains, and *Nocardia brasiliensis* compared with LZD. Using the current Clinical and Laboratory Standards Institute (CLSI) recommended method of broth microdilution, 103 isolates of *Nocardia* spp, including 29 *N. cyriacigeorgica*, 17 *N. farcinica*, 13 *N. nova* complex, 22 *N. brasiliensis*, 5 *N. pseudobrasiliensis*, and 5 *N. wallacei* were tested for susceptibility to TZD and LZD. Additional less common species (n=12 isolates) were also tested. For the most commonly encountered and clinically relevant species of *Nocardia*, TZD MIC_{50} values were 0.25 μg/mL for *N. nova* complex, *N. brasiliensis*, *N. pseudobrasiliensis*, and *N. wallacei*, with LZD MIC_{50} values of 1, 2, 0.5, and 1 μg/mL respectively. For *N. nova* complex, the TZD and LZD MIC_{90} was 2 μg/mL and for *N. brasiliensis*, the TZD MIC_{90} was 0.5 μg/mL and the LZD MIC_{90} was 2 μg/mL. TZD MIC_{50} and MIC_{90} values for both *N. cyriacigeorgica* and *N. farcinica* were 0.5 μg/mL and 1 μg/mL, respectively, compared to LZD MIC_{50} and MIC_{90} values of 2 and 4 μg/mL, respectively, for both species. TZD MIC_{90} values were 1 μg/mL for *N. cyriacigeorgica* and *N. farcinica*, compared to LZD MIC_{90} values of 4 μg/mL. This study shows that based on MIC_{90} values, TZD was 4 fold more active than LZD *in vitro* against species of *Nocardia* ($n \geq 10$), with the exception of available isolates from the *N. nova* complex (n=13) and *N. brasiliensis* (n=21) which were the same. These results may warrant evaluation of TZD as a potential treatment option for *Nocardia* infections.

Tedizolid or Tedizolid Combination Therapy with Rifampin Is Effective in a Rat Model of Methicillin-Resistant *Staphylococcus aureus* (Mrsa) Chronic Foreign Body Osteomyelitis

Author Block:

K. E. Greenwood-Quaintance, K-H. Park, R. Patel; Mayo, Rochester, MN

Abstract Body:

Background: MRSA implant associated infections, such as prosthetic joint infection (PJI), are difficult to treat. Tedizolid, a novel oxazolidinone, has MRSA activity *in vitro*. Rifampin is active against MRSA; however, when used as monotherapy, resistance may emerge. We compared tedizolid and tedizolid plus rifampin with vancomycin plus rifampin in a rat model of MRSA chronic foreign body osteomyelitis. **Methods:** The study strain (PJI-associated clinical isolate) tedizolid, vancomycin, and rifampin MICs were determined using CLSI guidelines. Steady state (after 3 days) pharmacokinetic profiles for intraperitoneal administration of 30 mg/kg tedizolid once daily, 50 mg/kg vancomycin twice daily, and 25 mg/kg rifampin twice daily were determined in 3-5 healthy rats. Rat chronic foreign body osteomyelitis was established by injecting MRSA into the proximal tibia and implanting a threaded K-wire. Four weeks after infection, rats received 21 days of no treatment (n=17), tedizolid (n=14), tedizolid plus rifampin (n=11), or vancomycin plus rifampin (n=13). After treatment, quantitative cultures of bone within 5 mm of the implanted wire were performed. **Results:** The MIC was 0.5, 1.0, and ≤0.015 µg/ml for tedizolid, vancomycin, and rifampin, respectively. The mean peak (0.5 hour) plasma concentration (µg/ml) / mean $AUC_{0\text{-}24}$ (µg·h/ml) for tedizolid, vancomycin and rifampin was 12 / 60, 47 / 264, 28 / 332, respectively. Total tedizolid AUC was 2-fold that seen at steady state for human 200 mg once daily intravenous dosing. The median quantity of control, tedizolid, tedizolid plus rifampin, and vancomycin plus rifampin was 5.76, 3.86, 2.95, and 0.50 $\log_{10}$ cfu/g bone, respectively. Bacterial quantities of all treatments were significantly lower than control. Tedizolid was not significantly different than tedizolid plus rifampin. Tedizolid plus rifampin was not significantly different than vancomycin plus rifampin. No appreciable rat weight loss was seen over the treatment period. Rats receiving tedizolid had some alopecia. Those receiving rifampin showed some coarse fur, mild lethargy, and alopecia. No tedizolid resistance was detected in isolates recovered from bones. **Conclusion:** Tedizolid alone and combined with rifampin is effective against MRSA in a rat model of chronic foreign body osteomyelitis.

Microbiological Diagnoses from a Recent Community-Acquired Bacterial Pneumonia (CABP) Trial - Solitaire-IV

Author Block:

A. Sheets, K. Keedy, B. Jamieson, D. Oldach, P. Fernandes; Cempra, Inc., Chapel Hill, NC

Abstract Body:

Background: CABP is the most common cause of death from infectious disease in the US, and most patients do not have a microbiological diagnosis. Solithromycin (SOLI) is a 4th generation macrolide with potent activity against CABP pathogens, including macrolide-resistant strains. Solitaire-IV was a global Phase 3 non-inferiority trial of IV-to-oral SOLI versus moxifloxacin (MOXI) in the treatment of CABP.**Methods:** The trial was conducted under the new FDA CABP Guidance with clinical outcomes measured using an objective endpoint of early clinical response (ECR) at 72 hours postdose. 863 patients with confirmed CABP (PORT II to IV) were randomized between January 2014 and July 2015 to receive IV SOLI or MOXI on Day 1 and were permitted to switch to oral dosing on subsequent days.A variety of techniques were used to enhance the detection of pathogens including cultures of blood and sputum, detection of *Streptococcus pneumoniae* and *Legionella pneumophila* antigen in urine, *L. pneumophila* and *Mycoplasma pneumoniae* serologies (4-fold diagnostic rise in titer between baseline and 4 week sera), culture and PCR of oropharyngeal swabs for *M. pneumoniae*, and quantitative PCR of nasopharyngeal swabs for *S. pneumoniae*.**Results:** SOLI was non-inferior to MOXI in ECR in the microbiological intent-to-treat population (80.3% vs 79.1%; 95% Confidence Interval: -8.1, 10.6). The most frequently identified pathogens were *S. pneumoniae* (18%), *M. pneumoniae* (8%), and *H. influenzae, S. aureus,* and *L. pneumophila* (all 4%). The rate of macrolide resistance in *S. pneumoniae* (defined as resistance to azithromycin [AZI] or erythromycin) was 27% and SOLI maintained activity against these isolates with MICs ≤1 mg/L. SOLI MICs were generally lower than MOXI and AZI for Gram-positive and atypical pathogens, while MOXI MICs were lower for Gram-negative pathogens.

Pathogen (N)	**MIC90**		
	AZI	**SOLI**	**MOXI**
S. pneumoniae (98)	>32	0.06	0.12
Macrolide-resistant *S. pneumoniae* (26)	>32	0.5	0.12
S. aureus (37)	>32	0.12	2
H. influenzae (35)	2	2	0.06
M. pneumoniae (26)	0.0005	≤0.000032	0.125

Conclusions: SOLI is a new macrolide with potent activity against typical and atypical CABP pathogens, including macrolide-resistant ones, and shows promise as a new macrolide for inpatient and outpatient treatment of CABP.

Candidate Vaccine Against Extra-Intestinal Pathogenic *E. coli*: A Multicenter Phase I, First-in-Human, Randomized, Placebo-Controlled Trial in Women with a History of Recurrent Urinary Tract Infection

Author Block:

A. Huttner[1], S. Harbarth[1], C. Hatz[2], K. Fae[3], T. Davies[4], G. van den Dobbelsteen[3], A. Hornacek[5], A. Dreyer[5], P. Martin[5], C. Alaimo[5], V. Gambillara[5]; [1]Infection Control Program, Univ. Hosp. of Geneva, Geneva, Switzerland, [2]Epidemiology, Biostatistics and Prevention Inst., Zürich, Switzerland, [3]Janssen Res. and Dev., Leiden, Netherlands, [4]Janssen Res. and Dev., Raritan, NJ, [5]LimmaTech Biologics, Schlieren, Switzerland

Abstract Body:

A novel bioconjugate candidate vaccine containing O-antigen polysaccharides from 4 *E. coli* serotypes (O1A, O2, O6A, O25B) was tested in a multicenter phase I randomized, single-blind, placebo-controlled study assessing its safety, immunogenicity and effect on the incidence of urinary tract infections (UTI) in non-pregnant healthy women with a history of recurrent UTI.Primary outcome was safety; secondary outcomes were immunogenicity and UTI incidence 9 months after injection.In total, 194 women were randomized to reduced-dose vaccine (n=6; 4ug polysaccharide), target-dose vaccine (n=93; 16ug polysaccharide) or placebo (n=95; vehicle). There were no vaccine-related serious adverse events (AE). Though local solicited AE (injection site pain and/or erythema) were slightly more frequent in the target-dose group compared to placebo (37/93 [39.8%] vs 32/95 [33.7%], p=0.386), there were no differences in the frequency of unsolicited AE, or changes in laboratory parameters among groups. Target-dose vaccine triggered significant increases (all $p<0.01$) in geometric mean titers for antibodies towards the 4 serotypes compared to baseline and to placebo. Antibody durability was observed in the target-dose group at 9 months. There were no significant differences in single-pathogen *E. coli* mean UTI (total number of UTIs/number of subjects) between target-dose group and placebo in ITT analyses (p=0.146), while a decrease was observed in the per-protocol analyses (p=0.038). No reduction in vaccine-specific mean UTI was observed in either ITT or PP analyses.In conclusion, *E. coli* bioconjugate vaccine was safe and immunogenic. Larger trials are needed to evaluate its clinical efficacy.**Study Support**: Janssen Research & Development, LLC, Raritan, NJ, USA**Registration**: ClinicalTrials.gov: NCT02289794

Extracellular Vesicles Purified from a Recombinant *Staphylococcus aureus* Isolate Elicit Protection Against Experimental Staphylococcal Infection

Author Block:

X. Wang, X. Li, J. Lee; Brigham and women's Hosp. and Harvard Med. Sch., Boston, MA

Abstract Body:

In the past decade, the high prevalence of methicillin-resistant *Staphylococcus aureus* in healthcare and community settings has become a serious public health concern due to treatment failures with a number of antimicrobial drugs. Conventional approaches toward *S. aureus* vaccine development have failed, and new innovative approaches are needed. The secretion of nano-scale extracellular vesicles (EVs) from *S. aureus* and other Gram-positive pathogens has been described recently. These EVs have been shown to package multiple antigens including lipoproteins, toxins, and enzymes, and the vesicle contents are protected from extracellular proteases by a hydrophobic membrane. Thus, it is feasible to develop EVs as a multivalent *S. aureus* vaccine candidate if we can further engineer them to improve safety and protective efficacy against *S. aureus* infections. To abrogate the toxicity of native EVs from USA300 strain JE2, we mutated the *agr* locus, which positively regulates the expression of exotoxins, and the *spa* gene, which encodes protein A that binds to the Fcγ domain of IgG and to the Fab domain of V_H3-type B cell receptors, disrupting the antibody response and inducing B cell apoptosis. EVs were isolated from culture supernatants of wild type JE2, Δ*agr*, and Δ*agr*Δ*spa* mutants with Opti-prep density gradient ultracentrifugation, and vesicle-like structures were observed by negative staining electron microscopy. As expected, EVs from both mutants exhibited negligible toxicity to rabbit blood cells, A549 lung epithelial cells, and neutrophil-like HL60 cells compared to EVs from the wild type JE2. In the absence of adjuvant, EVs were immunogenic in mice, and vaccination with EVs isolated from the Δ*agr*Δ*spa* mutant, but not EVs from the Δ*agr* mutant, significantly reduced lethality in a sepsis model following challenge with USA300 strain FPR3757. Our data indicate that EVs from the Δ*agr*Δ*spa* mutant offer potential as a vaccine against *S. aureus* infections. Moreover, by generating EVs from JE2Δ*agr*Δ*spa* engineered to express additional vaccine antigens like nontoxic Hla, vaccine efficacy may be enhanced.

Widespread Prevalence of *Staphylococcus pseudintermedius* Vaccine Candidate Antigens Identified by Serological Proteomic Analysis

Author Block:

N. Couto[1], L. Fernandes[1], J. Martins[2], A. V. Coelho[3], **C. F. Pomba**[1]; [1]Faculty of Vet. Med. Univ. of Lisbon, LISBON, Portugal, [2]2ITQB António Xavier, OEIRAS, Portugal, [3]ITQB António Xavier, OEIRAS, Portugal

Abstract Body:

The emergence of methicillin-resistant *S. pseudintermedius* (MRSP) has impaired the treatment of infections caused by these bacteria. The objective of this study was to identify potential vaccine candidate using the SERological Proteome Analysis (SERPA) approach and determine the prevalence of these proteins in a *S. pseudintermedius* population.To detect immunogenic *S. pseudintermedius* proteins, a Western blot analysis of 2DE gels (cell-wall and membrane fractions) was carried out with serum from healthy dogs (H) and dogs infected with *S. pseudintermedius* (D). Only immunogenic areas identified by ≥ 50% of the D sera and identified by < 50% of the H sera were excised and identified by MALDI-TOF/TOF MS. The genes encoding the proteins of interest were identified by PCR. A population of 347 *S. pseudintermedius* isolates were tested. A Western blot analysis of 2DE gels (cell-wall and membrane fractions) was carried out with serum from healthy dogs (H) and dogs infected with S. pseudintermedius (D). Only immunogenic areas identified by ≥ 50% of the D sera and identified by < 50% of the H sera were excised and identified by MALDI-TOF/TOF MS. The genes encoding the proteins of interest were identified by PCR using primers designed by Primer3. A population of 347 S. pseudintermedius isolates were tested, of which 16 were MRSP.Four and one highly immunogenic areas (containing more than one spot) were detected in the cell wall fraction and in the membrane associated fraction, respectively. We were able to identify 13 unique proteins after in-gel digestion of the highly immunogenic areas. Based on the predicted surface localization and/or crucial function in bacterial pathogenesis or survival (e.g. adhesion), four of the identified proteins seem promising candidate therapeutic targets: fibronectin binding protein SpsD, putative lipoprotein, ATP synthase subunit alpha AtpA and enoyl-[acyl-carrier-protein] reductase [NADPH] FabI. The gene encoding SpsD was present in 84%, AtpA gene in 97%, the putative lipoprotein gene in 97% and the FabI gene in 96 % of the isolates.The SERPA approach revealed 4 novel and highly prevalent candidate therapeutic targets for the control of *S. pseudintermedius* infections.

Oral Delivery of a Novel Recombinant *Streptococcus mitis* Vector Elicits Robust Vaccine Antigen-specific Oral Mucosal and Systemic Antibody Responses and T Cell Tolerance

Author Block:

M. Cayabyab, E. Xie, A. Kotha, T. Biaco, S. Nikita, J. Zou, P. Stashenko, M. Duncan, A. Campos-Neto; Forsyth Inst., Cambridge, MA

Abstract Body:

The pioneer human oral commensal bacterium *Streptococcus mitis* has unique biologic features that make it an attractive mucosal vaccine or therapeutic delivery vector. *S. mitis* is safe as a natural persistent colonizer of the mouth, throat and nasopharynx and the oral commensal bacterium is capable of inducing mucosal antibody responses. A recombinant *S. mitis* (*rS. mitis*) that stably expresses HIV envelope protein was generated and tested in the germ-free mouse model to evaluate the potential usefulness of this vector as a mucosal vaccine against HIV. Oral vaccination led to the efficient and persistent bacterial colonization of the mouth and the induction of both salivary and systemic antibody responses. Interestingly, persistently colonized animals developed antigen-specific systemic T cell tolerance. Based on these findings we propose the use of *rS. mitis* vaccine vector for the induction of mucosal antibodies that will prevent the penetration of the mucosa by pathogens such as HIV. Moreover, the first demonstration of *rS. mitis* having the ability to elicit T cell tolerance suggest the potential use of *rS. mitis* as an immunotherapeutic vector to treat inflammatory, allergic and autoimmune diseases.

Antibody Response Measured by Elisa and Opsonophagocytic Killing Assays Elicited by a Vaccine Targeting Extraintestinal Pathogenic *Escherichia coli*

Author Block:

D. R. Abbanat[1], K. Fae[2], T. Davies[1], K. Amsler[1], W. He[1], K. Contractor[1], C. Alaimo[3], A. Dreyer[3], V. Gambillara[3], J. Poolman[2], G. van den Dobbelsteen[2]; [1]Janssen Res. & Dev., Raritan, NJ, [2]Janssen Res. & Dev., Leiden, Netherlands, [3]LimmaTech Biologics AG, Schieren, Switzerland

Abstract Body:

Background: ExPEC4V, a vaccine targeting extraintestinal pathogenic *E. coli* (ExPEC) O-antigen serotypes O1A, O2, O6A, and O25B, is being evaluated for the treatment of ExPEC invasive disease. This study investigated the safety and immunogenicity of ExPEC4V in healthy women with a history of recurrent urinary tract infection.**Methods:**I n this Phase I staggered, single blind, placebo-controlled, multicenter study, 188 women were randomized (1:1) to receive either placebo, or the EXPEC4V vaccine consisting of four *E. coli* O-antigens bioconjugated to detoxified Exoprotein A from *P. aeruginosa*. Sera from all participants were tested for antibodies on day 1 (prevaccine), and days 30 or 270 postvaccine. IgG titers were measured by ELISA and functional antibodies by an Opsonophagocytic Killing (OPK) assay with differentiated HL60 cells and heterologous human complement.**Results:** Day 30 geometric mean (GM) IgG EC_{50} values (ELISA) were O1A: 9460, O2: 27973, O6A: 4475, and O25B: 2164, a 4.9 to 9.8 fold increase over respective baseline values. For each ExPEC serotype, ≥80% of participants (O1A: 81%, O2: 93%, O6A: 80%, O25B: 82%) showed a ≥2-fold increase in IgG antibodies from day 1 to 30. The proportion of participants with a ≥4-fold increase in IgG titers ranged from 57% (O1A and O6A) to 80% (O2). With the OPK assay, day 30 GM titers were O1A: 951, O2: 4133, O6A: 1542, and O25B: 415, a 2.0- to 14-fold increase over baseline values. The proportion of participants with a ≥2-fold increase in antibodies per serotype was: O1A: 63%, O2: 90%, O6A: 33%, and O25B: 55%; the proportion of participants with a ≥4-fold increase ranged from 20% (O6A) to 82% (O2). Day 270 antibody titer increases were slightly lower compared to day 30, with per serotype GM fold increases from baseline ranging from 3.8 - 7.3 for ELISA and 1.8 - 5.6 for OPK.**Conclusion:** The ExPEC4V vaccine induced an IgG immune response for all 4 serotypes, with functionality demonstrated by associated OPK activity. A durable vaccine response to the 4 serotypes was demonstrated over 270 days.

Inactivated *Shigella* as Effective Vaccines and Vaccine Vectors

Author Block:

I. Albino-Flores, E. S. Stibitz, **M. Osorio**; FDA, Silver Spring, MD

Abstract Body:

Shigellae and Enterotoxigenic *Escherichia coli* (ETEC) remain major causes of diarrhea among children in developing countries and travelers to these areas. However, currently there are no effective vaccines against these enteric pathogens. Previously we demonstrated the vaccine and vector potential of formalin inactivated *Shigellae*[1] by demonstrating the strong protective immune responses elicited in the mouse model. In addition we showed that these inactivated strains can serve as effective vaccine carriers for fimbrial antigens (CFA/I and CS3) of ETEC. However, we have observed that the harsh formalin treatment can negatively affect the immunogenicity of the ETEC fimbrial antigens. We therefore explored alternative methods of inactivating *Shigella*. Here we present our results examining the vaccine and vector potential of *Shigella* ghost cells expressing ETEC antigens (CVD1203). Bacterial ghost cells in general have been shown to be immunogenic and possess inherent adjuvant properties[2]. We have found that mice immunized orally or intranasally with ghost cells of *S. flexneri* expressing CFA/I and CS3 induced strong IgG titers to the homologous LPS and to the ETEC antigens. We show that these immune responses are protective as 100% of the vaccinated animals can be protected from challenge with the live homologous *Shigella* strain compared to negligible survival in mice given PBS. More recently, we have explored gamma-irradiation as an alternative method to inactivate *Shigella* cells, and have optimized conditions that result in complete inactivation of *Shigella* cells following irradiation. We are currently performing a comparative immunogenicity study with the various inactivated cell formulations to determine their ability to induce strong and protective immune responses to *Shigella* pathogens. These studies demonstrate that inactivated *Shigella* cells are highly immunogenic and can serve as effective carriers for exogenous antigens.

Development of a Multivalent Subunit Vaccine Against Tularemia Using Tobacco Mosaic Virus (TMV) Based Delivery System

Author Block:

A. A. Mansour[1], S. Banik[1], S. M. Rabadi[1], A. A. McCormick[2]; [1]New York Med. Coll., Valhalla, NY, [2]Touro Univ., Vallejo, CA

Abstract Body:

Background: *Francisella tularensis* (*Ft*); the causative agent of a fatal human disease tularemia is classified as a Category A Select Agent. No licensed vaccine is available for prevention of tularemia in the U.S.A. In this study, we used a novel Tobacco Mosaic Virus (TMV) based delivery platform for development of a fully protective multi-antigen subunit tularemia vaccine. Previously we have published that a trivalent TMV-conjugate vaccine confers 50% protection in immunized mice against respiratory *Ft* LVS challenge. In this study, we refined TMV-conjugate vaccine formulation to improve the level of protection in immunized C57BL/6 mice against respiratory tularemia.**Methods:** We refined our trivalent vaccine formulation (OmpA, DnaK and Tul4) by including dihydrolipoamide succinyl transferase (SucB). To improve Th1 type humoral response, we also included CpG adjuvant in the vaccine formulation. Each recombinant protein was conjugated individually to TMV, blended in equimolar concentration to yield a TMV-tetravalent conjugate vaccine. C57BL/6 mice were immunized intranasally (i.n.) on days 0, 14 and 28. Mice were challenged i.n. with $10LD_{100}$ of *Ft* LVS on day 45 post-primary immunization. Humoral, cell mediated and recall memory responses were evaluated in immunized mice to determine the vaccine efficacy.**Results:** 100% of immunized mice were protected against a $10LD_{100}$ respiratory challenge dose of *Ft* LVS. Mice vaccinated with TMV-tetravalent vaccine showed high levels of IgG1, IgG2a, 2b and 2c antibodies than those observed in mice vaccinated with trivalent vaccine formulation. A strong cell mediated immune response was observed against each individual recombinant protein. The splenocytes from immunized mice isolated on day 84 post-primary immunization induced high levels of both IL-17 and IFN-γ in co-culture assays, indicating generation of potent memory response in immunized mice.**Conclusions:** TMV serves as a suitable platform for delivery of multiple *Ft* antigens and provide 100% protection in mice against respiratory tularemia caused by *Ft* LVS. Immunization with TMV-tetravalent vaccine induces potent humoral and cell medicated immune responses. Study to evaluate the overall efficacy of TMV-tetravalent conjugate vaccine against virulent *Ft* SchuS4 is currently underway.

Intradermal Vaccination against *Pseudomonas aeruginosa* Induces Antibody and Cellular Immune Responses in the Lung

Author Block:

S. M. Baker, J. D. Clements, L. A. Morici; Tulane Univ., New Orleans, LA

Abstract Body:

Pseudomonas aeruginosa is a Gram-negative opportunistic bacterium that causes chronic lung infection in individuals with cystic fibrosis. Growing evidence suggests that a successful *P. aeruginosa* vaccine may need to elicit antibody and Th1- and Th17-$CD4^+$ T cells both systemically and in the lung to prevent chronic infection. The majority of *P. aeruginosa* vaccine studies in mice utilize intramuscular (IM) vaccination. However, IM immunization may not be the optimal route for eliciting mucosal immune responses. Recent work suggests that intradermal (ID) immunization in the context of certain classes of adjuvants can induce a mucosal immune response, as dermal dendritic cells process antigen and migrate to the draining lymph nodes where they induce the expression of mucosal homing markers on B and T cells. In order to determine if ID immunization could induce mucosal immune responses to *P. aeruginosa*, we immunized groups of five C57Bl/6 mice with 1-10 ug of a *P. aeruginosa* outer membrane protein (OMP) preparation combined with 1 ug of a double mutant of *E. coli* heat-labile toxin (dmLT) adjuvant. Control mice received OMPs or dmLT only. Mice were immunized ID at two anatomical locations, subcutaneously (SC), or IM. Antibody and T cell responses were assessed by ELISA and flow cytometry, respectively. ID vaccination with 1 ug of OMPs plus dmLT induced significantly more anti-pseudomonal serum IgG than the same formulation administered SC and significantly greater anti-pseudomonal IgG in the bronchoalveolar lavage fluid (BALF) compared to SC or IM vaccination. ID administration of 1 ug OMPs plus dmLT on the side of the mouse below the axilla induced significantly more anti-pseudomonal IgG in the BALF compared to ID vaccination on the ventral surface. ID immunization at both locations induced the production of IFN-gamma-producing CD4+ T cells in the lungs and mediastinal lymph nodes, however only ID vaccination below the axilla induced IL-17-producing CD4+ T cells in both tissues. These results demonstrate the potential of ID vaccination with OMPs plus dmLT to stimulate protective mucosal antibody and cellular immune responses in the lung. Studies are currently underway to assess protection in a mouse model of *P. aeruginosa* pulmonary infection.

Identifying Protective Immune Responses to Oligopeptide Permease A for the Development of a Vaccine Against *Moraxella catarrhalis*

Author Block:

A. C. Perez, T. F. Murphy; Univ. at Buffaly, SUNY, Buffalo, NY

Abstract Body:

Moraxella catarrhalis infections are a significant cause of morbidity and a huge financial burden globally. Development of a vaccine against this pathogen has the potential to prevent otitis media in children and respiratory infections in adults with chronic obstructive pulmonary disease. Oligopeptide permease A (OppA) is a potential candidate vaccine antigen that has been studied extensively. However, assessing the effectiveness of a potential vaccine in humans is challenging because of the lack of an identified correlate of protection against *M. catarrhalis* infections. Therefore, the overall goal of these studies is to identify protective immune responses to OppA in vaccinated animal models. Eight truncated constructs of the protein were designed, engineered and purified to identify B cell epitopes on OppA. Using serum from vaccinated rabbits, antibody titers to each construct were assessed by immunoblot assay and ELISA. The results from these studies showed that epitopes were present on each construct of the protein. Additionally, mice were immunized using multiple immunization strategies with OppA to identify an optimal vaccine formulation and schedule. Mice were subjected to aerosol challenge with *M. catarrhalis* and pulmonary clearance was determined. Overall, OppA induced enhanced pulmonary clearance, a potentially protective response, when OppA is given with incomplete Freund's adjuvant, alum, or AS04 adjuvants. While all formulations tested induced high antibody titers, the epitopes to which the antibody response is directed differed depending on the adjuvant and schedule. All together, these studies reveal that (1) OppA is highly immunogenic in vaccinated animals, (2) OppA has multiple B cell epitopes, (3) it induces protective responses in mice, and (4) adjuvant choice influences B cell epitope preference, which may aid in identification of the most protective regions of the protein. In conclusion, OppA is highly immunogenic and has great potential for use in a vaccine against *M. catarrhalis*.

Evaluating the Inclusion of Adenylate Cyclase Toxin Antigen into the Acellular Pertussis Vaccine

Author Block:

D. T. Boehm[1], J. Bevere[1], E. Sen[1], J. A. Maynard[2], E. L. Hewlett[3], M. Barbier[1], F. H. Damron[1]; [1]West Virginia Univ., Morgantown, WV, [2]Univ. of Texas at Austin, Austin, TX, [3]Univ. of Virginia, Charlottesville, VA

Abstract Body:

Bordetella pertussis is the causative agent of pertussis (whooping cough), a respiratory infection leading to a violent cough, which can be fatal. Acellular pertussis vaccines (ACV) replaced whole cell vaccines (WCV) in the US immunization schedule in the early 1990s, and for multiple reasons, pertussis is re-emerging despite 95% vaccine coverage. Adenylate Cyclase Toxin (ACT) is a major virulence factor that has been shown to be: required for the establishment of infection, an effective immunogen, and a protective antigen. In this study, we used a murine vaccination/infection model to evaluate the effectiveness and immunological profiles of ACV vaccines (1/5 human dose) +/- ACT compared WCV and unvaccinated control groups.CD1 mice received initial and booster vaccines consisting of either: PBS, WCV, ACV, ACV+ACT, ACV + a truncated ACT-RTX (residues 751-1706). Mice were infected with *B. pertussis* strain UT25 and were euthanized at 1, 3, and 8 days post challenge, and samples were collected and processed. Bacterial burden was measured and cytokine quantification was performed with arrays and ELISA.Vaccination with ACVs or WCV significantly decreased bacterial burden compared to the unvaccinated control group at all time points. The WCV group at all days post infection had noticeable splenomegaly, which appeared by flow cytometry to consist of an increased number of all cell types compared to all other groups. Addition of ACT or ACT-RTX did not decrease bacterial burden when provided with the $1/5^{th}$ human ACV dose. In the lung, WCV vaccinated mice had increased INF-γ and IL-17 compared to all other groups. Serum IL-17 was also observed to be increased in WCV compared to control infected mice, while ACV mice had similar IL-17 levels to uninfected mice. Vaccination with ACV-RTX induced IL-17 expression at 8 days post infection compared to ACV alone. Vaccination with ACT or ACT-RTX resulted in production of antibodies that could neutralize ACT in vitro. These promising observations suggest that inclusion of ACT in the ACV may alter the nature of the immunological response and potentially elicit more effective protection. Future studies, are underway to test different adjuvants with ACT, other antigen ratios, and additional time points post challenge.

Linear Epitope Mapping of Anthrax Toxin Lethal Factor Using Anti-Rlf Rhesus Macaque Sera

Author Block:

V. A. Semenova, E. Steward-Clark, P. Svoboda, J. Pohl; CDC, Atlanta, GA

Abstract Body:

Introduction: Lethal factor (LF) is a 90-kDa zinc-dependent metallo-protease which is a part of the tripartite anthrax toxin protein complex together with protective antigen (PA) and edema factor (EF). The licensed anthrax vaccine (AVA, BioThrax®) elicits antibodies to PA, however, anti-LF antibodies alone and in combination with anti-PA antibodies can contribute to neutralization of anthrax toxin. Little information is available about LF sequences which induce neutralizing antibodies. This study used overlapping synthetic peptide sequences to identify linear epitopes in LF determined by their reactivity to sera from recombinant LF (rLF) vaccinated rhesus macaques. **Methods:** Fmoc synthesis was used to prepare 39 N-terminally biotinylated peptides of 30 amino acid (AA) residues, overlapping by 10 AA. Sequences were synthesized as C-terminal amides, HPLC-purified and prepared as trifluoracetic acid salts. Peptides were captured on streptavidin coated (2 µg/ml) microtiter plates and screened for antibody binding by enzyme-linked immunosorbent assay (ELISA). Seroreactivity was evaluated using anti-rLF macaque standard AVR2079, anti-LF proficiency sera AVR2084-AVR2093 (n=11) and sera from individual macaques AVR1315 -1321 that received 5 injections of 50µg rLF (n=6). A peptide was considered antigenic if its ELISA Optical Density (OD) value was greater than the mean OD plus 3 Standard Deviations (SD) of controls.**Results:** Sera from rLF vaccinated macaques reacted with peptide sequences in all 4 domains of LF. Despite individual variations in response, all macaques showed consensus reactivity with peptides corresponding to 7 LF sequences: AA41-47, AA81-130, AA261-290, AA301-390, AA400-430, AA641-670, and AA681-710.**Conclusions:** Vaccination of macaques with rLF elicits antibody responses to linear peptide sequences in all 4 LF domains. There were several sequences that were recognized by antisera from all animals tested. The developed method will be used for developing serologic correlates of protection using sera from macaques that survived after challenge with aerosolized *Bacillus anthracis* Ames spores.*The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention.*

Characterization of a Live Attenuated Vaccine for Protection Against Multi-Drug Resistant *Acinetobacter baumannii*

Author Block:

S. Ainsworth[1], P. Ketter[2], J-J. Yu[1], M. Guentzel[1], B. Arulanandam[1]; [1]Univ. of Texas at San Antonio, San Antonio, TX, [2]US Army Inst. for Surgical Res., JBSA-Fort Sam Houston, TX

Abstract Body:

Background: Multi-drug resistant *Acinetobacter baumannii* (MDR-Ab) is an opportunistic pathogen associated with nosocomial and combat related infections sustained by military personnel. This emerging infectious disease is difficult to control due to enhanced multi-drug resistance limiting treatment options. **Objective**: Deletion of the thioredoxin gene (*trxA*) from a clinical isolate of MDR-Ab resulted in a 100-fold increase in LD_{50} relative to the wild type strain. Thus, the objective of this study was to test the efficacy of this attenuated strain as a vaccine against MDR-Ab. **Methods:** Mice were vaccinated by either intraperitoneal (i.p.) or subcutaneous (s.c.) injection of 2×10^5 CFU of the *trxA* mutant. Mice were then given a booster of equivalent inoculum 14 days later and challenged at 30 days post-vaccination by i.p. injection with a lethal dose of the WT Ci79 strain ($10 \times LD_{50}$). Serum was collected on days 14 and 28 post-vaccination to monitor antibody titers. Spleens were collected from vaccinated mice on day 28 and splenocytes were stimulated with UV killed Ci79 to assess T-cell responses. Livers, spleens, and kidneys were extracted from vaccinated mice 24 hours post lethal infection and observed for pathology.**Results:** Mice vaccinated with the *trxA* mutant were 100% protected against a lethal challenge of Ci79 regardless of vaccination route. Surprisingly, little if any immunoglobulin class switching was observed with IgM predominating. Spleens harvested from vaccinated mice exhibited negligible levels of IFNγ and IL-4 production when stimulated with UV killed WT Ci79. Additionally, organs collected from vaccinated mice displayed reduced pathology compared to organs from non vaccinated mice.**Conclusions:** The attenuated *trxA* mutant provides protection against a lethal dose of the WT strain through a T-cell independent mechanism. Additional studies are currently underway to evaluate cross strain protection and to further elucidate the exact mechanism of protection.

Contributions of *Clostridium difficile* Toxin A and Toxin B Regions in Antibody-specific Binding and Neutralizing Responses to a *Clostridium difficile* Toxoid Vaccine

Author Block:

N. Anosova[1], L. Li[1], U. Jetley[1], L. Barone[1], S. Liu[1], L. Cole[1], Y. Yan[1], S. Mundle[1], C. Rogers[1], J. Totman[2], R. B. Hunter[2], L. Quemeneur[3], P. Pietrobon[4], H. Kleanthous[1], S. Anderson[1]; [1]Sanofi Pasteur, Cambridge, MA, [2]Sanofi Genzyme, Cambridge, MA, [3]Sanofi Pasteur, Marcy l'Etoile, France, [4]Sanofi Pasteur, Swiftwater, PA

Abstract Body:

Background: *Clostridium difficile* infection (CDI) is the principal cause of nosocomial diarrhea and pseudomembranous colitis associated with antibiotic therapy. CDI is mediated by two large exotoxins, toxin A (TcdA) and toxin B (TcdB). There is ongoing discussion focused on the relative importance of antibodies against the different regions of TcdA and TcdB in mediating a protective response. While neutralizing antibodies to the C-terminal domain (CTD) of both toxins have long been implicated in efficacy, the ability of other domains of TcdB to elicit neutralizing antibodies has also been reported. Sanofi Pasteur's *C. difficile* candidate vaccine which contains highly purified formalin-inactivated preparations of full length TcdA and B is being developed for prevention of symptomatic disease. **Methods:** Here hamsters were immunized trice with a *C. difficile* vaccine and immune sera were collected 7 days post final immunization but prior to the lethal *C. difficile* challenge. The binding profiles of the sera collected from protected versus non-protected hamsters were generated in ELISA using recombinant toxin fragments. Neutralizing activity of the sera was tested in the Vero cell-based cytotoxicity assay. **Results:** A strong binding response towards C-terminal domain of TcdB was detected, however, other regions, such as N-terminal and central, also generated notable responses in sera of protected animals. Contributions of CTD-specific to the overall toxin-specific binding and neutralizing antibody responses were assessed. Augmentation of potency of antibody response to the multiple domains in contrast to the CTD only was studied. **Conclusions:** In this pre-clinical study we have attempted to identify differences in antibody binding as well as function profiles between vaccine candidate immunized hamsters that were protected against subsequent challenge and those that succumbed such that we could gain insight into the relative contributions of TcdA and TcdB domains in generating binding and neutralizing antibody responses to the vaccine.

Lipooligosaccharide Structural Variations Affect Efficacy of *Neisseria gonorrhoeae* Vaccine Antibody

Author Block:

S. Chakraborti, L. A. Lewis, P. Rice, S. Ram; Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract Body:

Background: *Neisseria gonorrhoeae* (*Ng*), the pathogen causing gonorrhea, a sexually transmitted infection is resistant to most antibiotics. The lack of a safe and effective vaccine makes gonorrhea a major public health challenge. Antibodies against a *Ng* lipooligosaccharide (LOS) epitope recognized by mAb 2C7 (2C7 epitope) are bactericidal. This epitope is expressed by >95% of clinical *Ng* isolates. Immunization with a peptide mimic of the 2C7 epitope attenuates *Ng* infection in a mouse vaginal colonization model. Binding of mAb 2C7 to *Ng* LOS requires lactose on heptose (Hep) II; expression of which is initiated by the phase-variable (pv) LOS glycosyltransferase (*lgt*) G. Glycan extensions from HepI are modified by three pv genes; *lgtA, lgtC* and *lgtD*. We aimed to determine effects of HepI glycan variation on mAb 2C7 function. **Methods:** A *Ng* mutant with HepII lactose (lgtG-ON) was used to engineer four mutants with varying HepI glycan extensions; *lgtA, C, and D* were inactivated by deletion (OFF) or locked-ON by synonymous point mutations in their homopolymer tracts. All mutants had HepII lactose and HepI with either: i) Lac (2-Hex), ii) Gal→Lac (3-Hex), iii) Lacto-N-neotetraose (LNT) (4-Hex), or iv) GlcNAc→LNT (5-Hex). Human complement (C′) was prepared by depleting IgG and IgM from normal human serum. C′-dependent killing by mAb 2C7 was measured by serum bactericidal assays (SBA) and opsonophagocytosis (OPA) using freshly isolated human polymorphonuclear leukocytes (PMNs). mAb 2C7 and C3 on bacteria were measured by flow cytometry.**Results:** HepI chain extensions modulate 2C7 binding (2-Hex >> 4-Hex ≈ 5-Hex > 3-Hex). While mAb 2C7 completely killed *Ng* with HepI 2-Hex in a SBA with 0.2 μg/mL, the 3-Hex mutant was fully resistant to 10 μg/mL. The 4- and 5-Hex mutants showed intermediate resistance and were killed by 4, but not 2 μg/mL of 2C7. In presence of 2C7 and C′, the 3-Hex mutant showed the least C3 deposition. The low level of C3 deposited of the 3-Hex mutant was sufficient to mediate ~64% killing by PMNs in an OPA.**Conclusions:** HepI glycan extensions modulate the binding and function of mAb 2C7. While three of four HepI mutants were killed in a SBA with mAb 2C7, the fourth and only SBA resistant mutant, HepI 3-Hex, was killed by PMNs. Thus, the 2C7 LOS epitope is a promising vaccine candidate that may surmount challenges posed by pv of HepI glycans that are present in infected humans.

Passive Targeting of Dendritic Cells by Poly (Lactic Acid)-B-Poly (Ethylene Glycol) Nanoparticles Encapsulated Outer Membrane Peptide of *Chlamydia trachomatis* for Enhanced Adaptive Immune Responses

Author Block:

S. Dixit, R. Sahu, S. Duncan, S. R. Singh, V. A. Dennis; Alabama State Univ., Montgomery, AL

Abstract Body:

In quest of a vaccine against *Chlamydia trachomatis*, the most reported sexually transmitted bacterial infection globally, we previously published the successful encapsulation and slow release of M278 (a peptide derivative of *C. trachomatis* major outer membrane protein) from PLA-PEG, and its elicitation of enhanced adaptive immune responses in immunized mice. However, it is important to investigate the mechanisms of immuno-stimulation resulting in induction of adaptive immune responses and the role of passively targeted dendritic cells (DCs) as effective antigen presentation cells (APCs) for bolstering these responses. Pro-inflammatory responses in the presence of IL-6 activate expression of costimulatory molecules (CD40, CD80, and CD86) and cytokine (IL-12p40) by DCs for skewing Th1 adaptive immune responses. In contrast, low expression of CD40, CD80, CD86 and IL-10 is skewed towards Th2 responses. In this study, we investigated the mechanisms of PLA-PEG-encapsulated M278 uptake and processing by DCs and focused on expressions of CD40, CD80, CD86; cytokines (IL-6, IL-12p40 and IL-10), and MHC expression profiles. DCs derived from mouse bone marrow cells were exposed to naked M278 as well as encapsulated M278 nanoparticles (NPs) for different time-points (4-72 hours) and doses (1.25-10 µg/mL) to determine their role in antigen presentation and cellular uptake. Results from flow cytometry revealed that encapsulated M278 enhanced the expression levels of CD86 and CD40 on DCs by 2-fold in comparison to naked M278. Cytokine ELISA data showed increased production levels of IL-6 and IL-12p40 over a 72-hour time-period, which are prerequisites for maturation of DCs as potent APCs. Lower dose of 1.25 µg/mL of NPs was as effective as 10 µg/mL of naked M278, suggesting the adjuvanticity of the NPs. Concomitantly, we observed low production of IL-10, with further decrease over time. Collectively, these data suggests that our encapsulated M278 vaccine comprises an effective antigen and adjuvant that can drive maturation of DCs by IL-6 and stimulation of IL-12p40 for elicitation of enhanced Th1 adaptive immune responses.

Characterization and Intracellular Tracking of *Chlamydia trachomatis* Recombinant Momp Encapsulated in Biodegradable Plga 85/15 Nanoparticles in Mouse Primary Dendritic Cells

Author Block:

R. Sahu, S. Dixit, S. Duncan, E. Nyairo, S. R. Singh, V. A. Dennis; Alabama State Univ., Montgomery, AL

Abstract Body:

Chlamydia is a sexually transmitted disease caused by the intracellular bacterium, *Chlamydia trachomatis* (CT). Vaccine development and alternative therapeutics are inimitable ways to eradicate or control its infection. Development of vaccine using nanoparticles for therapeutic use is advancing in the infectious disease field. Applicability of nanoparticles depends on their physical properties for their uptake, intracellular processing and degradation, which are vital for biosafety and therapeutic efficacy studies. Herein, we have developed a CT nanovaccine by encapsulating its immunogenic MOMP (major outer membrane protein) in biodegradable PLGA [poly (D, L-lactic-co-glycolic acid); 85:15 lactide: glycolide ratio] nanoparticles. We first subjected the encapsulated rMOMP to physio-structural techniques followed by its uptake and intracellular distribution by antigen presenting cells, specifically dendritic cells (DCs). Zeta sizing, Zeta potential, DSC (Differential Scanning Calorimetry), UV spectroscopy and FT-IR (Fourier Transform Infrared Spectroscopy) were used to determine the size, stability and successful encapsulation of rMOMP. Encapsulated rMOMP was small (~200 nm), thermally stable (90ºC), negatively charged (-13 mV) with > 90% encapsulation efficiency. Using Taqman qPCR we show that exposing mouse primary DCs to encapsulated rMOMP resulted in higher upregulation of the mRNA gene transcripts of TLR-2 and the co-stimulatory molecules, CD80, CD86 as compared with naked rMOMP. To validate the allocation of nanoparticles and released rMOMP from PLGA85/15 within DCs, intracellular localization was studied by fluorochrome labeling multiple organelles (cell membrane, mitochondria, endoplasmic reticulum and lysosomes). Each organelle was identified with specific primary antibody followed by secondary antibody tagged with distinct fluorescent dyes. Anti-MOMP antibody with divergent fluorescence was used for discerning the presence of naked rMOMP and encapsulated rMOMP within the labeled organelles. Fluorescence and overlapping analyses of images showed that fluorescent labeling using target-specific antibodies were advantageous in locating the rMOMP and encapsulated rMOMP within the intracellular compartments of DCs.

Novel Fusion Protein as a Potential Vaccine against Chlamydial Infection

Author Block:

S. Liang, D. C. Bulir, E. Simms, J. B. Mahony; McMaster Univ., Hamilton, ON, Canada

Abstract Body:

Background: Sexually transmitted *C. trachomatis* infections can lead to a number of complications, including pelvic inflammatory disease and hydrosalpinx, a correlate of tubal infertility. However, up to 90% of women with *C. trachomatis* infections experience subclinical infections. Women with asymptomatic infections do not have an impetus to seek medical help, making them even more susceptible to developing serious complications. The high rate of asymptomatic infections, taken together with the severity of the infection-induced pathology, suggests that controlling *C. trachomatis* infections requires a vaccine, despite the availability of antibiotics. We previously demonstrated that mice vaccinated with a fusion antigen (BD584) consisting of chlamydial type III secretion components (CopB, CopD, and CT584) were protected from infection and pathology. Here, we compare the relative protective efficacy of the individual components of BD584 against *Chlamydia* infection.**Methods:**Five groups (n=5) of female C57BL/6 mice were vaccinated intranasally with 20 µg of the fusion protein BD584, CopB, CopD, CT584, or CopB+CopD+CT584 together with 10 µg of CpG in PBS. A group (n=5) of control mice were vaccinated with PBS only. All mice were vaccinated at -6 and -3 weeks prior to challenge with 4 x 10^5 inclusion forming units of *C. muridarum*. Five days after challenge, vaginal swabs were collected to quantify bacterial shedding via qPCR. Mice were sacrificed 49 days after challenge and upper genital tracts were harvested to assess incidence of hydrosalpinx.**Results:**Mice vaccinated with BD584, CopB, CopD, CT584, and CopB+CopD+CT584 displayed similar bacterial load upon challenge with *C. muridarum*. However, mice vaccinated with BD584 were best protected from the development of hydrosalpinx.**Discussion:**A *C. trachomatis* vaccine is urgently needed. Here we compared the relative protective efficacy of a fusion protein against that of its individual components in a mouse model of *Chlamydia* infection. Although mice vaccinated with each individual component demonstrated similar levels of protection against infection, mice vaccinated with BD584 were best protected from hydrosalpinx. Further studies are needed to elucidate the mechanism underlying this disconnection between infection and pathology, which will aid in the development of a *Chlamydia* vaccine that primarily aims to prevent pathology.

Construction of a Vaccine to Protect Against Food Poisoning From *Campylobacter jejuni* Colonization of Poultry Meat

Author Block:

R. Korba, **L. M. Temple**; James Madison Univ., Harrisonburg, VA

Abstract Body:

Bordetella avium is a gram negative bacterium that causes an upper respiratory infection in poultry. Though the mortality rate for bordetellosis is low, it weakens their immune system leading to secondary infection. *Campylobacter jejuni* is often found in the flora of poultry, but causes food poisoning in humans when contaminated meat is ingested. There is no vaccine to prevent colonization of poultry by *C. jejuni,* so a vaccine that would lower the level of colonization could have a major impact on this significant food safety problem. We hypothesized that a characterized autotransporter in *B. avium* called Baa1 could serve as a genomic location for insertion of an antigen region from *C. jejuni*, replacing a portion of this non-essential gene. The autotransporter has three regions: a promoter, passenger, and transporter. The passenger domain is translocated through the barrel formed by the transporter and expressed on the outer surface of the bacterial cell. Mutants lacking *baa1* are non-virulent. Our constructs were made using the TA cloning vector in *E. coli* that does not replicate in *B. avium.* In our research, we have successfully cloned two separate genes from *C. jejuni* to replace the passenger domain in between the *B. avium* promoter and transporter regions. The transporter region was retained to provide the secretion mechanism for the antigenic region encoded by two genes, *flaA* and *cjaA*. The promoter and transporter regions were cloned together, then the *C. jejuni* genes were separately ligated using unique restriction sites between the two *B. avium* regions to restore the approximate length of the native gene. Cloning was verified through PCR. Multiple positive clones containing each *C. jejuni* genes were found. Because the TA cloning vector does not replicate in *B. avium,* it serves as a suicide vector to deliver the heterologous construct into the host. We have begun the allelic replacement process using tri-parental mating or electroporation and have strains with putative single crossover events that contain the entire plasmid. When these are confirmed, antibiotic selection will be removed so the second crossover can occur. Once this step is completed, expression of the antigenic region of *C. jejuni* will be accomplished using Western blots with available antibodies. Future studies include testing for virulence, determination of ID_{50} in chickens, and protection tests.

Developing Peptide Mimotope Vaccines for *Burkholderia*

Author Block:

R. C. Bernhards[1], **C. H. Weaver**[1], P. Guo[2], J. Zhang[2], B. Li[2], S-C. Lo[2], S. L. Welkos[1];
[1]USAMRIID, Fort Detrick, MD, [2]FDA, Silver Spring, MD

Abstract Body:

Burkholderia pseudomallei and *Burkholderia mallei* represent bacterial biothreats and are classified as Tier 1 select agents. *B. pseudomallei* causes melioidosis which is endemic to Southeast Asia and Northern Australia, while *B. mallei* causes glanders primarily in horses but is also capable of infecting humans. Both of these diseases have high mortality rates and there are currently no vaccines available for either of them. The capsular polysaccharide (CPS) and lipopolysaccharide (LPS) expressed by these pathogens are important virulence factors and have been evaluated as potential protective vaccine antigens in animals. However, such polysaccharides usually induce short term immune responses but not longer-term immune memory, and are often associated with significant toxicity in the vaccinated host. Therefore, development of safer and more defined and immunogenic derivatives of CPS and LPS antigens is a priority. Peptides or other small analogs which mimic the immunogenic epitopes of CPS or LPS are possible candidates for safer and more effective vaccines. Phage display panning was used to discover peptide mimotopes of CPS and LPS using highly specific and protective monoclonal antibodies. The peptides were then tested for specific binding to their respective monoclonal antibodies using ELISA and bio-layer interferometry (BLI). Using BLI, the dissociation constants were determined for each peptide to help rank them according to binding strength and dissociation properties. The best peptide candidates are being conjugated to carrier proteins and the protein conjugates will be re-evaluated using BLI and assessed for their ability to elicit protection from *Burkholderia* infection in mice and nonhuman primates. The goal is to develop a multivalent CPS/LPS vaccine that is highly protective against both *B. pseudomallei* and *B. mallei*.

A Complex Problem: Targeting Meningococcal Proteins for Serogroup B Vaccine Design

Author Block:

K. A. Matthias[1], M. B. Strader[1], J. Lee[2], D. S. Patel[2], W. Im[2], M. C. Bash[1]; [1]Food and Drug Admin., Silver Spring, MD, [2]Univ. of Kansas, Lawrence, KS

Abstract Body:

The development and implementation of vaccines derived from the purified capsular polysaccharide (Ps) of *Neisseria meningitidis* serogroups A, C, W, and Y have been highly successful at preventing invasive disease. Use of Ps vaccines is not feasible for elimination of serogroup B, however, as the capsule resembles human Ps moieties and is poorly immunogenic. For this reason, group B vaccine design has targeted outer membrane proteins (OMPs). Vaccine effectiveness correlates with the presence of serum bactericidal activity, suggesting a dominant role for antibody-mediated bacterial lysis in protection against *N. meningitidis in vivo*. Yet, meningococcal OMPs can be subject to phase and antigenic variation, making elicitation of broadly protective bactericidal antibodies difficult. The essential protein PorB, which is comprised of eight surface-exposed loops (L1-L8), is a vaccine candidate and a useful model for testing the impact of antigenic variability on antibody binding, cross-protection, and OMP complex formation. We generated a panel of isogenic strains expressing chimeric serogroup 15 (MC58) and 4 (Cu385 and BB1350) PorB types. We then assessed the effect of sequence mutation on antibody binding using PorB-specific monoclonal (mAbs) and polyclonal antibodies (pAbs). L1-specific mAb binding to PorB was affected by sequence changes to other loop regions, such that mAb binding to wild type PorB > PorB with heterologous L5-L6 > PorB with heterologous L7-L8 > PorB with heterologous L5-L8; binding levels correlated with bactericidal activity against the same strains. Strains exhibiting heterologous PorB sequence were likewise decreased in binding affinity of pAbs specific for L5-L8, demonstrating the observed effect was not relegated to L1 alone. Next, we examined the role of OMPs known to interact with PorB in affecting epitope recognition. Deletion of two of these, PorA and RmpM, had no effect on the ability of antibodies to bind to PorB, but did alter the size and composition of the OMP complexes formed. These data suggest that genetic mosaicism may result in antigenic diversity through interactions between loops and that vaccine candidates targeting individual epitopes may be more limited than suggested by protein sequence alone.

Mosquitocidal Properties of Igg Targeting the Voltage Gated Sodium Channel in Malaria Vector *Anopheles gambiae*

Author Block:

J. Donkoh[1], J. Meyers[2], B. Foy[1]; [1]Colorado State Univ., Fort Collins, CO, [2]Texas A&M Univ., College Station, TX

Abstract Body:

Insecticides are crucial for controlling the transmission of malaria parasites and the disease they cause. Voltage gated sodium channels (VGSC) are large transmembrane proteins that are responsible for generating action potentials in the neurons of malaria vector mosquitoes, facilitating neurophysiologic function. They are also targets of the pyrethroid and organochlorine classes of insecticides. VGSCs are important insecticide targets for malaria control, but often have mutations which make them resistant to chemical insecticides. We are attempting to target the VGSC of malaria vectors with specific immunoglobulins that could be ingested in the mosquito's blood meals from vaccinated hosts. VGSCs have many transmembrane domains that are connected by extracellular loops of amino acids that vary in length and importance relative to the molecular action of the channel function. We developed antibodies against extracellular loops in VGSC domains 1, 2 and 4 from the malaria vector mosquito *Anopheles gambiae*. Immunohistochemical staining of adult *An. gambiae* tissue sections with our antibodies showed binding in in tissues of the head and thoracic ganglia. Surprisingly, two our antibodies also showed unique tissue staining relative to the others in Malpighian tubules, ovaries and the flight muscles. To determine if our antibodies could kill An. gambiae, we injected a physiological dose (958ng/mL) of our anti-VGSC IgGs into the thorax of female mosquitoes and measured their survivorship compared to control-injected mosquitoes. These injections reduce mosquito survivorship compared to controls, suggesting that the antibodies bind to the channels *in vivo* and disrupt VGSC function. We are preparing to blood feed these same antibodies to groups of mosquitoes and expect that they will kill them relative to controls. This work constitutes the first steps in developing mosquitocidal vaccines that could be used to combat malaria transmission and disease in many parts of the world.

Resistance Incidence to Spr741 in Combination with Rifampin in Gram-Negative Isolates

Author Block:

N. COTRONEO, A. Rubio, T. R. Parr, Jr, T. Lister; Spero Therapeutics, Inc., Cambridge, MA

Abstract Body:

Background: SPR741 is a novel polymyxin B (PMB) analog that interacts with the outer membrane of Gram-negative bacteria, compromising the integrity of the lipopolysaccharide (LPS) barrier and enabling entry of antimicrobial compounds which otherwise lack significant activity, such as rifampin (RIF).**Methods:** The spontaneous resistance incidence (RI) of SPR741 in combination with RIF was assessed for seven isolates of *Escherichia coli* (Ec, n=3), *Acinetobacter baumannii* (Ab, n=3) and *Klebsiella pneumoniae* (Kp, n=1) in triplicate using an agar plating method with SPR741 at 4-32 ug/mL in combination with RIF at 0.1-64 ug/mL in comparison to RIF at 8x MIC. *Staphylococcus aureus* (Sa) RIF RI was also tested. A subset of isolates identified in the RI was passed 3x on non-selective agar and tested in modified CLSI-based agar dilution and broth microdilution MIC methods.**Results:** The RI to RIF ranged from 10^{-7} to 10^{-9} for all strains tested while SPR741 at 4-32 ug/mL in combination with RIF at 0.1-64 ug/mL RI was found to range from 10^{-6} to $\leq 10^{-9}$. An 88% resistance confirmation rate was obtained based on 215 colonies taken from multiple conditions tested using an agar based screening method. Two resistance phenotypes were apparent using this agar method:

Mutant Phenotype:	**Decreased RIF Susceptibility (%):**	**Decreased PMB Susceptibility (%):**	**Not Confirmed (%):**	**# Colonies Tested:**
***Ec* (n=3)**	66%	7%	27%	104
***Ab* (n=3)**	95%	0%	5%	62
***Kp* (n=1)**	67%	29%	4%	49

When elevated, RIF MICs were $\geq$128 ug/mL. Broth MICs of a subset of Ec isolates found to have elevated PMB MICs also demonstrated decreased susceptibility to 741 + clarithromycin (CLR), while susceptibility to amikacin, meropenem, and ciprofloxacin was unchanged for all isolates tested.**Conclusions:** RIF and RIF + SPR741 RI values in Ec, Ab and Kp were generally comparable and were similar to the RIF RI in Sa. Isolates with reduced susceptibility to RIF had RIF MICs $\geq$128 ug/mL, consistent with high level resistance conferred by *rpoB* mutations [AAC, **44**, 11 (2000)]. Cross-resistance to clinically relevant antibiotics aside from PMB was not

observed. Isolates with increased PMB MICs also had elevated MICs to SPR741 + CLR, however their virulence and potential clinical relevance has not been established.

Publishing Title:

Synergistic Effect of Gram-positive Agents Tested in Combination with a New Polymyxin Derivative (SPR741) against Multidrug-resistant (MDR) Gram-negative (GN) Pathogens

Author Block:

R. E. Mendes[1], P. R. Rhomberg[1], H. K. Becker[1], A. P. Davis[1], T. Lister[2], T. R. Parr[2], M. Vaara[3], R. K. Flamm[1]; [1]JMI Lab., North Liberty, IA, [2]Spero Therapeutics, Cambridge, MA, [3]Northern Antibiotics, Ltd, Espoo, Finland

Abstract Body:

Background: Few options are available for treating MDR GN infections and combination therapy is used to obtain activity greater than each individual component. The activity of clarithromycin (CLA) and rifampin (RIF) combined with SPR741 was assessed against wildtype (WT) and MDR GN isolates. **Methods:** WT and MDR *E. coli* (EC), *E. cloacae* (ECL), *K. pneumoniae* (KPN) and *A. baumannii* (ACB) were selected. CLA, RIF and SPR741 were tested by CLSI methods alone and in combination with SPR741 at fixed concentrations of 2 (F2), 4 (F4) and 8 (F8) μg/ml. Isolates with CLA-SPR741 (F8) MICs of ≥8 μg/ml were subjected to whole genome sequencing (WGS) for screening of MLS_B genes. **Results:** CLA had MIC_{50} values of 16-128 μg/ml against WT GN isolates, while CLA-SPR741 at F2 (MIC_{50}, 1-16 μg/ml), F4 (MIC_{50}, 0.12-1 μg/ml) and F8 (MIC_{50}, 0.12 μg/ml) showed MIC_{50} 8- to 2,048-fold lower than CLA. SPR741 at F8 had lowest MICs against MDR ECL ($MIC_{50/90}$, 0.12/2 μg/ml) and EC ($MIC_{50/90}$, 0.5/8 μg/ml), whereas this combination was less active against MDR KPN ($MIC_{50/90}$, 1/>32 μg/ml) and ACB ($MIC_{50/90}$, 32/>32 μg/ml). RIF tested alone had MIC_{50} values of 2-32 μg/ml against WT GN isolates, while RIF-SPR741 tested at F2 (MIC_{50}, 0.5-4 μg/ml), F4 (MIC_{50}, 0.06-0.25 μg/ml) and F8 (MIC_{50}, 0.015-0.12 μg/ml) decreased the RIF MIC_{50} values 4- to 2,048-fold. RIF-SPR741 at F8 had lowest MICs against MDR EC ($MIC_{50/90}$, 0.015/0.12 μg/ml) and ECL ($MIC_{50/90}$, 0.03/0.12 μg/ml), representing a 128- to 1,024-fold reduction in MICs compared to RIF. RIF had MICs 4- to 16-fold higher than the RIF-SPR741 combinations against MDR ACB. 14 GN were selected for WGS and showed *mph*(A or E), except for one EC that carried *erm*(B). **Conclusions**: CLA, RIF and SPR741 did not show direct *in vitro* activity against GN isolates. However, potent synergistic activity was observed when CLA, especially RIF, were combined with SPR741, which decreased CLA and RIF MIC up to 2048-fold.

Mechanism of Action of Spr-741, a Potentiator Molecule for Gram-Negative Pathogens

Author Block:

B. Murray[1], C. Pillar[1], M. Pucci[2], **D. Shinabarger**[1]; [1]Micromyx, LLC, Kalamazoo, MI, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: Few options are available for treating multidrug resistant infections caused by Enterobacteriaceae. SPR-741 is a polymyxin (PMB) derived potentiator molecule under development for use in combination therapies against Gram-negative infections. To understand the mechanism of action, membrane leakage and inhibition of macromolecular synthesis (MMS) pathways were studied using *Escherichia coli* ATCC 25922.**Methods:** The MIC of SPR-741 and PMB was determined by standard broth microdilution standard methods (CLSI M7). Membrane damage was examined by exposing *E. coli* ATCC 25922 to various concentrations of SPR-741, PMB, or tetracycline (TET) and measuring the release of ATP from cells after 30 min and 2 hr exposures. Inhibition of DNA, RNA, protein, cell wall, and lipid MMS using radiolabeled precursors was studied using the same concentrations of SPR-741, and included positive control drugs for each pathway.**Results:** The MIC for SPR-741 was 64 µg/mL for *E. coli* ATCC 25922, and the MIC for PMB was 0.25 µg/mL. Results from the ATP release assays are shown in the table below.

Drug/Incubation Time	ATP Release (µM) with Drug Exposure (µg/mL)				
	16 µg/mL	32 µg/mL	64 µg/mL	128 µg/mL	512 µg/mL
SPR-741 (30 min)	0.01	0.00	0.00	0.02	0.00
PMB (30 min)	0.10	0.12	0.16	-	-
SPR-741 (120 min)	0.00	0.00	0.00	0.00	0.03
PMB (120 min)	0.12	0.10	0.09	-	-

For evaluation of membrane damage, it was determined that very little intracellular ATP (0.03 µM) was released into the extracellular medium after a 2 hr exposure with up to 512 µg/mL (8-fold the MIC) of SPR-741. When tested at 8-fold the MIC, the negative control TET released 0.03 µM of ATP. Incubation of cells with 16-64 µg/mL of PMB (64-256 fold the MIC) resulted in the release of 3-5 times more ATP (0.10-0.16 µM). There was little inhibition of DNA, RNA or cell wall synthesis by SPR-741. Slight dose-dependent inhibition of protein synthesis occurred from 1-4 fold the MIC, and there was constant (25-46%) inhibition of lipid synthesis from 0.25-8

fold the MIC.**Conclusions:** SPR-741 had an MIC of 64 μg/mL against *E. coli* ATCC 25922. Compared to PMB, very little ATP was released from actively growing cells when exposed to high concentrations (512 μg/mL) of SPR-471 representing 8-fold the MIC. No clear dose-dependent inhibition of the 5 MMS pathways was detected for SPR-471.

Potentiation of Antibiotic Activity by a Novel Cationic Peptide, Spr741

Author Block:

D. Corbett[1], A. Wise[1], S. Birchall[1], E. Trimby[1], J. Smith[1], T. Lister[2], M. Vaara[3]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Spero Therapeutics, Cambridge, MA, [3]Northern Antibiotics Ltd, Espoo, Finland

Abstract Body:

Background: Novel approaches to the treatment of multi drug resistant (MDR) Gram-negative bacterial (GNB) infections are urgently required. One approach is to potentiate the efficacy of existing antibiotics whose spectrum of activity is limited by the permeability barrier presented by the GNB outer membrane (OM). Cationic peptides derived from polymyxin B have been used to permeabilise the OM of GNB, granting antibiotics that would otherwise be excluded access to their targets. We assessed the *in vitro* efficacy of combinations of SPR741 with conventional antibiotics against *Escherichia coli* (*Ec*), *Klebsiella pneumoniae* (*Kp*), and *Acinetobacter baumannii* (*Ab*).**Methods:** Efficacy was assessed in checkerboard assays. The MIC of SPR741, antibiotics, and combinations thereof was defined as the lowest concentration that inhibited growth of *Ec* ATCC 25922, *Ab* NCTC 12156 and *Kp* ATCC 43816. *Ec* BW25113, *ΔtolC* and *ΔacrA* were used to assess the contribution of the multi drug efflux pump AcrAB-TolC to susceptibility to the combinations. Interactions were assessed by calculating fractional inhibitory concentration indices (FICI) for each combination in which the MIC differed from compounds in isolation. Interactions were defined as: FICI > 4, antagonism; 0.5-4, no interaction; <0.5, synergy. The minimum bactericidal concentration of combinations in the presence of 5% surfactant (Survanta) was also determined.**Results:** Of 22 antibiotics tested, the MIC of 7 - azithromycin, clarithromycin (CLR), fusidic acid (FA), mupirocin, retapamulin (RET) rifampicin (RIF), telithromycin - against *Ec* and *Kp* was reduced 32 - 8,000-fold in the presence of 8-16 µg/mL SPR741; against *Ab*, similar potentiation was achieved with CLR, FA, RET, and RIF. SPR741 was able to potentiate antibiotics that are substrates of AcrAB-TolC, effectively circumventing the pump's contribution to intrinsic antibiotic resistance. RIF or CLR in combination with SPR741 were bactericidal at concentrations similar to the MIC irrespective of the presence of Survanta.**Conclusions:** The efficacy of several antibiotics with diverse targets was substantially increased when combined with SPR741. These studies support the development of SPR741 in combination with antibiotics for treatment of MDR GNB.

Bacterial Cytological Profiling of Spr741 Mechanism of Action Is Consistent with Membrane Permeabilization That Allows Penetration of Antibiotics into Gram-Negative (G-) Bacteria

Author Block:

J. Pogliano[1], M. Sharp[1], T. Lister[2], A. RUBIO[2]; [1]Linnaeus BioSci.s, San Diego, CA, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: SPR741 is a derivative of polymyxin B that sensitizes G- bacteria to antibiotics that are normally excluded by the outer membrane. To understand the mechanism by which SPR741 enhances sensitivity, we used bacterial cytological profiling (BCP), a microscopy based technique that provides insight into the mechanism of action for antibacterial compounds. Here, we assess SPR741 alone and in combination with a fluorescently labeled macrolide or penicillin, NBD-Azithromycin or Bocillin, respectively, along with other fluorescent stains to observe uptake into *Escherichia coli* (Ec). **Methods:** For profiling experiments, overnight cultures were diluted and grown to an OD_{600} 0.15, at 30^{o}C. Cultures were then split into 500 uL samples, mixed with increasing concentrations of SPR741 and incubated at 30^{o}C for 2 hours. Samples were stained with FM4-64, DAPI or Sytox Green, concentrated by centrifugation and examined by microscopy. For uptake experiments, Ec ATCC25922 cultures were grown to early logarithmic phase, diluted to ~10^7 cfu/mL and exposed to increasing concentrations of SPR741 for 2 hours. Cultures were then treated with 5 ug/mL of NBD-Azithromycin or Bocillin for an additional hour. Then samples were stained with FM4-64 and DAPI, washed three times, examined by microscopy and quantified using flow cytometry. **Results:** Profiling results demonstrate that SPR741 affects the cell envelope, causing subtle cell shape changes and increasing permeability to stains normally excluded by the outer membrane of *E. coli*. Quantitative flow cytometry experiments show that Ec is largely impenetrant to NBD-Azithromycin or Bocillin. Addition of 4 µg/mL or 8 µg/mL SPR741 increased the uptake of NBD-Azithromycin 4.7-fold and 6.9-fold, respectively. Preincubation with 4 µg/mL or 8 µg/mL of SPR741 also increased the accumulation of the fluorescent penicillin, Bocillin by 2.5-fold, and at higher doses (up to 32 µg/mL SPR741) increased Bocillin staining more than 5-fold. **Conclusions:** Results shown herein are consistent with SPR741 permeabilizing the outer membrane to allow penetration of normally impenetrant G+ antibacterials to the periplasm and cytoplasm of G- bacteria, like Ec.

Projection of Spr741 Human Pharmacokinetics and Efficacious Dose Using Three Species Allometric Scaling

Author Block:

P. Shastri[1], **S. Coleman**[2]; [1]WIL Res., Ashland, OH, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: SPR741 is a polymyxin derivative that is currently being investigated as a partner in combination with other antibiotics in the treatment of multi-drug resistant Gram-negative infections. Estimation of the efficacious human dose was made using a three species allometric scaling analysis. **Methods:** Human pharmacokinetic (PK) parameters for SPR741 were estimated using both fixed and floating exponent allometric scaling methods. SPR741 PK data from mouse, rat, and monkey studies were fit to a 1-compartmental model and the same model was used for human simulations. PK analysis was performed using Phoenix® WinNonlin® Version 6.3 (Pharsight Corp. [Mountain View, CA]). Mean plasma concentrations of SPR741 were used to derive PK parameters from preclinical studies. A one-compartment model was fitted to mean SPR741 PK profiles from mouse, rat, and monkey PK studies. A MixRatio (additive and multiplicative) weighting was applied for all PK modeling. Two sets of scaled human PK parameters for SPR741 that yielded a wide range of estimates were used to calculate Human Equivalent Dose (HED) and to simulate SPR741 concentrations in healthy subjects after a single one-hour IV infusion dose.**Results:** Human clearance and half-life estimates for SPR741 from various allometric approaches ranged from 51 to 103 mL/h/kg and 2.2 to 2.4 hours, respectively. Efficacy studies in mice with SPR741 demonstrated pharmacological activity with an AUC value of 60 µg*h/mL. The projected human efficacious dose for SPR741 ranges from approximately 200 to 400 mg administered three times per day using the scaled clearance and the AUC that demonstrated efficacy in the mouse studies. Human PK simulations were performed after a single IV infusion administration of SPR741 with the AUC ranging from 14 to 28, 28 to 56, 55 to 112, and 110 to 225 µg*h/mL at 100, 200, 400, and 800 mg, respectively.**Conclusions:** The projected human PK profile and efficacious dose of SPR741 are consistent with potential partner antibiotics. Further, these data in combination with the current nonclinical studies for SPR741 support advancement into more thorough nonclinical studies to enable clinical development.

***In Vitro* Activity of Faddi-287, a Representative of a Novel Series of Polymyxins (Pm) with Reduced Nephrotoxic Potential**

Author Block:

O. Lomovskaya[1], D. Rubio-Aparicio[1], K. Nelson[1], K. D. Roberts[2], P. E. Thompson[2], R. L. Nation[2], T. Velkov[2], J. Li[2], S. J. Hecker[1], D. C. Griffith[1], M. N. Dudley[1]; [1]The Med.s Company, San Diego, CA, [2]Monash Inst. of Pharmaceutical Sci., Melbourne, Australia

Abstract Body:

Background: The major objective of our PM discovery program is to develop novel compounds that retain PM-like potency but have significantly improved safety profiles. In this study we evaluated in vitro potency of FADDI-287, a representative of a series of novel PM(s) with much reduced nephrotoxic potential, against the panels of *Pseudomonas aeruginosa* (PA), carbapenem-resistant *Acinetobacter baumannii* (CRAB), and carbapenemase-producing, carbapenem-resistant *Enterobacteriaceae* (CP-CRE).**Methods:** Clinical isolates of PA (N=200), CRAB (N=210) and CP-CRE (N=176, 73 KPC, 78 MBL and 25 OXA-48-like producing strains) were tested by the reference broth microdilution method for susceptibility to FADDI-287, polymyxin B (PMB) and other comparators.**Results:** FADDI-287 ($MIC_{50/90}$, 0.25/0.5 µg/ml) was 4-fold more potent than PMB ($MIC_{50/90}$, 1/2 µg/ml) against CRAB isolates, and had much higher potency compared to other tested antibiotics ($MIC_{50/90}$ of tigecycline, minocycline, doxycycline, levofloxacin and meropenem of 4/8, 8/16, 64/>64, 16/64 and 32/>64 µg/ml, respectively). FADDI-287 ($MIC_{50/90}$, 1/1 µg/ml) had excellent activity when tested against PA: it was slightly more potent than PMB ($MIC_{50/90}$, 1/2 µg/ml) and much more potent that comparator agents ($MIC_{50/90}$ of levofloxacin, imipenem, aztreonam, cefepime, ceftazidime and amikacin of 0.5/32, 2/32, 8/32, 4/32, 4/64 and 2/32 µg/ml, respectively). The potency of FADDI-287 ($MIC_{50/90}$, 0.5/16 µg/ml) against the challenge panel of CP-CRE isolates was similar to that of PMB ($MIC_{50/90}$, 1/16 µg/ml). This panel was highly resistant to comparator antibiotics with MIC_{90} >64 µg/ml for levofloxacin, gentamicin, and all tested beta-lactams (meropenem, ceftazidime, aztreonam). The CRE panel contained 21 strains with MIC for PMB >4 µg/ml and all these strains had increased FADDI-287 MICs. Cross-resistance between PMB and FADDI-287 was also observed in PA and CRAB.**Conclusions:** FADDI-287 was very active against CRAB, PA and CP-CRE isolates warranting further preclinical evaluation of the promising series of novel PMs.

Impact of Dosing Regimens on the *In Vivo* Efficacy of Combinations of Novel Antimicrobial Cationic Peptide Spr741 and Rifampicin in Murine Thigh Infection Models

Author Block:

P. Warn[1], D. Corbett[1], J. Gould[1], G. Parker[1], G. Daws[1], P. Thommes[1], P. Evenden[1], T. Lister[2], T. R. Parr[2]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: Potentiation of new or existing antibiotics may be an alternative approach to bridge the gap in the pipeline of therapeutic options for MDR Gram-negative infections. In these studies we assessed the impact of different dosing regimens on the efficacy of combinations of a polymyxin derivative, SPR741, with rifampicin (Rif) in murine models of thigh muscle infection**Methods:** Male ICR mice were rendered neutropenic using 2 doses of cyclophosphamide. Thighs of the mice were infected by intramuscular injection on day 0 with *E. coli* IR60 [Bla_{NDM-1}]. Subcutaneous treatment was initiated 1h post infection with 120mg/kg total dose SPR741 fractionated as 1, 2 or 3 doses administered at 1, 4 and 8h post infection plus 60mg/kg/dose of subcutaneously Rif at 1 and 5h PI to determine the post antimicrobial response. Thigh burdens were quantitatively assessed at 5, 9, 13, 19 and 25h PI.In a second study 120mg/kg total dose of SPR741 was fractionated as 1, 2, 3, or 4 doses administered subcutaneously in combination with 60, 120, 180 or 240mg/kg total dose Rif subcutaneously at 1h; 1 and 13h; 1, 9, and 17h; or 1, 7, 13, and 19h post infection. Thigh burdens were quantitatively assessed at 25h post infection.**Results:** SPR741 and Rif were well tolerated by the animals in both studies. The isolate demonstrated vigorous *in vivo* growth of 2.7 - 3.6Log_{10}cfu/g thigh tissue in vehicles across studies. Following a single dose of the SPR741-Rif combination all burdens were reduced to below stasis for >9h, a second dose of Rif or a more fractionated regimen of SPR741 reduced burdens below stasis for >19h. When the SPR741-Rif combination was administered less frequently the only regimen to achieve burdens below stasis was a total dose of 40mg/kg SPR741 plus 60mg/kg Rif administered every 8h**Conclusions:** The combination of SPR741 with Rif was effective at reducing the thigh burden of mice infected with *E. coli* expressing Bla_{NDM-1}. The data from these two studies suggest that a minimum area under the curve (AUC) must be maintained over time to demonstrate efficacy for this combination and support continued development of SPR741 combinations for the treatment of MDR-GNB.

***In Vivo* Efficacy of Combinations of Novel Antimicrobial Peptide Spr741 and Rifampicin in Short-Duration Murine Lung Infection Models of *Klebsiella pneumoniae* Infection**

Author Block:

P. Warn[1], J. Teague[1], E. Burgess[1], L. Payne[1], D. Corbett[1], A. Sharp[1], T. Lister[2], T. R. Parr[2]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: Infections due to carbapenem-resistant Enterobacteriaceae (CRE) (*Klebsiella pneumoniae* carbapenemase [KPC] and (New Delhi Metallo-β-lactamase [NDM-1]) are being increasingly reported. Following infection, treatment options are restricted to drugs with modest efficacy or dose-limiting toxicity leading to sub-optimal outcomes. Potentiation of antimicrobial agents to increase potency and extend spectrum of activity has shown utility in pre-clinical studies. In these studies we assessed the efficacy of combinations of a novel antimicrobial cationic peptide (SPR741) with rifampicin (Rif) in murine models of acute pneumonia due to *K. pneumoniae*.**Methods:** Male ICR mice were rendered neutropenic using two doses of cyclophosphamide on days -4 and -1. Mice were infected by intranasal instillation on day 0 with either *K. pneumoniae* (Kp114 [Bla_{KPC}] or ATCC BAA 2146 [Bla_{NDM-1}]). Treatment was started 2h post infection (PI) with SPR741 administered at 2, 4.5 and 8h PI and Rif administered at 2 and 6h PI). SPR741 was administered at 10, 20 and 40mg/kg/dose, Rif was administered at 40 and 64 mg/kg/dose for Kp114 and ATCC BAA 2146 respectively. Mice were euthanized 10h post infection and the lungs quantitatively cultured.**Results:** SPR741 and Rif were well tolerated and all animals continued to the study end. Isolates demonstrated robust *in vivo* growth of 0.6 and 0.75Log_{10}cfu/g lung tissue between pre-treatment and harvest samples (Kp114 and ATCC BAA 2146 respectively). Monotherapy with SPR741 at 20mg/kg/dose or Rif had little effect on the burdens and did not achieve stasis against either isolate. In contrast, for Kp114 the combination of ≤10mg/kg/dose SPR741 with 40mg/kg/dose Rif led to reductions in burden of ≥1.6Log10cfu/g below stasis. For ATCC BAA 2146 the combination of 40mg/kg/dose SPR741 with 64mg/kg/dose Rif led to reductions in burden of 0.85Log10cfu/g below stasis.**Conclusions:** The combination of SPR741 with Rif was highly effective at reducing the lung burden of mice infected with *K. pneumonia* including strains expressing Bla_{KPC} and Bla_{NDM-1}. These studies support continued development of novel antimicrobial cationic peptides for the treatment of MDR Gram-negative infections.

***In Vivo* Efficacy of Combinations of Novel Antimicrobial Cationic Peptide Spr741 and Clarithromycin (Clr) in Short-duration Murine Thigh and Lung Models of Gram-negative Infection**

Author Block:

P. Warn[1], A. Sattar[1], P. Thommes[1], D. Corbett[1], K. Holden[1], T. Lister[2], T. Parr[2]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: Due to an increasing incidence of multi-drug-resistant Gram-negative infections (MDR-GNB) new therapeutic options are urgently required. SPR741 is cyclic peptide that permeabilizes the outer membrane of GNB. When used in combination, in some cases, it can increase the intracellular exposure of inpermeant antimicrobials. In these studies we assessed the efficacy of combinations of SPR741 with CLR in murine models of thigh and lung infection**Methods:** Male ICR mice were rendered neutropenic using 2 doses of cyclophosphamide. Mice were infected either IM into the lateral thigh muscle or by IN instillation on day 0 with either *E. coli* (*E.c*.) (ATCC 25922 and IR60 [Bla_{NDM-1}]) (thigh only), *Klebsiella pneumoniae* (*K.p*.) ATCC BAA 2146 [Bla_{NDM-1}] or Kp114 [Bla_{KPC-3}] (lung only) or *Acinetobacter baumannii* (*A.b.)* (ATCC BAA 747). Treatment was initiated 1h (thigh) or 2h (lung) post infection (PI) with SPR741 given subcutaneously at 1, 3.5 and 7h (thigh) or 2, 4.5 and 8h (lung) PI and CLR given IV at 1h (thigh) or 2h (lung) PI. SPR741 was administered at 10, 20 and 40 mg/kg/dose, and CLR was administered at 125 mg/kg (E.c. ATCC 25922 only) or 100 mg/kg. Mice were euthanized 9h (thigh) or 10h (lung) PI and the thigh or lung quantitatively cultured**Results:** SPR741 was well tolerated. Isolates demonstrated robust *in vivo* growth between pre-treatment and harvest samples. Monotherapy with SPR741 at 20 mg/kg/dose or CLR had little effect on the burdens. In contrast in all thigh burden models combinations with >20 mg/kg/dose thigh SPR741 with CLR led to reductions in burden (1.8, 0.4, 3.3 and 1.6 Log_{10}cfu/g below stasis for ATCC 25922, IR60, ATCC BAA 2146 and ATCC BAA 747, respectively), In lung burden models combinations with 40mg/kg/dose SPR741 with CLR led to reductions in burden (1.8, 1.2Log_{10}cfu/g below stasis for Kp114 and ATCC BAA 747 respectively) but was ineffective against ATCC BAA 2146**Conclusions:** The combination of SPR741 with CLR was effective at reducing the thigh burden of mice infected with *E.c., K.p.* and *A.b* including strains expressing Bla_{NDM-1}. It was also effective in pneumonia models due to a *K.p.* strain expressing Bla_{KPC-3} and *A.b.* These studies support continued development of SPR741 for the treatment of MDR-GNB

Pharmacology Of The Novel Polymyxin Faddi-287 In Preclinical Models

Author Block:

M. Sabet[1], Z. Tarazi[1], T. Nolan[1], J. Parkinson[1], D. Rubio-Aparicio[1], K. D. Roberts[2], P. E. Thompson[2], R. L. Nation[2], T. Velkov[2], J. Li[2], S. J. Hecker[1], O. Lomovskaya[1], M. N. Dudley[1], **D. C. Griffith**[1]; [1]The Med.s Company, San Diego, CA, [2]Monash Univ., Melbourne, Australia

Abstract Body:

Background: The widespread dissemination of antibiotic resistance in gram negative pathogens has necessitated the increased use of potentially nephrotoxic polymyxins. We have developed a new series of polymyxin B (PMB) derivatives with improved safety profiles and activity against major MDR bacteria. This study aimed to demonstrate the activity of FADDI-287 in animal models of infection. M**ethods:** The minimum lethal dose (MLD) and nephrotoxicity of FADDI-287 and PMB were determined in Swiss mice. PK studies were conducted to compare drug exposure in mice and rats. For the neutropenic mouse thigh infection using *A. baumannii* or *P. aeruginosa*, Swiss mice were infected with ~10^6 CFU/thigh. Doses were administered IP at various intervals starting 2 h post-infection and continued over 24 h. For the rat lung infection model using *A. baumannii*, Sprague-Dawley rats were infected with ~10^7 CFU/lung. FADDI-287 and PMB were administered IV BID starting 2 h post-infection and continued over 24 h. For both infection models, untreated control groups were sacrificed at the start of treatment and both untreated and treated groups were sacrificed 24 h after the start of treatment, infected tissues harvested, homogenized, and plated to determine colony counts. **Results:** The table summarizes the toxicity, PK, and efficacy in mice.

Compounds	MLD IV (mg/kg)	Kidney Changes (6 x 10 mg/kg; IP)	*f*AUC (mg*hr /L) 5 mg/kg (IP)	24h *f*AUC at EC_{50} vs. *P. aeruginosa*
PMB	7.5	Minimal to Severe Nephrosis	1.39	5.72
FADDI-287	15	No change	0.88	5.33

In the mouse thigh infection model, equivalent exposures of FADDI-287 and PMB produced similar bacterial killing against *P. aeruginosa*. In the mouse thigh and rat lung infection models against *A. baumannii*, FADDI-287 showed much better bacterial killing (-1.98 [mouse] and -0.79 [rat] log CFU/lung) than PMB (-0.23 [mouse] and +1.21 [rat] log CFU/lung) at similar exposures. **Conclusion:** FADDI-287 was less acutely toxic, less nephrotoxic, but with

comparable to superior efficacy compared to PMB at similar exposures. Further studies on the activity of FADDI-287 are warranted.

In Vitro* Activity of Spr741 Against Recent Clinical Isolates of *Escherichia coli* and *Klebsiella pneumoniae

Author Block:

M. Hackel[1], T. Lister[2], T. R. Parr, Jr.[2], M. Vaara[3], D. Sahm[1]; [1]IHMA, Inc., Schaumburg, IL, [2]Spero Therapeutics, Cambridge, MA, [3]Northern Antibiotics, Espoo, Finland

Abstract Body:

Background: SPR741 is a potentiator compound currently under development by Spero Therapeutics. The objective of the present study was to investigate the *in vitro* activity of SPR741 in combination with rifampin or clarithromycin against 199 recent clinical isolates of *Escherichia coli* and *Klebsiella pneumoniae*.**Methods**: Minimal inhibitory concentrations (MICs) were determined following CLSI microdilution guidelines against a global collection of 100 *E. coli* and 99 *K. pneumoniae* from 2014-2015. Compounds tested included rifampin and clarithromycin alone, and in combination with SPR741 at fixed concentrations of 2, 4 and 8 µg/mL.**Results**: Addition of fixed concentrations of SPR741 reduced the MIC values of rifampin and clarithromycin at all concentrations tested, with the greatest effect seen at a concentration of 8 µg/mL. Clarithromycin and rifampin MICs for *E. coli* were reduced ≥5 dilutions for 94% and 100% of isolates, respectively. For *K. pneumoniae*, clarithromycin and rifampin MICs were reduced ≥5 dilutions for 58% and 86% of isolates, respectively. Results are shown in the Table with MIC_{50} values shaded and MIC_{90} values bolded.Frequency distribution (n) of 199 *E. coli* and *K. pneumoniae* at each MIC.

Organism (n)	Compound	MIC (µg/mL)											
		≤0.03	0.06	0.12	0.25	0.5	1	2	4	8	16	32	64	>64
E. coli (100)	CLR										1	2	11	**86**
	CLR SPER 8	1	1	5	19	**39**	19	7	3	3	2	1		
	RIF								6	35	**47**	5	2	5
	RIF SPER 8	**90**	4			2	1	2		1				
K. pneumoniae (99)	CLR													**99**
	CLR SPER 8					4	8	23	**22**	10	8	6	5	**13**
	RIF										12	**69**	8	**12**
	RIF SPER 8	6	22	**23**	18	5	4	5	1	4	4		1	2

CLR, clarithromycin; SPER, SPR741; RIF, rifampin

Conclusions: SPR741 exhibited strong potential for increasing the *in vitro* activity of clarithromycin and rifampin against many *E. coli* and *K. pneumoniae*. Further development of this potentiator compound could provide a valuable therapeutic option for treating infections caused by resistant gram-negative bacilli.

Abstract Body:

Background: SPR741 is a potentiator compound currently under development by Spero Therapeutics. The objective of the present study was to investigate the *in vitro* activity of SPR741 in combination with rifampin, clarithromycin or meropenem against 100 recent clinical isolates of *Acinetobacter baumannii*. **Methods:** Minimal inhibitory concentrations (MICs) were determined following CLSI microdilution guidelines against a global collection of 100 *A. baumannii* from 2014-2015. Compounds tested included rifampin, clarithromycin and meropenem alone, and in combination with SPR741 at fixed concentrations of 2, 4 and 8 µg/mL.**Results**: Addition of fixed concentrations of SPR741 reduced the MIC values of clarithromycin, rifampin, and meropenem at all concentrations tested, with the greatest effect seen at a concentration of 8 µg/mL. Reductions in MIC of 3 doubling dilutions and 5 doubling dilutions, respectively, with the addition of 8 µg/mL of SPR741 were: clarithromycin: 26% and 56%; rifampin: 63% and 45%; meropenem: 9% and 0%. Results are shown in the Table with MIC_{50} values shaded and MIC_{90} values bolded.Frequency distribution (n) of 100 *A. baumannii* at each MIC.

Compound	MIC (µg/mL)												
	≤0.03	0.06	0.12	0.25	0.5	1	2	4	8	16	32	64	>64
CLR							1		5	4	9	15	**66**
CLR SPER 2				1		4	16	17	9	4	6	5	**38**
CLR SPER 4		1		5	13	17	7	8		4	3	5	**37**
CLR SPER 8		4	3	16	20	6	2	3	1	2	10	2	**31**
RIF			1		1	4	41	28	**17**	1	3	4	
RIF SPER 2		1	1	9	32	17	23	**11**	1	2	3		
RIF SPER 4	1	1	17	27	14	10	**22**	4	1		3		
RIF SPER 8	3	32	13	10	11	12	**15**	1		2	1		
MEM		1	8	6	3	2	1	2	1	3	14	29	**30**
MEM SPER 2		4	9	4	3	1	1	2	1	6	21	29	**19**
MEM SPER 4	1	6	9	4		1	2	2	2	10	27	23	**13**
MEM SPER 8	1	1	11	6	1	3	2	1	9	17	23	**20**	5

CLR, clarithromycin; SPER, SPR741; RIF, rifampin; MEM, meropenem

Conclusions: SPR741 exhibited strong potential for increasing the *in vitro* activity clarithromycin and rifampin against many *A. baumannii*, while the effect on meropenem was more modest. Further development of this potentiator compound could provide a valuable therapeutic option for treating infections caused by this difficult to treat pathogen.

Potentiation of Antibiotic Activity by Novel Antimicrobial Cationic Peptides: Potency and Spectrum of Activity of Spr741

Author Block:

A. Wise[1], D. Corbett[1], A. Dorali[1], T. Langley[1], K. Skinner[1], L. Payne[1], T. Lister[2]; [1]Evotec (UK) Ltd, Manchester, United Kingdom, [2]Spero Therapeutics, Cambridge, MA

Abstract Body:

Background: Novel approaches to the treatment of multi drug resistant (MDR) Gram negative bacterial (GNB) infections are urgently required. Cationic peptides derived from polymyxin B have previously been shown to permeabilize the outer membrane (OM) of GNB, thus granting antibiotics that would otherwise be excluded access to their targets when administered in combination. We assessed the *in vitro* potency of combinations of the cationic peptide, SPR741 with selected antibiotics against MDR and clinical isolates of *Escherichia coli* (*Ec*), *Klebsiella pneumoniae* (*Kp*), and *Acinetobacter baumannii* (*Ab*).**Methods:** The potency of SPR741 in combination with azithromycin (AZ), aztreonam (AZT), clarithromycin (CLR), fusidic acid (FA), meropenem (MEM), mupirocin (MUP), rifampicin (RIF), and retapamulin (RET) was assessed using a susceptibility testing method based on CLSI guidelines M7-A10. Assays were performed against 25 *Ec*, 25 *Kp*, and 17 *Ab* MDR and clinical isolates, in Mueller-Hinton broth-II (cation adjusted) containing 0, 2 or 8 µg/mL SPR741. The minimum inhibitory concentration (MIC) was defined as the lowest concentration of antibiotic required to inhibit visible bacterial growth. MIC values were determined for each antibiotic/SPR741 combination and maximum reductions in MIC of the antibiotic in the combination were determined.**Results:** Combination with SPR741 resulted in potentiation of test antibiotics against isolates of *Ab*, *Ec*, and *Kp*. For *Ab*, potentiation followed the order FA > RIF > CLR > RET > MEM > AZ > AZT > MUP, with 128 fold reductions in MIC relative to antibiotic alone (MIC reduced from >128 to ≤ 2 µg/mL in the combination). For *Ec*, potentiation followed the order RIF > MUP = FA > AZ = RET > AZT > MEM = CLR; maximum RIF MIC reduction of >2000 fold (MIC reduced from >128 to ≤0.125 µg/mL). For *Kp*, potentiation followed the order RET > RIF = AZ = CLR > MUP > MEM = FA > AZT; the MIC of RET was reduced 32 fold (MIC reduced from 128 to 4 µg/mL).**Conclusions:** SPR741 effectively reduced the MIC of currently utilized antibiotics against MDR isolates of *Ab*, *Ec*, and *Kp*, extending the promising spectrum of activity of these combinations, and supporting continued development of SPR741 for the treatment of MDR GNB.

Effect Of An Antimicrobial Stewardship Intervention On Outcomes For Patients With Severe *clostridium Difficile* Infection

Author Block:

G. Eschenauer, T. S. Patel, T. Gandhi, C. Chenoweth, L. Washer, B. Chen, H. Welch, J. DeLeon, K. Rao, **J. Nagel**; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Treatment of *Clostridium difficile* infection (CDI) is an ideal target for antimicrobial stewardship programs (ASP), as ASPs have been effective in improving care in patients with a variety of infections. Unfortunately, studies to date have not rigorously evaluated the impact of ASP involvement on complications attributed to CDI.**Methods**: We performed a quasi-experimental study of adult patients with severe CDI prior to (n= 231) and after (n=227) a real-time ASP review was initiated. In the ASP review (ASPR) group, a pharmacist member of the ASP was notified in real time of positive CD results and consulted with the care team to initiate optimal therapy, minimize concomitant antibiotic and acid-suppressive therapy, and recommend surgical/infectious diseases consultation (ID) in complicated cases. The primary outcome was a composite of 30-day mortality, ICU admission, colectomy/loop ileostomy, and/or recurrence. A blinded review panel of ID physicians determined whether outcomes were attributed to CDI.**Results**: A significantly higher percentage of patients in the ASPR group received vancomycin (87% vs. 59%, respectively, $p<0.0001$) and vancomycin therapy was initiated earlier (mean 1.05 days vs. 1.70 days, respectively, $p=0.04$), compared to the pre-ASPR group. The incidence of the composite outcome was not significantly different between the ASPR and pre-ASPR groups (13.7% vs. 15.2%, respectively, $p=0.65$).**Conclusions**: ASP review and intervention in patients with severe CDI improved process measures. A decrease in composite outcomes was not found, which may be due to low baseline rates of attributable surgery (2%), mortality (3%) and ICU admission (6%) in our institution.

Customizing an Electronic Medical Record to Automate the Workflow and Tracking of an Antimicrobial Stewardship Program

Author Block:

M. Katzman, J. Kim, M. Lesher, M. Loser, M. Ward, F. Glasser; Penn State Hershey Med. Ctr., Hershey, PA

Abstract Body:

Background: Documenting the actions and effects of an antimicrobial stewardship program (ASP) is essential for quality improvement and continued support by hospital leadership. Thus, our ASP (reference 1) tallies the number of charts reviewed, types of recommendations in 16 categories, to whom and how recommendations were communicated, whether they were followed, and any resultant days of antimicrobials avoided or added. Before 2014 we used a secure spreadsheet, but since then we have used a customized adaptation within Cerner PowerChart, the electronic medical record (EMR) at our institution, to track these data, facilitate our workflow, and enhance our ASP. **Methods and Results:** Our system involves the creation of a novel and intuitive ASP form in each patient EMR reviewed by the ASP, and two mutually exclusive tracking systems: one for active forms (to facilitate the daily ASP workflow) and one for finalized forms (to generate cumulative data reports). The ASP form combines autopopulated fields, checkbox options, spaces for concise entry of relevant text, and built-in logic to open portions of the form as appropriate and require certain entries before it can be closed. Forms are created by the ASP pharmacist, edited by the ASP physician, then reaccessed to record whether the recommendation was followed. The pharmacist subsequently records any antimicrobial days added or avoided, and the physician performs a final reconciliation and proofing of the form to bring it to final status. All ASP forms that have not reached final status are visible to ASP personnel on a real-time "MPage" that displays the information from each form in a single row that also contains two hyperlinks: one to access the patient chart and one to open the ASP form for updating. In contrast, our ASP Reports Program scans PowerChart every night to compile the data from all finalized ASP forms so they can be converted into sets of 63 graphs that can display a wealth of data — over any selected time span — by month, quarter, semiannually, or annually. **Conclusions:** We have customized Cerner PowerChart to facilitate the daily workflow and track the activities of our ASP. This user-friendly system has automated much of the documentation, enhanced the completeness and validity of the data recorded, facilitated data analysis, and freed up time to expand the activities of our ASP.

Antibiotic Use for Surgical Prophylaxis as a Risk Factor for Surgical Site Infections at Three Egyptian Hospitals

Author Block:

T. Saied[1], S. Hafez[2], S. Girgis[3], H. Morsi[2], T. Youssef[3], E. Abdou[1], M. Talaat[1]; [1]Global disease detection and response program, U.S. Ctr.s of Disease Control and US Naval Med. Res. Unit no.3, Cairo, Egypt, [2]Faculty of Med., Alexandria Univ., Alexandria, Egypt, [3]Faculty of Med., Ain Shams Univ., Cairo, Egypt

Abstract Body:

Background: Data on antibiotic use for surgical prophylaxis (SP) are limited in Egypt. The objective of this study is to assess the risk factors for surgical site infections (SSI) including antibiotic use for SP.**Methods:**Surveillance of SSI was conducted through prospective active surveillance at three surgical hospitals. Collected data included: patient demographics (age and gender), surgery related risk factors (type, duration, wound classification, use of implants, and use of drains) and surgical prophylaxis (antibiotic type, timing of preoperative dose, and post-operative duration). SSIs were identified using case definitions of CDC's National Healthcare Safety Network (NHSN). Antibiotic use for SP was evaluated using clinical practice guidelines for antimicrobial prophylaxis in surgery developed jointly by the American Society of Health-System Pharmacists, the Infectious Diseases Society of America, the Surgical Infection Society, and the Society for Healthcare Epidemiology of America.**Results:**A total of 2144 surgeries were included in the study during the period of September 2014-August 2015. SSI rates varied between hospitals (Hospital A: 2.8%, Hospital B: 6.3 %, Hospital C: 6.5%) with an overall rate of 4.5 % (96/2144). Univariate analyses showed significantly higher risk of SSI in surgeries at hospitals B and C, abdominal surgeries, emergency operations, clean-contaminated wounds, use of drains, administering SP > 1 hour before incision, use of antibiotics other than those recommended by the guidelines, and extending SP > 24 hours after operation ($p < 0.05$). Independent risk factors identified by logistic regression were surgeries at hospital B (adjusted Odds Ratio [OR], 2.3; 95% Confidence Interval [CI], 1.3-4.08), administering SP > 1 hour before incision (adjusted OR, 2.3; 95% CI, 1.5-3.7), and extending SP > 24 hours after operation (adjusted OR, 2.06; 95% CI, 1.3-3.3).**Conclusions:**Noncompliance with the guidelines regarding timing of the preoperative dose and duration of post-operative SP contribute to acquiring SSI. Enforcing policies for SP is an essential measure to prevent SSIs in the study hospitals.

Impact of an Antimicrobial Stewardship Program Using the Bedside Teaching Method Targeting Trainees of the Hematopoietic Stem Cell Transplantation Division: A Quasi-experimental Study at a Tertiary Care Cancer Center

Author Block:

K. Okinaka, T. Fukuda; Natl. Cancer Ctr. Hosp., Tokyo, Japan

Abstract Body:

Background: Very few studies have reported regarding the efficacy of an antimicrobial stewardship program (ASP) focusing on hematopoietic stem cell transplantation (HSCT). This study aimed to assess the effect of ASP using the bedside teaching method.**Methods:** We retrospectively reviewed the medical records of patients who were admitted to the HSCT division at the National Cancer Center Hospital from June 2013 to June 2015. The study period was divided into three phases: pre-intervention (Phase 1: June-December 2013), early-intervention (Phase 2: January-June 2014), and late-intervention phases (Phase 3: July 2014-June 2015). During Phases 2 and 3, an infectious disease (ID) physician examined all the patients who had fever during the pre-engraftment phase. Subsequently, the ID physician discussed the treatment strategy with the residents in charge of the patients as necessary.**Results:** A total of 205 HSCT (allogeneic-HSCT: 177) were performed during the study period and were distributed evenly among each phases. Eleven patients died because of infections within 100 days post-HSCT, and 3 of them died due to *Stenotrophomonas maltophilia* bacteremia. ASP intervention did not alter the number of beta-lactam (BL) prescriptions, the number of carbapenem prescription, the median treatment duration with BLs, and the number of BL represcription within 7 days. However, the median treatment duration with carbapenems was significantly decreased at each phase (Kruskal-Wallis test: 13 vs. 10 vs. 7 days; $p < 0.01$). The rate of de-escalation in BL prescriptions was significantly increased at each phase (Fisher's test: 9% vs. 14% vs. 19%; $p < 0.01$), and 34% of de-escalation was performed during neutropenia. The incidence density rates of *S. maltophilia* bacteremia tended to decrease (Fisher's test: 0.94 vs. 0.67 vs. 0.18 bacteremia/1000 patient-day; $p = 0.08$). The all-cause and infectious disease mortality rate during 100 days post-HSCT were similar among each phase (Log rank test: $p = 0.93$, and $p = 0.60$, respectively).**Conclusions:** Our findings suggested that ASP using the bedside teaching method has the potential to be effective in the HSCT setting wherein the problems associated with multi-drug resistant pathogens, such as *S. maltophilia*, are critical.

Evaluation of Appropriate Use of Antifungal Agents in a Tertiary Care Hospital in Greece

Author Block:

K. Korantanis[1], A. Markogiannakis[1], M. Gamaletsou[2], M. Samarkos[1], G. Daikos[1], **N. V. Sipsas**[1]; [1]Natl. and Kapodistrian Univ. of Athens, Athens, Greece, [2]Univ. of South Manchester, Athens, United Kingdom

Abstract Body:

Background: Studies have shown that misuse of antifungals (AF) is common in the hospital setting. Our aim was to the assess the quality of antifungal use in our institution as the first step for the implementation of a targeted antifungal stewardship program**Methods:** This study was conducted at a 550 bed tertiary teaching hospital inAthens, Greece. Starting in September 2014 and for 13 months all prescriptions of AF were prospectively assessed by using a pre-established protocol. All patients receiving AF were prospectively evaluated by the study team when the drug was first administered and at discharge. The adequacy of AF use was evaluated by using a predefined point score that considered indication, drug selection, dosage, adjustments after microbiology results, switching to an oral agent, length of treatment, serum levels monitoring, and interactions. The criteria used to define the appropriateness of AF prescription were adopted from the existing treatment guidelines. Each prescription was characterized as “appropriate”, “appropriate but not optimal,” and “inappropriate”, by consensus.**Results:** We assessed 208 consecutive prescriptions of antifungal agents for the treatment of 147 in-patients (male 89, mean age 58.7 y). AF were prescribed by the attending physicians in 69.3% of cases, and by infectious diseases specialists in 30.7%. The main underlying diseases were hematological malignancy (124, 59.6%), solid tumor (35, 16.8%), and HIV infection (9, 4.3%). Overall, 101 (48.5%) of prescriptions came from medical, 53 (25.5%) from hematology, and 36 (17.3%) from surgery departments and 18 (8.6%) from the intensive care unit. The main reasons for starting antifungals were prophylaxis 65 (31.25%); empirical 120(57.69%); pre-emptive 7 (3.36 %) and targeted treatment 19 (9.13%). Overall, 94 (45.1%) of the prescriptions have been characterized as appropriate, 25 (12%) appropriate but not optimal and 89 (42.7%) as inappropriate. The most common mistakes were no indication for AF (54.4%), selection of an inappropriate AF (27.2%), incorrect dosage (11.2%) or duration of treatment (12%).**Conclusions:** Inappropriate use of AF is unacceptably common in our institution, in accordance with similar findings from many hospitals around the world.

Publishing Title:

Impact of a Clinical Decision Support System (Cdss) on Time to Appropriate Empiric and Targeted Antibiotics in Gram Negative Bacteremia

Author Block:

T. Vo, S. Kuhn, S. Fogg; Wesley Med. Ctr. (WMC), Wichita, KS

Abstract Body:

Background: Bloodstream infections (BSI) are a common infection in the United States and have been associated with increased mortality, hospital stay, and costs. Delaying the time to appropriate therapy in gram negative BSI has been associated with increased rates of mortality. CDSS have demonstrated to improve antibiotic selection, reduce antibiotic costs, and shorten hospital length of stay (LOS). At WMC, a CDSS was implemented in June of 2014.The purpose of this study is to compare time to ordered appropriate empiric antibiotic (EA) and targeted antibiotic (TA) therapy in gram negative bacteremia before and after the implementation of a CDSS. **Methods:** This is a retrospective, single site, observational study comparing time to ordered appropriate empiric and targeted antibiotic therapy in gram negative bacteremia before and after the implementation of a CDSS. Patients (pts) identified with positive blood cultures (PBC) as one or more of the following- *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella pneumoniae, Enterobacter cloacae, Proteus mirabilis,* or *Acinetobacter* species between the dates of January 1, 2013 to June 30, 2013 for the pre-intervention (pre-I) period and January 1, 2015 to June 30, 2015 for the post-intervention (post-I) period will be included. The primary outcome is the time to ordered appropriate empiric and targeted antibiotic therapy. Secondary outcomes include intensive care unit (ICU) and overall hospital LOS. **Results:** Pre-I (n=50) vs post-I (n=33): Thirty-one pts (62%) vs. 25 (76%) pts were on appropriate EA therapy prior to PBC. Of the pts not on appropriate EA prior to PBC, the mean time ± standard deviation (SD) to appropriate EA therapy was 8.64 ± 9.78 hours (hr) vs. 1.50 ± 1.05 hr (p = 0.005). Ten (20%) vs. six pts (18%) were on appropriate TA, respectively. Of the pts on inappropriate TA therapy, the mean time ± SD to appropriate TA therapy was 59 ± 22 hr vs 57 ± 26 hr (p = 0.81). Mean overall hospital LOS was 200 hr ± 134 hr vs 334 ± 667 hr (p = 0.26). Mean ICU LOS (pre-I n=29; post-I n=15) was 92 ± 75 hr vs 474 ± 981 hr (p = 0.15). **Conclusions:** At WMC, CDSS made a statistical difference in time to appropriate EA but no difference in time to appropriate TA, overall hospital LOS, or ICU LOS. The decreased time to appropriate EA may improve patient outcomes.

The PK-PD Compass: Transforming the Landscape of Antimicrobial Stewardship

Author Block:

C. C. Bulik[1], S. M. Bhavnani[1], J. C. Bader[1], L. Zhang[1], D. R. George[1], S. Ahmed[2], S. Sajid[2], M. Trang[1], K. L. Sweeney[1], P. G. Ambrose[1], C. M. Rubino[1]; [1]ICPD Tech., Latham, NY, [2]Appstronomy, Herndon, VA

Abstract Body:

Antimicrobial stewardship programs face many challenges, including a lack of antibiotic dose, interval, and duration guidance. There is no one method or tool which accounts for patient demographic data, pathogen susceptibility, and PK-PD data when advising clinicians on the selection of antimicrobials and dosing regimens. We developed the PK-PD Compass, an educational mobile device application (APP), to address these deficiencies. The APP consists of a Monte Carlo simulation (MCS) algorithm which integrates PK data, PK-PD targets, patient-specific characteristics, and pathogen susceptibility data. A total of 29 infection categories, 33 drugs, and MIC surveillance data for associated pathogens (SENTRY) were included. Population PK models for each drug were identified, evaluated, and refined as needed. Susceptibility breakpoints utilized were based upon FDA and CLSI criteria. Results were validated by comparing APP- and model-derived percentage probabilities of PK-PD target attainment (%PTA) with a maximum tolerated difference of 10%. Incorporating these data into one interface allows clinicians to select the infection, pathogen, and antimicrobials of interest and obtain the %PTA for each regimen based upon patient characteristics (see **Figure**). As evidenced by the absolute median (min-max) difference of 4.3 (2.0-7.8), APP- and model-derived %PTA values across drugs were highly concordant. Using a MCS algorithm, an APP was developed to serve as an educational tool to support the implementation of PK-PD-driven antimicrobial stewardship programs. Using this APP, clinicians can now confidently answer the questions of "what drug, what dose, and what duration" at the patient's bedside.

A Cardiology and Antimicrobial Stewardship Team Collaboration to Identify and Improve the Management of High-Risk Antimicrobial-Warfarin Drug-Drug Interactions

Author Block:

N. Ha, S. Hanigan, K. Yang, H. Mak, B. Kurtz, M. Dorsch, **J. Nagel**; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Drug-drug interactions (DDIs) with warfarin and antimicrobial agents frequently cause INR instability, which can affect the risk for bleeding and thrombotic events. The purpose of this study is to assess the impact of a comprehensive guideline for the management of 16 significant warfarin and antibiotic, antifungal or antiviral drug interactions. The guideline emphasizes improving identification of high-risk antimicrobial-warfarin DDIs during hospitalization; empiric modification of warfarin dosing based on the individual antimicrobial interaction and baseline INR; providing patient education; documentation of the DDI in the medical chart; communication with outpatient providers regarding the DDI and anticipated antimicrobial stop date; and providing warfarin dosing recommendations upon discontinuation of antimicrobial agent. **Methods:** This retrospective, single-center, quasi-experimental, pre-post study compared endpoints 3 months before and after guideline implementation, into an established pharmacists-run anticoagulation service. The primary outcome was time within therapeutic range (TTR), which represents the proportion of the time the INR was therapeutic during the DDI. **Results:** 78 pre-guideline and 31 post-guideline patients were included, and baseline characteristics were similar between groups. Implementation of the guideline resulted in greater in-hospital TTR (72% vs. 50%, p=0.04), and improved TTR across transitions of care (70% vs. 46%, p=0.01). Documentation of DDI in the pharmacy anticoagulation discharge summary significantly improved in the post-guideline group (40% vs. 14%, p=0.02) and numerically improved within the daily pharmacy progress notes (94% vs. 82%, p=0.13). The implementation of the guideline was associated with a numeric reduction in bleeding events compared to the pre-guideline group (0 events vs. 4 events, p=0.11). **Conclusion:** This antimicrobial stewardship initiated intervention represents a novel single-center approach to optimize the comprehensive management of significant antimicrobial-warfarin drug-drug interactions, which resulted in improved communication with outpatient providers via the discharge summary and improved INR time within therapeutic range.

Antibiotic History Influences Microbial Evolutionary Dynamics in Subsequent Treatment

Author Block:

P. Yen, J. Papin; Univ. of Virginia, Charlottesville, VA

Abstract Body:

It remains unclear how history of antibiotic exposure affects subsequent resistance evolution trajectories in sequential therapies. Knowledge of potential evolutionary dynamics of resistance given prior history of drug exposure can help clinicians prescribe regimens that minimize resistance levels. We studied how history of past drug exposure affects the development of resistance during subsequent drug therapy in *Pseudomonas aeruginosa*. We serially passaged replicates of *P. aeruginosa* to increasing concentrations of piperacillin (PIP), tobramycin (TOB) and ciprofloxacin (CIP) daily for 20 days. These single-drug resistant mutants were then passaged to the other two drugs for 20 days, resulting in six sets of mutants evolved to two drugs each. Minimum inhibitory concentrations (MICs) of all drugs were measured for all lineages during the adaptive evolution. We observed drug sequence-specific effects where: adaptation to the first drug limits subsequent adaptation to the second drug (e.g. past PIP adaptation limits subsequent development of TOB resistance), adaptation to the second drug decreases the resistance to the first drug (e.g. evolution to CIP after PIP or TOB result in loss of PIP or TOB resistance, respectively), or final resistance levels depend on the order of the sequence (e.g. PIP resistance is less when evolved to PIP then CIP, compared to the reverse order). The figure shows the MICs of the three drugs on days 1, 20, and 40 for the different lineages and depicts the sequence-specific effects. These effects show how adaptation history to antibiotics can complicate strategies for mitigating resistance of bacterial pathogens. Effective antibiotic stewardship must account for these effects in the development of antibiotic resistance in order to deter the onset of the post-antibiotic era.

Establishing a Long-term Model for Improvement of Blood Culture Bottle Fill Volumes

Author Block:

P. A. Erdman[1], A. Michael[1], E. Floyd[2], W. Hess[1], D. Myers[1], M. England[1], J. Snyder[2], D. Craft[1]; [1]Hershey Med Ctr, Hershey, PA, [2]Univ of Louisville Hosp., Louisville, KY

Abstract Body:

Background: CAP requires clinical microbiology labs to have a system for monitoring blood culture volumes (MIC.22640). Fill volume and diagnostic yield are correlated; according to the manufacturer, 8-10 mls is the recommended fill volume. In response to this initiative, we developed a program to monitor fill volumes to include partnering with the hospital staff. Methods: The BD Epicenter (BD, Sparks, MD) is an add-on software system to automatically monitor blood culture volumes in BD BACTEC™ Plus Aerobic/F bottles throughout the hospital. To validate, we filled 50 bottles with known volumes of donor blood and placed them in the BD BACTEC FX blood culture incubator. We also partnered with ICUs in which we held educational sessions and sent a monthly lab "report card" to the nurse manager with trends in blood volume. Results: The mean software generated volume of blood per bottle was 6.1 mls (n=50) and the mean manual volume of blood per bottle was 6.4 mls (n=50) with a standard deviation of 1.5 and 1.9, respectively. The microbiology lab began monitoring hospital-wide blood volumes in 2014. Specific discussions and partnership with the SICU began in January 2015. Educational sessions took place on 04/08/15 and 10/15/15 which resulted in an increase in blood volume trends following each session.

Conclusions: We validated the BD Epicenter blood culture volume software and demonstrated its use as an automated system for monitoring blood culture bottle volume. In addition, setting up a partnership with a specific patient unit and the use of 'report cards' had a direct positive correlation on increasing fill volumes. Increasing blood volumes should equate to a higher yield of positive blood cultures and fewer false negative cultures.

Predictors of Readmission and Failure of Outpatient Parenteral Antimicrobial Therapy Completion Across a Large Integrated Healthcare Network

Author Block:

M. Schmidt, L. McCurdy, S. Abraham, F. Gohs, B. E. Hearn, M. Spencer; Carolinas Hlth.care System, Charlotte, NC

Abstract Body:

Background: Outpatient parenteral antimicrobial therapy (OPAT) prescribing has increased as there has been a trend toward early discharge of hospitalized patients with infections. There is limited literature on readmission and failure of OPAT completion, key measures of successful treatment. This study aims to elucidate the predictors of readmission and non-completion of therapy in patients seen across facilities within Carolinas HealthCare System (CHS). Understanding these predictors may inform future interventions that improve treatment efficacy and patient outcomes. **Methods:** Data were collected electronically between 2014 and 2015 for patients initiating OPAT. Patient demographics, treatment indication, complications, therapy completion, readmission and other variables were collected using RedCap. Patients >18 years of age with complete follow-up data were included (n=1,681) while those who died were excluded. Predictors were identified using readmission and non-completion as outcomes in a Poisson model that reported incident risk ratios and controlled for age, race, gender and indication for OPAT utilization. **Results:** The study cohort readmission rate was 13.6%, and 25.0% of patients that did not complete OPAT as initially prescribed. In adjusted analyses for readmission, when OPAT treatment was modified due to failure or worsening infection, readmission risk increased by 62.3% (IRR 1.623; 95% CI 1.24-2.12). Having OPAT performed at an infusion center decreased risk of readmission by 70.0% (IRR 0.30; 95% CI 0.12-0.73) when compared to therapy at home. Having an adverse drug reaction increased the risk of non-completion by 7-fold (IRR 7.6; 95% CI 4.8-12.1). Other predictors of non-completion were: change in antimicrobial mid-course (IRR 2.55; 95% CI 1.8-3.6), financial issues (IRR 3.52; 95% CI 1.2-10.4), access complications (IRR 1.9; 95% CI 1.3-2.7) and readmission (IRR 7.5; 95% CI 6.0-9.1). **Conclusions:** These results suggest that having OPAT performed at an infusion center versus home may decrease the risk of readmission. Testing interventions to prevent non-completion, such as mitigating adverse drug reactions, providing financial assistance or improved monitoring to prevent IV access complications, may identify ways to improve outcomes.

Antimicrobial Prescribing Practices in the Outpatient Setting Across a Large Healthcare System

Author Block:

M. Schmidt, M. Spencer, J. Roberge, H. Petruso, L. Davidson; Carolinas Hlth.care System, Charlotte, NC

Abstract Body:

Background: The CDC estimates that 30-50% of antibiotics prescribed for hospitalized patients are either unnecessary or inappropriate, contributing to increases in multidrug resistant organisms and infections. In the outpatient setting, prescribing behavior has not been well-described. This study investigates provider and practice characteristics in the outpatient setting to understand patterns of prescribing behavior and to inform new approaches for outpatient antibiotic stewardship. **Methods:** Data on outpatient provider and practice antimicrobial prescribing was collected from electronic medical records at Carolinas HealthCare System between Jan 2014 and Aug 2015 (n=2,318). The primary outcome was the number of antimicrobials prescribed per 1000 patient encounters. Unadjusted analyses of provider and practice characteristics used Wilcoxon rank-sum trend analysis. An ordinary least squares model was used for adjusted analyses. **Results:** Unadjusted analysis of prescribing by practice type showed that urgent care practices had significantly higher antimicrobial prescribing than all other practice types ($p<0.001$). After adjusting for provider gender, race, year, PCMH recognition and provider level, providers in urgent care practices prescribed 371 (95% CI 55-689; $p=0.021$) and primary care practices prescribed 201 (95% CI 101-301; $p<0.001$) more antimicrobials per 1000 encounters compared to all other practice types. Among all types of providers, mid-level providers prescribed antimicrobials more often than did physician providers ($p<0.001$). The adjusted model identified that mid-level providers prescribed 141 more antimicrobials per 1000 encounters than did physician providers (95% CI 45-237; $p=0.004$). **Conclusions:** There are significant differences between types of providers and practices in antimicrobial prescribing patterns in the outpatient setting. One of the key limitations of this analysis is the need for indication information to determine when prescribing is appropriate. Further study is warranted to investigate key drivers of provider and practice prescribing patterns and to test interventions that improve appropriate prescribing and patient outcomes. These interventions may reduce overuse of antimicrobials and mitigate the increasing prevalence of multidrug resistant organisms.

Outpatient Parenteral Antimicrobial Therapy (OPAT) for Infective Endocarditis (IE) in Patients Aged Over 80 Years

Author Block:

X. Kortajarena, **M. Á. Goenaga**, H. Azkune, M. J. Bustinduy, M. Ibarguren, A. Fuertes, R. Garcia, O. Ibarguren; Hosp. Univ.rio Donostia, Donostia, Spain

Abstract Body:

Background: OPAT is becoming more frequent in recent years. It is unclear whether the age could be a risk factor per se. The aim of this research is to describe our experience in OPAT for IE patients and to compare the differences between patients older and younger than 80 years old.**Methods:** We included all IE patients treated with OPAT in our hospital from 1996 to 2015. Demographic, diagnostic, treatment and outcome data were collected.**Results:** 194 cases were included. Mean age: 65 (range 25-92).163 (84%) under 80 and 31 (16%) over 80 years old. Etiology in younger and older subgroup respectively: S. aureus (11.7/6.5%), enterococcus species (15.3/9.7%), coagulase-negative staphylococcus (17.8/9.7%), viridans group streptococci (35/51.6%), other (15.3/12.9%) and negative cultures (4.9/9.7%). Type of affected valve: native (49.7/48.4%), prosthetic (33.1/22.6%), electrocatheter (9.2/16.1%) and unknown (8/12.9%). Affected valve: aortic (42.3/41.9%), mitral (30.7/19.4%), right-sided valves (3.1/9.7%), multivalvular (6.7/0%), electrocatheter (9.2/16.1%) and unknown (8/12.9%).Used antibiotics: vancomycin (4.9/3.2%), daptomycin (12.9/12.9%), cloxacilin (14.7/6.5%), ampicilin (24.5/22.6%), ceftriaxone (31.9/48.4%) and other antibiotics (11/6.5%). We found no statistical differences in the etiology (p= 0.376), type of affected valve (p=0.413), affected valve (p=0.15) and used antibiotics (p=0.533).**Conclusions:** An increasing trend in the prevalence of viridans group streptococci was seen in over 80 years subgroup, as well as an increase in the use of ceftriaxone. Surgical therapy rate is higher in younger patients subgroup, which probably justifies the longer hospital stay. Despite this fact, total length of treatment was similar in both groups. No statistical differences were seen in complications, re-admissions and mortality.In conclusion, elderly patients would be good candidates for OPAT in IE, as long as they were correctly selected and with an adequate monitoring.

Consumption of Antibiotics in the Community by Adults in Greece

Author Block:

H. Maltezou[1], G. Adamis[2], P. Tsonou[1], P. Katerelos[1], P. Gargalianos[3]; [1]Hellenic Ctr. for Disease Control and Prevention, Athens, Greece, [2]Gennimatas Gen. Hosp., Athens, Greece, [3]Gennimatas general Hosp., Athens, Greece

Abstract Body:

Background: Greece is among the European countries with the highest consumption of antibiotics. We studied the antibiotic consumption of adults in the community in this country.**Methods:** Cross-sectional study conducted during March-July 2014. **Results:** We studied 309 adults (mean age: 71.8 years, range: 16-98). Of them, 293 (94.8%) had received ≥1 antibiotic course the past year (mean duration: 11.6 days). In total, 419 antibiotic courses were consumed by them (mean number of courses the past year: 1.4), including 285 (68%) following examination by a physician, 72 (17.2%) following phone consultation, 30 (7.2%) following suggestion by a pharmacist and 16 (3.8%) as self-medication (the antibiotic was already available at home). Prevalent reasons for consumption were urinary tract infection (34.6%), pneumonia (17.7%), bronchitis (11%), skin infection (10.7%), gastroenteritis (8,1%), and phanyrnotonsilitis (7,2%). Prevalent antibiotics were amoxicillin-clavulanate for sinusitis, skin infection and pharyngotonsillitis (72,7%, 45% and 43.4%, respectively), amoxicillin for acute otitis media (30%), clarithromycin for bronchitis (34.8%), moxifloxacine for pneumonia (36.9%), and ciprofloxacin for gastroenteritis and urinary tract infection (66.7% and 47.3%, respectively). In the multivariate analysis, an older age and asthma were statistically significantly associated with a higher antibiotic consumption (p-values <0.001 and 0.002, respectively).**Conclusions**: Antibiotic consumption of adults in Greece is mainly driven by physicians. Good compliance of physicians with the international antibiotic guidelines was found in several clinical indications. Continuing medical education will improve antibiotic prescription practices.

Cultivation in Consortia and Subsequent Isolation of *Stomatobaculum Sp.* hot-097, a Member of the Human Oral Microbiome

Author Block:

A. J. Collins, F. E. Dewhirst; The Forsyth Inst., Cambridge, MA

Abstract Body:

Determining the roles of species comprising the oral microbiome in human health and disease is greatly facilitated by having isolates of each species in pure culture. Of the approximately 700 species comprising the human oral microbiome, investigators have succeeded in cultivating 65% of them in pure culture. About 3% of recently cultivated oral taxa are auxotrophic for factors not present in commonly-used rich media. They were successfully cultivated by cross streaking with a helper strain (such as *Staphylococcus aureus* or *Propionibacterium acnes*) which supplied the required factor(s). Other oral bacteria, such as *Fretibacterium fastidiosum,* required repeated laboratory passage in consortia before it would form macroscopic colonies adjacent to consortia members. Presumably genetic changes were selected for during passage that eventually permitted it to grow under laboratory conditions, a process that has been termed "domestication". The previously uncultivated oral bacteria *Stomatobaculum* sp. HOT-097 does not appear to be a simple auxotroph, but rather prefers growth in broth to growth on plates. In a study of the abundance of bacterial species at 9 oral sites in 20 subjects, *Stomatobaculum* sp. HOT-097 was found by Illumina 16S sequencing to be present in highest numbers (9% of reads) on the tongue of subject 3. A sample from the enriched subject-site was grown in enrichment broth. 16S qPCR suggested *Stomatobaculum* was present as about 0.1% in this initial consortium. The culture was densely plated on BHI-0.2% citrate blood agar and small regions of the consortia were picked and subcultured. Presence of Stomatobaculum was confirmed by PCR with taxon-specific primers and these cultures were further passaged. In these consortia on agar plates, *Stomatobaculum* was enriched to approximately 25% of the consortia, however *Stomatobaculum* colonies could not be isolated or passaged to fresh plates. After transferring a consortium to broth culture and selecting with the antibiotics sulfamethoxazole and trimethoprim, a nearly-pure culture of *Stomatobaculum* was successfully obtained. The *Stomatobaculum* could readily be grown and passaged in broth culture, but growth is inhibited on agar plates. A class of as-yet-uncultivated bacteria may share *Stomatobaculum* sp. HOT-097's reticence to grow on solid surfaces and therefore be cultivated using broth or other methods.

Early Life Colonization of the Nasopharyngeal Microbiome: A Longitudinal Study in the Gambia

Author Block:

B. M. Hanson[1], B. Kwambana[2], A. Worwui[2], M. Antonio[2], J. S. Brown[1], D. S. Phillips[1], E. Sodergren[1], G. Weinstock[1]; [1]The Jackson Lab. for Genomic Med., Farmington, CT, [2]Med. Res. Council Unit, Banjul, Gambia

Abstract Body:

Background: *Streptococcus pneumoniae* is the most common cause of pneumonia in children under 5 worldwide, killing an estimated 1 million each year with the majority of deaths in developing countries. To mitigate the morbidity and mortality of this disease, pneumococcal conjugate vaccine (PCV) is administered. Most validation and investigative studies of these PCVs were performed in developed countries, and now national vaccine programs are being implemented throughout the world. In The Gambia, such a national program began several years ago with the implementation of the 7-valent PCV, moving to the 13-valent PCV to cover additional serotypes relevant within The Gambia. This study enrolled infants within The Gambia to 1) assess the appropriateness of the strains included within the PCV13 vaccine, determining the patterns of pneumococcal carriage in the first two years of life with widespread use of PCV13, 2) To characterize the normal development of the nasopharyngeal microbiome in the first two years of life, and 3) study the greater environmental context for the child, including the microbes on the mother and household contacts, to reveal routes of colonization. **Methods:** We conducted a longitudinal study, enrolling 120 newborns in The Gambia between March 2013 and September 2015 and followed them up for the first two years of life. Risk factor data and nasopharyngeal samples (NPS) were collected each month, including the three visits when the infants received the PCV13. In addition, NPS from household contacts and several samples from the mother including blood, milk, and NPS were collected.DNA was extracted from the samples and the V1-V3 region of the 16S ribosomal RNA (rRNA) gene was sequenced using the Illumina MiSeq platform. With this rich dataset, we will describe the overall characteristics of the nasopharyngeal microbiome among our cohort, as well as describe the variability of the microbiome during the first two years of life.**Results:** Sample collection was completed in September 2015. To date, 1844 infant, 1225 mother, and 796 household contacts samples have been extracted. Extraction, sequencing, and analysis is ongoing and results will be presented at the conference.

Bacterial Communities Vary over Multiple Spatial Scales in the Human Oral Cavity

Author Block:

D. M. PROCTOR[1], G. C. Armitage[2], S. A. Lee[2], N. M. Davis[3], S. P. Holmes[4], D. A. Relman[3]; [1]Stanford Univ. Sch. of Med., Palo Alto, CA, [2]UCSF Sch. of Dentistry, San Francisco, CA, [3]Stanford Univ. Sch. of Med., Stanford, CA, [4]Stanford Univ., Stanford, CA

Abstract Body:

Background: We have previously shown that microbial communities inhabiting tooth surfaces vary along a spatial gradient between the front and the back of the mouth. Based on this observation, we sought to test the hypothesis that microbial communities exhibit spatial structure not just on supragingival tooth surfaces but on oral mucosal tissues as well. **Methods:** To explore this question, we analyzed a dataset generated from 676 samples and 3 individuals, allowing for the high-resolution spatial mapping of communities inhabiting the buccal and lingual aspects of teeth, the keratinized gingiva, buccal mucosa, and alveolar mucosa adjacent to each tooth. DNA was extracted from each sample and used as template for barcoded amplification and sequencing of the V4-region of the bacterial 16S rDNA gene by Illumina HiSeq. **Results:** Tissue type (R^2= 0.15) accounts for as much variation as interpersonal variation (R^2 = 0.13), as revealed by permutational multivariate ANOVA on Bray Curtis distances. We then performed a multiple-tables analysis on tissue type in order to determine whether communities inhabiting each tissue share a common structure. Importantly, this analysis revealed that microbial communities vary along an ecological gradient between the anterior and posterior of the mouth across all tissues. Moreover, communities inhabiting the buccal and lingual surfaces of sites could be distinguished from one another in a principal coordinates analysis (PCoA), suggesting spatial segregation of communities at a spatial scale as small as opposing aspects of teeth. PCoA of neighbor matrices confirmed that microbial communities vary over multiple spatial scales from the local (by aspect within tissues) to the regional (between tissues and across the dental arches). **Conclusions:** These shared, non-random spatial structures imply that a common environmental variable, perhaps salivary flow, acts consistently across tissue types, shaping community structure across multiple spatial scales in the oral cavity.

The Oral Microbiome of Pre-Columbian Caribbean Inhabitants

Author Block:

T. M. Santiago-Rodriguez[1], Y. M. Narganes-Storde[2], L. Chanlatte-Baik[2], G. A. Toranzos[2], R. J. Cano[1]; [1]California Polytechnic State Univ., San Luis Obispo, CA, [2]Univ. of Puerto Rico, San Juan, PR

Abstract Body:

IntroductionThe human oral microbiome is comprised of diverse bacteria; yet, little is known about the effects that culture may exert on this community structure and composition. Ancient microbiome studies may represent an opportunity to elucidate the possible effect of culture to the oral microbiome.**Methods**We investigated the microbiome of dental calculi from a pre-Columbian Caribbean culture using 16S rRNA gene high-throughput sequencing and compared it to the microbiome of coprolites from the same culture, and modern oral and gut samples.**Results**Bacterial relative abundances differed when compared to modern samples, suggesting that culture may have an effect on the bacterial composition of the human oral microbiome. Dental calculi and coprolites exhibited some resemblance in their microbiome composition, but there were also taxonomic differences that may be site-specific. While certain predicted functional profiles of dental calculi were similar to the coprolites, other resembled modern oral microbiomes. Specific functional categories associated with diseases were found to be more represented in dental calculi.**Conclusions**Results suggest that ancient oral microbiomes may reflect differences in culture. The present study also adds to the knowledge of ancient microbiomes by characterizing dental calculi from a Caribbean culture, opening the opportunity to reconstruct the ancestral state of the human oral microbiome.

High-Throughput Its1 Sequencing Reveals Distinct Characteristics Of Skin Fungal Communities In Childhood

Author Block:

J-H. Jo, C. Deming, E. A. Kennedy, S. Conlan, E. C. Polley,W-l. Ng, NISC, J. A. Segre, H. H. Kong; NIH, Bethesda, MD

Abstract Body:

Background: Skin is colonized by various microbes, including fungi. Understanding the fungal component of the microbiome is necessary because several commensal fungi are also opportunistic pathogens and many pathogenic fungi can cause cutaneous disorders. Previous reports suggested fungal communities in children might differ from adults. For instance, the commensal *Malassezia* was shown to be less common in young children, and several cutaneous fungal infections such as tinea capitis are more frequently observed in children. However, differences in the fungal communities (mycobiomes) on the skin of healthy children versus adults are incompletely known.**Methods:** Here, we utilized next-generation sequencing (NGS) based internal transcribed spacer-1 (ITS1) profiling, to define mycobiomes of prepubertal children.**Results:** We determined that the mycobiome landscape of children is significantly different from adults. Lipid-dependent *Malassezia*, which was predominant in adults (98.8 ± 0.5%), was less frequent (73.4 ± 23.1% for children on sebaceous sites), and fungal diversity was increased on the skin of children. Moreover, the interpersonal variation of mycobiome is significantly higher among children, suggesting heterogeneity and permissivity of the skin of young hosts. Species-level interrogation showed specific bias towards *Malassezia globosa* in prepubertal skin. Most striking example was the forehead, where 74.5 ± 30.1% of *Malassezia* was *M. globosa* in children, in contrast to 5.9 ± 7.7% in adults.**Conclusions:** Our analyses demonstrated distinctive features of the prepubertal skin mycobiome, and suggested shifts in fungal communities during early sexual maturation. This pilot study highlights the need for longitudinal mycobiome studies will provide insights into understanding the interplay between the skin, commensal microbes, and clinically significant fungal infections.

Abstract Body:

We characterized the microbiota colonizing blast-induced wounds using culture-independent pyrosequencing. 16S and 18S ribosomal RNA genes were sequenced to profile fungal and bacterial communities from 110 serial effluent samples, obtained from extremity wounds of 21 U.S. service members. Clinical metadata included closure outcomes, injury severity score, wound type, traumatic brain injury score, and heterotopic ossification. The majority of the samples had high relative abundances of *Acinetobacter spp.,* and *Pseudomonas spp*. Sequencing amplified housekeeping genes from a subset of samples revealed diversity within these genera. Fungal species of *Chaetomium, Malassezia,* and *Aspergillus* were frequently present in the wounds. Correlation between wound outcome and microbiome composition was not statistically significant.

E. A. Kennedy[1], A. Gallagher[2], J. O. Hourihane[2], P. G. Fallon[3], D. Murray[2], J. A. Segre[1], H. H. Kong[1], A. D. Irvine[4]; [1]NIH, Bethesda, MD, [2]Univ. Coll., Cork, Ireland, [3]Trinity Coll., Dublin, Ireland, [4]Our Lady's Children's Hosp. Crumlin, Dublin, Ireland

Abstract Body:

Background: Disease flares of atopic dermatitis (AD, "eczema") are generally associated with a low-diversity skin microbiota dominated by *Staphylococcus aureus*. The relationship between this dysbiosis and the development of AD is unclear.**Methods:**We randomly selected 50 infants from the Cork BASELINE longitudinal birth cohort for microbiome sampling at three timepoints in the first six months of life at 4 skin sites relevant to AD. We identified 10 infants who developed AD and analyzed them alongside 10 control infants who did not develop AD. We performed 16S ribosomal RNA sequencing and analysis.**Results:**Bacterial community structures shifted over the different time points, as did within-sample (alpha) diversity, suggesting that age strongly affects the skin microbiome in infants. Overall, there was no clear clustering between patients and controls at each site and time point sampled. Unlike what is seen in older AD patients, these subjects did not have noticeably dysbiotic communities and were not colonized by *S. aureus*. However, infants who had affected skin at month 12 had statistically significant differences in bacterial communities on the inner elbow at month 2 as compared to infants who were unaffected at month 12. In particular, staphylococci were significantly less abundant in those patients that were affected at month 12, suggesting that this genus may protect against the later development of AD. Bacterial communities were similar between infants born by C-section or vaginally.**Conclusions:**This study suggests that young infants with AD are not colonized with *Staphylococcus aureus*, unlike older patients. Additional studies are needed to determine if colonization with other staphylococci modulates the skin immunity and later development of AD.

16s Sequencing Reveals Site-specific Signatures of the Paranasal Sinuses and Lower Airways of Cystic Fibrosis Patients

Author Block:

S. K. Lucas, R. Yang, A. Nicholson, J. M. Dunitz, H. Boyer, R. Hunter; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Chronic rhinosinusitis (CRS) is an inflammatory disorder of the paranasal sinuses that has nearly 100% prevalence in classical cystic fibrosis (CF) patients (mutation class I-III). Recent research suggests that the microbiome of the paranasal sinuses is developed through initial contact with the environment, and seeds the microbiota of the lower respiratory tract through an island biogeography model of colonization; however, this dynamic has not been thoroughly investigated in CF patients where lower respiratory infections contribute significantly to the mortality of the disease. Here we evaluated the microbiome of the upper and lower respiratory environments using matched sinus and lung sputum samples from CF patients. Expectorated sputum samples were obtained from 10 CF patients in the hours prior to undergoing functional endoscopic sinus surgery (FESS) for treatment of chronic rhinosinusitis and paired sinus mucus was obtained during surgery. DNA was extracted from the paired samples, the V4 hypervariable region of the 16S rRNA gene was sequenced using an Illumina MiSeq, and the sequences were analyzed using the Quantitative Insights Into Microbial Ecology (QIIME) pipeline. We found that the sinus and lung microbiome are distinct from one another when analyzing community alpha diversity metrics for richness and evenness. Additionally, ordination analyses point to sinus and lung environments as being stronger determinants of microbial community structure than the individual patient. Our findings indicate that while the paranasal sinuses and lungs may still comprise a unified airway, in which lower airway infections are seeded by the sinus, it is important to regard these two locations as discrete microbial environments. Further studies should target ecological pressures in the paranasal sinuses that may contribute to microbial community structure and potential pathogenicity.

Hosp., Lausanne, Switzerland, [4]Fasteris SA, Plan-les-Ouates, Switzerland, [5]., ., Switzerland

Abstract Body:

Backgroung: The airways of cystic fibrosis (CF) patients are chronically infected by various microorganisms including *Pseudomonas aeruginosa* which predominates in adults and contributes to lung destruction. Lung transplantation (LT) is a recognized treatment for CF patients with end-stage disease. However, CF- adapted *P. aeruginosa* residing in the sinuses of the recipient seed the new lung leading to infections and allograft damage. This occurs despite the preexisting healthy donor lung microbiota.Therefore the lung allograft of CF recipients represents an opportunity to study *in patient* the bacterial adaptation to a novel environment and its interactions with a well-established microbiota. **Methods:** We collected sequential airway samples from conductive and respiratory zones of CF and non-CF patients at regular time intervals during 2 years post-LT. 16S rRNA sequencing and taxonomic analyses were performed to evaluate the dynamics of bacterial populations during graft colonization.**Results:** Four hundred airway samples were collected from 12 CF and 51 non-CF patients and bacterial composition was determined for the first 192 samples. Our longitudinal analysis of the graft microbiota showed that: i) colonization by *P. aeruginosa* occurred in the first days post-LT despite intensive antibiotic treatments, ii) presence of *P. aeruginosa* was associated with a decrease of the microbial diversity and richness. A large-scale analysis allowed us to characterize the dynamics of the graft colonization by the microbiota. In addition, the influence of bacterial richness and diversity as well as particular microbial signatures on lung functions were evaluated.**Conclusion:** Increasing our understanding of the dynamics of *P. aeruginosa* invading the donor microbiota and adapting to its new non-CF environment might help to design new preventive strategies aiming to improve graft survival.

Nasal Microbiome Features of *Staphylococcus aureus* Colonization and Infection During Critical Illness

Author Block:

B. J. Kelly, F. D. Bushman, R. G. Collman; Univ. of Pennsylvania, Philadelphia, PA

Abstract Body:

Background: Intranasal colonization with *Staphylococcus aureus* (SA) is a risk factor for nosocomial SA infection. Prior studies in healthy subjects have demonstrated features of intranasal bacterial community composition associated with the presence or absence of intranasal SA. We sought to evaluate the bacterial community features associated with SA colonization and infection in a cohort of critically ill subjects at high risk for nosocomial SA infection.**Methods:** We prospectively enrolled 15 intubated subjects from a medical intensive care unit at an academic medical center and collected flocked swab samples from the anterior nares at 24-48 hour intervals for the duration of intubation. DNA was extracted using the MoBio PowerSoil kit, and the V1-V2 hypervariable region of the 16S rRNA gene was amplified for sequencing on the Illumina MiSeq platform. Operational taxonomic units (OTUs) were clustered at 97% sequence similarity and taxonomy assigned using BLAST against the Living Tree Project database. Clinical bacterial culture and chart diagnosis data were also obtained.**Results:** From 15 subjects, we collected 42 samples. 31 samples had evidence of SA by 16S rRNA gene sequencing. Two subjects were diagnosed with SA pneumonia and a third with SA bloodstream infection. Differences in bacterial community composition (1) between SA-positive and SA-negative samples, and (2) between SA-infected and SA-uninfected subjects were evaluated. Principal coordinate analysis of pairwise unweighted Jaccard distances revealed clustering of SA-positive samples. Linear discriminant effect size (LEfSe) analysis identified *Corynebacterium tuberculostearicum* as most strongly associated with the absence of SA colonization (effect size 5.15, $p = 0.039$) and with the absence of SA infection (effect size 5.00, $p < 0.001$).**Conclusions:** The presence of *Corynebacterium tuberculostearicum* in the anterior nares bacterial community is associated with the absence of SA colonization and the absence of SA infection.

Sequence-Based Analysis Of Human Microrna Expression Associated With Dynamic Vaginal Microbiota

Author Block:

S. B. Smith[1], J. Ravel[2]; [1]Univ. of Maryland, College Park, MD, [2]Univ. of Maryland, Baltimore, MD

Abstract Body:

Bacterial Vaginosis (BV) is a condition of the human vagina characterized in part by a paucity of *Lactobacillus* spp. and the presence of a wide array of strict and facultative aerobes such as *Gardnerella vaginalis*, *Atopobium vaginae*, and *Mobiluncus* spp. In some women BV is associated with symptoms such as odor, itching and discharge, while in other it is asymptomatic. The etiology of BV remains unknown. Characterization of the vaginal microbiota sampled daily over 10 weeks has shown that some women experience transitions from *Lactobacillus*-dominated to BV-associated states independently of sexual or hygiene behaviors. Leveraging these daily samples, the types and abundance of a small RNA class known as microRNAs (miRNAs) are being used to gain insight into BV etiology and the host regulatory mechanisms that drive these transitions using miRNAseq. We hypothesize that specific miRNA are associated with transitions to a BV-associated Community State Type (CST) by affecting specific host functions. Results indicate the miRNASeq approach is sufficient to consistently detect miRNAs across human vaginal self-collected swab samples from different women and CSTs. Furthermore, the correlation of BV-associated bacteria and metadata with miRNA read counts revealed patterns that could be used to help understand BV recurrence and symptomology. The highest-ranking miRNAs are being validated and used to further develop predictive paradigms in BV.

Severity of *Clostridium difficile* Infection Varies with the Type of Diets in a Murine Model of Infection

Author Block:

J. Scaria[1], S. Faisal[2], K. Jayaram[2], S. M. Lipkin[3], **Y. Chang**[2]; [1]South Dakota State Univ., Brookings, SD, [2]Coll. of Vet. Med., Cornell Univ., Ithaca, NY 14853, Ithaca, NY, [3]Cornell Univ., New York, NY

Abstract Body:

Clostridium difficile infection (CDI) is the leading cause of infectious diarrhea in the United States. Outcome of CDI varies from mild diarrhea to severe colitis and fatalities. Primary risk factor for CDI is the antibiotic induced gut microbiome dysbiosis. We hypothesized that type of patient's diet could shift the gut microbial population and such microbiota shift might influence the severity and outcome of infection. We tested this hypothesis in a murine model of infection. Experimental groups of five mice were maintained on two different isocaloric diets; high protein-low fiber diet or Low protein-high fiber diet for one month, further segregated into three treatment groups; control untreated mice, mice treated with antibiotic cocktail alone and mice treated with antibiotic cocktail plus *C. difficile* spore infection (intragastric administration of 1000 CFU). All mice including the control group received a single intra-peritoneal dose of clindamycin one day prior to initiation of the antibiotic/*C. difficile* challenge. Mice were euthanized 3 days post infection and cecum contents were collected for 16s rRNA based microbial population survey. Another fraction was flash frozen in liquid nitrogen and freeze dried and was used for LC-MS based metabolome analysis. Our results showed that mice receiving high protein-low fiber diet was more susceptible to CDI and there was 60% mortality in this group while all animals given low protein-high fiber diet survived. Microbiome population structure analyzed using 16s rRNA amplicon sequencing revealed that antibiotic treatment caused expansion of Enterobacteriacea in all groups while the maximum numbers were found in high protein-low fiber diet fed group. Metabolite analysis of cecal contents revealed that levels of secondary bile acids and short chain fatty acids were reduced in high protein-low fiber diet fed mice. Overall, our results indicate that type of diet particularly; high protein-low fiber diet may increase the severity of CDI.

Dietary Zinc Alters the Gut Microbiota and Decreases Resistance to Clostridium Difficile

Author Block:

J. P. Zackular, J. L. Moore, L. J. Juttukonda, A. T. Jordan, Y. Zhang, W. J. Chazin, R. M. Caprioli, E. P. Skaar; Vanderbilt Univ., Nashville, TN

Abstract Body:

Clostridium difficile is the most commonly reported nosocomial pathogen in the United States and is an urgent public health concern worldwide. Over the past decade, incidence, severity, and costs associated with *C. difficile* infection (CDI) have increased dramatically. The primary risk factor for CDI is antibiotic use, which reduces colonization resistance to *C. difficile* by altering the resident gut microbiota. Interestingly, the number of non-antibiotic associated CDI cases is on the rise, suggesting that unexplored environmental, nutrient, and host factors likely play an important role in mediating susceptibility to *C. difficile.* One largely unexplored factor in both gut microbiota homeostasis and *C. difficile* pathogenesis is zinc (Zn) availability. Zn acquisition is an essential colonization factor for numerous pathogens and dietary Zn levels have been strongly linked to increased risk of gastrointestinal infections. In this study, we hypothesized that dietary Zn levels are a key factor shaping the ecology of the gut microbiota and in turn impact susceptibility to *C. difficile*. We used next generation sequencing to demonstrate that increased levels of dietary Zn significantly alter the structure and diversity of the gut microbiota in mice. In addition, we demonstrate that excess dietary Zn dramatically reduces the threshold of antibiotics needed to abolish colonization resistance to *C. difficile*. In mice colonized with *C. difficile*, increased dietary Zn also severely exacerbates *C. difficile*-associated disease (CDAD). Furthermore, the host metal binding protein calprotectin was determined to be essential for combating CDI by limiting Zn at the site of infection. Together, these data demonstrate that nutrient Zn levels play a key role in determining the outcome of the tripartite interaction between the host, *C. difficile*, and the gut microbiota. Furthermore, excess dietary Zn reduces community resistance to perturbation, which increases susceptibility to *C. difficile*. The profound impact of excess Zn on the gut microbiota may have broad implications for numerous microbiota-associated gastrointestinal disorders.

Host-specific Fecal Microbiota Transplantation is More Effective in Treating Recurrent *Clostridium difficile* infection in a Murine Model

Author Block:

A. M. Seekatz[1], C. M. Theriot[2], K. C. Vendrov[1], V. B. Young[1]; [1]Univ. of Michigan Med. Sch., Ann Arbor, MI, [2]North Carolina State Univ. Coll. of Vet. Med., Raleigh, NC

Abstract Body:

Recurrent *Clostridium difficile* infection (CDI) occurs in 20-30% of patients following successful treatment of an initial episode of CDI. Defects in the gut microbiota, the indigenous bacterial community within the gastrointestinal tract, are hypothesized to contribute to the development of recurrence. Fecal microbiota transplantation (FMT) has emerged as an effective treatment for recurrent CDI, and although its success correlates to an increase in microbes associated with a healthy gut community, the specific microbes that enable recovery remain elusive. We have previously characterized a murine model of recurrent CDI, and observed that mouse fecal matter (mFMT) is sufficient to clear *C. difficile*. To identify potential bacterial members or community structures in humans that promote recovery from recurrent CDI, we treated recurrent animals with feces from a) healthy human donors (hdFMT) and b) pre-FMT human recipients (hrFMT) from previously successful FMT human donor-recipient pairs. We hypothesized that hdFMT would be successful in clearing *C. difficile* in our model. While mFMT from multiple mouse colonies was successful in clearing *C. difficile*, FMT from human sources was significantly less effective. We used 16S rRNA analysis to identify bacterial taxa associated with *C. difficile* clearance. Interestingly, we observed significant overlap between mFMT- and hdFMT-treated animals regardless of disease outcome. In particular, both FMT treatments resulted in an increase in several Bacteroidetes, such as the *Bacteroides* and *Porphyromonadaceae* groups, and Firmicutes, including several *Clostridiales* and *Lachnospiraceae* groups. These results emphasize the importance of the development of specific host-microbe interactions, and suggest that host specificity to gut microbial communities important in the dynamics of *C. difficile* colonization. Future studies that incorporate both human and murine models in identifying bacteria with a benefit to human health should consider how host specificity significantly impacts outcome.

Commensal *Bacteroidetes* Induce Expression of Reg3γ and Prevent *Clostridium difficile* Infection

Author Block:

H. Bangar, Yee-Shiuan Chen, George Weinstock, Heidi Andersen, D. Haslam; Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract Body:

Background: *Clostridium difficile* infection (CDI) causes severe colitis that persists even after antibiotic treatment. Fecal microbiota transplant (FMT) has been demonstrated to be highly effective in treating protracted CDI. However, the identity of the protective organism(s) and the mechanism by which FMT attenuates CDI disease is not well understood. **Methods:** The fecal microbiome from susceptible and resistant mice before and after antibiotics was analyzed by whole metagenome shotgun sequencing. Either crude fecal microbiota from resistant mice or pooled protective bacterial species were transplanted to susceptible mice by oral gavage. Thereafter, mice were orally gavaged with *C. difficile* spores. Animals were observed for signs of disease and mortality. RNA-Seq analysis, flow cytometry, and histopathology were performed in each group to interrogate the mechanisms of protection.**Results:** Genetically identical C57BL/6 mice showed stark difference in susceptibility to CDI depending on the environment in which they were raised. Fecal material transplantation from CDI-resistant mice to CDI-susceptible mice resulted in protection from CDI, which correlated with an increased abundance of key *Bactoroidetes spp*. We demonstrated that oral inoculation with these key bacterial species prevented CDI-associated intestinal inflammation and stem cell injury by blocking access to colonic crypts from *C. difficile*. These protective effects were critically dependent on the crypt-associated antimicrobial peptide, Reg3γ.**Conclusions:** We identified the key *Bacteroidetes* spp. that provide protection from CDI by inducing production of antimicrobial peptides that are necessary for preventing *C. difficile* from accessing the intestinal crypts. Loss of these key species affects the production of antimicrobial peptides, which results in compromise to the physical barrier of the inner mucus layer.

Investigating *Clostridium difficile*-Microbiome Interactions to Characterize Potential Mechanisms for Colonization Resistance

Author Block:

J. M. Auchtung, R. A. Britton; Baylor Coll. of Med., Houston, TX

Abstract Body:

Clostridium difficile is the leading cause of antibiotic-associated diarrhea and nosocomial infections. Numerous studies have demonstrated that the gastrointestinal microbiome plays a key role in inhibiting infection by *C. difficile*. Multiple mechanisms by which the microbiome mediates resistance to *C. difficile* colonization have been proposed, including competition for resources and production of toxic metabolites such as short chain fatty acids, secondary bile acids, and bacteroicins. Recent research has focused on conversion of primary bile acids to secondary bile acids (e.g., deoxycholate) that inhibit growth of vegetative *C. difficile* cells as the primary mechanism through which the microbiota inhibits *C. difficile* colonization. We recently developed fecal mini-bioreactor arrays (MBRAs) that allow for anaerobic, continuous-flow cultivation of up to 96 communities simultaneously. We have shown these MBRA communities are resistant to *C. difficile* and disruption of community structure with antibiotics allows *C. difficile* to proliferate, produce toxins, and sporulate. We have now used this model to investigate the role of bile acid transformation in providing colonization resistance against *C. difficile*. Analysis of bile acid content in MBRA supernatants demonstrated that communities were capable of converting taurocholate to a mixture of cholate and deoxycholate. Treatment of communities with clindamycin reduced levels of deoxycholate and increased levels of cholate. We also asked whether communities could prohibit proliferation of vegetative *C. difficile* in the absence of bile acids. We found that bile acids were not required to mediate colonization resistance, indicating other mechanisms that prohibit *C. difficile* proliferation play a significant role in our model. Ongoing studies are focused on identifying and characterizing these other mechanisms that prevent *C. difficile* colonization. Understanding the mechanisms by which the microbiome inhibits *C. difficile* proliferation will likely play an important role in refining the composition of microbial therapeutics used to treat *C. difficile* infection.

Dietary Predictors of Successful Fecal Microbiota Transplant Treatment of *Clostridium difficile* Infection

Author Block:

J. J. Farrell[1], D. K. Martin[2], S. V. Thompson[3], A. Bogner[2], J. Bonello[2], H. M. Guetterman[3], K. S. Swanson[3], H. Holscher[3]; [1]Univ. of Illinois Coll. of Med., Peoria, IL, [2]OSF Med. Ctr., Peoria, IL, [3]Univ. of Illinois, Urbana, IL

Abstract Body:

Background: In healthy populations, diet contributes to gastrointestinal microbiota stability, diversity, and composition. But the impact of diet on recovery of intestinal microbial diversity following fecal microbiota transplantation (FMT) is not known. We hypothesized that patients with higher intakes of fermentable fibers would be more likely to establish intestinal microbial diversity following FMT. **Methods:** IRB approval was obtained to offer FMT for to patients with *Clostridium difficile* infection (CDI) refractory to conventional treatment begining November 2013. All FMT patients were invited to submit Diet History Questionnaires (DHQs) starting in October 2014. Participants completed the National Cancer Institute (NCI) Diet History Questionnaires (DHQII, Past Month with Portion Size) prior to FMT, and at 30 and 90 days post FMT. Questionnaire data were processed using NCI's Diet*Calc software and Healthy Eating Index scores were generated from the Diet*Calc output using SAS 9.4 and NCI macros. Success was defined as resolution of symptoms of CDI following FMT. Failure was defined as diarrhea with > 3 stools/day or retreatment (either oral vancomycin or a second transplant) within 30 days of FMT.**Results:** 16 patients and 2 donors completed FFQs (14 women, 2 men; mean age=53 years). FMT success was observed for 12/16 (75%) patients. Patients with successful FMT reported higher consumption of both fruit and fiber than patients with a failed FMT ($p < 0.05$). The percent of energy from carbohydrate was higher in patients with successful FMT ($p = 0.04$). Macronutrient percentages were also significantly different between FMT success and failure groups.**Conclusions:** Our objective was to study dietary factors predictive of FMT success. The data support our hypothesis that higher consumption of dietary fiber is predictive of microbiota transplantation success among patients presenting to our tertiary FMT referral center.

Diet and FMT Outcome		
Diet	Success	Failure
Total Fruit	3.39 ± 0.44	1.46 ± 0.77
Fiber (per Kcal)	0.88 ± 0.08	0.57 ± 0.15

***staphylococcus Aureus*-Induced Mucin Secretion By Goblet Cells: Dependency On Nlrp3 Inflammasome Activation And Release Of Mature Il-1β**

Author Block:

D. A. Dartt[1], D. LI[1], M. Lippestad[1], R. Hodges[1], M. Gilmore[2], M. Gregory-Ksander[1]; [1]Schepens Eye Res. Inst./Massachusetts Eye and Ear, Boston, MA, [2]Massachusetts Eye and Ear, Boston, MA

Abstract Body:

Purpose: Mucins protect mucosal surfaces the conjunctiva by entrapping bacteria and preventing bacterial invasion. We previously demonstrated that pathogenic *S. aureus* activates the NLRP3 inflammasome in ocular surface conjunctival goblet cells, resulting in secretion of the pro-inflammatory cytokine IL-1β and the mucins MUC5AC. This study was performed to determine if NLRP3 inflammasome activation is required for *S. aureus*-induced mucin secretion and if it is dependent upon the release of mature IL-1β.**Methods:** Cultured conjunctival human goblet cells were incubated with siRNA for NLRP3 or TLR 2 and stimulated with toxigenic *S. aureus* RN6390. Goblet cells were stimulated with IL-1β or *S. aureus* in the presence of an IL-1 receptor antagonist (IL-1Ra), an intracellular Ca^{2+} chelator, and an extracellular regulated kinase (ERK) 1/2 inhibitor. High molecular weight glycoconjugate (HMGC) secretion including MUC5AC was measured.**Results:** NLRP3 and TLR2 siRNA inhibited goblet cell HMGC secretion induced by *S. aureus*. Mature IL-1β stimulated goblet cell secretion in a dose-dependent manner. IL-1Ra blocked goblet cell HMGC secretion stimulated by *S. aureus* or IL-1β alone. IL-β-induced HMGC secretion was blocked by chelating intracellular Ca^{2+} or inhibiting ERK1/2 activityation.**Conclusions:** Goblet cell-derived mature IL-1β secretion is dependent upon both NLRP3 and TLR2 and mediates *S.aureus*-induced HMGC secretion by increasing intracellular [Ca^{2+}] and activating ERK1/2. These data reveal the pluripotent activities of goblet-cell-derived IL-1β secretion, induced by pathogenic *S. aureus,* could induce immune cell recruitment to clear pathogens andinduce HMGC secretion to enhance the mucosal ocular surface barrier to infection.

NLRP3 Inflammasome Plays an Important Role in the Innate Immune Response to *Acinetobacter baumannii* Infection

Author Block:

B. Sukumaran, N. Dikshit; Duke-NUS Med. Sch., Singapore, Singapore

Abstract Body:

Background: *Acinetobacter baumannii* is an emerging multi- or pan-drug resistant nosocomial and community associated bacterium that is increasingly becoming a serious health threat world-wide. Pneumonia, bacteremia, urinary tract infections, and wound infections are some of the important clinical manifestations of *A.baumannii* infection. However, the innate immune pathways leading to various clinical outcomes associated with *A. baumannii* infections are not fully characterized yet. We identified that *A. baumannii* invades and survives within host cells and hypothesized that intracellular innate immune receptors might play a role in the host defense to *A. baumannii* infection. Inflammasomes are intracellular multiprotein complexes that play critical roles in innate immunity. But whether inflammasome pathway plays any role in the pathogenesis of *A. baumannii* infection is not studied yet.**Methods:** *In vitro* infection models using mouse bone marrow-derived macrophages and *in vivo* murine pneumonia infection models using NLRP3 knockout mice were used to assess the role of NLRP3 in controlling *A. baumannii* infection.**Results:** Our studies demonstrate that the most extensively studied inflammasome, NLRP3, is an important player in the host defense and inflammatory response associated with *A. baumannii* infection. We show that *A.baumannii* infection primes as well as activates the NLRP3 inflammasome assembly in mouse bone marrow-derived macrophages. *A.baumannii* infection induced IL-1β/IL-18 production is entirely dependent upon ASC/NLRP3/Caspase-1 axis. *A.baumannii* activates NLRP3 inflammasome by various overlapping mechanisms such as ROS generation/ Potassium ion imbalance.**Conclusions:** Thus we identified a previously unrecognized role for inflammasome components in the host innate immune response to *A. baumannii* infection and this information may provide alternative therapeutic approaches to tackle *A. baumannii* infections.

Tir-Mediated Signaling Responses in the Social Amoeba Dictyostelium Discoideum

Author Block:

T. White, M. Fink, M. Berlett, K. Stephens, A. Zapf, M. Weichseldorfer, M. Snyder, 21252, M. Snyder, 21252; Towson Univ., Towson, MD

Abstract Body:

Cells of the innate immune system use pattern recognition receptors (PRRs) to detect conserved molecular motifs on a wide variety of microbial pathogens. The best characterized PRRs are the Toll-like receptors (TLRs), which utilize toll/interleukin-1 receptor (TIR) domains to initiate signaling responses. Among the signaling pathways activated downstream of mammalian TLRs are NF-kB, caspase and MAPK-mediated pathways, as well as the generation of reactive oxygen species (ROS). The social amoeba Dictyostelium discoideum phagocytizes bacteria for nutritional purposes. While its genome does not encodes for full-length TLRs, the model organism does express several TIR domain-containing proteins, including D. discoideum TirA, which previously has been shown to play a role in the growth of D. discoideum in the presence of Gram-negative bacteria. Furthermore addition of lipopolysaccharide (LPS), a component of the Gram-negative cell wall has been shown to enhance D. discoideum's bactericidal activities in a TirA- and ERK-dependent manner. While D. discoideum does not encode for NF-kB or caspases, exposure of D. discoideum to bacteria does result in the activation of MAPK-ERK signaling pathways as well as the generation of ROS. Here we find that both ERK phosphorylation, as well the generation of ROS, are reduced in TirA-deficient cells as compared with WT cells in response to Gram-negative, but not Gram-positive bacteria. In contrast, ERK phosphorylation in response to folic acid does not appear to be greatly affected by the absence of TirA. We are currently investigating the role of additional signaling molecules in the response of D. discoideum to Gram-negative bacteria. In addition to these procedures we are also attempting to solve the structure of D. discoideum TIR domains through the use of X-ray crystallography. By obtaining this structural information new insights into the conserved mechanisms of TIR domain signaling in may be revealed.

Cellular Mechanisms Of Alpha-Hemolysin-Mediated Activation Of The Nlrp3 Inflammasome

Author Block:

E. A. D. Ezekwe, Jr, J. A. Duncan; Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract Body:

Background:*Staphylococcus aureus* toxin, α-hemolysin, is secreted as a soluble monomer that forms a heptameric pore in the membranes of a range of host cell types. Hemolysin binds and activates A Disintergin and Metalloprotease 10 (ADAM10) and is a well-chronicled virulence factor in staphylococcal disease. ADAM10 activity is important for toxin-mediated pathology in a number of cell types. In host monocytes, α-hemolysin activates the nucleotide-binding domain and leucine-rich repeat containing gene family, pyrin domain containing 3 (NLRP3) inflammasome leading to production of the pro-inflammatory cytokines (IL-1β, IL-18) and pyroptotic cell death. Human airway epithelial cells express the components of the NLRP3 inflammasome but the involvement of this signaling pathway in the cellular response to α-hemolysin is unknown. We hypothesized that both ADAM10 and NLRP3 are involved in host cellular responses to α-hemolysin in both monocytic and respiratory epithelial cells. **Methods:** To elucidate the role of ADAM10 and its protease activity in α-hemolysin-mediated activation of the inflammasome, we used the immortalized monocyte cell line, THP1. Cells were treated with siRNA against or chemical inhibitors of ADAM10, challenged with α-hemolysin, and NLRP3-inflamamsome activation assessed by measuring secreted IL-1β, cell death, and activation of caspase-1.To test for evidence of α-hemolysin –mediated inflammasome activation in respiratory epithelial cells, we used primary human tracheobronchial epithelial (hTBE) cells and measured their secretion of IL-1β in response to hemolysin challenge.**Results:** Loss of ADAM10 cell surface expression led to diminished α-hemolysin-mediated activation of the NLRP3 inflammasome and cell death. ADAM10 protease activity, however, was not required for NLRP3 activation in human monocytes. hTBEs secrete mature IL-1β in response to α-hemolsyin treatment, suggesting a role for the inflammasome in their response to α-hemolysin.**Conclusions:** This work demonstrates that ADAM10 is a receptor but not an active signaling participant in inflammasome activation by α-hemolysin in human monocytes. Preliminary evidence also suggests that the inflammasome may play a role in epithelial cell responses to α-hemolysin.

Amoebal Endosymbiont *Protochamydia* isolated from a Hospital Can Induce Il-8 In Human Immortal Hep-2 Cells

Author Block:

J. Matsuo[1], T. Fukumoto[2], T. Okubo[1], S. Nakamura[3], K. Akizawa[2], H. Shibuya[2], C. Shimizu[2], H. Yamaguchi[1]; [1]Hokkaido Univ., Sapporo, Japan, [2]Hokkaido Univ. Hosp., Sapporo, Japan, [3]Juntendo Univ., Tokyo, Japan

Abstract Body:

Obligate intracellular bacteria belonging to *Parachlamydiaceae*, such as *Protochlamydia* or *Parachlamydia*, survive in free-living amoebae, *Acanthamoeba*. Since the bacteria are considered to be a causative agent of respiratory tract infections in human, the infections are likely to be an emerging infection. Regarding this, we have previously shown that *Parachlamydia* DNA was widely distributed with *Acanthamoeba* DNA in a hospital, inferring from the finding that the bacteria may have an impact on hospital infections (1). In this study, we therefore attempted to isolate *Acanthamoeba* harboring endosymbionts from hospital environments and evaluated the bacterial infectivity and cytokine inducibility to human immortal HEp-2 cells. Fifty smear samples were collected from the floor (n = 30) and sink outlets (n = 20) in Hokkaido University Hospital. The survey was conducted repeatedly at different periods (February to March and August in 2012). The smear samples (1 m x 1 m) were suspended in Page's amoeba saline and centrifuged. The resulting pellets were cultured on a non-nutrient agar covered with heat-killed *E. coli*. Finally, *Acanthamoeba* was axenically cultured in PYG medium. Amoebal endosymbionts were detected by PCR and DAPI staining. Next, the bacteria were briefly purified by centrifugation and incubated with *Acanthamoeba* reference strain (C3) or HEp-2 cells for 5 days. The bacterial copy number was measured with qPCR. Proinflammatory cytokine IL-8 was also detected in culture supernatant of HEp-2 cells with ELISA. As a result, six *Acanthamoeba* strains were successfully cultured in PYG. Of them, three were found to harbor chlamydiae, *Protochlamydia* (W9) or *Neochlamydia* (Y20, Y23). Since *Protochlamydia* W9 exclusively could infect and propagate in C3 amoebae, the bacteria were used for the experiments with HEp-2 cells. However, the data showed that *Protochlamydia* W9 could not propagate in HEp-2 cells. Meanwhile, elevated IL-8 secretion was observed depending upon the bacterial stimulation. Taken together, these results suggested that *Protochlamydia* could spread within amoebae in hospital environments and induce inflammatory responses to human once the bacteria were brought to hospital environments.

R. S. Doster[1], L. M. Rogers[1], D. M. Aronoff[1], J. A. Gaddy[2]; [1]Vanderbilt Univ. Sch. of Med., Nashville, TN, [2]Tennessee Vally Hlth.care System, Nashville, TN

Abstract Body:

Background: Group B *Streptococcus* (GBS) infections are important causes of preterm birth and neonatal sepsis. Placental macrophages (PMs) are resident leukocytes present in gestational tissues. We sought to identify PM functions during GBS infection. **Methods:** PMs were incubated *ex vivo* with GBS clinical isolates (MOI 20:1 x 1 hr) before processing and imaging with scanning electron (SEM) or confocal microscopy. Extracellular traps (ETs) were quantified as percent of PMs producing ETs per field of SEM (750X magnification). Extracellular trap production was confirmed via confocal microscopy staining with Sytox Green for extracellular DNA and Hoechst 33342 for nuclei. ETs were then stained for matrix metalloproteinases (MMP) 7, 8 and 9 using polyclonal antibodies (abcam) followed by incubation with a fluorochrome conjugated secondary antibody. Transcriptional changes in MMP production were assessed using RT-PCR after infection of macrophages with GBS cells for 2 hours at MOI of 100:1.**Results:** PMs produced ETs in response to GBS infection as evidenced by characteristic appearance and extracellular DNA staining via SEM and confocal microscopy. DNAse treatment dissolved these structures. GBS infection also induced transcriptional upregulation of MMP 7,8 and 9, which have been implicated in premature rupture of membranes and preterm birth. We then examined if ETs could be a mechanism by which MMPs are released during infection. ETs from GBS infected cells stained strongly for MMP-7 and MMP-8, but not MMP-9.**Conclusions:** GBS infection induced transcription of MMPs and ET formation in PMs. These structures contained MMP-7 and 8. MMP-7 (matrilysin) and MMP-8 (human neutrophil collagenase) catalyze the breakdown of fibronectin, laminin, and collagens important for fetal membrane structural integrity. These MMPs are found to be elevated in amniotic fluid of patients with intra-amniotic infection and premature rupture of membranes. Thus this immune strategy thought to trap invading microbes may also result in localized damage to fetal membranes during infection, potentially contributing to premature membrane rupture. Future work will evaluate the impact of these MMP-rich ETs on membrane integrity.

Group B *streptococcus* Infection Induces Siglec-14 Expression and M1 Activation in Human Monocyte-Derived and Mouse Decidual Macrophages

Author Block:

J. A. Sutton[1], L. M. Rogers[2], D. M. Aronoff[2]; [1]Meharry Med. Coll., Nashville, TN, [2]Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract Body:

Group B *Streptococcus* (GBS) is a leading cause of neonatal death and sepsis. The fundamental mechanisms by which GBS evades innate immune defenses in the gravid uterus are not fully elucidated. In response to stimuli, macrophages are activated along a spectrum ranging from a proinflammatory "M1" state to an anti-inflammatory "M2" state. Through molecular mimicry, sialic acid on the capsular surface of GBS binds to sialic acid binding immunoglobulin-like lectins, siglecs, on macrophages to modulate inflammatory responses. Polymorphisms in paired inhibitory and activating receptors, Siglec-5 and Siglec-14, respectively, are associated with preterm birth and GBS infection. This study aims to define changes in human MDMφ and mouse decidual macrophage activation and Siglec-5/Siglec-14 expression in response to GBS infection. MDMφs were infected with GBS or polarized *in vitro* with M1 (IFNγ + LPS) and M2 (IL-4 or IL-10) stimuli. Resulting phenotypes were characterized by qRT-PCR to evaluate siglec and polarization marker gene expression. Cytokines (TNFα, IL-1β, and IL-10) were evaluated by ELISA. To mimic human ascending vaginal infection *in vivo*, C57BL/6 mice were inoculated vaginally with GBS at day E13.5 for 48h. Subsequently, decidual macrophages were isolated and analyzed for polarization markers (CD11c and CD206) via flow cytometry. Our findings in MDMφ suggest that GBS infection upregulates expression of M1 genes (CCR7, CD80) and downregulates M2 genes (CD209, CD163). GBS infection induced release of M1 cytokines (TNFα, IL-1β) and M2 cytokine IL-10. Siglec-14 expression was upregulated in response to GBS while Siglec-5 exhibited little to no modulation. GBS infection in mouse decidual macrophages demonstrated a shift towards M1 polarization as evidenced by the decrease of surface CD206 and increase in surface CD11c. These results suggest that GBS induces M1 activation while activating Siglec-14 but not the inhibitory Siglec-5. Such responses might contribute to the inflammatory complications associated with chorioamnionitis such as membrane rupture, fetal inflammatory response syndrome, and premature labor. Taken together, our studies provide new insights into the role of macrophage polarization and siglec biology in GBS pathogenesis.

Dendritic Cell Involvement and Innate Defense Determinants in *Pseudomonas aeruginosa* Colonization of the Corneal Epithelium

Author Block:

M. M. Metruccio[1], C. K. P. Tam[1], M. E. Stern[2], **D. J. Evans**[3], S. M. J. Fleiszig[1]; [1]UC Berkeley, Berkeley, CA, [2]ImmunEyeZ LLC, Orange County, CA, [3]Touro Univ., Vallejo, CA

Abstract Body:

Healthy epithelial-lined tissue surfaces are remarkably resistant to bacterial colonization and infection. Nevertheless, contact lens wear can compromise corneal epithelial barrier function via unknown mechanisms leading to sight-threatening infections. Previously, we showed that corneal epithelial barrier function against *P. aeruginosa* requires MyD88, the TLR and IL-1R adaptor protein expressed by both epithelial cells and dendritic cells in the corneal epithelium. Here, we examined the roles of dendritic cells (DCs), specific TLRs and IL-1R. Intact, or superficially-injured (tissue-paper blotted) whole eyes from wild-type C57BL/6 and TLR or IL-1R gene knockout mice were imaged by confocal microscopy to compare *P. aeruginosa* colonization and traversal over 6 h. Transgenic diphtheria toxin receptor mice were used to selectively deplete corneal DCs, and qPCR used to assess corneal transcriptional changes with bacterial challenge. Intact corneas of TLR4 or IL-1R knockout mice were more susceptible to bacterial adhesion. TLR5 was required to prevent bacterial traversal, but not surface adhesion. Corneal DCs located in the stroma of uninjured corneas showed profound changes in shape (suggesting activation) after bacterial challenge, and extended long dendritic processes in close proximity to the epithelial surface. If corneas were superficially-injured before bacterial challenge, DC processes extending to the epithelial surface colocalized with adherent bacteria. Superficially injured DC-depleted corneas showed a 3-fold increase in *P. aeruginosa* adherence ($p < 0.05$, Mann-Whitney U test) and displayed differential mRNA expression for select innate immunity genes, including down-regulation of IL-6 (3-fold) and IL-1R (2-fold) in response to bacterial inoculation. These data show that multiple MyD88-dependent receptors contribute to corneal innate defense against bacterial adhesion and subsequent epithelial traversal. They also show that DCs in the stroma detect and respond to bacteria at the healthy corneal surface and protect it against bacterial adhesion. How DCs deep within the cornea detect bacteria at the surface to impact epithelial barrier function remains to be determined.

Evaluation of Neutrophil Activity against *Nocardia brasiliensis* Hujeg-1 and Strains Obtained from Continuous *In Vitro* Passaging

Author Block:

L. Vera-Cabrera, J. Garza-Chapa, C. Molina-Torres, J. Ocampo-Candiani; Hosp. Univ.rio, U.A.N.L., Monterrey, Mexico

Abstract Body:

Background: *Nocardia brasiliensis* is the main causative agent of mycetoma in Mexico. Little is known about the virulence/host resistance events occurred in this neglected infectious disease. In order to study the physio pathogenic mechanisms involved in this infection, we have previously subcultured a N. brasiliensis isolate, obtained from a mycetoma human case, during 400 times. After 200 passages the bacteria presented several changes, including lost of virulence for mice, the growth in broth as an homogeneous suspension instead of filamented colonies, the decrease of acid-fastness, and the cell-wall density. Based on these findings, we hypothesized that important changes in the Nocardial cell-wall occurred, and this may explain the lost of virulence after 200 continuous passage. In this work we compared the susceptibility of the parental isolate to that of three passaged strains (P200, P300 and P400) to human PMN granulysins including HPN I-3, LL-37 and HBD-3; killing assays were also performed with these N. brasiliensis strains using human PMN, and rat neutrophils. The latter has been reported to be resistant to the *N. brasiliensis* infection. **Methods:** Bacterial unicellular suspensions from the original islate (P0), and the subcultured strains were prepared, and the susceptibility to destruction by granulosyns were determined. Human PMN were obtained from volunteer healthy donors, and rat neutrophils were obtained from female Wistar rats. In both cases , PMN were purified using the Ficoll/Hypaque method. PMN were infected at a 3:1 relationship and incubated for 180 min; CFU were determined at the beginning and the end of the experiment.**Results:** In the granulosyns susceptibility assays human neutrophils were unable to destroy P0 nocardial cells under these conditions, and no differences with the subcultured strains were observed. Neutrophils from rat were able to decrease 40% of the nocardial cells after 180 min of incubation. Interesently, P300 induced strongly the induction of PMN nets, even after a few seconds of incubation. **Conclusions:** The lack of virulence of the subcultured isolates do not seem to reside in an increased susceptibility to PMN killing.

Pre-exposure of Methicillin-resistant *Staphylococcus aureus* (Mrsa) to Subinhibitory Daptomycin Concentrations Enhances the Activity of Human Neutrophils Against Mature Biofilms

Author Block:

M. Simitsopoulou, P. Kadiltzoglou, I. Stamouli, C. Antachopoulos, **E. Roilides**; Aristotle Univ. of Thessaloniki, Thessaloniki, Greece

Abstract Body:

Background: Biofilms (BF) formed by MRSA on the surface of catheters or implanted biomaterials are associated with persistent infections. Neutrophils (PMN) have a central role in the innate host responses against pathogens. We hypothesized that sub-MIC daptomycin (DAP) concentrations can modify the activity of PMN against MRSA mature biofilms. **Methods:** 12 MRSA isolates from patients with sepsis were incubated at 10^6 CFU/mL in TSB growth media at 37°C for 24h. BF formation was assessed by staining with 1% safranin and measuring OD at 595nm. For MIC determination, BF were incubated with 2-fold dilutions of DAP at 0.007-256mg/L for 24h. MRSA strains were grown in TSB at 37°C for 24h in the presence of sub-MIC DAP concentrations of 1, 2 and 4mg/L. Pretreated and untreated MRSA were then grown in fresh TSB at 37°C for 24h to produce mature BF. PMN were isolated from healthy donors by dextran sedimentation/ficoll centrifugation. BF were then incubated with PMN for additional 24h at effector to target ratios (E:T) 2:1, 1:1, 1:3, 1:4, 1:5. Sub-MIC50 was determined as the minimum concentration that caused <50% biofilm damage (BD) compared to untreated controls. PMN-induced damage measured as % reduction of metabolic activity was assessed by XTT assay. All MRSA strains were tested in triplicate. ANOVA with Dunnett's post-test was used.**Results**Of the 12 MRSA strains, 3 were found to form intermediate BF. BF MIC50 for DAP of these 3 isolates was 32 mg/L. When PMN were added to drug-pretreated BF, there was a significant increase of PMN-induced % damage against MRSA exposed to 1, 2 and 4mg/L at 2:1 and 1:5 E:T ratios as compared to drug-untreated controls (2:1, 78%±5, 89%±4, 88%±4 vs 60%±7 and 1:5, 43%±8, 50%±8, 73%±3 vs 11.6%±6; $p<0.05$). A significant enhancement of PMN-induced % damage against MRSA was also observed at 1:1, 1:3 and 1:5 E:T ratios but with MRSA exposed to DAP concentrations of 2 and 4mg/L ($p<0.01$). The highest %BD (>86%) was achieved at 2:1 E:T at 2 and 4mg/L of DAP pretreatment.**Conclusion**Pre-exposure to sub-MIC DAP concentrations increases BF susceptibility to PMN antibacterial activity against MRSA. These findings may be clinically important in treatment of *S. aureus* biofilm-associated infections and warrant further study in animal models.

Activation, Impaired Tumor Necrosis Factor-α Production, and Deficiency of Circulating Mucosal-Associated Invariant T Cells in Scrub Typhus

Author Block:

S. Kang, H-M. Jin, Y-N. Cho, E. Won, B-S. Kim, S. Kim, U. Kim, J. An, H-C. Jang, S-I. Jung, S-J. Kee, Y-W. Park; Chonnam Natl. Univ. Med. Sch. and Hosp., Gwangju, Korea, Republic of

Abstract Body:

Background: Scrub typhus is a mite-borne bacterial infection of humans caused by *Orientia tsutsugamushi* prevalent in Asia, Northern Australia, and the Indian subcontinent. The dysregulation of immune responses is known to contribute to disease pathogenesis in scrub typhus, but the nature and mechanism of immune alterations are poorly define. The current study was aimed at examining the level and function of Mucosal-associated invariant T (MAIT) cells in patients with scrub typhus and evaluating the clinical relevance of MAIT cell levels.
Methods: Thirty-eight patients with scrub typhus and 53 health control (HC) subjects were enrolled in the study. The patients were further divided into subgroups according to disease severity. MAIT cell level and function in the peripheral blood were measured by flow cytometry.**Results:** Circulating MAIT cell levels were found to be significantly reduced in scrub typhus patients compared with HCs (median 0.69% versus 1.37%, $P < 0.05$). A linear regression analysis revealed that the level of MAIT cells was related to level of alanine aminotransferase, alkaline phosphatase positively ($P = 0.043$ and $P = 0.009$), and inversely correlated with age and disease severity ($P = 0.001$ and $P = 0.047$). A comparison of phorbol myristate acetate (PMA) and ionomycin (IM) - stimulated cytokine production in MAIT cells showed that the tumor necrosis factor-α (TNF-α) production was significantly impaired in acute phase of *O. tsutsugamushi* infection compared to HCs (median 15.6% versus 45.0%, $P < 0.05$). The impaired production of TNF-α was significantly recovered in convalescent phase compared to acute phase of infection (median 56.8% versus 34.1%, $P < 0.05$). In addition, this MAIT cell dysfunction was associated with upregulation of activation marker CD69, which was significantly higher in scrub typhus patients than in HCs (median 36.8% versus 6.0%, $P < 0.0001$). **Conclusions:** This study shows that circulating MAIT cells are activated, numerically and functionally deficient in patients with scrub typhus. These abnormalities possibly contribute to immune system dysregulation in scrub typhus infection.

Overactive Bladder Phenotype Observed in Urothelial Cells Treated with Bacterial Supernatant

Author Block:

E. E. Hilt, M. M. Pearce, S. Zhang, A. J. Wolfe, P. Le; Loyola Univ. Chicago, Maywood, IL

Abstract Body:

Background: The etiology of Overactive Bladder (OAB) remains poorly understood and diagnosis is primarily symptom-based. A new paradigm emerges that involves the contribution of a non-neuronal acetylcholine response in the urothelium. The recent discovery that a female urinary microbiota exists raises the question: could some bacterial product affect the acetylcholine response in the urothelium? **Materials:** Using an established urothelial cell line, we treated urothelial cells with bacterial cell-free supernatant from organisms associated with OAB and asked if there was a difference in the expression profiles of acetylcholine receptors and enzymes required for acetylcholine synthesis. **Results:** Treatment with bacterial cell-free supernatants of the OAB-associated bacterial species, *Streptococcus anginosus*, increased the urothelial cell expression of acetylcholine receptors and carnitine acetyltrandferase, the enzyme that synthesizes acetylcholine in urothelial cells. **Conclusion:** Our findings suggest that bacterial products from OAB-associated bacteria could target the urothelium to increase the production of non-neuronal acetylcholine. These data support the hypothesis that the FUM or components of the FUM may contribute to etiology of OAB.

Immunological Responses to Poly Glutamic Acid Polymers from *Bacillus* Species

Author Block:

T. M. Jelacic, W. J. Ribot, J. Chua, A. M. Friedlander; USAMRIID, Frederick, MD

Abstract Body:

Several *Bacillus* species produce poly-gamma-glutamic acid polymers (PGAs). The PGA produced by *Bacillus anthracis* is unique in that it is composed solely of D isomer glutamic acid while other *Bacillus* species produce mixed D, L isomer PGAs. We hypothesized that the exclusive use of the D isomer confers an advantage against the host immune system so we compared the responses of human innate immune cells to the pure D isomer PGA from *B. anthracis* to their responses to two mixed D, L isomer PGAs, a predominantly D isomer PGA from *B. subtilis chungkookjang* and a predominantly L isomer PGA from *B. subtilis*. Large differences were observed when the cytokine responses of differentiating monocytes were assessed. As the level of D isomer decreased, cytokine release increased and diversified. Pure D *B. anthracis* PGA elicited only very modest amounts of IL-8 and IL-6 while the predominantly D *B. subtilis chungkookjang* PGA elicited significantly larger amounts of IL-8 and IL-6 ($P < 0.01$, n = 5 donors for both) and also elicited IL-10 and TNF alpha. The predominantly L *B. subtilis* PGA in turn elicited significantly more IL-8 ($P < 0.01$), IL-6 ($P < 0.05$), IL-10 ($P < 0.01$), and TNF alpha ($P < 0.01$) than did *B. subtilis chungkookjang* PGA and elicited release of IL-1 beta as well. Similar differences in the magnitude and diversity of the cytokine response were observed when immature dendritic cells (iDCs) from the same group of donors were tested. *B. anthracis* PGA only elicited very modest amounts of IL-8, while *B. subtilis chungkookjang* PGA elicited larger amounts of IL-8 ($P < 0.001$) and also elicited IL-6. *B. subtilis* PGA in turn elicited significantly more IL-6 than did *B. subtilis chungkookjang* PGA ($P < 0.01$) and also elicited release of IL-12p70, IL-10, IL-1 beta and TNF alpha. Since a cocktail of TNF alpha, IL-6, IL-1 beta, and PGE_2 can be used to mature human iDCs *in vitro*, we assessed the PGA treated DCs for signs of maturation. *B. subtilis* PGA induced maturation of DCs as measured by increases in expression of CD83 and CCR7, and by CCR7 dependent chemotaxis. Neither *B. anthracis* nor *B. subtilis chungkookjang* PGA induced DC maturation. From these results, we conclude that the exclusive use of D isomer in *B. anthracis* PGA greatly blunts the magnitude and diversity of the cytokine response by monocytes and iDCs and furthermore, does not induce DC maturation, thus providing *B. anthracis* with an advantage against the host immune system.

The O-Antigen of *Salmonella enterica* Serovar Paratyphi A Functions in Evasion of Complement Activation

Author Block:

T. Wangdi, H. Hiyoshi, A. J. Baumler; Univ. of California, Davis, Davis, CA

Abstract Body:

Paratyphoid fever, a severe systemic infection caused by Salmonella enterica serovar Paratyphi A (S. Paratyphi A) is a prevalent human disease with well-documented epidemiology but poorly understood pathogenesis. Paratyphoid fever is indistinguishable from typhoid fever (caused by S. enterica serovar Typhi) in its clinical presentation, but differs markedly from human gastroenteritis, which is caused by non-typhoidal Salmonella serovars, such as S. enterica serovar Typhimurium. We have previously shown that differences in the clinical presentation of typhoid fever and gastroenteritis are due in part to an evasion of complement activation mediated by the Vi capsular polysaccharide, a S. Typhi-specific virulence factor encoded by Salmonella pathogenicity island 7 (SPI7). The similarity in the clinical presentation suggests that S. Typhi and S. Paratyphi A use similar virulence strategies, however, SPI7 is not present in the latter. Here we show that the O-antigen of S. Paratyphi A lipopolysaccharide (LPS) fulfills a similar function during infection as the Vi capsular polysaccharide of S. Typhi. The S. Typhi Vi capsular polysaccharide inhibited a complement-dependent induction of reactive oxygen species (ROS) production in HL60 human neutrophil-like cells. Similarly to S. Typhi, S. Paratyphi A inhibited ROS production in HL60 cells while S. Typhimurium triggered a robust induction of ROS production. However, replacing paratose (O2 antigen) in the O-antigen of S. Paratyphi A with abequose (O4 antigen), a sugar present in the O-antigen of S. Typhimurium, markedly increased ROS production by HL60 cells. Furthermore, heterologous expression of the S. Typhimurium long O-antigen chain-length determinant gene wzzB in S. Paratyphi A resulted in kinetics of ROS production by HL60 cells that were similar to those induced by S. Typhimurium. These data suggest that unlike non-typhoidal Salmonella serovars, S. Typhi and S. Paratyphi A inhibit complement-dependent ROS production by neutrophils. However, while S. Typhi uses the Vi capsular polysaccharide to inhibit ROS production, S. Paratyphi A possesses O-antigen modifications that serve a similar function. We conclude similarities in the virulence strategies of typhoidal Salmonella serovars represents are the result of convergent evolution.

Pneumococcal Serotype 35B Is a Novel Ficolin-2 Target, and Epidemiological Data Suggest That Ficolin-2 Protects Children from Serotype 35B Invasive Disease

Author Block:

K. A. Geno, B. L. Spencer, M. H. Nahm; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract Body:

Background: Ficolin-2 (FCN2) is a pattern recognition molecule that activates complement via the lectin pathway. FCN2 binds many capsular types (serotypes) of the pathogen *Streptococcus pneumoniae* (pneumococcus) that encode the O-acetyl transferase *wcjE*. We previously reported that FCN2 protects children against invasive pneumococcal disease (IPD) by at least one such serotype, 11A. *wciG* is another O-acetyl transferase encoded by some serotypes, including 10C, which does not bind to ficolin-2. Surprisingly, we observed FCN2 binding to serotype 35B, which does not encode *wcjE* but encodes *wciG*. We studied the nature of FCN2 binding to serotype 35B and studied US epidemiology to determine whether FCN2 protects children against serotype 35B IPD. **Methods:** FCN2 and complement deposition were assayed by flow cytometry with specific antibodies. A serotype 35BΔ*wciG* strain was generated by allelic exchange mutagenesis of a serotype 35B clinical isolate. Epidemiological data were provided by the Centers for Disease Control and Prevention. **Results:** FCN2 bound to several isolates of serotype 35B pneumococcus. FCN2 binding was inhibited by known FCN2 inhibitors and purified 35B capsular polysaccharide, but not by phosphocholine. FCN2 opsonization was associated with complement opsonization in C1q-depleted serum. Deletion of *wciG* resulted in loss of FCN2 recognition. FCN2-opsonized serotypes 11A, 31, and 35B are largely absent from IPD among children in the US. **Conclusions:** We previously showed that *wcjE*-mediated O-acetylation is a ficolin-2 ligand on pneumococcal capsules. Serotype 35B, which does not encode *wcjE*, is also bound by FCN2, and thus WciG-mediated O-acetylation represents a novel FCN2 ligand. Epidemiological evidence supports the notion that children are protected against 35B infection, and infection models of FCN2-opsonized serotypes should be established for further study.

Graphen Induces Different Host Immune Response Before and After Deactivation of Endotoxin

Author Block:

K. Gokulan[1], M. Lahiani[2], K. Williams[1], M. Khodakovakaya[3], S. Khare[1]; [1]Food and Drug Adminstration, Jefferson, AR, [2]Univ. of Arkansan Little Rock, Little Rock, AR, [3]Univ. of Arkansas at Little Rock, Little Rock, AR

Abstract Body:

Engineered nanomaterials (ENM) offer considerable commercial potential and pharmaceutical applications. In pharmaceutical platforms, it is critical that ENM be carefully evaluated for their toxicity before use. Synthesis, storage, added surface coating, dispersants, and handling of the nanomaterial can result in the final product becoming contaminated with endotoxin,. The objective of this study was twofold: first, graphene nanomaterials were tested for the presence of endotoxin and strategies were developed to reduce the level of this contaminant. Second, a study was conducted to distinguish the specific immune response exhibited due to endotoxin contamination.Unaltered and functionalized graphene were used in this study. To detect endotoxin in the supplied material, the gel clot LAL assay and chromogenic-based LAL endotoxin system were used. Our results revealed that the graphene contained significant amounts of endotoxin. Comparative analysis of various depyrogenic strategies was conducted. However, the concentration of endotoxin remained above national regulatory authorities recommended limits at the graphene concentration >1ug/ml. Macrophages were incubated with depyrogenated and pristine graphene to test any differences in the phagocytosis of these material as well as gene expression of immune response related genes.The mechanism of uptake of depyrogenated graphene was different from that of the native graphene by macrophages. Both native and depyrogenated graphene caused down regulation of CD14 receptor on the macrophages; which may be due to the induction of a signal transduction cascade involved in the binding of endotoxin on CD14. Furthermore, there were several similarities, as well as differences, in the expression of Toll-like receptor signaling, NOD-like receptor signaling genes, and downstream signal transduction molecule during the exposure of depyrogenated graphene. Most interestingly, depyrogenated graphene-exposed macrophages dampened the expression of the NF-kB signaling pathway. This study affirms that endotoxin contamination should be assessed while evaluating the cellular toxicity, to differentiate nanomaterial-specific toxicity from the endotoxin effects.

Molecular Regulation of Host Inflammation During Influenza a Virus Infection

Author Block:

R. Visconti[1], C. Williams[1], R. Wurth[1], J. A. Harton[2], **E. Yager**[1]; [1]Albany Coll. of Pharmacy and Hlth.Sci., Albany, NY, [2]Albany Med. Coll., Albany, NY

Abstract Body:

The innate immune system recognizes influenza A viruses through multiple mechanisms, with recent studies revealing a critical role for the cytoplasmic NLRP3 inflammasome complex which promotes the maturation of the pro-inflammatory cytokine interleukin 1-β (IL-1β). Virus-induced NLRP3 inflammasome activation is critical for host defense and tissue repair during flu infection. Conversely, it is also evident that excessive NLRP3 inflammasome activity, especially during infection by highly pathogenic or pandemic strains of virus, can result in dysregulated inflammation that is detrimental to the host. Recent studies have identified a small molecule (pyrin-only protein 2 or POP2) that blocks the formation and activation of inflammasome complexes in humans. Because POP2 can interact with the pyrin domain of NLRP3, we hypothesize that POP2 functions to regulate the robust NLRP3-dependent IL-1β responses elicited during human IAV infection. Data from our continuing studies indicate that POP2 gene expression and function "cycles" with the expression of pro-IL-1β in PMA-differentiated human THP-1 monocytic cells exposed to seasonal and pandemic strains of influenza A viruses. Additionally, POP2 gene expression was found to be up-regulated in human donor PBMCs exposed to influenza A viruses. These findings support our notion that POP2 plays a critical role in ensuring a controlled, inflammatory response during human influenza A virus infection to favor protection over pathology.

Nlrp10 Promotes Host Innate Immunity in Sepsis

Author Block:

P. Baral, S. Batra, S. Jeyaseelan; Louisiana State Univ., Baton Rouge, LA

Abstract Body:

Rationale: Sepsis is one of the leading causes of the death in Uniteed States and rest of world among infectious disease-caused death. It represents a complex systemic response to severe microbial infection. The molecular and cellular basis of immune response in sepsis is not fully understood. The NLRP10 has been implicated to regulate the inflammation and adaptive immunity. However, it remains unknown whether NLRP10 regulates the host innate defense mechanisms in response to microbial challenge.**Methods:** To test the hypothesis that NLRP10 plays an important role in regulating the host innate response, we employed a cecal ligation and puncture (CLP)-induced polymicrobial sepsis model in NLRP10 deficient mice (crossed in C57BL/6 mice background) and *in vitro* bacterial infections in primary mouse cells to demonstrate the importance of this molecule in sepsis.**Results:** NLRP10 found to be essential for restricting the bacterial outgrowth and the sepsis-induced lethality in mice following CLP. Moreover, NLRP10 is essential for the activation of NF-κB and MAPKs in sepsis. Further, it was observed to induce key host innate defense mechanisms during microbial sepsis, including phagocytosis, NADPH oxidase, autophagy and neutrophil extracellular trap formation.**Conclusions:** Our findings further a number of advancements in our understanding of the biological role of NLRP10 in innate host response against bacterial infection. Particularly, involvement of NLRP10 in regulating key hostinnate responses, including MAPK and NADPH oxidase activation and innate defense mechanisms, are novel findings which may be helpful in future for considering NLRP10-based therapy for the treatment of sepsis.

Differences in Innate Immune Response in the Middle Ear of Otitis Prone and Non-Otitis Prone Children

Author Block:

R. Kaur[1], J. Casey[2], M. E. Pichichero[1]; [1]Rochester Gen. Hosp., Rochester, NY, [2]Legacy Pediatrics, Rochester, NY

Abstract Body:

Background: Acute Otitis Media (AOM) causes an inflammatory response in the middle ear. We assessed differences in innate immune responses in the middle ear at multi-cell levels involved in bacterial defense at onset of AOM in otitis prone (OP) (experienced ≥3 episodes of AOM within 6 months or ≥4 episodes within a year) and non-otitis prone children (NOP) (experienced 1 or 2 episodes of AOM only).**Methods:** Data reported here are from 24 children which were aged matched at 12±1 months old in two groups; OP children (n=12) and NOP children (n=12). Genes of TLRs. Nod-like and RIG-I-like receptors signal transduction molecules, downstream effectors important for inflammation and apoptosis including cytokines and chemokines were studied using real-time PCR array (SA Biosciences) from RNA of MEF samples collected by tympanocentesis. Changes in gene expression of >2 fold and $P<0.05$ were considered significant. Protein levels estimation of differentially regulated genes were determined using Luminex in MEF samples to confirm the real-time expression data.**Results:** Most of the 84 genes analyzed had similar expression in the two study groups. However, differential expression in two populations was identified for several important genes. OP children showed 4 fold higher IL8 expression compared to NOP children; significant difference ($p<0.05$) was also observed for IL8 at protein level estimation. Higher fold expression of secretory leukocyte protease inhibitor (SLPI) which is considered to be the predominant neutrophil elastase inhibitor in secretions was also significantly higher in OP children. Interferon regulatory factor 7 and its related signalling molecules of IFN-α, TICAM2, CCL5 showed significant downregulation in OP children compared to NOP indicates OP children are probably more prone to viral upper respiratory tract infections and consequent bacterial AOM. Although some pathogenic specific genes expression was observed in OP vs NOP chilldren but overall similar trend in differences is shown whether AOM was caused by *H. influenzae* or *S. pneumonia.***Conclusions:** Innate immune responses are differentially regulated in otitis prone compared to non-otitis prone children that likely contribute to otitis proneness condition in children.

Expression of IFNG and TNFA in Inflammatory Cells from *Burkholderia pseudomallei* Chronically Infected BALB/c and C57BL/6 Mice

Author Block:

J. L. Dankmeyer, C. K. Cote, S. L. Welkos, S. R. Trevino, D. P. Fetterer, C. Soffler, P. L. Worsham, K. Amemiya; US Army Med. Res. Inst. of Infectious Diseases, Frederick, MD

Abstract Body:

Background: Melioidosis, which is caused by *Burkholderia pseudomallei* (Bp), is endemic in South East Asia and Northern Australia. Because of a wide number of strains that have been isolated from human melioidosis patients, we have been evaluating their virulence in a mouse model of melioidosis. We detected endogenous expression of TNFα and IFNγ in monocytes/macrophages, NK cells, and granulocytes in splenocytes from chronically infected mice but not in acutely infected mice. **Methods:** BALB/c and C57BL/6 mice were infected with the 12 different human isolates of Bp by aerosol exposure to determine their 21 day LD_{50}. No survivors were obtained after 21 days from two isolates. Blood was collected for antibody and cytokine/chemokine analysis, and spleens for colony forming units (CFU), changes in cell composition, cytokine/chemokine analysis, and *in vitro* cellular immune responses. Antibody responses to Bp K96243 were determined by ELISA. Cytokine/chemokine expression in serum, spleen extracts, and splenocyte cultures were determined by Luminex technology. Splenocyte composition and intracellular cytokine expression were analyzed by flow cytometry. Intracellular cytokine expression was detected by incubation of cells with IFNγ-APC or TNFα-APC. **Results:** More than 100 spleens were examined of which 26 had a pyogranuloma that were from chronically infected mice. Nine other spleens were swollen with little CFU and no pyogranulomas. In infected spleens there was an increase in monocytes/macrophages, NK cells, granulocytes in both types of mice, while in the swollen spleens there were fewer inflammatory cells. There was a significant increase in IL-1α and IL-1β expression in spleen extracts. We also detected the presence of endogenous IFNγ and TNFα in 16 of the infected spleens in the inflammatory cells. We saw low levels of TNFα in T cells but not IFNγ. In swollen spleens there was less endogenous TNFα and IFNγ than in infected spleens and none in normal appearing spleens. **Conclusions:** *B. pseudomallei* can cause a chronic infection in mice with a continuous production of IL-1α and IL-1β. Inflammatory cells but not T cells were producing IFNγ, while some TNFα could be seen in T cells that appeared to be associated with the presence of a pyogranuloma.

Serotypic Differences in Dendritic Cells Responses in Shigella

Author Block:

C. Narayan, BR Thapa, JK Mahajan, Vishal Kant, Balvinder Mohan, Neeam Taneja; PGIMER, Chandigarh, India

Abstract Body:

Background: Dendritic cells (DC) are key regulators of immune response with the ability to affect both the innate and adaptive immune responses and are abundant in the gut mucosa. The severity of shigellosis varies with the serotype involved with *S. dysenteriae* (SD) producing the severest infections and complications with *S. sonnei* (SS) being at other end of spectrum usually causing mild self-limiting diarrhea .While shigellae are known to induce the apoptosis of mature DCs, there is no information in cytokine milieu of DCs incubated with different serotypes of *Shigellae***Methods:** Monocyte derived dendritic cells (MoDCs) were developed from healthy human PBMC after 8 days of culture. They were characterized by four-color flow cytometry technique using Becton Dickinson FACS ARIA III, equipped with 488 nm and 630 nm argon laser and analysed by FACS Diva 6.1.2 Software on the basis of CD11c positive, HLA-DR positive and CD3 negative. DCs were infected with different Shigella serotypes. After 24 hour post infection, relative expression of cytokines IL-1β, IL-6, IL-8, TNF-α, IL-12p70, IL-17, IL-22 and IL-23 was studied by Real Time PCR and data was analysed by Graph prism5. **Results:** IL-8, IL-17A, IL-22A and IL-23 expressions were highest in MoDCs stimulated with *S. dysenteriae* serotype1 and significant serotypic differences were noted between SD & SF and between SD & SS. The transcription levels of IL-23 were down regulated in *S. flexneri* & *S. sonnei* in comparison to normal MoDCs. IL-8 appears to be a major molecule orchestrating mucosal inflammation in shigellosis. It is the primary cytokine which induces neutrophil chemotaxis. SD1 induces more Th17 response which displays pro-inflammatory functions. IL23 is responsible for the expansion of Th17 previously differentiated.IL-23 promotes the development and expansion of activated CD4+ T cells. **Conclusions:** DCs are critical sentinel cells that relay microbial presence either directly or indirectly to naive T cells .In this study we found that Shigella dysenteriae caused maximum release of IL-8. Similarly SD also caused highest release of IL-17A and IL-22A. It was the only serotype which increased IL-23. These findings could explain more severity of SD as compared to SF and SS.

Common Correlates of Protection Against *Francisella tularensis* Identified Using Mice and Rats

Author Block:

R. De Pascalis[1], A. Hahn[2], L. Mittereder[1], N. Donart[2], B. Frey[1], H. Brook[1], T. Wu[2], K. Elkins[1]; [1]Food and Drug Admin., Siver Spring, MD, [2]Univ. of New Mexico Hlth.Sci. Ctr., Alburquerque, NM

Abstract Body:

The Live Vaccine Strain (LVS) against tularemia, caused by *Francisella tularensis (Ft)*, is not licensed in US and has uncertain protection against the virulent Type A *Ft*. Thus, better prophylactic vaccines are needed, as well as methods to test their efficacy. Unlike more common human infections, for which vaccine efficacy can be evaluated by field trials, evaluating efficacy against sporadic diseases like tularemia requires alternative strategies. Measuring correlates of protection may complement or replace efficacy large-scale clinical trials, and facilitate studies via the "Animal Rule." Recently, we demonstrated that combining *in vitro* stimulation of murine *Ft* LVS-immune cells with subsequent genomic characterization discriminates *Ft* vaccines of different efficacy, and thus we identified potential correlates of protection. To further explore correlates, we extended our studies to a different animal model. Here, Fischer 344 rats were vaccinated with a panel of LVS-derived vaccines and subsequently given a respiratory challenge with lethal Type A *Ft*. The *in vivo* efficacy of different vaccines was compared with the ability of PBLs from vaccinated rats to control *in vitro* functions and with relative gene expression. Overall the *in vitro* functions, including control of LVS intramacrophage replication, IFN-gamma secretion, and NO production, reflected the hierarchy of protection. In addition, the expression of a panel of genes was more up-regulated in cells from the groups of rats administered the better vaccines. In contrast, genes in cells from naive or poorly protected groups exhibited lower expression or down-regulation. Most importantly, selected potential correlates that were previously identified using murine LVS-immune PBLs were also differentially expressed in rat PBLs. These included IFN-gamma, IL-21, Nos2, LTA, T-bet, IL-12rbeta2, CCL5, CXCL11, GzmB. This method therefore may allow the identification of common potential correlates of protection in multiple animal species, using a clinically accessible cell source, and it has potential for screening of new vaccines candidates.

Roles of Interleukin-17 and Neutrophil-Mediated Host Responses in Murine *Clostridium difficile* Colitis

Author Block:

H. Konishi, T. Yamaguchi, T. Nakagawa, C. Kajiwara, S. Kimura, Y. Ishii, K. Tateda; Toho Univ., Tokyo, Japan

Abstract Body:

Background: Increased neutrophil number in the blood is a well-known hallmark of severe cases of *C. difficile* colitis (CDC). A recent study has reported that IL-23, a major IL-17 inducer, play a role in CDC in animals and humans. However, roles of IL-17, especially neutrophil-mediated host responses, in CDC remained controversial. In the present study, we investigated roles of IL-17 and neutrophil-mediated host responses in mice model of CDC. **Methods:** BALB/c background of IL-17A and F deficient mice (IL-17 KO) were pretreated with an antimicrobial mixture, and challenged orally with *C. difficile* BI/NAP1/027 ($1\text{-}3\times10^6$ cfu/mouse) for survival and host responses. After the challenge, mice were sacrificed at 2 days post infection. Blood and intestine samples (cecum/colon) were examined for cellular infiltration (flow cytometry) and cytokine productions (ELISA and RT-PCR array).**Results:** Significantly lower mortality was observed in IL-17 KO mice (10%), comparing to the control (70%). Neutrophil number in blood was significantly higher in control mice than IL-17KO mice. In accordance with blood results, the number of neutrophils in the intestine was higher in control mice than IL-17 KO mice. In ELISA analysis of intestinal samples, lower productions of inflammatory cytokines in IL-17 KO mice were demonstrated in CXCL1, G-CSF and IL-1β, but not CXCL2, IL-4, IL12p70 and TGF-β. RT-PCR array in intestinal samples demonstrated higher expressions of IL-6 and IL-12b and lower levels of lactoferrin in IL-17 KO mice, whereas no difference was observed in other factors, such as MPO, Slpi, Myd88 and Nod1.**Conclusions:** Our data demonstrated that IL-17 KO mice were more resistant to CDC in mice. The survival benefit was well associated with less neutrophil accumulation and weak inflammatory host responses. Pathogenic roles of neutrophils, especially IL-17-mediated host responses, are warranted for future's investigation.

***Cryptosporidium parvum* Induces an Intestinal Epithelial Innate Immune Response Involving Type III Interferon**

Author Block:

S. H. Ferguson[1], D. M. Foster[1], B. Sherry[1], S. T. Magness[2], J. L. Gookin[1]; [1]North Carolina State Univ., Raleigh, NC, [2]Univ. of North Carolina, Chapel Hill, NC

Abstract Body:

Cryptosporidium spp., a zoonotic intestinal epithelial parasite, is the second leading cause of infectious diarrheal death in children under 5 in developing countries, and lethal in immunocompromised individuals worldwide. The host immune response is critical for defense against *Cryptosporidium parvum* (*Cp*) however the cellular mechanisms are poorly understood. To gain insight into the host strategy for defense against *Cp*, we examined the transcriptional response of the intestinal epithelium (IECs) to *Cp* in experimentally infected piglets. Upregulated genes were dominated (39%) by targets of interferon (IFN) signaling with ISG15 being the most highly induced (21 fold). We hypothesized that *Cp* induces a strong IFN-mediated host immune response that may be attributed to a recently discovered, epithelial derived, Type III interferon IFN-λ.The identity, origin, and cellular target(s) of IFN in *Cp* infection were investigated using a well-established neonatal piglet model and primary porcine IECs (IPEC-J2). Orogastrically infected and age-matched control piglet ileal IECs and lamina propria (LP) were collected for qRT-PCR and immunoblotting to identify and localize expression of IFN-α, -β, -γ, -λ1, and -λ3, IFN-λR1, and ISG15. To determine if *Cp* infection of IECs alone is sufficient to induce IFN-λ and IFN-λ-dependent gene expression, IPEC-J2 cells were immunoblotted to confirm expression of IFN-λR1 and treated with either *Cp* or rIFN-λ and ISG15 expression examined by qRT-PCR.Infection of piglets with *Cp* resulted in a ~100 fold increase in ileal mucosal expression of IFN-λ3 (p= 0.05). Constitutive and *Cp*-induced expression of IFN-λR1 was identified in both the epithelial crypts and LP. Corresponding with localization of IFN-λR1, ISG15 was significantly upregulated (~59 fold, p=0.008) in the crypt-enriched LP fractions of *Cp* infected piglet ileum. In IPEC-J2 cells, *Cp* infection was sufficient to induce expression of IFN-λ3 and rIFN-λ3 induced ISG15 in a dose-dependent manner.This study identifies expression of IFN-λ as a key response of IEC to *Cp* infection and suggests an important role for IFN-λ in host defense. These observations come from a powerful *in vivo* model of *Cp* infection in which the function of IFN in innate immune defense can be explored.

Prelp Enhances Host Innate Immunity against Respiratory Tract Pathogens

Author Block:

G. Liu, D. Ermert, Y-C. Su, B. Singh, M. Johansson, K. Riesbeck, A. M. Blom; Lund Univ., Malmö, Sweden

Abstract Body:

Respiratory tract infections are the leading cause of deaths globally. Increasing antibiotic resistance and low coverage of available vaccines requires alternative therapeutics to treat respiratory tract infections. Here we report that proline/arginine-rich end leucine-rich repeat protein (PRELP) could be a potential therapeutic candidate. PRELP is present in alveolar fluid, resident macrophages/monocytes, myofibroblasts, and adventitia of blood vessels of lung tissue. PRELP specifically binds respiratory tract pathogens *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*, but not other tested bacterial pathogens. PRELP binds the majority of clinical isolates of *M. catarrhalis* (n = 49), and interacts directly with the ubiquitous surface protein (Usp) A2/A2H of *M. catarrhalis*. PRELP increases C3b deposition and membrane attack complex formation on *M. catarrhalis*, thereby enhancing the killing of *M. catarrhalis* by human serum. Moreover, PRELP competitively inhibits binding of complement inhibitor C4BP on *M. catarrhalis*. Taken together, PRELP enhances the killing of *M. catarrhalis* by human serum via inhibition of C4BP binding. Thus, PRELP might be used as a therapy to modulate the innate immune responses toward respiratory tract pathogens, particularly *M. catarrhalis*.

An Analysis of the Impacts of Green Tea on Bacterial Growth and Phagocytosis by Macrophages

Author Block:

A. K. Meyers, C. Thompson; Loyola Univ. Maryland, Baltimore, MD

Abstract Body:

The emergence of significant drug resistance in bacteria has pushed many researchers to develop and evaluate methods to fight this growing problem. One important example of such methods are the use complementary and alternative medicines (CAMs). CAMs are a group of medicines and/or practices that are used in addition to or as an alternative to typical Western medicinal practices. Research has shown that this group is comprised of potentially valuable therapeutic agents with some being purported to improve immune system function. The objective of this proposal is to evaluate the efficacy and mechanism of action for green and black teas, CAMs that has been suggested to improve our body's natural antimicrobial responses- in essence, treating from within. Specifically, the focus of this project was to analyze the effects of green and black teas on phagocytosis: the mechanism by which certain white blood cells "eat" and kill bacteria. Both black and green teas were brewed and added at different concentrations to bacterial broth. As expected, the growth of *Staphylococcus aureus* in the presence of these teas showed no significant differences in growth or survival as compared to controls. Next, RAW 264.7 cells were treated with a simulated human digest of black or green teas and allowed to phagocytose GFP-expressing *Staphylococcus aureus*. Using confocal microscopy, images were taken depicting several time points of phagocytosis that were then compared visually to control cells. These experiments indicated that phagocytosis proceeded faster in the presence of green tea, but not black tea, at all four stages of phagocytosis (attachment, entry, maturation, and degradation). Currently, we are using fluorescence-based assays (in microplates and via confocal) to assess the differences in calcium signaling (speed and quantity) as a potential mechanism that is governing this increased phagocytic speed. Together, these data suggest that green tea (and, potentially, black tea) are able to enhance the microbicidal activity of our innate immune system without directly impacting bacterial growth. Further research is necessary to determine whether these teas and other CAMs have merit as therapeutic agents to enhance the immune response to bacterial infection, but, if the data are encouraging, this could represent a novel, inexpensive, and easy mechanism for improving health and combatting antibiotic resistance.

Activation of the Non-Canonical NF-kB Pathway Following Internalization of Bacteria Expressing a Functional Type III Secretion System

Author Block:

M. C. Duncan[1], **N. G. Herrera**[1], K. S. Johnson[1], J. N. Engel[2], V. Auerbuch[1]; [1]Univ. of California, Santa Cruz, Santa Cruz, CA, [2]Univ. of California, San Francisco, San Francisco, CA

Abstract Body:

The type III secretion system (T3SS) is a bacterial nano-machine utilized by dozens of pathogens to inject effector proteins into mammalian cells, thereby manipulating host defense mechanisms such as phagocytosis. In turn, the mammalian innate immune system has evolved the ability to recognize bacterial deployment of a functional T3SS, triggering activation of several host-signaling pathways. Previously, we showed the *Yersinia pseudotuberculosis* T3SS activates host NF-kappaB, a proinflammatory transcription factor. In this study, we sought to better characterize NF-kappaB induction by the *Yersinia* T3SS. Utilizing both confocal fluorescence microscopy and RNA interference, we found that wildtype *Yersinia*, which remains extracellular by inhibiting phagocytosis through the actin targeting T3SS effectors YopEHO, triggered NF-kappaB activation independently of the non-canonical NF-kappaB kinase NIK. In contrast, *Yersinia* lacking actin-targeting effectors induced a NIK-dependent NF-kappaB response and processing of the non-canonical NF-kappaB subunit p100 to p52 was assessed via western blot analysis. Furthermore, blocking actin polymerization and bacterial uptake using cytochalasin D prevented this NIK dependency. *Yersinia* lacking any T3SS function triggered very low levels of either canonical or non-canonical NF-kappaB. We observed similar results using *Pseudomonas aeruginosa*, which expresses a related T3SS and the actin-targeting effector ExoT. These data indicate that internalized bacteria expressing a functional T3SS trigger NIK-mediated p100/p52 processing. Non-canonical NF-kappaB is primarily important in lymphocyte development and bone metabolism, but has also been associated with the innate immune response to viruses and certain bacteria. Our results suggest that non-canonical NF-kappaB may also play a role in the innate immune response to the bacterial T3SS, and that mammalian cells may be able to distinguish between intra- and extracellular T3SS.

Cytoplasmic Activation of an Alternative Flagellar System in *Burkholderia pseudomallei*: Implications for the Innate Immune Response to Infection

Author Block:

J. Maloy, J. La, J. Miller; Univ. of California, Los Angeles, Los Angeles, CA

Abstract Body:

Burkholderia pseudomallei (*Bp*) is a facultative intracellular pathogen endemic to Southeast Asia and Northern Australia and is the causative agent of melioidosis. *Bp* isolates have been segregated into genetically distinct Southeast Asian or Northern Australian clades with variations in clinical manifestations corresponding to geographical source. Northern Australian isolates carry an ancestral *Burkholderia thailandensis*-like flagellar and chemotaxis cluster (*BTFC*), while Southeast Asian isolates carry a *Yersinia*-like fimbral cluster (*YLF*) in its place. The *BTFC* locus plays a role in pathogenesis of Northern Australian *Bp* strains by promoting intracellular motility. While *Bp* extracellular swimming motility requires a polar flagellum encoded by the *fla1* locus, motility in the cytoplasm of host cells requires either *bimA*-induced actin polymerization or flagellar motility encoded by the *BTFC* locus. The *BTFC* locus activates intracellular expression of lateral flagella in response to an unidentified cytoplasmic signal. Innate immune mechanisms, particularly NLRC4-driven pyroptosis and production of IL-1β, are critical for host response to *Bp* infection. While previously attributed to type-3 secretion system (T3SS) components, we show that the NLRC4 response is partially dependent on the *BTFC* locus flagellin encoding gene *(fliC2)* in *Bt* and Australian strains of *Bp.* Deletion of *fliC2* results in a decrease in IL-1β production in *wild-type* (*wt*) murine macrophages, without affecting IL-1β release in macrophages deficient in *nlrc4*. Additionally, reconstitution of the NLRC4 inflammasome in 293T cells renders them susceptible to rapid cell death in response to infection with *wt*, but not *ΔfliC2 Burkholderia.* These data suggest that the *BTFC* locus plays an important role in intracellular pathogenesis of *Burkholderia*, and may be an important factor influencing the host innate immune response to infection with Australian strains of *Bp*.

TLR3 Is a HSV-1 Sensor That Rapidly Protects CNS Neurons from Infection

Author Block:

O. Ewaleifoh[1], B. Zimmer[2], S. Zhang[3], L. Notarangelo[4], J. L. Casonava[3], G. Smith[1]; [1]Northwestern Univ., Chicago, IL, [2]Mem. Sloan Kettering, NY, NY, [3]Rockefeller Univ., New York, NY, [4]Harvard Univ., Boston, MA

Abstract Body:

Introduction: In born errors in Toll Like Receptor 3 (TLR3), results in increased susceptibility to Herpes Simplex Encephalitis (HSE) in humans. How TLR3 limits HSV-1 infection remains unclear. Induced pluripotent stem cell (iPSC) generated from patient skin cells have made it possible to investigate central nervous system (CNS) resistance to HSV-1 infection in a culture model. **Methods:** Using human iPSC-derived neurons from healthy control and HSE patient's deficient in TLR3, we examined the mechanism of TLR3 protection following infection with recombinant HSV-1.**Results:** Our studies indicate that the anti-HSV activity of TLR3 is unique to CNS neurons and absent from the peripheral nervous system (PNS). Data will be presented supporting that TLR3 senses RNA anchored on the virion surface. The response was rapid and STAT1-independent, with HSV-1 entry and retrograde transport in axons blocked.**Conclusion:** Our results indicate an unusual TLR3-dependent block to infection is operational in CNS neurons that is rapid and interferon independent.

Molecular Basis of Brain Infection by *Listeria monocytogenes*

Author Block:

P. Ghosh, E. M. Halvorsen, D. E. Higgins; Harvard Med. Sch., Boston, MA

Abstract Body:

Listeria monocytogenes is an intracellular bacterial pathogen that is frequently associated with foodborne infection. Of particular concern is the ability of *L. monocytogenes* to breach the blood-brain barrier (BBB) to invade the central nervous system (CNS), leading to life-threatening meningitis and encephalitis. The identity of factors necessary for *L. monocytogenes* invasion of the brain has remained elusive. To further our understanding of *L. monocytogenes* infection of the brain, we evaluated the contribution of InlF, a member of the internalin family of surface proteins previously shown to be important for host cell binding and entry. Mice were infected with wild-type or *ΔinlF* bacteria to determine the effect of InlF on *L. monocytogenes* virulence. These studies showed that InlF plays a critical role for successful *L. monocytogenes* colonization of the brain in mice. Subsequent affinity chromatography and mass spectrometry experiments identified host cell Vimentin as a binding partner for InlF. Host cell invasion assays were performed following blocking of surface Vimentin with anti-Vimentin antibody or in the presence of Withaferin A, a chemical inhibitor that leads to cleavage and reorganization of Vimentin. These studies resulted in inhibition of *L. monocytogenes* host cell invasion suggesting that cell surface Vimentin is involved in bacterial internalization by host cells. Further confocal microscopy experiments revealed that *L. monocytogenes* is able to bind cell surface Vimentin and that InlF facilitates *L. monocytogenes*-Vimentin interaction. The requirement of Vimentin for host cell invasion was further confirmed using infection studies with host cells lacking Vimentin. More importantly, *L. monocytogenes* infection experiments with Vimentin normal (Vim+) and knockout (Vim−) mice confirmed the importance of Vimentin for *L. monocytogenes* colonization of the brain. Taken together, these studies for the first time demonstrate an interaction between a host cell receptor (Vimentin) and a bacterial surface protein (InlF) with specific relevance to *L. monocytogenes* brain infection *in vivo*.

Inhibitory Effects of Oligosaccharides on Enteric Pathogen Association with the Gastrointestinal Barrier

Author Block:

P. Chen, N. Kong, B. C. Weimer; Univ. of California Davis, Davis, CA

Abstract Body:

Bacterial enteric pathogens cause millions of cases of food poisoning in humans and livestock each year and result in billions of dollars in medical care costs and lost revenue. The three leading causes of foodborne, bacterial gastroenteritis are *Salmonella* Typhimurium (*S.* Typhimurium), *Escherichia coli* (*E. coli)*, and *Listeria monocytogenes* (*L. monocytogenes*). In lieu of antibiotics, non-digestible, dietary oligosaccharides, such as mannan and fructo-oligosaccharides, are commonly used as feed additives for livestock to prevent enteric pathogen association with the host. Additionally, human milk oligosaccharides (HMO) are suspected to play a role in minimizing enteric pathogen colonization. In this study it was hypothesized that the presence of oligosaccharides would decrease enteric pathogen association in a dose-dependent manner. Efficacies of HMO and commonly used feed additives, mannan-oligosaccharides and fructo-oligosaccharides, in blocking pathogen association with differentiated colonic epithelial cells (Caco-2) were evaluated using modified gentamicin protection assays in the presence of each oligosaccharide. Results from this study demonstrated that *S.* Typhimurium, *E. coli*, and *L. monocytogenes* each responded differently to specific oligosaccharide treatments. Treatment with mannan-oligosaccharides resulted in increased S. Typhimurium host association as oligosaccharide concentration increased. Treatment with fructo-oligosaccharides resulted in dose-dependent increases in host association in all three pathogens. Pre-blocking of Caco-2 monolayers with HMO was the only treatment that resulted in a dose-dependent decrease in host association across all three pathogens. Pre-blocking with HMO was the only treatment that resulted in decreased host association in *L. monocytogenes* whereas pre-blocking with mannan and fructo-oligosaccharides caused an increase in *L. monocytogenes* host association. These results illustrate the independent effects of different oligosaccharides on enteric pathogens, emphasizing the effects of diet changes on pathogen susceptibility and persistence.

Role of the Extracellular Membrane Sensing Loop of Gras in Resistance to Distinct Cationic Antimicrobial Peptides in *Staphylococcus aureus*

Author Block:

A. Cheung[1], A. Bayer[2], M. Yeaman[2], Y. Xiong[2], N. Donegan[1], **S. Yang**[3]; [1]Geisel Sch. of Med. at Dartmouth, Hanover, NH, [2]Los Angeles BioMed. Res. Inst., Torrance, CA, [3]Chung Ang Univ., Ansung, Korea, Republic of

Abstract Body:

BACKGROUND: The *Staphylococcus aureus* two-component regulatory system, GraRS, is involved in resistance to killing by distinct host defense cationic antimicrobial peptides (HD-CAPs) by regulating downstream target genes such as *mprF* and *dltABCD.* However, the detailed mechanisms by which the extracullular sensing loop (EL) of the GraS senses specific HD-CAPs in not well defined. **Methods: Strains:** Isogenic set of *S. aureus* strains: **i**) COL parent; **ii**) its Δ*graS* knockout; and **iii**) six plasmid-complemented Δ*graS* strains expressing distinct point-mutations within the GraS sensing loop (P38H, F38G, F38A/P39A, F38G/P39G, D35/37/41K, D35/37/41G). These mutations introduced specific changes in charge, bulk and/or polar angles within the sensing loop.**MICs to Daptomycin (DAP) or Polymyxin B:** standard E-test or broth microdilution assays.**HDP susceptibility assays:** standard 2h killing assays using 5×10^3 *S. aureus* CFU vs. LL-37 (PMNs) and RP-1 (platelets).**Surface charge:** cytochrome c binding assay.**Gene expression:** standard qRT-PCR.**Animal virulence model:** A catheter-induced aortic valve infective endocarditis (IE) model in rabbits.**RESULTS:** The COL Δ*graS* mutant was unable to induce *mprF* and *dltA* transcription and, in turn, exhibited significantly increased susceptibilities to DAP, RP-1 and LL-37. Further, the six Δ*graS* mutants expressing point-mutated GraS ELs displayed both moderate increases in PMB and HD-CAPsusceptibility, as well as reductions of *mprF* and *dltA* induction by PMB. Reductions in net positive surface charge were observed in both triple mutants, D35/37/41K and D35/37/41G strains, correlating with the gene expression data. *In vivo*, the Δ*graS* knockout strain displayed significant reductions in bacterial counts achieved in all target tissues in the rabbit IE model ($\geq$ 4-6 $\log_{10}$cfu/g reductions).**CONCLUSIONS:** These results demonstrate that GraS sensor plays an important role in sensing HD-CAPs to induce adaptive survival responses to these molecules in *S. aureus*.

Comparative Analysis of *Escherichia coli* O157 Growth and Protein-expression, *In Vitro* & *In Vivo*, in Rumen Fluid of Cattle

Author Block:

I. T. Kudva, T. Casey, J. D. Lippolis, J. Trachsel, H. K. Allen; Natl. Animal Disease Ctr., USDA/ARS, Ames, IA

Abstract Body:

Cattle are the primary reservoirs for *Escherichia coli* O157 (O157), a Shiga toxin-producing *E. coli*, with potential for serious extraintestinal sequelae in humans. In a recent study (Kudva IT *et al*. BMC Microbiol. 2014; 14:48), we reported that when cultured in rumen fluid from dairy cattle on the maintenance diet (high in fiber), O157 expresses proteins involved in survival rather than those contributing to virulence. This observation was in contrast to the well-established expression of virulence factors by O157 during colonization of the human host. In the current study, we evaluated if similar results would be obtained when different O157 strains are grown, (i) *in vitro* in rumen fluid from animals on other diets usually provided to dairy cattle, and (ii) *in vivo* within the rumen of fistulated animals on the same diets, using a new method that not only allows such *in vivo* studies in the cattle rumen but also permits reuse of animals. Rumen-fistulated, dairy cattle were fed either the maintenance diet as reported previously, or a lactation diet (high in protein). Three different strains of O157 were studied: EDL 933, 86-24 and a super shed isolate SS-17. As expected, the two diets had differing influences on the ruminal pH and volatile fatty acid (VFA) profiles. The ruminal pH ranged from 6.2 - 7.0, with total VFA concentrations of 109 - 141 μM/ml, among animals fed the maintenance diet. On the other hand, animals fed the lactation diet had ruminal pH ranging between 5.14 - 6.0, and total VFA of 125 - 241 μM/ml. O157 strains demonstrated different growth patterns in these rumen fluids, after 48 h at 39^{o}C, in both the *in vitro* and *in vivo* assays. A greater reduction in O157 viable counts was observed in rumen fluid from, or rumen of, cattle fed the lactation diet compared to the maintenance diet. We are presently profiling the proteomes of O157 isolates recovered from the *in vitro* and *in vivo* assays, to obtain insights into mechanisms adapted by these O157 strains in rumen fluid with different compositions. Such data will be helpful in formulating effective therapeutic and/or diagnostic modalities to curtail O157 in cattle.

A Previously Undescribed *Pneumocystis jirovecii* Cytochrome B Mutation Associated with Atovaquone Exposure

Author Block:

S. Le Gal[1], N. Argy[2], J. Clain[3], W. Vindrios[2], M. Virmaux[4], R. Dorent[2], J. Lucet[2], Y. Yazdanpanah[2], M. Wolff[2], S. Houzé[2], **G. Nevez**[1]; [1]Brest Univ. Hosp., Brest, France, [2]Bichat Univ. Hosp., Paris, France, [3]IRD, Paris Descartes Univ., Paris, France, [4]Brest Univ., Brest, France

Abstract Body:

Background: Several mutations at the cytochrome b gene of *Pneumocystis jirovecii* (*P.jirovecii*) associated with atovaquone exposure have already been reported. *Pneumocystis* pneumonia (PCP) prophylaxis at the heart transplantation unit of Bichat University Hospital (Paris, France) is essentially based on atovaquone use. In this context, our objective was to genotype at the cytochrome b gene *P.jirovecii* isolates obtained from heart transplant recipients monitored at this hospital. **Methods:** Twenty-two *P. jirovecii* DNA isolates obtained from the 11 heart transplant recipients and 11 unlinked control patients who were contemporaneously diagnosed with *Pneumocystis* infections were examined for genotyping. The cytochrome b gene was amplified and sequenced from both strands. Sequences were aligned and compared with the reference sequence. A medical chart survey was also performed to determine whether the patients had past history of atovaquone prophylaxis or treatment.**Results:** *P.jirovecii* genotyping was successful in 10 out of the 11 heart transplant recipients and in 9 out of the 11 unlinked patients. All heart transplant recipients and 1 out of the 11 patients of second group had past history of atovaquone exposure respectively (11/11vs. 1/11, p <0.01). Type CYB2 harboring a previously undescribed mutation on position 350 (C350T) was identified in 9 out of the 10 heart transplant recipients whereas it was not identified in the second patient group (9/10 vs. 0/11, p <0.01). This transition C350T is associated with an amino acid change Ala 144 Val at the Qo site, which is the target of atovaquone. These results may be explained by *i)* atovaquone selection pressure of the mutant CYB2 type, ii) *P.jirovecii* circulation within the heart transplant recipient population.**Conclusions:** This newly described non-synonymous mutation C350T at the cytochrome b gene of *P.jirovecii* may be associated with atovaquone exposure and its detection may represent a circulation marker of the fungus among patient populations.

Effects of *Pseudomonas aeruginosa* Biofilms on Wound Healing in a Diabetic Murine Model

Author Block:

C. L. Larrivee, J. A. Gibson, A. M. A. Hunt, S. Navitskaya, S. O'Reilly, J. V. Busik, C. M. Waters; Michigan State Univ., East Lansing, MI

Abstract Body:

Diabetes and obesity have reached epidemic proportions in the United States. According to 2011 CDC reports diabetes affects 25.8 million people, or 8.3% of the U.S. population. Due to the high blood glucose, neuropathy is a common occurrence in diabetic patients which can lead to poor detection of any wounds on the body. Wounds that go undiagnosed have a high chance of becoming infected, and bacterial biofilms have recently been implicated as an underlying cause of chronic non-healing wounds. Using a diabetic murine model, we examined the impact of biofilm formation on the rate of wound healing in diabetic versus non-diabetic mice. C57/BL6 non-diabetic and C57/BL6 streptozotocin induced diabetic mice were wounded. Two surgical wounds 4mm in diameter were created on the backs of each mouse, 5mm splints were sutured around each wound to prevent contraction and dressings were applied to prevent scab formation. While one wound served as control the other was inoculated 24 hours post-surgery with 3 day-old biofilms of a bioluminescent strain of *P. aeruginosa* derived from PAO1 (Xen 41, Perkin Elmer) and in another experiment with a high biofilm forming mutant (*wspF* Xen41). The rate of healing and biofilm viability were then monitored via *in vivo* imaging system (IVIS) and by microscopy until complete recovery. This study established that diabetic mice not infected with biofilms do present a delay in healing compared to non-diabetics. Infection by Xen 41 postponed closure of wounds in the non-diabetic mice but retarded healing even further in diabetic ones. In addition, IVIS imaging showed a rapid decrease in biofilm viability in the non-diabetic mice in contrast to a general initial increase in biofilm in the diabetics. Infection of wounds by biofilms of *wspF* Xen 41 had even more impacting results: infected diabetics were incapable of combating the infection which resulted in death of over 40 percent of the cohort. In conclusion the presence of biofilms impacts wound healing even further than diabetes alone. Furthermore the biofilm forming properties of the infecting strain may decrease clearance by the immune system resulting in higher mortality. Future experiments will investigate the molecular mechanism that contribute to diabetic chronic wounds.

A *Salmonella SdiA* Mutant Shows Decreased Ability to Colonize the Inflamed Mouse Gut

Author Block:

K. A. Miller, M. C. Swearingen, A. Sabag-Daigle, B. M. M. Ahmer; Ohio State Univ., Columbus, OH

Abstract Body:

Quorum sensing in bacteria is a way to regulate genes in response to population density. The best characterized quorum sensing system is LuxR/LuxI in *Vibrio fischeri*. LuxI is an acyl homoserine lactone (AHL) synthase. These AHLs bind to LuxR which induces expression of specific host interaction genes. Although many bacteria Proteobacteria contain LuxR/LuxI type systems, there are some that only encode a LuxR homolog and no LuxI. These LuxR homologs that lack a LuxI interaction partner are called solo LuxRs. SdiA is a solo LuxR homolog that is conserved among the *Escherichia, Salmonella, Enterobacter, Cronobacter, Citrobacter,* and *Klebsiella.* Most of these organisms that encode SdiA lack a LuxI homolog and do not produce their own AHLs. Instead, SdiA is used to detect the AHLs synthesized by other bacteria. The SdiA regulon appears to be unique in each genus. In *Salmonella*, the regulon consists of two loci and a total of seven genes. The first locus is the *rck* operon, which is encoded on the virulence plasmid and includes six genes (*pefI, srgD, srgA, srgB, rck,* and *srgC).* The function of most of these genes is unknown, but it has been shown that Rck is responsible for resistance to complement killing and promotes adherence and invasion of epithelial cells. The *srgA* and *pefI* genes affect the *pef* operon, SPI2, and motility. The second locus is a single gene, *srgE,* which encodes an effector of the SPI2-encoded type III secretion system. Here, we have determined that SdiA provides a fitness advantage to *Salmonella* in the CBA/J model of *Salmonella*-induced inflammation. This phenotype is observed during the time that the mouse gastrointestinal tract becomes inflamed. Surprisingly, this fitness phenotype is not observed during a competitive infection in which the wild-type and the *sdiA* mutant are inoculated together. Thus, it appears that the mutant can be complemented in trans by the wild-type. Further experiments are underway to determine if *srgE* or the *rck* operon are involved in this fitness phenotype.

Limited Maximal Activity without Marked Loss of Potency of Antibiotics against Intracellular Forms of *Staphylococcus aureus* and *Pseudomonas aeruginosa*: An Analysis with 13 Bactericidal Antibiotics from 7 Different Pharmacological Classes in a Pharmacodynamic Model of Human THP-1 Infected Monocytes

Author Block:

F. Van Bambeke, **P. M. Tulkens**; Université catholique de Louvain, Bruxelles, Belgium

Abstract Body:

Background: Uptake, survival, and secondary release of bacteria from phagocytes may explain the relapsing and recurrent character of many infections. We have developed a pharmacodynamic model to measure the potency and maximal activity of antibiotics against *S. aureus* and *P. aeruginosa* phagocytized by human THP-1 monocytes. In brief, infected cells are exposed for 24h to drugs concentrations ranging from 0.01 to 100 x the MIC to obtain full concentration-dependent responses and calculate pertinent pharmacodynamic parameters based on Hill equation [sigmoidal dose-response] (see general reference). **Methods:** Data obtained with fully susceptible *S. aureus* (ATCC25923) or *P. aeruginosa* (PAO1) strains and 13 antibiotics markedly bactericidal in broth were reviewed. Potency (C_s) was defined as the extracellular concentration causing a static effect (no apparent intracellular bacterial growth; expressed in multiples of the MIC as measured in broth [CLSI method]), and maximal activity (E_{max}) as the decrease of the intracellular CFUs over post-phagocytosis level as extrapolated for an infinitely large extracellular drug concentration. **Results:** The Table illustrates that while all antibiotics showed a C_s (potency) against intracellular bacteria similar or only slightly larger than their MIC in broth (no marked loss of potency), none, except oritavancin, achieved the CLSI-defined bactericidal effect (≥ 3 $\log_{10}$ CFU decrease), (marked loss of maximal efficacy [E_{max}]). Bacteria collected from cells and regrown in broth showed unaltered MICs (no selection of resistant subpopulations). **Conclusion:** Across the 7 classes of bactericidal antibiotic examined, all molecules but one failed to be bactericidal intracellularly although largely maintaining their potency. If also taking place in vivo, this may limit the overall efficacy of antibiotic treatments.

An *In Vitro* Study of Invasion and Virulence of *Francisella tularensis* Strains in Macrophage Cells

Author Block:

S. Chubinidze[1], T. Shutkova[1], M. Grdzelidze[1], E. Nalbandishvili[1], S. Tsanava[1], R. Arner[2], G. Chanturia[1]; [1]Natl. Ctr. for Disease Control and Publ. Hlth., Tbilisi, Georgia, [2]Metabotia, San Francisco, CA

Abstract Body:

Francisella tularensis, the causative agent of tularemia, was detected in Georgia over seven decades ago. Recently, the Repository of Bacteria and Viruses of the National Center for Disease Control and Public Health (NCDC) collected more than one hundred *F. tularensis* strains through surveillance funded by the Defense Threat Reduction Agency (DTRA).*Francisella tularensis* is a facultative intracellular bacterium, able to survive/replicate within macrophages and various non-phagocytic cells. Cell invasion assays using J774 mouse macrophage cells are used to model this. In the DTRA funded project "Epidemiology and Ecology of Tularemia in Georgia", a cell invasion assay using J774 cells infected with five strains (different SNP genotypes) *of F. tularensis* as well as LVS was conducted in triplicate in BSL-3 containment at NCDC.Macrophage cells ($3x10^5$ cells, total volume of 1 mL/well) were added to 12-well plates. *F. tularensis* ($3x10^7$cfu/100µL) was added to each well (100 bacteria per macrophage). The precise concentration of bacterial culture was determined after plating serial dilutions on CHAB and counting colonies.The invasion, survival, and replication ability of the strains was determined by lysing macrophages at different incubation time points (0, 24, 48, and 72 hours) and plating serial dilutions (10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}, and 10^{-5}) of the lysate on CHAB plates; cells were washed three times with DPBS prior to lysis. The isolated colonies were counted and the number of bacterial doublings between time points calculated using the formula: (log of 24; 48; 72 hour counts - log 0; 24; 48 hour counts) x 3.32. An increase in the number of colonies from the 0 hour time point to other time points indicates replication within the macrophages.Wild *F. tularensis* strains showed a higher ability to invade macrophages and grow intracellularly than LVS. Increases in colony numbers were observed across incubation time points. Differences in the invasion, survival, and replication ability among wild strains was observed. Further testing of additional strains from the NCDC collection is ongoing. This research represents common/standard microbiological methods for determining virulence, which is an important part of bacterial characterization.

Host Responses to Oral Challenge with *Porphyromonas gingivalis* and Nicotine in HLA-DRβ1-Bearing Humanized Mice

Author Block:

I. Sandal[1], D. D. Brand[1], J. Luo[2], A. Prislovsky[1], K. Whittington[1], C. Dong[3], E. F. Rosloniec[1], A. Karydis[2]; [1]Dept. of VA, Memphis, TN, [2]Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN, [3]Tsinghua Univ., Beijing, China

Abstract Body:

Background: Periodontal disease (PD) is a chronic pro-inflammatory response to oral pathogens such as *Porphyromonas gingivalis* which culminates in alveolar bone loss and loss of dental structure and function. Like rheumatoid arthritis, periodontal disease is influenced strongly by lifestyle factors such as tobacco use, but also greatly influenced by genetic components, such as the "shared epitope," which refers to a conserved linear sequence of amino acids in the DRβ1 chain of the HLA-DRα/β heterodimer between amino acids 67 and 74. Aggressive PD (the most destructive form of PD) is also now thought to be associated with specific HLA haplotypes including DRβ1.**Methods**: Using IL-17F^{rfp} and Foxp3^{gfp} reporters in I-A° C57BL/6 mice expressing chimeric mouse/human HLA-DRβ1 (B6.DR1 mice), we find gingival brushing with *P. gingivalis* results in rapid transient Th17 responses in the peripheral blood and cervical lymph nodes.**Results**: Evidence of a chronic infection can be detected in these nodes three months after oral inoculation. In addition to Th17 responses, we also find a concomitant increase in Th17-related cytokine production that parallels the Th17 activity. Furthermore, we measured a brisk production of antibodies directed against *P. gingivalis* and also against cyclic citrullinated peptides (these ACPAs are widely used as the principle early diagnostic for RA) as well as a loss in trabecular bone that can be detected in peri-articular bone structures, e.g. distal to the alveolar bone structures normally measured in PD models. We also find that trans-dermal nicotine treatment decreases the percentage of $CD4^+$ T cells expressing the Th17 phenotype in the cervical lymph nodes, whether this results in greater numbers in the gingival tissues or simply fewer Th17 cells overall has not yet been determined.**Conclusions**: Our findings suggest that periodontal disease can have far-reaching effects in bone morphology which may be driven by Th17/cytokine/ACPA activity even in the absence of other pathologies.

Single Population Bottlenecks in the Pathogenesis of *Streptococcus pneumoniae*

Author Block:

M. Kono, M. A. Zafar, S. Hamaguchi, J. Weiser; New York Univ. Langone Med. Ctr., New York, NY

Abstract Body:

Streptococcus pneumoniae, a commensal resident of the human nasopharynx, is one of the leading pathogens among children. Especially in the setting of influenza virus co-infection, pneumococcal diseases tend to be more severe and transmission from host-to-host more common. During the multiple steps of infection, the pathogen may have to pass through 'bottlenecks' where its population and diversity is severely restricted, potentially resulting in weak points for intervention and prevention of diseases. In this study, we utilized an infant mouse model for evaluating pneumococcal colonization, disease and transmission among siblings with or without co-infection with influenza. Influenza virus increased the bacterial load of colonization, risk of otitis media and transmission rate. To assess bacterial population bottlenecks, three isogenic mutants, each tagged with a different antibiotic resistance marker were constructed. The bottlenecks and the impact of influenza co-infection were evaluated by examining the distribution of isogenic mutants passing through each stage in pathogenesis following IN challenge and the establishment of colonization. A mathematical model revealed single cell population bottlenecks during bacteremia and transmission among influenza co-infected mice. The number of shed bacteria correlated with the size of the bottleneck in transmission. Treatment with a TLR 3 agonist recapitulated the effect of influenza in driving increased bacterial shedding. The bottleneck in bacteremia was tighter in the setting of influenza and likely due to events before accessing the bloodstream because no bottleneck was observed following IP challenge. Within-host genetic adaptation did not appear to contribute to passage through the bottleneck, because a strain that previously passed through the bottleneck was no more likely to cause bacteremia or transmission when rechallenged compared to strains that had not passed through the bottleneck. We concluded that host innate immune response is the major factor in determining the size of the population bottleneck both in transmission and bacteremia.

Comparisons of Phenotypic and Monosaccharide-Binding Characteristics of Cf-Adapted *Pseudomonas aeruginosa* for Predictors of Binding

Author Block:

D. L. Chance, W. Wang, T. P. Mawhinney; Univ. of Missouri, Columbia, MO

Abstract Body:

Frequent, and eventually chronic, infections with the opportunist *Pseudomonas aeruginosa* (PA) are common for patients with cystic fibrosis (CF). Toward informing new anti-infective treatment strategies, ongoing studies are profiling carbohydrate-binding patterns of CF host-adapted PA. Quantitative binding heterogeneity has been observed between CF isolates with respect to glycopolymers with α-galactose (α-Gal) or β-N-acetylgalactosamine (β-GalNAc) as the pendant sugar. To assess whether specific bacterial features could be predictive of the category of enhanced monosaccharide binding, clinical isolates and laboratory strains shown to bind α-Gal and β-GalNAc glycopolymers were surveyed for phenotypic, enzymatic, and structural characteristics. Monosaccharide binding was determined microscopically with enumeration of fluorescent bacteria following exposure to fluorescent glycopolymers possessing pendant α-Gal or β-GalNAc, and provided quantitative differences among those reactive species. Phenotypic analyses employed rich and selective media plate culture and illustrated signature heterogeneity of PA characteristics of motility, mucoidy, pyocyanin production, colony morphology, texture, color, diffusible pigments, and hemolytic tendencies. Enzymatic profiling via automated microbial identification system provided anticipated similarities in activities defining the species and revealed intraspecies metabolic flexibility. TEM imaging of negatively stained specimens gave evidence of flagella for both motile and nonmotile species, and pili for a subset of isolates. Evaluation for trends and correlations of binding with phenotype, metabolic characteristics, and/or structural features, focused on α-Gal and β-GalNAc high and moderate reactivity, provided no reliable predictors of enhanced binding. Minor trends: nonmotile isolate binding was more frequently in higher category than motile strains; throat isolates tended toward higher category binding for β-GalNAc. Paired nonmucoid/mucoid CF isolates showed no uniform binding trends or enzymatic correlations. To conclude, this survey yielded no single feature or constellation of characteristics which appears to serve as a surrogate predictor of enhanced binding to the monosaccharides α-Gal and β-GalNAc for CF host-adapted *P. aeruginosa*.

Identification of a Novel Virulence Factor Associated with Multi-drug Resistant *Acinetobacter baumannii*

Author Block:

P. M. Ketter[1], J-J. Yu[2], M. Guentzel[2], J. Seshu[2], K. Klose[2], A. Cap[1], B. Arulanandam[2]; [1]US Army Inst. for Surgical Res., JBSA-Fort Sam Houston, TX, [2]Univ. of Texas at San Antonio, San Antonio, TX

Abstract Body:

Background: Multi-drug resistant *Acinetobacter baumannii* (MDR-Ab) is an emerging infectious disease associated with wound and respiratory infections. While ubiquitous in the environment, MDR-Ab is primarily encountered as a hospital acquired infection (HAI) resulting in significant costs to both patient and hospital. Although MDR-Ab gastrointestinal (GI) tract colonization is common, no studies have assessed mechanism(s) contributing to this phenomenon. Similarly the role of SIgA in either GI tract colonization or respiratory infection is not understood.**Objective:** Assess the protective role of SIgA MDR-Ab GI tract colonization.**Methods:** Wild-type (WT) or SIgA deficient mice were challenged orally with MDR-Ab to assess survival and colonization. Sections of small intestine were collected from infant mice for *ex vivo* attachment assays. Supernatants from MDR-Ab cultures incubated with SIgA were assessed by non-reducing SDS-PAGE and Western blot. RNAseq analysis was performed on mRNA extracted from bacterial pellets. MDR-Ab mutants were generated by homologous recombination. Mutant strain virulence and colonization was assessed by intraperitoneal (i.p.), and oral challenge, respectively.**Results:** SIgA deficient mice exhibited significantly ($p < 0.05$) increase survival and bacterial clearance following MDR-Ab oral challenge. MDR-Ab intestinal attachment was also significantly ($p < 0.0005$) decreased in the absence of SIgA. Breakdown of SIgA by MDR-Ab was observed via Western blot, however, the banding pattern suggested a reductive mechanism. Use of disulfide reductase inhibitors dithionitrobenzoic acid (DTNB) and PX-12 confirmed these findings. Significant ($p < 0.05$) up-regulation of thioredoxin-A (*trxA*) expression was observed by RNAseq. Deletion of *trxA* ablated secreted reductase activity, reduced mortality by 100-fold, and impaired GI tract colonization.**Conclusion:** MDR-Ab GI tract colonization requires SIgA and is mediated by secreted TrxA. Furthermore, inhibition or elimination of *trxA* expression reduces GI tract colonization indicating it may be a novel target for vaccine and chemotherapies.

Investigating the Role of the LytR Response Regulator in Group B Streptococcal Colonization and Disease

Author Block:

L. Deng[1], R. Mu[1], T. Weston[1], R. Liles[2], K. Doran[1]; [1]San Diego State Univ., San Diego, CA, [2]Louisiana State Univ. at Alexandria, ., LA

Abstract Body:

Streptococcus agalactiae (Group B *Streptococcus*, GBS) is typically a commensal bacterium that colonizes the vaginal tract of healthy women. However, in immune compromised individuals, such as pregnant women, the elderly, and newborns, GBS may transition to an invasive pathogen, resulting in pneumonia, sepsis, urinary tract infections, and meningitis. Despite currently recommended intrapartum antibiotic prophylaxis for GBS-positive mothers, GBS remains the leading cause of neonatal sepsis and meningitis. Little is known about what triggers GBS to switch from asymptomatic colonization to causing invasive disease. One way that bacteria respond to environmental changes is through two-component systems (TCS). TCS typically consist of a membrane-associated stimulus sensor and a cytoplasmic response regulator that alters gene expression. We hypothesize that the LytSR TCS in GBS may play a role in the bacteria's ability to persist in the host and to cause disease. We have tested a mutant GBS strain that lacks the LytR gene in our murine meningitis model and histological studies reveal that it induces increased inflammation of the tissue surrounding the brain as compared to wild type GBS. Additionally, using RT-qPCR, we have seen that human brain microvascular endothelial cells secrete more inflammatory cytokines such as IL-6, IL-8, CXCL1, and IL-1 when infected with the LytR mutant and we confirmed IL-6 and IL-8 protein expression through ELISA. Interestingly, the LytR mutant is cleared rapidly in our murine colonization model while wild type bacteria are able to persist in the mouse vaginal tract. We found that most mice clear the LytR mutant by six days post-inoculation while mice inoculated with wild type GBS remain stably colonized. Further characterizing the action of the LytR regulator during GBS infection can provide insight into how the bacteria stimulates the host inflammatory response. Ongoing studies are underway to identify downstream gene targets of the LytR response regulator in order to better understand the changes in gene expression that occur in the bacteria during the transition from asymptomatic colonization to inflammatory disease. Ultimately, uncovering how LytR signaling affects bacterial colonization and virulence may lead to the development of more effective therapies to prevent GBS infections.

Chemotactic Motility of *V.vulnificus* Is Required for Lethality in Mice

Author Block:

K. Yamazaki, T. Kashimoto, T. Kado, S. Ueno; Kitasato Univercity, Towada, Japan

Abstract Body:

Background: *V.vulnificus* is highly motile bacteria with single polar flagellum that is capable of rotating at a high-speed, and known as a causative agent for severe sepsis in immunocompromised individuals who is suffering underlying diseases. Flagellar deletion mutants of *V.vulnificus* are less virulent than that of parental strain in animal models, indicating that the flagellum is crucial to the infection process. The direction of flagellar rotation is based on chemotaxis which is response to environmental factors to access their beneficial conditions. Flagella are complex extracellular structures that require large amounts of energy for operation, so that lacking flagella affect secretory proteins and bacterial growth. To know whether the bacterial motility and chemotaxis were required for virulence in vivo or not, we generated the motility (Δ*pomA*) and the chemotaxis (Δ*cheY*) mutants that retained the complete flagellum, and then the pathogenesis of these two mutants were compared with that of wild-type (WT) in several assays.**Methods:** Generation of mutants; The ΔpomA and ΔcheY were generated by homologous recombination. PomA is required for generation of torque for flagellar rotation, therefore the ΔpomA lost motility but retains the flagellum. CheY is a key regulator of direction of flagella rotation, therefore the lacking of this gene lead to continue swimming straight in bacteria. Cytotoxicity assay; the cytotoxic effect on the HeLa cells were evaluated by Lactate dehydrogenase (LDH) release assay.In vitro swarming assay; Swarming assay was performed by using 0.3% agar containing Luria-Bertani broth. Determination of 50% lethal dose (LD_{50}); LD_{50} values were calculated according to the method of Reed and Muench (Reed and Muench, 1938).**Results:** There were not significant differences in the cytotoxicity against HeLa cells between wild-type, Δ*pomA* and Δ*cheY*. The in vitro swarming motility of the Δ*pomA* and the Δ*cheY* were completely abolished. The LD_{50} of the Δ*pomA* and the Δ*cheY* increased 5- and 2.5-fold, respectively, in comparison with that of the WT.**Conclusions:** Our data indicated that the absence of motility and chemotaxis would not affect the protein secretion, and cytotoxicity in HeLa cells. However, the increase in the lethality for mice of the Δ*pomA* and the Δ*cheY* suggested that chemotactic motility of *V.vulnificus* is required for systemic infection.

***Pseudomonas aeruginosa* Outer Membrane Vesicles Triggered by Human Mucosal Fluid and Lysozyme Can Prime Host Tissue Surfaces for Bacterial Adhesion**

Author Block:

M. M. E. Metruccio[1], D. J. Evans[2], M. M. Gabriel[3], J. L. Kadurugamuwa[4], S. M. J. Fleiszig[1]; [1]UC Berkely, Berkeley, CA, [2]Touro Univ., Vallejo, CA, [3]Alcon Res., Ltd., Duluth, GA, [4]Alcon Res., Ltd., Fort Worth, TX

Abstract Body:

Indwelling medical devices, including contact lenses, are risk factors for *P. aeruginosa* infection. *P. aeruginosa* is among those bacteria that can release Outer Membrane Vesicles (OMVs) capable of fusing with host cells to alter their function. Here, we tested the hypothesis that mucosal (tear) fluid triggers OMV release to compromise an epithelial barrier. *P. aeruginosa* strain PAO1 was treated with human tear fluid or its constituents before OMV purification (differential centrifugation, filtration, and ultracentrifugation). Cytotoxicity of OMVs and their impact on barrier function against *P. aeruginosa* were tested using human telomerase immortalized corneal epithelial cells (LDH release assay, CFU counts of traversed bacteria) and mouse corneas (Live/Dead staining, GFP, confocal imaging). Whole mounted OMV treated mouse corneas were also labeled with Ly6G/C specific antibody, a myeloid cell marker. By 1 h, human tear fluid and the tear component lysozyme each greatly enhanced OMV release compared to PBS controls (~100 fold). TEM and SDS-PAGE showed these OMVs were similar in size and protein composition, but differed from biofilm-harvested OMVs. Lysozyme-induced OMVs were cytotoxic to human corneal epithelial cells *in vitro* and murine corneal epithelium *in viv*o. OMV exposure *in vivo* primed the cornea for bacterial adhesion (~4-fold, $P < 0.01$), and enhanced Ly6G/C expression at the corneal surface suggesting neutrophil recruitment. Sonication of OMVs spared cytotoxic activity, but reduced capacity to promote adhesion suggesting the latter required OMV-mediated events beyond cell killing. These data suggest that mucosal fluid induced OMVs could contribute to loss of epithelial barrier function during medical device-related *P. aeruginosa* infections.

LIC13059 and LIC10879 Coding Sequences are Novel Adhesins from *Leptospira interrogans*

Author Block:

P. R. M. Pereira[1], L. G. Fernandes[1], G. O. Souza[2], S. A. Vasconcellos[2], A. L. T. O. Nascimento[1]; [1]Inst. Butantan, São Paulo, Brazil, [2]Univ.e de São Paulo, São Paulo, Brazil

Abstract Body:

Background: Leptospirosis is the most widespread zoonosis and also a major cause of economic loss in animal production worldwide. It has been considered a major emerging infectious disease in the last ten years and it is included in the list of Neglected Tropical Diseases, according to the World Health Organization. The study of new surface antigens, not yet described in *Leptospira interrogans* literature, is intriguing and may indicate an unprecedented knowledge in the initial pathogen-host interaction and a new option in the search for prophylactic targets or serodiagnosis. We set out to clone and express the protein encoding by LIC13059 and LIC10879 to investigate their roles in the interaction with human host components. **Methods:** PCR products were obtained from *L. interrogans* serovar Copenhageni genomic DNA amplification with specific primers. The DNA inserts subcloned in pGEM-T vector were cloned into the expression vector pAE. Strains of *E. coli* Star pLysS were used for expression. The recombinant proteins were purified by metal affinity chromatography. Circular dichroism was carried out on spectropolarimeter. Extracts of different species and serovars of *Leptospira* were prepared in SDS-PAGE, transferred to nitrocellulose membranes and probed with antisera to recognize the native protein. The interaction of recombinant proteins with tissue and plasma components of the host was evaluated by ELISA. **Results:** The genes were amplified without the signal peptide and the recombinant proteins were expressed in form of inclusion bodies. After refolding and purification, circular dichroism analyzes showed that the proteins are structured, mainly in β-sheet. The proteins encoded by the genes are shown to be conserved in the pathogenic strains and absent in saprophytic one. The two recombinant proteins interact with plasminogen, fibrinogen and laminin, and all the interactions were dose-dependent and saturable. rLIC13059 bound to fibrinogen was capable of inhibiting the formation of fibrin clot. The plasminogen captured by both recombinant proteins could be converted into plasmin, a mechanism that could help bacterial penetration in the host. **Conclusions:** Our data suggest that these novel proteins may participate in *Leptospira*-host interactions.

***Burkholderia cenocepacia* Infects Macrophages Trough Induction of Macropinocytosis**

Author Block:

R. Rosales-Reyes[1], D. Calderón-Campos[1], D. Alcántar-Curiel[1], C. Sánchez-Gómez[2], M. A. Valvano[3], J. I. Santos-Preciado[1]; [1]UNAM, Mexico, Mexico, [2]HIMFG, Mexico, Mexico, [3]Queens Univ., Belfast, United Kingdom

Abstract Body:

Background: *Burkholderia cenocepacia* is an opportunistic pathogen that causes respiratory tract infections in patients with cystic fibrosis. Infection can lead to rapid decline of lung function and in some cases to the fatal cepacia syndrome. This bacterium survives within a membrane vacuole in macrophages. The *B. cenocepacia*-containing vacuole shows maturation arrest manifested by a significant delay in acidification and fusion with the lysosome. The mechanism of bacterial invasion to macrophages has not been described.**Methods:** Bone marrow derived macrophages and IC21 macrophage cell line were infected with *B. cenocepacia*. The interactions between *B. cenocepacia* and macrophages were evaluated by light-video-microscopy, immunofluorescence microscopy, and by Gentamicin protection assays. The macropinocytosis induction was evaluated by Flow cytometry and by scanning electron microscopy. The macrophage cell death was determined by LDH quantification and the TNFα release of infected macrophages was assessed by ELISA.**Results:** With the use of light-video-microscopy and confirmed by scanning electron microscopy we identified that *B. cenocepacia* infects macrophages through macropinocytosis induction on the contact site. The invasion of this bacterium into macrophages was inhibited with the pretreatment with Wortmannin and LY294002. With the use of a mutant in the type III secretion system (dT3SS) we determined that the efficiency of bacterial invasion was reduced by 50%, suggesting that *B. cenocepacia* can infect macrophages using another pathway. In addition, the infection of macrophages with *B. cenocepacia wt* or dT3SS does not affect their ability to release of TNFa and the induction of cell death.**Conclusions:** *B. cenocepacia* infects macrophages through the induction of macropinocytosis.

Intestinal Invasion By Neonatal *escherichia Coli* Clinical Isolates Is Enhanced By Bacterial Growth At Low Ph

Author Block:

B. K. Cole, M. Ilikj, **S. Chavez-Bueno**; Univ. of Oklahoma HSC, Oklahoma City, OK

Abstract Body:

Background: *E. coli* ingestion causes septicemia in newborns. Bacteria must survive the stomach acid prior to intestinal translocation into the bloodstream. Two neonatal *E. coli* septicemia isolates, RS218 and SCB34, differ in their ability to cause bacteremia in newborn rats. RS218 causes bacteremia when inoculated either intraperitoneally (IP) or orally, whereas SCB34 is virulent only when given orally but not IP. Whether their intestinal invasiveness increases by low pH exposure is unknown. Our main objective was to compare growth, and intestinal invasion of RS218 and SCB34 exposed to different pH. In addition, we assessed transcription of the acid resistance regulator *gadE*. **Methods:** Growth was tested in tissue culture medium (TCM) made with DMEM/Ham's F12 plus fetal calf serum, at pH 7.8 or pH 5. Optical density at 600 nm was measured with the Bioscreen C Reader System. Invasion of T84 intestinal cells was assessed by a modified gentamicin protection assay. RS218 or SCB34 were grown in TCM at pH 7.8 or 5, immediately prior to infecting T84 cells (MOI=10). After 1 hr incubation, the T84 cells were washed and amikacin (in lieu of gentamicin due to SCB34 resistance) was added for 2 hrs before lysis. The recovered intracellular bacteria were counted to calculate percent invasion relative to the inoculum. Expression of *gadE* was assessed by real-time PCR at either pH. Data were normalized to *gapA*; the $2^{-\Delta\Delta CT}$ method was used for analysis. **Results:** Growth of RS218 and SCB34 in mid-log phase was no different at either pH. During stationary phase, growth of each strain was impaired at pH 5 *vs* pH 7.8, but less markedly for SCB34 compared to RS218 ($p<.001$). Invasion of intestinal cells was significantly greater after each strain was grown at pH 5 compared to pH 7.8, with respective values for SCB34 of .47% *vs* .23% ($p<.02$), and for RS218 of .36% *vs* .21% ($p<.04$). Transcription of *gadE* was significantly greater at pH 5 than at pH 7.8 in both strains during stationary phase but not in mid-log phase. **Conclusions:** SCB34 showed better growth than RS218 at low pH. Invasiveness of both strains was enhanced by low pH exposure, particularly in SCB34. Upregulation of *gadE* was observed in both strains at low pH. Further investigation of neonatal *E. coli* virulence factors that respond to acid stress is crucial to develop strategies against neonatal sepsis.

Uropathogenic *Eschericia coli* Mechanisms of Intracellular Invasion

Author Block:

A. Shea, W-J. Kim, D. Jimenez, Y. Daaka; Univ. of Florida, Gainesville, FL

Abstract Body:

Urinary Tract Infections (UTIs) are the source of 7 million clinic visits and $2 billion in medical costs each year in the United States. Uropathogenic *Escherichia coli* (UPEC) are the causative organism in over 80% of confirmed infection cases. Furthermore, nearly 50% of women worldwide will develop an UTI at some point during their lifetime, and many of these patients will experience recurrent infections. The ability of UPEC to invade host epithelium is hypothesized to be a major source of disease recurrence through providing a quiescent reservoir of bacteria for subsequent infection. This project aims to clarify the mechanisms of bacterial invasion into host epithelial cells of the urinary tract, specifically the kidney and bladder epithelium. A preliminary screening experiment assessed the ability of different UPEC strains to invade human kidney and bladder epithelial cells. An *in vitro* gentamicin protection assay was used to quantify the relative number of invasive bacteria for each strain. While many strains were able to invade human kidney epithelial HK2 cells (ATCC CRL-2190) and bladder epithelial cells (ATCC HTB-9), this invasive phenotype was highly variable. This project aims to expose the molecular mechanisms involved during UPEC invasion of host epithelial cells. The goals are to (1) identify bacterial virulence factors promoting UPEC invasion, (2) determine which host cell membrane components are essential for bacterial entry, and (3) elucidate the intracellular signaling cascade mechanisms manipulated by the bacteria in order to promote entry. Understanding bacterial invasion of human urinary epithelial cells on a molecular level allows for the development of preventative measures which can be applied to the clinic, affecting nearly half of women worldwide.

The Gliding Phenotype of *Mycoplasma pneumoniae* on Glycan Receptor Populations

Author Block:

C. Reeves, E. Arnold, D. Leman, L. Chen, J. Locklin, D. C. Krause; Univ. of Georgia, Athens, GA

Abstract Body:

Mycoplasma pneumoniae, best known as the etiologic agent of "walking pneumoniae", is a common cause of human respiratory tract infections. Two receptor populations are believed to be recognized in airway colonization: α2-3 sialoglycoproteins (SGP) and sulfated glycoplipids (SGL). SGP receptor binding is specific to the α2-3 linked sialic acid residue, removal of which results in a loss of attachment. SGL binding is specific for Gal($3SO_4$)β1 residues and is partially inhibited by the presence of dextran sulfate. In the current study we examined *M. pneumoniae* interactions with glass surfaces coated with the SGP laminin or the SGL sulfatide to explore differences in adherence and gliding motility. Analysis of receptor-coated surfaces by Fourier Transform - Infrared Spectroscopy confirmed the presence of the receptor moieties, while ellipsometry showed an increase in coating thickness with higher concentrations for SGL and suggested the presence of a uniform monolayer for SGP. *M. pneumoniae* binding to the coated surfaces was assessed by light microscopy. We observed approximately a three-fold increase in binding to SGL over a concentration range of 1-10 μg, as expected. Likewise, binding to SGP increased approximately 2.5-fold over a concentration range from 0.2-10 μg. *M. pneumoniae* cells on SGP were motile, as expected, and as SGP concentration and thus receptor density increased, the number of motile cells and average gliding velocity likewise increased. Surprisingly, mycoplasmas bound to SGL remained static at all concentrations tested. These results indicate that the nature and density of receptors can influence the *M. pneumoniae* gliding phenotype, which might impact pathogenesis, persistence, and infection outcome.

Mechanisms of St258 *Klebsiella pneumoniae* Invasion across the Airway Epithelium

Author Block:

D. Ahn, M. Wickersham, Z. Wang, T. Cohen, A. Uhlemann, A. S. Prince; Columbia Univ., New York, NY

Abstract Body:

The carbapenem resistant ST258 *K. pneumoniae* frequently cause respiratory infections and bacteremia. We postulated that ST258 strains have acquired mutations that facilitate persistence in the lung and lead to invasive infection. The clearance of KP35, a local ST258 strain and a KPRR1 control strain from the murine lung and blood were compared, along with changes in tight junction proteins. KP35 was poorly cleared with $>10^4$ cfus in the lung at 96 h and $>10^3$cfus recovered from the spleen at 48h. Proteomics of airway fluid revealed that KP35 induced changes in adherens junctional proteins. Transient increases in ezrin and occludin were confirmed by qRT-PCR. Confocal imaging and immunoblots illustrated increased occludin at the epithelial junctions at 4 hours, followed by a marked decrease at 24h. KP35 transmigration across polarized airway epithelial cells was over 2 logs greater than the KPPR1 control. Sequence comparison indicated acquisition of 26 proteinases among the 150 novel ortholog groups in KP35 not present in KPPR1. These findings suggest KP35 adaptation to the airway and targeting of epithelial junctional proteins to cause invasive infection.

Host Glycan Remodeling - Sweet Cross Talk between the Host and the Microbe

Author Block:

N. Arabyan[1], D. Park[1], H. Yu[1], S. Foutouhi[1], C. C. Williams[1], P. Desai[2], J. Shah[3], N. Kong[1], R. Jeannotte[1], X. Chen[1], C. B. Lebrilla[1], B. C. Weimer[1]; [1]Univ. of California, Davis, Davis, CA, [2]Univ. of California, Irvine, Irvine, CA, [3]Univ. of Minnesota, St. Paul, MN

Abstract Body:

The host gut epithelial membrane is shielded by complex glycans to protect the cell. Gastroenteritis begins when invasive pathogens bind and degrade the glyans at the epithelial barrier to gain access of host membrane. While glycan degradation is crucial for infection, this process is poorly understood. We hypothesized that *Salmonella* deploys its glycosyl hydrolases (GHs) to target and degrade host glycans leading to altered infection and glycan remodeling. *Salmonella* was grown in defined medium containing 18 different synthetic glycans modeled after human glycans as the sole carbon source. Significantly differentially expressed ($q<0.05$) GHs were identified and genetically deleted to determine the specific effect on adhesion and invasion *in vitro* with differentiated colonic epithelial cells (Caco-2). HPLC-Chip-TOF MS was used to determine the glycan composition and structure with specific set of enzymes used during infection. Growth analysis showed that *Salmonella* is able to digest and metabolize synthetic glycans. GHs recognized terminal monosaccharides and significantly ($p<0.05$) altered invasion *in vitro*. Sialic acid depletion reduced adherence of *Salmonella* during infection. *Salmonella* used its two GHs *nanH* and *malS* for internalization. Host glycans were altered during *Salmonella* association via the induction of N-glycan biosynthesis pathways leading to host glycan remodeling by increasing fucosylation, mannosylation, and hybrid glycan content, while decreasing sialylation. *Salmonella* increased invasion in Caco-2 cells lacking high-mannose and hybrid glycans which could suggest that high-mannose and hybrid glycans provide protection to the host. Gene expression analysis indicated that the host cell responded by regulating more than 50 genes showing that remodeled glycans are in response to *Salmonella* infection. Our study established the glycan structures on colonic epithelial cells, determined that *Salmonella* required two GHs for internalization, the host cell remodeled the glycan during infection, and host glycan landscape influences the host-microbe interaction. Microbial GHs are understudied and unrecognized virulence factors that may be new therapeutic targets.

Effects of Subinhibitory Carvacrol Levels on *Bacillus cereus* Virulence During Endophthalmitis in Retinal Pigmented Epithelial Cells (Arpe-19)

Author Block:

N. Rajabli, S. McDowell, J. L. McKillip; Ball State Univ., Muncie, IN

Abstract Body:

Background: *Bacillus cereus* is one of the major pathogens causing posttraumatic endophthalmitis in humans. *B. cereus* can result in permanent eye damage within 24 hours after initial infection *via* production of multiple extracelluar virulence factors. Carvacrol, an antimicrobial essential oil, may be a promising treatment for *B. cereus* endophthalmitis. Specific events of transcriptional regulation of virulence genes in *B. cereus* during infection of human retinal pigment epithelial (RPE) cells are not well understood. Our aim is to measure relative levels of regulator and virulence gene expression in SIC carvacrol-stressed *B. cereus* during infection of laboratory-cultured ARPE-19 cells. Results of this work will elucidate mechanisms of virulence regulation in this increasingly important food and clinical pathogen.**Methods:** ARPE-19 cells were treated with 10^5 *B. cereus* alone, and *B. cereus* + SIC (1mM) of carvacrol. Relative differences in expression of *plcR*, *nprC*, *hblC*, and *nheA* regulator and virulence gene expression in *B. cereus* treated with SIC of carvacrol, and untreated *B. cereus* was quantified by mean cycle threshold (C_T) value comparisons using real-time PCR, and statistically analyzed using one-way ANOVA in Minitab17. Furthermore, *plcR* gene expression was measured through detection of the green fluorescent protein (GFP) production using transformed *B. cereus* ATCC 14579 with a promoter trapping expression vector (pBAD:*plcR*:GFP) treated with and without the SIC of carvacrol (1mM). The bacteria were inoculated in ARPE-19 cells and visualized using fluorescence microscopy and results quantified by enumeration of fluorescing bacteria within ARPE-19 cells.**Results:** Results reveal that Untreated *B. cereus* invaded ARPE-19 cells significantly less compared to SIC carvacrol-treated bacteria, which revealed full internalization within 48h. GFP(*plcR*)-expressing *B. cereus* were detected as fluorescing significantly more under carvacrol conditions compared to control replicates.**Conclusions:** These data indicate that sublethal chemical stress by carvacrol significantly increases potential virulence of this pathogen, *via* an increase in the global regulator (PlcR) production.

The Role of Flagella Frequency and Influence of Spatial Organization on the Attachment Force of Giardia Lamblia

Author Block:

M. Barefoot, H. Elmendorf, T. Picou; Georgetown Univ., Washington, DC

Abstract Body:

Giardia lamblia is the intestinal pathogen responsible for giardiasis, a diarrheal disease that affects more than 1.2 million people worldwide. An overall objective of the laboratory's research is to understand how *Giardia* attaches to the luminal wall of the small intestine. We hypothesize that the beating of *Giardia's* ventral flagella generates fluid movement, establishing a negative pressure differential, which is primarily responsible for the force of attachment. While evidence exists to support this model, a causal link between flagella beating and attachment has yet to be explicitly demonstrated. I am conducting experiments plating *Giardia* cells on polyacrylamide gels of different concentrations to model attachment under varying fluid flow conditions. Gels with increasing concentration of polyacrylamide are more porous and allow for more fluid flow. *Giardia* on these gels are then imaged by confocal microscopy to determine the corresponding flagella frequency. A potential correlation between flagella frequency and fluid flow would help to causally link flagellar motion to the attachment mechanism. In addition, the spatial arrangement of *Giardia* may also influence attachment by altering fluid flow rates, similar to what has been seen for cooperative flow in ciliate feeding mechanisms. Potentially, fluid flow could similarly be optimized by the spatial arrangement of *Giardia* to maximize attachment force. I have found that the flagella frequency of *Giardia* in pairs is significantly different between the top and bottom parasite (P=5.919e-7). I am performing Particle Image Velocimetry (PIV) to analyze the radius of the flow field out the back end of the parasite and determine the spatial distance between *Giardia* that still can influence the flow. Using this distance to define clustered and paired *Giardia* arrangements, the flagella frequency will be determined and compared to the flagella frequency of singly isolated *Giardia*.

Impact of *Escherichia coli* Colonization on Susceptibility to Gastrointestinal Inflammation

Author Block:

H. Kittana; Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract Body:

Several researchers have reported a significant increase in the abundance of specific bacterial species during intestinal inflammation, especially *Escherichia coli,* in a subset of Crohn's disease patients. We sought to determine how different commensal *E. coli* strains influence disease outcome during acute gut inflammation. Using four *E. coli* strains isolated from healthy mice, we observed that two isolates (SWW33 and CEC-1) enhanced intestinal inflammation triggered by treatment with a subpathological dose of dextran sulfate sodium (DSS) in C3H mice harboring a benign gut microbiota known as the altered Schaedler flora (ASF) that is devoid of any *Escherichia* species. In contrast, two commensal *E. coli* strains (CEC-7 and CEC-8) failed to exacerbate disease severity in ASF mice following the moderate-dose DSS treatment. Disease progression was found to be independent of bacterial burden in the gut as colonization levels for each *E. coli* strain did not change significantly following DSS treatment. We also found that SWW33 and CEC-1 colonized mice produced higher levels of the pro inflammatory cytokines IL-6, IFN-gamma and the macrophage recruiting chemokine GM-CSF in the cecum following DSS treatment as compared to control mice or mice colonized with either CEC-7 or CEC-8. Together, these finding suggest that CEC-1 and SWW33 elicit a different and potentially more pathogenic immune response compared to CEC-7 and CEC-8, resulting in increased inflammation and disease severity. Further experiments to determine the specific cell types producing the IL-6 as well as determining the requirement for IL-6 in disease onset are ongoing.

Coreceptor Role of CCRL2 for Human and Simian Immunodeficiency Viruses

Author Block:

S. Islam[1], N. Shimizu[2], A. Jinno-Oue[2], H. Hoshino[2]; [1]Jahangirnagar Univ., Dhaka, Bangladesh, [2]Gunma Univ., Maebashi, Japan

Abstract Body:

Background: Most of the typical chemokine receptors (CKRs) have been identified as coreceptors for various human and simian immunodeficiency viruses (HIVs and SIVs). Several atypical CKRs (ACRs) have also been reported as functional coreceptors. We first time evaluated and described the possible HIV/SIV coreceptor-role of an ACR member, CC-type chemokine receptor like-2 (CCRL2) in this study. **Methods:** Human glioma cell line, NP-2 is normally resistant to all HIV and SIV. The cell was transduced with amplified CD4 as receptor and CCR5, CXCR4 and CCRL2 as coreceptor-candidates to produce indicator NP-2/CD4/Coreceptor cells. Co-culture infection was conducted with C8166/CCR5 cells at 0.1 multiplicity of infection (MOI). Infections were detected by indirect immunefluorescence assay (IFA). Multinucleated giant cells (MGC) in syncytia were quantified after staining with Giemsa. Proviral DNA was detected by PCR and reverse transcriptase (RT) activity was examined.**Results:** Primary isolates, HIV-1HAN2, HIV-2MIR and SIVsmE660 utilized CCRL2 as a new coreceptor. IFA detected viral antigens in infected cells. The results were confirmed by detection of proviral DNA and measurement of reverse transcriptase (RT) in the spent cell-supernatants. MGC were detected in HIV-2MIR and SIVsmE660 infected NP-2/CD4/CCCRL2 cells. HIV-2MIR and SIVsmE660 were found more potent users of CCRL2 than HIV-1HAN2.**Conclusions:** In vitro experiments showed CCRL2 to function as a new coreceptor for some limited primary HIV/SIV isolates. The findings may contribute new insights into HIV/SIV transmission and pathogenesis; however, its in-vivo relevance should be evaluated. Suitable ligands of CCRL2 or its antagonist could be potential HIV entry-inhibitor drug targets.

Determining the Adhesion and Invasion Potential of *Bacteroides vulgatus* and *Veillonella parvula* on Human Colonic Epithelial Cells

Author Block:

A. Blocker, A. Johnson, E. Norcross; Mississippi Coll., Clinton, MS

Abstract Body:

Background: Inflammatory Bowel Diseases (IBD), including Crohn's Disease and Ulcerative Colitis, are diseases involving the gastrointestinal tract. Recent research suggests that the microbiota of the intestine plays a role in the initiation and aggravation of both diseases. Current theories propose the overabundance of opportunistic pathogens, alterations in the commensal bacteria and dysbiosis as potential roles of intestinal microbiota in the pathogenesis of IBD. *Veillonella parvula* and *Bacteroides vulgatus* are two putative pathogenic microbes involved in IBD, but their specific roles have yet to be elucidated. **Methods:** The adhesion and invasion potential of *V. parvula* and *B. vulgatus* were examined using human colonic epithelial cell line C2BBe1. For adhesion assays, bacterial inoculums were incubated aerobically for 30 minutes with C2BBe1 cells prior to trypsinization. Cells were serially diluted and colony forming units (CFUs) were determined anaerobically. For invasion assays, bacterial inoculums were incubated with C2BBe1 cells aerobically for 2 hours, washed and incubated with antibiotic media for an additional hour. Cells were trypsinized then lysed prior to CFU determination.**Results:** Both bacterial strains yielded similar recovery of adherent bacteria. *B. vulgatus* had adherence of 1.86 x 10^4, 3.27 x 10^4, and 3.99 x 10^5 CFU/mL following bacterial inoculums of 10^7, 10^8, and 10^9 CFU/mL, respectively. *V. parvula* had adherence of 5.11 x 10^3, 8.28 x 10^4, and 3.09 x 10^5 CFU/mL following bacterial inoculum 10^7, 10^8, and 10^9 CFU/mL, respectively. *B. vulgatus* had invasion of 2.83 x 10^3, 1.82 x 10^4, and 5.91 x 10^4, CFU/mL following inoculum 10^7, 10^8, and 10^9 CFU/mL, respectively. Interestingly, *V. parvula* failed to invade C2BBe1 cells.**Conclusion:** The differences in the adhesion and invasion potential of each bacterium may play a role in the pathogenesis of IBD. Further research is needed to confirm the importance of bacterial invasion of gut epithelial cells in IBD and determine if the adhesion and invasion of these bacterial species leads to significant bacteria-induced inflammation.

Exploring Gut Microbial Diversity in Indian Healthy Individuals, Inflammatory Bowel Disease and Colon Cancer Patients Using Metagenomics

Author Block:

V. Bamola[1], R. Chaudhry[1], R. Kapardar[2], B. Lal[2]; [1]All India Inst. of Med. Sci., New Delhi, India, [2]The Energy and Resources Inst., New Delhi, India

Abstract Body:

Background: Gastrointestinal tract (GI) of human is one of the common niches for microflora. These microbes play an important role in intestinal homeostasis in human. GI microbial imbalance can lead to pathological conditions including inflammatory bowel disease (IBD) and colon cancer. Since the dietary habits of Indian population are different from that of the Western world, therefore, findings of studies on gut microbial diversity in various sets of Western population cannot be extrapolated to their Indian counterparts. We have initiated a study to assess gut microbial diversity in Indian population with reference to health and disease.**Methods:** Stool samples have been collected from specific groups including vegetarian (N=13) non-vegetarian (N=12), colon cancer (N=12) and IBD (N=13). Metabolic profiling of gut bacteria was done by fatty-acid methyl ester (FAME) analysis. Amplified ribosomal DNA restriction analysis (ARDRA) using *HaeIII* has been carried out in samples and 16S rDNA library of these were prepared. The taxonomic distinction between the data sets was revealed by comparing and mapping of sequences using Ribosomal data base project (RDP).**Results:** Results indicate that microflora of a healthy adult showed high number of *Bacteroidetes* (84%) and less of *Firmicutes* (4%). When compared with age and sex match patient of colon cancer, there was a remarkable decrease in *Bacteriodetes* (52%) and increase in *Firmicutes* (29%). There was difference in the class Clostridia which was 2 % in healthy individual and 24 % in colon cancer patient. The IBD patients had higher percentage of Bacteroidetes than Firmicutes but lower Bacteroidetes: Firmicutes ratio than healthy non-vegetarian adult. Sequencing was able to indicate the presence and absence of anaerobes even when conventional culture failed to grow. FAME analysis showed significantly lower levels of butyric acid in IBD patients compared to healthy controls.**Conclusions:** RDP profiling shows remarkable differences with unique diversity attributed to unique Indian diet. Results are indicative of role of gut microflora in colonic health and provide insight into microbial community in health and disease and will help to establish certain microbial biomarkers.

Disentangling Diet And Phylogeny Reveals Both Horizontal And Vertical Evolution Of Microbiomes

Author Block:

M. Groussin[1], F. Mazel[2], J. G. Sanders[3], C. S. Smillie[1], S. Lavergne[2], W. Thuiller[2], E. J. Alm[1]; [1]Massachusetts Inst. of Technology, Cambridge, MA, [2]Univ. Grenoble Alpes, Laboratoire d'Ecologie Alpine, Grenoble, France, [3]Harvard Univ., Cambridge, MA

Abstract Body:

Background: In mammals, host evolutionary history (phylogeny) and diet primarily drive compositional differences of gut microbiota between host species. However, these factors are so deeply confounded, it may be impossible to fully understand their respective impact on the evolution of gut microbiota.**Methods:**Here, we develop a new phylogenetic framework to analyze compositional diversities between communities and disentangle diet and phylogeny. Our approach allows us to precisely characterize the bacterial taxonomic levels at which these two factors primarily shape community compositions. We then use probabilistic approaches to quantify to what extent horizontal and vertical inheritance of symbionts impact gut microbiota evolution with respect to diet and phylogeny.**Results:**Our study shows that host phylogeny and diet drive community assembly at different temporal scales of bacterial evolution. Host diet selects deep microbial lineages, consistent with the conservation of diet-related functions at large bacterial taxonomic scales. Host phylogeny, however, finely discriminates among recently diverged bacterial lineages, consistent with intimate interactions between bacteria and host genetics. Dietary shifts during mammalian evolution are associated with a non-random process of horizontal acquisitions of bacteria, resulting in nested gut microbiota compositions that reflect the nested structure of diets. These shifts did not erase the signal of vertical inheritance of microbiota along host phylogeny: both young and ancient (up to 80 Myr) mammalian clades harbor specific compositions and the proportion of bacteria showing signs of co-speciation (56% of OTUs) is much higher than chance would predict.**Conclusion:**Together, our results shed light on the underlying complexity of horizontal and vertical processes driving the evolution of mammal:microbiota symbiotic systems and reconcile previous, seemingly inconsistent empirical observations on the relative contribution of host phylogeny and diet. Our results open new avenues to further understand the functional and evolutionary drivers of animal:microbiota systems.

Diet-Linked Dynamics of the Human Gut Microbiome

Author Block:

G. ABU-ALI[1], J. Lloyd-Price[2], R. S. Mehta[3], K. L. Ivey[1], J. Izard[4], E. Rimm[1], A. T. Chan[3], C. Huttenhower[1]; [1]Harvard Chan Sch. of Publ. Hlth., Boston, MA, [2]Broad Inst., Boston, MA, [3]Massachusetts Gen. Hosp., Boston, MA, [4]Forsyth Inst., Cambridge, MA

Abstract Body:

Background: We report on the gut microbiomes of 307 participants from the Health Professionals Follow-Up Study, a prospective cohort designed to relate nutrition to health outcomes and, here, to link the microbiome to dietary patterns.**Methods:** The gut metagenome of each participant was surveyed at four timepoints with short (1-3 days) and long (6 month) intervals. Metatranscriptomes were also generated for 96 participants. These data are complemented with seven-day dietary recalls and long-term dietary histories from food frequency questionnaires. Taxonomic profiling and metabolic reconstruction were performed using MetaPhlAn2 and HUMAnN2, respectively.**Results:** In addition to echoing the microbial population structure of similar Western adult cohorts, functional profiling showed that several pathways had bimodal distributions across timepoints, implying a stable substructure possibly related to differences in diet and lifestyle among a subset of ~20 participants. Of the 730 transcriptionally active metabolic pathways, 225 were significantly and stably over-transcribed with RNA/DNA ratios >2. Diversity analysis echoed the structure of other healthy populations and, consistent with previous reports, indicated that taxonomic composition was stable over time. The most abundant taxa were not necessarily the most prevalent (e.g. Akkermansia muciniphila and Ruminococcus bromii), showing greater divergence from an ecological neutral model than has been observed in other cohorts. Lastly, strain-resolved analysis lent support to consistent and stable inter-individual differences, with both genomic variants and functional content differing within species among individuals and over time.**Conclusions:** Deeper insight into the structure and diet-linked variability of the microbiome will guide future efforts in personalized preventative interventions and, eventually, lifestyle-based health maintenance.

Machine Learning Reveals Microbiome Differences in Exercise Mouse Models

Author Block:

E. Lamoureux, S. Grandy, M. Langille; Dalhousie Univ., Halifax, NS, Canada

Abstract Body:

Background: The human microbiome is known to have a complex, yet vital relationship with human health. While both exercise and the gut microbiome have been shown to be important contributors to health, the direct effects of exercise on the intestinal microbiota in a controlled setting remains understudied. The purpose of this study was to characterize changes in the gut microbiome in response to varying forms of exercise using a mouse model with a controlled environment and diet. **Methods:** Mice were randomly assigned into one of three exercise treatments: voluntary wheel running, forced exercise through the use of a treadmill, and a control group with no access to exercise equipment. Food intake, weight, and body mass composition were monitored over the experimental period. Bacterial 16S rRNA gene sequencing from fecal samples was conducted by the CGEB-IMR using an Illumina MiSeq. Data was analyzed and microbiome differences between treatment groups were evaluated using the standard operating procedures from Microbiome Helper. Further analysis was explored using machine-learning techniques, including Random Forests.**Results:** Mice within the voluntary exercise group were found to intake more food and weigh significantly more than control mice and mice undergoing forced exercise. Microbiome analysis revealed on average 1094 operational taxonomic units per sample, but did not initially identify any major differences between exercise treatments. Machine-learning methods trained with microbiome data could reliably predict the correct treatment for each sample 81% of the time, suggesting a modest but measurable shift in the gut microbiome in response to exercise.**Conclusions:** Our study shows that exercise has an identifiable but limited effect on the gut microbiome and questions the impact of exercise on the human microbiome.

Rapid Urbanization in China is Associated with Increased Abundance of Commonly Observed Western Gut Microbes

Author Block:

K. Winglee[1], A. G. Howard[2], W. Sha[3], R. Gharaibeh[3], J. Liu[4], D. Jin[4], A. A. Fodor[1], P. Gordon-Larsen[2]; [1]Univ. of North Carolina at Charlotte, Charlotte, NC, [2]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Univ. of North Carolina at Charlotte, Kannapolis, NC, [4]Hunan Ctr. for Disease Control and Prevention, Changsha, China

Abstract Body:

Background: The composition of the human microbiome, the set of microorganisms found on or in a host, is correlated with a number of diseases, including obesity, diabetes and cancer. These diseases are also associated with urbanization, and although it has been shown that microbial community composition varies across continents and in traditional versus Westernized societies, few studies have examined urban-rural differences in neighboring communities within a single country undergoing rapid urbanization.**Methods**: Using next generation sequencing of the 16S rRNA gene, we assessed differences in the microbial community of rural versus recently urban subjects from the Hunan province of China. In addition, we analyzed the microbiota-related plasma metabolites.**Results**: There were significant differences in both the microbial and metabolite composition between rural and urban participants at the lower taxonomic levels, although there was no significant difference above the family level. Furthermore, when we compared the taxa in our study to the American cohort from the Human Microbiome Project (HMP), microbes with higher relative abundance in Chinese urban samples were substantially more prevalent in the HMP.**Conclusions**: The microbial changes linked to urbanization in our study have been shown to be associated with diseases in other studies. We hypothesize that selection pressure from urbanization rapidly affects the relative abundance of microbes at more derived levels of the phylogenetic tree, although these changes have not propagated to higher levels. This suggests that urbanization has resulted in convergent evolution in American and urban Chinese microbial composition, causing similar patterns of abundant microbes through similar lifestyles on different continents.

Calorie Restriction Significantly Alters the Intestinal Microbiota of Mice

Author Block:

S. A. Matyi[1], A. Unnikrishnan[1], K. Garrett[1], A. Ericsson[2], A. Richardson[1]; [1]Univ. of Oklahoma Hlth.Sci. Ctr., Oklahoma City, OK, [2]Univ. of Missouri Metagenomics Ctr., Columbia, MO

Abstract Body:

Calorie restriction (CR) as a dietary intervention has been shown to not only extend the lifespan of a variety of animals but can also delay the onset of age-related diseases and improve physiological functions that decline with age. Therefore, it is generally accepted that CR delays aging. Because intestinal microbiota has been shown to play an important role in host health and disease such as obesity and diabetes and because diet is a major influence that can change the composition and function of the intestinal microbiota, we studied the effect of life-long CR on the composition of the intestinal (cecum and fecal) microbiota of mice. Young and old male mice were housed in a specific pathogen-free animal facility and fed *ad libitum* or given a 40% calorie restriction diet. The microbiota of both the feces and cecum were characterized by high-throughput sequencing the V4 region of the bacterial 16S rRNA gene. Here we show that 40% CR significantly changed the overall composition of the intestinal microbiota of old mice. The microbiota of the old CR mice were enriched for similar phylotypes found in young mice, while the old animals fed *ad libitum* were comprised of different phylotypes. In addition, we found that the diversity of the intestinal microbiota declined with age and was preserved by CR. We have also determined if changes in the microbiota are correlated to changes in the transcriptome of colon mucosa. Our data suggest that the preservation of the young intestinal microbiota profile found within old CR mice may play a role in the prevention or delay of age-related diseases as well as the extension in lifespan seen with CR.

Gut Microbiota and Cytomegalovirus (Cmv) Infection Interact to Influence Development of the Immune System in Rhesus Macaques

Author Block:

N. R. Narayan, G. Méndez-Lagares, A. Ardeshir, D. Lu, D. Hartigan-O'Connor; Univ. of California, Davis, Davis, CA

Abstract Body:

Background: Environmental factors such as the gut microbiota and chronic latent viral infections have profound impacts on the immune system. Cytomegalovirus (CMV), for example, is a common asymptomatic infection that causes significant changes in the immune system of the host. While a great deal of work has elucidated the effects of individual factors such as CMV, however, little work has been devoted to assessing interactions between viral infections and the gut microbiota.**Methods:** We examined 71 healthy rhesus macaque juveniles (43 CMV-negative, 28 CMV-positive), collecting rectal swabs and peripheral blood. Peripheral blood mononuclear cells (PBMCs) were isolated and we used flow cytometry to assess a comprehensive set of immune markers, including those expressed by subsets of B cells, T cells, and innate immune cells. The microbiota associated with the lumen was assessed by 16S rRNA sequencing of rectal swab samples.**Results:** Both CMV infection and many members of the gut microbiota independently associated with features of the immune system. While CMV infection did not associate with significant shifts in gut microbiota composition, abundances of *Faecalibacterium* and *Bifidobacterium* were decreased in CMV-positive macaques. Linear mixed-effects modeling revealed that CMV infection shifted the relationship between some bacteria and immune subsets. For example, *Prevotella* abundance was significantly associated with various activated monocyte subsets, but only in CMV-negative animals.**Conclusions:** The gut microbiota and CMV influence the immune system individually and in their interactions. Further work will focus on the sources of this interaction, which may be due to altered host innate cell signaling.

An Ecophylogenetic Approach to Determine the Evolutionary History of the Mammalian Gut Microbiome

Author Block:

C. A. Gaulke, **T. J. Sharpton**; Oregon State Univ., Corvallis, OR

Abstract Body:

Identifying those gut microbes that co-evolve with mammals is important to our understanding of the mechanisms and health implications of host-microbiome interactions. For example, microbiota that are conserved across mammalian species may express a trait that has been subject to selection throughout the evolution of these mammals, possibly because it is critical to health. While advances in environmental DNA sequencing have transformed our understanding of how enteric microbes are distributed across mammalian species, these data are frequently analyzed using phylogenetically agnostic approaches. Such approaches can obscure the detection of diverged groups of bacteria that have been conserved across mammalian species. To provide enhanced resolution into evolutionary associations between gut microbiota and mammals, we innovated a high-throughput ecophylogenetic method, known as ClaatTU (Cladal Taxonomic Units). ClaaTU analyzes phylogenies assembled from environmental DNA sequences collected from a set of microbial communities and profiles the presence and abundance of each monophyletic clade in each community. As a result, it enables the identification of specific microbial clades that are distributed across host communities in a manner indicative of being associated with mammalian evolution. To demonstrate this, we first evaluated the accuracy of this method using statistical simulations. We then applied ClaaTU to several mammalian microbiome datasets spanning varying evolutionary distances and identified clades of gut bacteria that are (1) conserved across groups of mammals, (2) unique to specific mammalian lineages, and (3) putatively co-diversifying with their hosts. Our findings indicate that some mammalian gut microbiota were anciently acquired and subsequently retained in extant lineages, indicating that they may play an important role in mediating host-microbiome interactions and maintaining host health.

Gut Microbiome of Animal Model Systems: A Comparison of Macaque, Vervet, Mouse and Human

Author Block:

E. J. Bautista[1], K. Mihindukulasuriya[2], Y. Zhou[1], J. R. Kaplan[3], Y. Nobel[4], A. J. Jasinska[5], M. J. Blaser[6], N. B. Freimer[7], E. Sodergren[1], G. M. Weinstock[1]; [1]The Jackson Lab., Farmington, CT, [2]Washington Univ. Sch. of Med., St. Louis, MO, [3]Wake Forest Univ., Winston-Salem, NC, [4]Columbia Univ. Med. Ctr., New York, NY, [5]Univ. of California, Los Angeles, CA, [6]THe New York Univ., New York, NY, [7]Univ. of California-Los Angeles, Los Angeles, CA

Abstract Body:

Animal model systems are important tools to study behavior, metabolic disorders, host-gut microbe interactions, immunity and obesity. Obesity is a growing problem worldwide, leading to increases in diabetes, hypertension, heart disease, stroke, arthritis, high cholesterol and some cancers. Adoption of a Western diet, coupled with a more sedentary lifestyle is key factors in the increase in childhood and adult obesity, both in the Western and developing worlds. Further, diet helps to mold the gut microbiome.Here, we use both macaques and vervets as models to study the effect of diet on the gut microbiome. Macaques were under high fat diet with soy or casein as their protein source. Meanwhile, vervets on standard monkey chow diet were change to a typical American Diet (TAD). We also compare the microbiome of vervet and macaque to the microbiome of mice and humans. Samples were processing following standard protocols for DNA extraction and 16S targeted sequencing. Our pipelines for 16S rRNA were used to determine the taxonomic composition and the metabolic functional potential associated with it.A preliminary comparison analysis show macaques on a casein-based diet have a larger proportion of Prevotella than macaques on a soy-based diet. While Prevotella dominates all vervet stool samples, the amount of Prevotella present was reduced following the introduction of TAD.The gut diversity of macaques was higher with soy, rather than casein, as a protein source. Vervets on a chow diet have higher gut diversity compare to the ones on TAD diet. Currently, we are working on analyzing the metabolic functional potential of the samples, to further understand the impacts of the change in diet on the microbiome.Finally, macaques showed the greatest diversity, followed by vervets, mice and humans. Vervet and macaque gut microbiomes are dominated by Prevotella, humans by bacteriodes and mice by Akkermansia.

Assembly of the *Bacteroides thetaiotaomicron* Starch Utilization System (SUS)

Author Block:

M. Foley; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

The human gut microbiota plays an essential role in maintaining optimal health, yet little is known about how many of these organisms harvest nutrients from their environment. Dietary glycans are a controllable variable that shape the composition of the human gut microbiota, and microorganisms that colonize this niche have strategies to efficiently compete for these nutrients. A dominant phylum of the gut, the Gram-negative Bacteroidetes, can utilize numerous dietary and host-derived glycans. Many gut Bacteroidetes devote significant portions of their genome towards polysaccharide utilization loci (PULs) that each encode several proteins that bind, degrade, and import different sugars. Each PUL is individually regulated and encodes for proteins that target a unique glycan structure. Conserved across all known PULs are homologs of the prototypical starch utilization system (Sus) proteins SusC, a TonB-dependent transporter (TBDT), and SusD, a starch binding protein, originally described in the model species Bacteroides thetaiotaomicron (Bt). In the Sus, SusCDEFG operate on the cell surface to capture, degrade and import starch into the cell. SusC and SusD are both required for Bt growth on starch and interact, although the nature of this interaction and other proteins present in this complex are not described. My data demonstrate that SusE, like SusD, can provide a starch-binding site for glycan transport through SusC, which highlights a new feature of the SusE-like family of proteins within the Bacteroidetes. Furthermore, using quantitative proteomics I demonstrate that SusCDE interact in the membrane, and that the stoichiometric ratio of interacting proteins is affected by formaldehyde crosslinking. In hopes of understanding the relationship between the SusCDE complex and the remaining proteins SusFG, I employ single molecule imaging to visualize SusE, SusF, and SusG dynamics in the membrane of live cells. Imaging shows that, unlike the highly mobile SusG, SusE and SusF are static, although the reason for this is unclear. The goal of my research is to understand how these Sus protein interactions facilitate glycan utilization. Because homologs of these proteins are central to all PULs, understanding how they work together to import starch will inform a general model of the Sus-like paradigm used by the Bacteroidetes for glycan uptake.

Mannosides: An Antibiotic-Sparing Treatment For The Eradication Of Upec Reservoirs From The Host

Author Block:

C. N. Spaulding, A. Kau, Z. Cusumano, J. Janetka, J. I. Gordon, S. J. Hultgren; Washington Univ. in St. Louis, St. Louis, MO

Abstract Body:

Urinary tract infections (UTI) represent a disease which: i) affects ~60% of women; ii) displays a high rate of recurrence; iii) is associated with significant morbidity and has a sizeable economic impact and; iv) is increasingly being caused by multidrug resistant bacteria. The most common causative agent of UTI is uropathogenic *E. coli* (UPEC). UPEC reside in the gut microbiota, are shed in the feces and can be introduced into the bladder. The role of the gut as a primary source of UPEC that lead to UTI is widely accepted, yet little is known about the basis of UPEC gut colonization. To colonize a host, UPEC express a family of adhesive fibers called pili. In mice, acute bladder colonization requires the adhesin protein present at the tip of the type 1 pilus, FimH, to bind to mannosylated proteins expressed on the surface of bladder epithelial cells. Once the bacteria bind the host surface, they can invade the luminal epithelial cells where they can replicate to high levels while protected from many host defenses; thus promoting ongoing infection. We have developed anti-adhesive mannosides that specifically block UPEC's ability to colonize the bladder by binding to FimH with several orders of magnitude higher affinity than the natural receptor. We have shown that mannosides are capable of treating and/or preventing UTI in the mouse model. Here we show that type 1 pili also enhance UPEC intestinal colonization. Interestingly, in mice colonized with human UPEC isolates, treatment with the mannoside results in decreasing colonization of the uropathogen in the gut with minimal other effects on gut microbial ecology, including no significant effects on the abundance of normal resident *E. coli* strains in the microbiota. Eliminating the UPEC reservoir in the gut may help to reduce the rate of recurrent UTI. Thus, this type of therapeutic provides an antibiotic-sparing method, which if translated to the clinic may have the potential to: i) treat patients with UTI and/or; ii) reduce the rate of recurrences by eliminating the UPEC reservoir from the gut. Additionally, a number of studies show that disrupting the gut microbiota with antibiotics may affect its functional properties in ways that are deleterious to the host. Therefore, a compound that can target UPEC, without damaging the remainder of the gut microbiota holds promise as an antibiotic-sparing therapy.

Pancreatic Ductal Adenocarcinoma and Intestinal Microbiome Diversity

Author Block:

S. Pushalkar[1], D. Daley[2], M. Usyk[1], C. Zambrinis[2], G. Miller[2], D. Saxena[1]; [1]New York Univ. Coll. of Dentistry, New York, NY, [2]New York Univ. Langone Med. Ctr., New York, NY

Abstract Body:

Inflammation induced pancreatic ductal adenocarcinoma (PDAC) accounts for 85% of the pancreatic cancers. Gut bacteria play a functional role in maintaining the homeostasis. Accumulating evidence suggests the role of bacterial infections in the manifestation of several malignancies. We hypothesized that intestinal microbial communities may influence PDAC progression. Microbial DNA was extracted and illumina MiSeq sequencing of 16S gene amplicons was used to characterize the gut microbiota in the patients with pancreatic ductal adenocarcinoma (PDA, n=10) and non-PDAC controls (NML, n=10). Bacterial community analysis using Quantitative Insights Into Microbial Ecology (QIIME) and R revealed high abundance of phyla *Firmicutes* (51.8-57.3%) and *Bacteroidetes* (27.0-30.4%) in PDA and NML cohorts. Approximately 4% increase in the levels of *Proteobacteria* ($p>0.1$) and *Fusobacteria* ($p=0.052$), though not significant was observed in the PDAC patients as compared to non-PDAC controls. Taxa, *Veillonella* ($p<0.001$), unclassified *Veillonellaceae* ($p<0.001$), *Fusobacterium* ($p<0.01$), and *Klebsiella* ($p<0.01$) were significantly associated with PDAC patients. Principal coordinate analysis showed two distinct clusters of non-cancer controls and PDAC patient population in response to variation in the host microenvironment. The results suggest dysbiosis in microbial membership and structure and presence of certain microbial signatures associated with pancreatic carcinogenesis. These findings and future studies with larger patient population could facilitate better insights in elucidating the role of gut microbiota in the pancreatic tumor microenvironment that could be of clinical and therapeutic significance.

Relationships between Mosquito Intestinal Bacteria and Mosquito-Borne Virus Infection

Author Block:

C. M. Bonavita, J. Anderson; Radford Univeristy, Radford, VA

Abstract Body:

Abstract**Background:**Dengue viruses are endemic to the tropics and affect roughly 390 million people annually. Symptoms include high fever, joint pain, hallucinations, and in some severe cases hemorrhaging. Currently there are no effective preventative or treatment methods for dengue virus. Previous research suggests that intestinal bacteria may hold properties that can manipulate disease transmission in mosquitoes.**Methods:**For my experiment, my goal was to collect dengue vectors from the Madre de Dios region of eastern Peru and to compare the bacteria resident in infected vs. uninfected mosquitoes, as well as differences between the in-forest, near-forest, and in urban area microbiome of the mosquitoes.**Results:**We collected 52 mosquito samples, of which only 10 were potential dengue vectors. Since it is unlikely that we would find the virus in that small a sample pool, we also began examining variations in bacterial communities in mosquitoes from various locations in Virginia using 16S rRNA sequencing or SSCP analysis of asymmetric PCR. *Aedes albopictus* mosquitoes from three locations in Virginia could be distinguished based on their bacterial communities.**Conclusions:**We are currently investigating the relationship of bacteria to Eastern equine encephalitis virus infection in *Culiseta melanura* mosquitoes from the Great Dismal Swamp in Virginia. Much is still unknown about the bacteria that colonize mosquito vectors of disease and how they interact with the pathogens. Our work adds to the growing understanding of those bacteria, and how they might be used to interfere with pathogen transmission.

***Helicobacter pylori* γ-Glutamyl Transpeptidase is a Potentiator of Vaca-dependent Vacuolation in Gastric Cells**

Author Block:

B. Ho, **S. Ling**; Natl. Univ. of Singapore, Singapore, Singapore

Abstract Body:

H. pylori, the etiological agent of gastroduodenal diseases possesses vacuolating cytotoxin (VacA) that causes cellular vacuolation in host cells in the presence of permeant weak bases, ammonia. We report here the role of γ-glutamyl transpeptidase (GGT), a secretory enzyme of *H. pylori*, in enhancing VacA-dependent vacuolation formation in *H. pylori*-infected gastric epithelial cells. The process involves GGT hydrolysing glutamine and releasing ammonia that accentuates the VacA-induced vacuolation. In contrast, *H. pylori ggt* isogenic mutant (*Δggt*) induced significantly less vacuolation in AGS and primary gastric epithelial cells as compared to the parental strain ($P<0.05$) as shown using semi-quantitative neutral red uptake assay, indicating that GGT potentiates the vacuolating effect of VacA. Not surprisingly, vacuolation was significantly reduced ($P<0.05$) in either the absence of GGT substrate (glutamine) or in the presence of a competitive GGT inhibitor, serine-borate complex. Notably, the addition of purified recombinant GGT (rGGT) *to Δggt*-infected cells markedly restored the vacuolating ability of the mutant, but, rGGT itself did not induce vacuolation independently. Similarly, the addition of exogenous ammonium chloride as a source of ammonia also rescued the ability of *Δggt* to induce vacuolation. Real-time phase-contrast microscopy lends support to the vacuolation events. Taken together, generation of ammonia through glutamine hydrolysis by *H. pylori* GGT is the cause in potentiating VacA-dependent vacuolation. Our findings illustrate GGT as a vital virulence factor in *H. pylori*-associated gastric diseases.

The Role of Immunity on *Streptococcus pneumoniae* Shedding and Transmission in an Infant Mouse Model

Author Block:

T. Zangari, Y. Wang, J. N. Weiser; New York Univ. Sch. of Med., New York, NY

Abstract Body:

Epidemiological studies on the effects of the *S. pneumoniae* (Spn) conjugate vaccine in childhood show that its major benefit is the ability to block the establishment of nasopharyngeal colonization and to reduce Spn transmission in the population. In this study, we sought to understand how anti-*S. pneumoniae* immunity affects transmission from host to host. We hypothesized that a critical factor in transmission is the number of Spn shed from the nasopharynx. Using an infant mouse transmission model, we examined the role of immunity on shedding of Spn by pups infected at 4 days-of-life.To study the role of immunity in infant mice, it was necessary to induce immunity in the mother. Adult, female C57BL/6J mice were either infected intranasally (IN) with ~3000 CFU of streptomycin (str)-resistant type 23F or type 4 Spn isolates, or were mock infected. The females were then bred and their pups infected IN with the same strain. Nasal shedding was monitored for 5 days post-infection by tapping the nose of the pups on str plates and enumerating colonies. On day 13 of life the pups were euthanized. Serum was collected and assessed by whole cell ELISA for IgG to the Spn strain with which the mice were infected. Bacteria were collected from the upper respiratory tract by tracheal lavage and colonization was measured by quantitative culture.ELISA showed that sera of pups from infected mothers had a significantly higher anti-*S. pneumoniae* titer compared to pups from mock infected mothers ($p < 0.0001$). There was, however, no significant difference in Spn colonization between immune and non-immune pups. Despite similar levels of colonization, pups with a high anti-type 23F IgG titer shed significantly less Spn than pups from mock-infected mothers ($p < 0.0001$). Similarly, pups with a high anti-type 4 IgG titer shed significantly fewer bacteria than pups from mock-infected mothers ($p = 0.0054$). The effect of maternally-derived immunity of infected pups on transmission of Spn to uninfected littermates will be discussed. Our findings provide a possible mechanistic explanation for the reduced levels of Spn transmission among immunized children.

Investigation of Potential Virulence Factors in a Novel *Pseudomonas* Species

Author Block:

E. Klempic, M. Brockett, J. E. Zvornicanin, B. L. Blocher, P. L. Lawrence, J. H. Shinn-Thomas, L. R. Aaronson; Utica Coll., Utica, NY

Abstract Body:

Pseudomonas sp. UC17F4 is a novel species that was isolated from the skin of red-backed salamanders collected in Central New York State. UC17F4 is a unique bacterial species that produces both extracellular pyomelanin and intracellular eumelanin. We have explored the possibility that bacterial melanins are a virulence factor utilizing the microscopic nematode *Caenorhabditis elegans* as a model host organism. *C. elegans* larvae were transferred to lawns of UC17F4 under conditions where the bacteria produced eumelanin. We observed that L1 and L2 stage larvae did not survive in the presence of this bacterium, while L3, L4, and adult worms did. In the present study, UC17F4 was grown on Lawrence minimal media (LMM), a citrate-enriched chemically-defined medium, that allows melanization. On LMM, UC17F4 caused complete loss of L1 stage worm viability between 12-24 hrs. When LMM was supplemented with 0.25% peptone (LMMP) to emulate the composition of Nematode Growth Medium and enhance melanogenesis, L1 worms died within 4 hours after transfer to bacterial lawns. We hypothesized that the rapid loss of viability on LMMP was due to the production of proteases, which could degrade the thin cuticle of larval worms, while the delayed loss of viability on LMM media was due to toxic effects of eumelanin as the worms consumed the bacteria. To test this hypothesis, protease production by UC17F4 biofilms was measured using a fluorometric enzyme assay. Three media formulations were used: LMM, LMMP, and citrate-free LMMP. All biofilm studies showed that the bacteria produced protease only in the citrate-free LMMP, suggesting that citrate represses protease production through carbon catabolite repression. These data also refute our hypothesis that proteases are responsible for the rapid death of worms on LMMP, because bacteria grown on citrate-free LMMP do not kill C. elegans. We also observed that UC17F4 produces higher levels of extracellular pyomelanin on LLMP than on the other media, which could contribute to the rapid loss of viability in the worms. Our findings indicate that protease is not a potential virulence factor in UC17F4, and we are continuing to identify other factors that may be responsible for quick death in juvenile nematodes.

Bacterial Adrenergic Sensors Regulare Virulence of Enteric Pathogens in the Gut

Author Block:

R. M. Russell, V. Sperandio; Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract Body:

Enteric pathogens such as enterohemorrhacig *E. coli* (EHEC) and *Citrobacter rodentium*, which is largely used as a surrogate EHEC model for murine infections, are exposed to several host neurotransmitters in the gut. Epinephrine and norepinephrine have been extensively reported to increase virulence gene expression in EHEC, acting through two bacterial adrenergic sensors: QseC and QseE. However, EHEC is unable to establish itself and cause its hallmark lesions, attaching and effacing (AE) lesions, on murine enterocytes. To address the role of these neurotransmitters during enteric infection, we employed *C. rodentium*. Both EHEC and *C. rodentium* harbor the locus of enterocyte effacement (LEE) that is necessary for AE lesion formation within the colon. Here we show that expression of the LEE ,as well as other virulence genes is activated by epinephrine and/or norepinephrine, similarly to previous reports in EHEC. Both QseC and QseE are required for LEE gene activation in *C. rodentium*, and the qseC and *qseE* mutants are attenuated for murine infection. *C. rodentium* has decreased ability to colonize and cause disease in dopamine hydroxylase (Dbh -/-) knockout mice, which do not produce epinephrine and norepinephrine. Both adrenergic sensors, QseC and QseE are required for C. rodentium to sense epinephrine and norepinephrine during murine infection. Expression of the LEE genes is decreased in Dbh-/- animals compared to WT, and are mediated through QseC and QseE during murine infection. These data indicate that epinephrine and norepinephrine are sensed by bacterial adrenergic receptors during enteric infection to promote activation of their virulence repertoire.

Trefoil Factor Family Member 2 Regulates Susceptibility to *Escherichia coli* K1 Infection in Neonatal Rats

Author Block:

A. J. McCarthy[1], A. Redin Alonso[2], G. M. H. Birchenough[3], P. W. Taylor[1]; [1]Univ. Coll. London, London, United Kingdom, [2]London Sch. of Hygiene & Tropical Med., London, United Kingdom, [3]Univ. of Gothenburg, Gothenburg, Sweden

Abstract Body:

Background: Neonatal rat pups are susceptible in an age-dependent manner to systemic fatal infection following intestinal colonization of *Escherichia coli* K1. The incomplete development of gastrointestinal (GI) defences, including the mucus barrier, may facilitate translocation of colonizing bacteria into the bloodstream. Thus, two-day-old (P2), but not nine-day-old (P9), rat pups are highly susceptible to *E. coli* K1 infections. This is associated with suppressed expression of trefoil factor family member 2 (TFF2), a small peptide that stabilizes mucin and protects the GI epithelial layer. **Objective:** To investigate the role of trefoil factors in protection against *E. coli* K1 infection by characterizing the spatial expression of *Tff1*, *Tff2* and *Tff3* and mucin maturation during neonatal development, and by determining of the role of TFF2 in regulating infection susceptibility. **Methods:** Temporal changes in *Tff1*, *Tff2* and *Tff3* gene expression and mucin quality were assessed using qRT-PCR and immunohistochemistry in GI sections (P2, P4, P6 and P9), respectively. We compared the ability of *E. coli* K1 to colonize, translocate and cause systemic infection in wildtype and *Tff2*-/- rat P9 pups. **Results** *Tff1* and *Tff2*, but not *Tff3*, increased in expression in the proximal-, middle-, distal- small intestine and colon over the P2 to P6 developmental period, then decreased from P6 to P9. The mucin layer underwent substantial maturation from P2 to P9. The absence of TFF2 in rats did not impact *E. coli* K1 colonization of the GI tract, but did significantly alter the progression to a bacteremic state over 7-days (wildtype 0 %, *Tff2*-/- 100%). A proportion of *Tff2*-/- (22%), but not wildtype (0%), animals exhibited signs of severe systemic infection within 25 days. Two-dimensional bioluminescent imaging confirmed the presence of systemic infection in *Tff2*-/- rats. **Conclusions:** Maturation of the neonatal GI tract over P2 to P9 is accompanied by regulation of trefoil factor expression; in particular, TFF2 appears to play a key role in determining the susceptibility of neonatal rats to *E. coli* K1 infection.

Pseudomonas aeruginosa* GroEL-Mediated Production of PTX3 Enhances the Phagocytic Clearance of *Staphylococcus aureus

Author Block:

H. Shin, **J. Jeon**, U. Ha; Korea Univ., Sejong, Korea, Republic of

Abstract Body:

Background: Infections are often not caused by a colonization of *Pseudomonas aeruginosa* alone but by a consortium of other bacteria. However, little is known about the impact of *P. aeruginosa* on the growth of other bacteria upon coinfection. **Methods**: We measured mRNA and protein levels of PTX3 by applying real-time Q-PCR and ELISA. The effect of PTX3 for the clearance of *Staphylococcus aureus* was examined by a phagocytosis analysis. **Results**: We found that *P. aeruginosa* was capable of inducing the expression of PTX3, and the induction was mediated by secreted proteins present in culture supernatants obtained from *P. aeruginosa*. By fractionating and analyzing the culture supernatants, it was found that the responsible protein was GroEL encoded by PA4385 of *P. aeruginosa*. Site-directed mutated GroEL lost its ability to increase the expression of PTX3 compared to its intact GroEL. Since PTX3 plays an important role in increasing the phagocytosis of microbes, we determined that *P. aeruginosa* GroEL-mediated production of PTX3 indeed enhances the phagocytic clearance of *S. aureus*. **Conclusions**: *P. aeruginosa*-derived GroEL is able to increase the production of PTX3, contributing to increasing the clearance of competitive *S. aureus* infection against same host during coinfection.This research was supported by Basic Science Research Program (NRF-2013R1A1A2059846) and the BK21 plus program of the Ministry of Education, Korea.

Efflux Pump of Siderophore Staphyloferrin A in *Staphylococcus aureus* Contributes to Bacterial Fitness in Abscesses and Epithelial Cells

Author Block:

H. Nakaminami[1], Q. C. Truong-Bolduc[2], C. Chen[2], E. S. Kim[3], Y. Wang[2], D. C. Hooper[2]; [1]Tokyo Univ. of Pharmacy and Life Sci., Tokyo, Japan, [2]Massachusetts Gen. Hosp., Boston, MA, [3]Seoul Natl. Univ. Bundang Hosp., Gyeonggi-do, Korea, Republic of

Abstract Body:

Recently, two major facilitator superfamily (MFS)-type efflux pumps SfaA and SbnD which are involved in the secretion of the *Staphylococcus aureus* siderophores staphyloferrin A and staphyloferrin B, respectively, were characterized. We have already demonstrated that some staphylococcal MFS-type efflux pumps contribute to bacterial fitness in the murine abscess model and epithelial cells. Furthermore, we found the expression of *sfaA* and *sbnD* genes increased 31- and 4.1-fold in the abscesses, respectively. To assess the further function of SfaA and SbnD in *S. aureus* fitness, we tested its effect on the murine abscess model and intracellular replication in A549 epithelial cell line.We used *S. aureus* RN6390, its Δ*sfaA*, and Δ*sbnD* mutants. Susceptibilities of antimicrobial agents, fatty acids, and polyamines for parent strain RN6390, Δ*sfaA*, and Δ*sbnD* mutants were compared. Swiss Webster male mice that were 4 to 6 weeks old were used for the abscess model. Intracellular replication experiments for parent strain RN6390, Δ*sfaA*, and Δ*sbnD* mutants were performed using the ATCC CCL-185 human lung adenocarcinoma cell line A549.The knockout of *sfaA* and *sbnD* genes did not affect the susceptibilities of the tested chemicals. In competition assays of the murine abscess model using equal inocula of a Δ*sfaA* or Δ*sbnD* mutant and parent strain RN6390, the Δ*sfaA* mutant exhibited growth defects of 2.2-fold. Additionally, intracellular replication was decreased 2.8-fold in the Δ*sfaA* mutant. In complementation experiments, the Δ*sfaA* mutant carrying plasmid-encoded *sfaA* restored the growth fitness in abscesses and epithelial cells. However, Δ*sbnD* mutant showed no growth defect both in abscesses and epithelial cells.Our findings indicate that the efflux pump of the siderophore staphyloferrin A contributes to the ability of *S. aureus* replicate in abscesses and within epithelial cells.

Roles Of The Putative Type Iv-Like Secretion System Key Component Vird4 In Pathogenesis Of *streptococcus Suis* Type 2

Author Block:

X. Jiang, Y. Yang, J. Zhou, W. Fang; Zhejiang Univ., Hangzhou, China

Abstract Body:

Streptococcus suis type 2 (SS2) is a zoontic pathogen causing septic infection, meningitis, bronchopneumonia in pigs and humans. There were two major outbreaks in China in 1998 and 2005 with the infected persons exhibiting streptococcal toxic shock syndrome probably due to excessive release of inflammatory cytokines. However, the major bacterial factors that triggerd the cytokine storms remain unclear. The *S. suis* type 2 genome contains a small cluster of genes including virD4 encoding the putative type IV secretion component. To explore the functions of virD4 in SS2 pathogenesis, a virD4 in-frame deletion mutant was created and tested for virulence-related phenotypes in cultured cell lines and mouse model. We found that virD4 contributed to virulence as shown by about 2-fold increase of LD_{50} and easy clearance in mice with the delta-virD4 mutant, as compared with its parent strain. Deletion of virD4 rendered the bacteria more easily phagocytosed and readily killed in the whole blood, indicating that virD4 might be an anti-phagocytic factor. The delta-virD4 mutant showed reduced level of IL-6 and IL-1beta in the mouse model as well as in macrophage lines RAW264.7 (murine) and 3D4/2 (swine). To mimic the oxidative stress from respiratory burst, both the virD4 mutant and parent strains were subjected to hydrogen peroxide stress to examine differentially expressed proteins in the culture supernatants by MALDI-TOF/MS. Of these numerous proteins involved in DNA damage repair, nucleotide biosynthesis, carbohydrate metabolism and stress modulation, two conserved proteins attracted our attention: Peptidyl-prolyl isomerase (prsA) involved in protein secretion and folding was nearly 9-fold lower in the culture supernatant of the virD4 deletion mutant than its parent strain, while tagatose 1,6-diphosphate aldolase (LacD.1) involved in lactose/galactose metabolism and in regulation of virulence factors was high in the virD4 deletion mutant. Their relationship to virD4 and antiphagocytic activities as well as other functions in SS2 pathogenesis are being explored.

Influence of Sae and Agr Regulated Factors on the Escape of *Staphylococcus aureus* from Human Macrophages

Author Block:

L. Münzenmayer[1], T. Wolz[1], B. Schulte[1], S. E. Autenrieth[1], M. Fraunholz[2], **C. Wolz**[1]; [1]Univ. Tübingen, Tübingen, Germany, [2]Biozentrum Würzburg, Würzburg, Germany

Abstract Body:

Background: *Staphylococcus aureus* is not a classical intracellular pathogen, but can survive within phagocytes and many other cell types. The pathogen is also able to escape from cells by mechanisms that are only partially understood.**Methods:** We constructed and analysed a series of isogenic *S. aureus* mutants of the USA300 derivative JE2 for their capacity to destroy human macrophages from within. The fate of bacteria was monitored by cell counting, fluorescence microscopy and image stream analysis.**Results**: Intracellular *S. aureus* JE2 caused severe cell damage in human macrophages, and could efficiently escape from within the cells. Damage of macrophages induced by intracellular bacteria was neither linked to activation of apoptosis related caspases 3, 7 or 8 nor to NLRP3 dependent inflammasome activation. To obtain this full escape phenotype including an intermittent residency in the cytoplasm the combined action of the regulatory systems Sae and Agr were required. Mutants in Sae or mutants deficient in the Sae target genes *lukAB* and *pvl* remained in high numbers within the macrophages causing reduced cell damage. Mutants in the regulatory system Agr or in the Agr target gene *psmα* were largely similar to wild type bacteria concerning cell damage and escape efficiency. However, these strains were rarely detectable in the cytoplasm emphasizing the role of PSMs for phagosomal escape.**Conclusion**: Sae regulated toxins largely determine damage and escape from within macrophages, whereas PSMs are mainly responsible for the escape from the phagosome into the cytoplasm.

***In Vivo* Infections with Isogenic 'Phase-Locked' Mutants Illustrate Differences in Colonization Characteristics of Two Major Expression Variants of a Mycoplasma Multigene Family Encoding Variable Surface Lipoproteins**

Author Block:

R. Chopra-Dewasthaly, S. Hegde, W. Jechlinger (Deceased), J. Spergser, R. Rosengarten; Inst. of Microbiol., Univ. of Vet. Med., Vienna, Austria

Abstract Body:

Though implicated to play important roles in mycoplasma-host interactions, the biological significance of large multigene families causing phase variation of immunodominant surface antigens in mycoplasmas has never been directly proven. Using *M. agalactiae* and its high-frequency variable system of Vpma surface lipoproteins as a model, we investigated the *in vivo* significance of such a variable system by comparing the infection characteristics of two major expression variants (VpmaY and VpmaU) of type strain PG2. 'Phase-Locked Mutants' (PLMs), namely PLMU and PLMY, served as ideal tools as they steadily expressed a single Vpma product without further switching. PLMU was found to be outcompeted by PLMY during co-challenge experiments using the sheep intramammary as well as the conjunctival infection model. Quantitative and qualitative mycoplasma testing was performed on various clinical samples collected during infection and necropsy. Vpma phenotypes in recovered mycoplasma populations were assessed via colony immunoblots using monospecific anti-Vpma rabbit hyperimmune antisera. Results indicated an almost complete dominance of PLMY in local infection sites (udders/milk samples, eye/nasal swabs) and repression of the isogenic mutant PLMU in early stages of infection. Apart from these co-infection experiments, sheep were also infected individually with PLMU and PLMY exclusively via the intramammary route. Most interestingly, during the first 24 h p.i., milk obtained from sheep infected with PLMU showed a rapid decline in mycoplasma counts, clearly demonstrating a defect in the host colonization potential of PLMU. In contrast, the CFU counts for PLMY started increasing in milk after 2 h p.i. Results indicate that mycoplasmas expressing VpmaY show a better colonization and survival in the host than those expressing VpmaU. These results lead to the interesting hypothesis that *M. agalactiae* can shift from a local stage to a more systemic stage under certain conditions by switching the expression to VpmaU. This is the first report where mycoplasma PLMs are used in infection studies to prove the *in vivo* significance and differential roles of phase-variable lipoproteins

Mycoplasma agalactiae* Induces Cytopathic Effects in Infected Cells Cultured *In Vitro

Author Block:

S. Hegde, S. M. Hegde, R. Rosengarten, **R. Chopra-Dewasthaly**; Inst. of Microbiol., Univ. of Vet. Med., Vienna, Austria

Abstract Body:

Virulence determinants of mycoplasmas are complex and largely unknown. The disease pathology and the severity of symptoms are usually attributed to the immune responsiveness of the host rather than to the direct effect of the pathogen. This study concentrates on *Mycoplasma agalactiae* that causes Contagious Agalactia in sheep and goats, mainly characterized by mastitis, keratoconjuncitivitis and arthritis. Although the typical pathological features of tissue damage in cases of mastitis are often correlated with host inflammatory cells, the direct role of *M. agalactiae* on host cell damage has never been studied. Here, we investigated the effect of *M. agalactiae* infection on cultured cells *in vitro* using HeLa cells as model system. Compared to the uninfected controls, the presence of *M. agalactiae* was shown to alter the cell morphology, observed 36 h after infection as considerable cell elongation, cytoplasm shrinkage and plasma membrane blebbing. Chromatin condensation and increased caspase-3 cleavage in infected cells after 48 h of infection suggests an apoptosis-like phenomenon. Additionally, *M. agalactiae* infection led to growth retardation and lysis of HeLa cells. Measurement of the amount of LDH released after *M. agalactiae* infection revealed a time- and dose-dependent increase in cell lysis. A significant decrease in LDH release after gentamicin treatment of infected cells confirmed the direct role of cytadhering mycoplasmas in inducing cell lysis. This is the first study demonstrating the ability of *M. agalactiae* to induce irreversible cytopathic effects in infected cells which likely play a role during *in vivo* infection and disease.

Functional Characterisation of Meningococcal Neisseria Autotransporter Lipoprotein (NALP)

Author Block:

O. Dufailu[1], N. J. Oldfield[1], A. Aslam[2], J. Mahdavi[1], D. A. A. Ala 'Aldeen[1], K. G. Wooldridge[1]; [1]Univ. of Nottingham, Nottingham, United Kingdom, [2]Umm al-Qura Univ., Mecca, Saudi Arabia

Abstract Body:

Neisseria meningitidis is normally a human nasopharyngeal commensal but is also capable of causing life-threatening septicaemia and meningitis. Autotransporter (or type V-secreted) proteins are an important class of virulence factors found in many Gram-negative pathogens including Neisseria species. Eight autotransporters have been identified in meningococci: IgA1 protease, NhhA, AutA, AutB, NadA, App, MspA and NalP (also known as AspA). NalP is a phase-variably expressed serine protease which cleaves a number of cell surface proteins including itself, MspA, App, IgA1 protease, Lactoferrin-binding protein B (LbpB) and Neisserial heparin-binding protein A (NhbA). The consequences of this proteolytic activity on meningococcal pathogenesis are yet to be fully determined, but have already been shown to influence the sensitivity of meningococci to killing by human whole blood and the ability of meningococci biofilm formation. To enhance our understanding of the role of NalP during meningococcal pathogenesis, we purified functional recombinant NalP passenger domain under non-denaturing conditions using immobilized nickel chromatography. We demonstrated host cellular uptake of the purified recombinant NalP passenger domain using confocal microscopy. Furthermore, NalP was shown to be proteolytically active in *in vitro* assays, and to cleave a number of host proteins likely to play important roles in host-pathogen interactions.

***pseudomonas Aeruginosa* Isolates From Chronically Infected Patients With Cystic Fibrosis Show Host Tolerance By *ex Vivo* Viability Studies**

Author Block:

S. Yuan, P. Macpherson, Q. Xuan; Seattle Children's Hosp., Seattle, WA

Abstract Body:

Background: *Pseudomonas aeruginosa* (*Pa*) frequently colonizes the respiratory tract of patients with cystic fibrosis (CF) and is associated with increased severity and mortality in these patients. However, it is known that CF airway adapted *Pa* never invades host blood stream. This study is aimed at comparing bacterial host tolerance by examining *ex vivo* viability of wild-type and CF airway-adapted *Pa* in cultures containing human whole blood.**Methods:** Two strains of *Pa* were used for *ex vivo* bacterial viability studies using 1 ml aerobic cultures containing human whole blood from a healthy adult. While PA14 was used as a wild-type control, a PA-C3 strain was a methionine auxotrophic variant from a CF patient with chronic *Pa* infection. Bacterial viability was examined by serial dilutions of cultures every 8 hours. Logarithmic transformed colony counts (logCC) were used for analysis. Culture materials were also smeared by Gram and Wright stains for observation of bacterial and blood cell morphology.**Results:** Significantly different bacterial *ex vivo* viabilities were detected between PA14 and PA-C3 in cultures containing human whole blood. With the inoculating bacterial concentration of logCC 5.96 for PA14 and logCC 5.78 for PA-C3 respectively, the viability of PA14 rapidly declined to be undetectable with logCC of <2.00 while PA-C3 logCC of 4.45 at 8 hours. Although PA14 and PA-C3 both showed decline in viability, their respective logCCs within the first 24 hours remained significantly different shown by Δlog range of 1.00-2.45 between the two strains. Staining microscopy showed a similar range based on the presence of bacteria, but host cell disintegration started visually recognizable at 24 hours and rapidly thereafter.**Conclusion:** PA-C3 is more tolerant to host immunity shown by its less affected viability *ex vivo* in cultures containing human whole blood materials in the first 24 hours. In contrast to CF *Pa*, wild type PA14 can be rapidly cleared by host blood materials in the first 24h when host cellular materials remain relatively intact. The characteristic tolerance to host clearance of auxotrophic PA-C3 is reflective of symbiotic changes selected long-term within a localized host environment.

The Therapeutic Potential of Dnase I in the Treatment of Acute Infective Endocarditis Caused by *Staphylococcus aureus*

Author Block:

H. Chi-Chieh, Chiau-Jing Jung, Jean-San Chia; Oral Biology, Taipei, Taiwan

Abstract Body:

Background: *Staphylococcus aureus* is the most common etiologic agent of acute infectious endocarditis (IE), which is a bacterial infection on the damaged or prosthetic heart valves . Pathologically, IE is featured by the presence of vegetation on the injured heart valve, which is composed of bacteria biofilm and platelet-fibrin complex. Our previous results showed that neutrophil extracellular traps (NETs) induced by bacteria-platelet interaction promote the vegetation formation and digestion of NETs with DNase I prevents vegetation expansion in the streptococcal experimental infectious endocarditis rat model. However the effect of DNase I in *S. aureus*-induced acute IE is unknown. **Method and results:** In *S. aureus*-induced experimental IE rat model, we found microaggregates of bacteria form biofilms with NETs, platelets and fibrins inside the vegetation, which is distinct from what we observed in streptococcal experimental IE rat model. However, DNase I could also significantly decrease bacteremia and the spread of bacteria, and prevent vegetation formation in the rat with acute experimental IE caused by *S. aureus*. **Conclusion:** The underlying mechanism of the pathogenesis of acute IE caused by *S. aureus* is quite different with chronic IE caused by oral streptococci, and DNase I is a potentially new therapeutic approach in the controlling of IE.

Variable Virulence in Mice of O26:H11 *Escherichia coli* Strains That Encode Stx2d and Intimin

Author Block:

E. Trojnar[1], C. Petro[1], P. Mariani-Kurkdjian[2], A. O'Brien[1], **A. R. Melton-Celsa**[1]; [1]USUHS, Bethesda, MD, [2]Hôpital Robert Debré, Paris, France

Abstract Body:

Background: Shiga toxin (Stx)-producing *E. coli* (STEC) strains can cause diarrhea-associated disease outbreaks and, potentially, the life-threatening sequela of infection called the hemolytic uremic syndrome (HUS). There are two major types of Stx, Stx1 and Stx2, which are typically encoded within inducible lysogenic bacteriophages. In a recent publicaion, several HUS-associated O26:H11 STEC isolates from France were characterized. Some of those strains were reported to encode an intestinal mucus-activated Stx2 subtype called Stx2d and the adhesin intimin. In this study, we evaluated the virulence in mice of six of those clinical isolates.**Methods:** The activation capacity or inducubility of the toxin produced by the strains was measured on Vero cells after incubation with mouse intestinal mucus at a concentration of 1 mg/ml or with 0-15 ng/mL ciprofloxacin (Cip). *In vivo* studies were done in streptomycin (Str)- or Str- and Cip-treated male BALB/c mice.**Results:** *In vitro* the Stx2d from all strains showed similar levels of cytotoxicity and degrees of activatability. However, the capacity of the toxin to be induced by Cip from the different O26:H11 isolates ranged from 0- to 600-fold. Although all of the clinical isolates came from patients with the HUS, we observed significant differences in mouse virulence: two strains caused lethality with or without Cip treatment of the mice, two caused disease only when the animals were treated with Cip, and finally, for two isolates, we only observed slight weight loss or mortality regardless of whether the mice were treated with Cip or not.**Conclusion:** Our study highlights the difference in the mouse pathogenicity of six O26:H11 STEC clinical isolates that make Stx2d. We hypothesize that the virulence differences among the strains might be associated with variable toxin induction by Cip and *in vivo* Stx2d levels. The fact that some of these strains only caused mortality when induced by Cip underscores the importance of not treating STEC-associated diarrhea with an antibiotic that can induce toxin expression.

Novel Importer Proteins AliC and AliD Enhance Virulence of Nonencapsulated *Streptococcus pneumoniae*

Author Block:

J. L. Bradshaw, H. R. Pipkins, L. E. Keller, L. S. McDaniel; Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract Body:

Nonencapsulated *Streptococcus pneumoniae* (NESp) is an emerging pathogen that colonizes the human nasopharynx and has been associated with noninvasive disease such as otitis media (OM) and pneumonia. Expression of the polysaccharide capsule is thought to be required to establish invasive bacteremia and meningitis; thus, current vaccines target the capsule of invasive serotypes. Surprisingly, recent surveillance of invasive pneumococcal disease (IPD) isolates has correlated NESp expressing oligopeptide permeases AliC and AliD with IPD cases. Our study investigates the impact of AliC and AliD on virulence of emerging NESp. MNZ85 and MNZ41 are NESp carriage isolates that express AliC and AliD. Isogenic deletion mutants of *aliC* and *aliD* were created in MNZ85 and MNZ41. Pneumococcal adhesion and invasion of human epithelial cells was assessed utilizing Detroit 562 pharyngeal and A549 pulmonary cells. In vitro assays examining biofilm production and pneumolysin expression were also performed. Pneumococcal colonization was examined in a mouse model following intranasal challenge. Additionally, virulence during an OM infection was investigated in a chinchilla model, and bacterial survival within chinchilla whole blood was quantified in an in vitro assay. The deposition of host immune complement factor, C3b, on the bacterial surface was also measured. Significant differences in epithelial cell adhesion and invasion varied among bacterial strains and epithelial cell lines. Biofilm viability and production increased in deletion mutants, but pneumolysin expression significantly decreased when AliC or AliD was absent. The expression of AliC and AliD enhanced murine nasopharyngeal colonization and was required for OM in a chinchilla model. Furthermore, a deletion of AliC or AliD drastically reduced NESp survival in chinchilla whole blood. Depostion of C3b on the bacterial surface diminished when AliC and AliD were present. Altogether, our data demonstrates that virulence of NESp is enhanced by the presence of AliC and AliD and gives insight as to how relatively avirulent NESp are associated with IPD. Further characterization of NESp virulence mechanisms is becoming more essential as vaccine efforts continue to result in rising NESp isolations.

Expression of the Nonencapsulated Virulence Protein PspK in Encapsulated *Streptococcus pneumoniae*

Author Block:

H. R. Pipkins, L. E. Keller, J. L. Bradshaw, L. S. McDaniel; Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract Body:

Streptococcus pneumoniae colonizes the human nasopharynx and can cause a wide range of diseases. Most pneumococcal infections are associated with encapsulated pneumococci, making the capsular polysaccharide the target of licensed pneumococcal vaccines. This selective pressure is causing an increased distribution of non-vaccine serotypes, including nonencapsulated *S. pneumoniae* (NESp). A subset of NESp express pneumococcal surface protein K (PspK). We have shown that PspK increases nasopharyngeal colonization, which is required for disease to occur. Due to the natural competence of pneumococci, we predict encapsulated strains could obtain NESp virulence genes. Acquisition of these genes could produce novel, more virulent strains, thus leading to an increase in pneumococcal disease. Therefore, the purpose of our study was to assess the effects of PspK expression in encapsulated pneumococci. An ectopic plasmid expressing PspK was used to generate $PspK^+$ strains of encapsulated pneumococci D39, EF3030, WU2, and TIGR4, serotypes 2, 19F, 3, and 4, respectively. We also developed capsule deletion mutants (Δcap) of each strain via allelic replacement and transformed those mutants with the $PspK^+$ plasmid. We then examined the adhesion and invasion of these strains to human pharyngeal or lung epithelial cells. To determine effects in vivo, we used a mouse model of nasopharyngeal colonization and a chinchilla model of otitis media (OM). PspK expression significantly increased EF3030 and D39 adhesion and invasion of lung cells. WU2 adhesion to pharyngeal cells was also increased, while TIGR4 and D39 pharyngeal adhesion was not significantly altered by PspK expression. In vitro adhesion/invasion results for the Δcap mutants varied. PspK expression did increase murine colonization of the Δcap mutants, but did not alter murine colonization of the encapsulated strains. Expression of PspK increased CFU recovered from our TIGR4 OM model as well. Although PspK expression does increase cellular adhesion of encapsulated pneumococci in vitro, we conclude that it does not increase murine nasopharyngeal colonization in these strains. However, PspK expression does in part compensate for loss of virulence by Δcap mutants in a mouse model. Thus, NESp virulence factor PspK may have a strain dependent impact on pneumococcal virulence.

Copper at Host-pathogen Interface During Urinary Tract Infection

Author Block:

S. Subashchandrabose; Wake Forest Sch. of Med., Winston-Salem, NC

Abstract Body:

Urinary tract infection (UTI) caused by uropathogenic *Escherichia coli* (UPEC) is one of the most common bacterial infection in humans. Recently, we established the transcriptional profile of UPEC clinical isolates *in vivo* (UPEC RNA isolated from UTI urine sample) and *in vitro* (cultured in urine from healthy volunteers and in LB), using RNA-seq. UPEC genes involved in copper detoxification (*cop*, *cus*, and *cue*) were found to be specifically up-regulated during human UTI. We further demonstrated that: (i) urine Cu content in patients with UTI is higher than healthy subjects; (ii) UPEC undergoes Cu stress during colonization of the human urinary tract; (iii) In mice, UPEC mutants lacking a Cu efflux system are attenuated compared to the parental strain; and (iv) oral Cu supplementation reduces bladder colonization by UPEC in mice. However, the mechanism of copper mobilization to urine remains unknown and is the major question addressed here. Ceruloplasmin is the predominant copper-binding protein in mammals. Therefore, we hypothesized that ceruloplasmin is the source of copper in urine. Urine samples from UTI patients and healthy volunteers were collected and analyzed by Western blotting to detect the presence of ceruloplasmin. Our results indicate that ceruloplasmin is present only in UTI urine samples but not in urine from healthy volunteers. Addition of copper or purified ceruloplasmin to urine from healthy volunteers results in up-regulation of UPEC copper efflux genes, similar to that observed during human UTI. This observation indicates that increased Cu efflux gene expression in UPEC during UTI is a specific response to the presence of copper and ceruloplasmin. Currently, we are investigating the role of UPEC *cop* copper efflux system on the pathogenesis of UTI in a mouse model of infection. In summary, we present evidence for the molecular source of copper found in urine during UTI. Our findings shed new light on the host-pathogen interaction during bacterial UTI.

Study of the Virulence Induced by T3ss and T6ss in *Bordetella bronchiseptica*

Author Block:

M. Cartelle Gestal, K. Dewan, E. Harvill; Univ. of Georgia, Athens, GA

Abstract Body:

Background:*Bordetella* spp. Include important emerging pathogens which infect humans, as well as domestic and wild animals. *B. bronchiseptica* has the widest host range providing researchers a reliable model for the study of *Bordetella spp*. Previous studies have described virulence factors in *Bordetella* spp. but knowledge of their regulation and contributions to virulence remain limited.In order to understand the virulence factors and their regulations, the aim of this study is to explore the role of T3SS and T6SS secretion systems in interactions with the host.**Methods:**The strains used in this study are; RB50 (wild type *B. bronchiseptica*), RB50ΔbscN (a T3SS knock out mutant), RB50ΔclpV (a T6SS knock out mutant) and RB50ΔbscNΔclpV (a double knock out mutant missing both T3SS and T6SS). Mutants were created by allelic exchange. Secreted proteins were precipitated with 21% ammonium sulphate. Cytotoxicity assays were performed using mouse macrophages (264.7 Raw cells).**Results:**Significant differences in the secreted proteins were observed between the wild-type and the three mutant strains. Proteins well expressed in the wild-type were found to be under-expressed in the knock-out mutants (figure 1). These results indicate that T3SS and T6SS play a major role in the protein expression profile in *B. bronchiseptica*.Cytotoxicity assays revealed that the single mutants RB50ΔbscN and RB50ΔclpV showed decreased cytotoxicity in comparison to the wild-type strain RB50 while cytotoxicity of the T3SS/T6SS double mutant was considerably increased.**Conclusions:**The greater cytotoxicity of the double mutant, relative to single mutants and wild type, suggests that with the removal of both secretion systems an alternative virulence pathway is activated in this strain.

***Leptospira interrogans* Promotes a Decrease in Antithrombin III and Prothrombin Serum Levels**

Author Block:

L. G. Fernandes[1], A. F. Filho[2], G. Souza[2], S. Vasconcellos[2], E. Romero[3], A. L. Nascimento[1]; [1]Inst. Butantan, São Paulo, Brazil, [2]Univ. of São Paulo, São Paulo, Brazil, [3]Inst. Adolfo Lutz, São Paulo, Brazil

Abstract Body:

Background: Pathogenic bacteria of the genus *Leptospira* are the causative agent of leptospirosis, an emergent infectious disease that affects human and animals worldwide. Severe forms of the disease in humans include jaundice, multiple organ failure and intense hemorrhage. Up to now, mechanisms associated with the hemorrhage foci are yet poorly understood. The relevance of the interaction between coagulation and inflammation in response to severe infection is becoming increasingly clear. Acute inflammation due to a severe infection or trauma results in a systemic activation of coagulation. **Methods:** Thrombin inhibitors and prothrombin levels in human serum samples were evaluated by clotting assays and western blotting. The binding of different leptospiral strains to antithrombin was performed by western blotting. The activation of coagulation (consumption of inhibitors and factors) was validated in hamster model of infection. **Results:** Despite the low levels of antithrombin III in convalescent human serum samples, virulent, culture-attenuated and saprophyte strains of *Leptospira*, are unable to bind and/or degrade this thrombin inhibitor, suggesting an indirect mechanism of pathogenesis. Lower levels of prothrombin were found in serum samples at the onset and convalescent phase of the disease when compared to normal human sera. The concomitant decrease level of antithrombin III and prothrombin suggests a process of stimulated coagulation, which is corroborated by the increase of prothrombin fragment F1+2in the serum samples. The data obtained with hamsters experimentally infected strongly point out that hemorrhage is correlated with decreased levels of thrombin inhibitors and prothrombin. **Conclusion:** Inflammation elicited by leptospires could induce an activation of coagulation, which leads to a diffuse and systemic clot formation and exhaustion of coagulation factors, and subsequently hemorrhage.

Establishment of Pathogenic *Leptospira* Infection via One of the Natural Modes of Transmission, the Transdermal Route

Author Block:

N. NAIR[1], L. Richer[2], M. Gomes-Solecki[1]; [1]Univ. of Tennessee Hlth.Sci. Ctr., Memphis, TN, [2]Immuno Technologies Inc., Memphis, TN

Abstract Body:

Leptospirosis is caused by spirochetal bacteria of the genus *Leptospira* and is a major zoonotic disease infecting humans through contaminated water, soil and food sources. Rodents are the major reservoir for this bacterium, which colonizes the kidney and is shed in urine. According to WHO and CDC, direct contact of the contaminated source with mucosal membranes of the body, or abrasions on the skin, are the entry ports for infection. Hence understanding the natural mode of transmission is critical. In this study we aim to address this issue by studying one of the natural modes of transmission, the transdermal route.We experimentally infected C3H/HeJ mice with 10^8 CFU of *Leptospira interrogans* serovar Copenhageni by generating a transdermal wound on the dorsal skin of the mouse. Sterile 1xPBS was applied to the wound control group. Untreated mice were included as naïve controls. Body temperature and weight were monitored for 15 days post infection (dpi). Urine and blood samples were collected to determine bacterial load using quantitative PCR (qPCR). Upon euthanasia, kidney, lung and liver were excised to determine cytokine induction. Histopathology of kidney was performed using PAS staining. Antibody production (total as well as *Leptospira* specific) was determined from sera.There was significant hypothermia and loss of weight observed from 12 to 15 dpi. Data from blood qPCR revealed dissemination of *Leptospira* ($4x10^5$ bacterium/microliter blood) from day 6 until day 12 post-infection. Urine qPCR data indicated high *Leptospira* shedding, ($1x10^6$ spirochete/microliter) from day 10 onwards. Histopathological analysis revealed extensive damage to renal corpuscles, which is consistent with the amount of *Leptospira* detected in the kidney. There was significant induction of *Leptospira* specific IgM and IgG and of TNFa, IFNg, IL1b, MIP-2, RANTES, KC, and IL10 cytokines, suggesting pathogen induced inflammation.Our study shows that transdermal route of *Leptospira* infection is an efficient model for studying a natural mode of disease transmission and establishment of infection.

Polyamine Transport in Pneumococci: A Proteomics Perspective

Author Block:

A. N. Rai[1], L. A. Shack[1], E. Swiatlo[2], B. Nanduri[1]; [1]Mississippi Stat Univ., Mississippi State, MS, [2]Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract Body:

Background: *Streptococcus pneumoniae* is the most common bacterial etiology of community-acquired pneumonia, bacterial meningitis and otitis media worldwide. Genomic plasticity, antibiotic resistance and extreme capsular antigenic variation complicates the design of effective therapeutic strategies. Polyamines such as putrescine, spermidine and cadaverine are essential for pneumococcal virulence. Stringent regulation of intracellular concentration of polyamines in bacteria is controlled by transport and biosynthesis. In pneumococcus, the polyamine transport operon, *potABCD* is highly conserved across different serotypes. We previously showed that a polyamine transporter mutant (*ΔpotABCD*) of *S.pneumoniae* TIGR4 could not survive in the lung tissue in a mouse model of pneumonia. Since polyamines have profound effects on protein expression, we performed expression proteomics to delineate the pneumococcal virulence factors regulated by polyamines. **Methods:** Here, we compared protein expression between the wild-type and *ΔpotABCD* in TIGR4 strain by 1D LC ESI MS/MS. Expression proteomics was validated by western analysis. **Results:** Our results show that the expression of pneumococcal proteins such as choline binding protein A (PcpA), choline binding protein E (CbpE), oligopeptide transport system permease protein (AmiC) and glycosyltransferase (Gtf1) increased in response to genetic deletion of polyamine transport system. In addition, capsular polysaccharide biosynthesis protein (Cps4F), pneumolysin (Ply), iron-compound ABC transporter (Sp_1032), oligopeptide-binding protein (AmiA), and aspartate-semialdehyde dehydrogenase (Asd) showed reduction in expression in response to deletion of transport operon. **Conclusion:** Here, we conclude that the failure of *ΔpotABCD* to establish infection in mice is due to reduced expression of critical pneumococcal virulence factors such as Ply and Cps4F to name a few. A thorough functional characterization of proteins responsive to altered polyamine metabolism can help develop intervention strategies against pneumococci.

Identification and Regulatory Characteristics of *Vibrio vulnificus plp* Encoding a Phospholipase Essential for Pathogenesis

Author Block:

K. Jang, Z-W. Lee, S. Choi; Natl. Res. Lab. of Molecular Microbiol. and Toxicology, Dept. of Agricultural Biotechnology, Ctr. for Food Safety and Toxicology, and Res. Inst. for Agriculture and Life Sci., Seoul Natl. Univ., 08826, Seoul, Korea, Republic of

Abstract Body:

Mucin glycoprotein is a major component of mucus layer that is the major site of entry for enteric pathogens including *Vibrio vulnificus* and serves as the initiation surfaces for host-microbe interactions. To identify *V. vulnificus* genes induced by mucin, transcriptomes of *V. vulnificus* cells grown with mucin-containing media or exposed to the mucin-secreting HT-29 MTX cells were analyzed using RNA-seq. Among the genes specifically induced by exposure to mucin and mucin-secreting host cells, a gene, annotated as *plp* encoding a putative phospholipase Plp, was identified and further characterized. The amino acid sequences of *V. vulnificus* Plp (*Vv*Plp) were 67% identical to those of *Vibrio anguillarum* phospholipase (*Va*Plp). To examine the role of *Vv*Plp, a mutant with disruption of the *plp* gene was constructed by allelic exchanges, and its virulence was evaluated. Compared with the wild type, the *plp* mutant showed a low level of cytotoxicity toward the HT-29 MTX cells and reduced virulence in mice. The *plp* mutant exhibited significantly lower phospholipase activity that the wild type in the egg yolk emulsion plate, implying that *Vv*Plp contributes to the lipolytic activity of the pathogen and thereby is essential for the pathogenesis. Examination of global regulatory proteins on the expression of *plp* revealed that the transcription activator HlyU and cyclic AMP receptor protein (CRP) upregulate the *plp* expression. The cellular levels of HlyU and CRP were not significantly affected by one another, indicating that the regulator proteins function cooperatively to activate *plp* rather than sequentially in a regulatory cascade. The regulatory proteins directly bind to the upstream of the *plp* promoter P_{plp}. DNase I protection assays, together with the deletion analyses of P_{plp}, demonstrated that HlyU binds to three specific sequences centered at -174, -141.5, and -109.5, and CRP binds specifically to the sequences centered at -68. Consequently, the combined results indicated that *V. vulnificus plp* encodes a phospholipase essential for virulence and is cooperatively regulated by HlyU and CRP.

Genome-wide Identification of Genes Required During Bloodstream Infection in Multi-drug Resistant *Acinetobacter baumannii*

Author Block:

S. Crepin, S. Smith, H. L. T. Mobley; Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract Body:

Acinetobacter baumannii, an opportunistic gram-negative bacterium, is rapidly emerging as a leading nosocomial pathogen, particularly among immunocompromised individuals and for patients in intensive care units. *A. baumannii* can infect a wide range of anatomic sites including the respiratory tract, the bloodstream, and wounds. Its long-term persistence on abiotic surfaces and resistance to disinfectants and antibiotics exacerbate the potential of this bacterium as a nosocomial pathogen. However, despite its clinical importance, relatively little is known about the molecular basis of *A. baumannii* pathogenesis. To address this, we constructed a transposon library of 50,000 mutants in the multi-drug resistant strain AB0057 and we performed transposon-directed insertion-site sequencing (TraDIS) experiments to identify mutants with fitness defects in the neutropenic mouse model of bloodstream infection. By comparing relative abundance of insertion sites within the genome in the inoculum and post-infection libraries, we identified a total of 1428 genes and 29 intergenic regions showing a fitness defect of at least 2-fold. By performing a Clusters of Orthologous Groups (COGs) analysis of the fitness factors, the most representative categories were amino acids transport and metabolism, transcription factors and cell wall, cell membrane, and envelope biogenesis categories. To confirm the TraDIS results, genetically defined mutants were constructed. Mutants in fimbriae, secretion systems, c-di-GMP metabolism genes and lytic murein transglycosylases exhibited a fitness defect in the murine spleens and livers. Work is in progress to define the molecular mechanisms of pathogenesis that involve these genes. In summary, using high-throughput screen and targeted mutations, we identified the complete set of genes required for *A. baumannii* infection of the bloodstream. These results represent a major step towards understanding the pathogenesis of *A. baumannii* and will allow us to formulate strategies to manage or prevent *A. baumannii* infections.

Iscr-Mediated Control Of The Hmurstuv Hemin Uptake System In *yersinia Pseudotuberculosis*

Author Block:

L. Schwiesow, H. Miller, 95060, J. Dreiling, N. Herrera, D. Balderas, V. Auerbuch; Univ. of California, Santa Cruz, Santa Cruz, CA

Abstract Body:

The HmuRSTUV hemin uptake system allows *Yersinia* species to uptake and utilize hemoproteins as a source of iron. However, excess heme is toxic and several bacterial heme tolerance mechanisms have been discovered. HmuR is a TonB-dependent outer membrane receptor for heme and hemoproteins. HmuS is thought to be involved in heme tolerance, while HmuTUV comprise a hemin ABC transporter, which transports heme and hemoproteins from the periplasmic space into the bacterial cytoplasm. Our lab previously demonstrated that the human gut pathogen *Yersinia pseudotuberculosis* requires the iron-sulfur cluster-containing global transcriptional regulator IscR to cause disease. Our initial transcriptome analysis revealed that IscR was important for controlling expression of *hmuSTUV*, but not *hmuR*. We hypothesized that IscR controls *hmuSTUV* independently of *hmuR*, perhaps to mitigate heme toxicity under certain conditions *in vivo*. Through use of transcriptional reporters, we show that IscR drives expression of *hmuSTUV* from an intergenic region between *hmuR* and *hmuS*, but cannot drive expression of the promoter upstream of *hmuR*. In addition, we demonstrate that a *Y. pseudotuberculosis* Δ*iscR* mutant has a survival defect when incubated in whole blood, but that overexpression of *hmuSTUV* in the Δ*iscR* genetic background restores this defect. Furthermore, overexpression of *hmuR* in the context of WT *iscR* decreases survival in whole blood. Considering that hemoproteins are a main source of iron in blood, these results suggest that IscR controls expression of *hmuSTUV* to allow for the detoxification of heme brought into the cell by HmuR and indicates that IscR may be important for *Yersinia* growth in blood during disseminated infection.

Co-Regulation of *Xanthomonas campestris* Iron Homeostasis, Chemotaxis, and Motility by Accessible Iron and a Novel Iron-Responsive Transcriptional Regulator XibR

Author Block:

S. S. Pandey, P. K. Patnana, S. Chatterjee; Ctr. for DNA Fingerprinting and Diagnostics, Hyderabad, India

Abstract Body:

Cellular iron homeostasis of pathogenic bacteria is crucial for survival, growth and proliferation inside the hosts to develop infections (1). Regulation of iron uptake/metabolism associated factors is poorly understood in plant bacterial pathogens. In *Xanthomonas*, Fur (ferric uptake regulator) is the sole known regulator for siderophore biosynthesis and iron uptake system (2). For the first time, we identified the involvement of a novel iron-responsive NtrC family transcriptional regulator (XibR) in the regulation of iron homeostasis associated functions in *Xanthomonas campestris* pv. *campestris* (Xcc) through a genetic screen for altered siderophore production. Our study revealed that XibR regulates the expression of genes involved in iron uptake/metabolism such as siderophore biosynthesis, iron storage, and ferric iron uptake genes. We found that XibR promotes chemotaxis and motility under the low iron condition in Xcc. In this study, we also reported that XibR-ferric iron complex directly binds to the promoters of *xss* (*Xanthomonas* siderophores synthesis), *mot*, and *flg* operons and regulates the expression differentially depending on availability of iron. We showed that XibR is required for optimal biofilm formation and virulence. XibR positively regulates the expression of biofilm and virulence-associated genes such as pili assembly chaperones, type-II/type-III secretion systems and effectors, *hrp* genes, and certain virulence-associated factors. We also identified the role of Xcc siderophore in infection establishment by promoting survival and growth of bacteria under the low iron environment of the host.

Mechanisms of Differential Virulence between *Streptococcus pneumoniae* and *Streptococcus mitis*

Author Block:

H. E. Marshall[1], F. C. Petersen[2], J. S. Brown[1]; [1]Univ. Coll. London, London, United Kingdom, [2]Univ. of Oslo, Oslo, Norway

Abstract Body:

Streptococcus pneumoniae and *Streptococcus mitis* are naso-oropharyngeal commensals that are genetically similar. However, *S. pneumoniae* is highly pathogenic and a common cause of pneumonia and septicaemia, whereas *S. mitis* rarely causes disease. We hypothesise that differences in sensitivity to innate immunity may underlie these differences in virulence phenotype. We compared sensitivity of *S. pneumoniae* and *S. mitis* to neutrophil killing. After opsonisation with serum but not with heat-treated serum or PBS, *S. mitis* was markedly more sensitive to neutrophil killing compared to *S. pneumoniae*. These differences suggested *S. mitis* was relatively complement sensitive, and flow cytometry assays of C3b/iC3b deposition confirmed there was increased complement opsonisation of *S. mitis* compared to *S. pneumoniae*. *S. pneumoniae* resistance to complement is partially dependent on binding of the immune regulator Factor H by the surface protein, PspC. We investigated Factor H binding to *S. mitis* using flow cytometry. The results demonstrated that there was no significant factor H binding to *S. mitis*. By inserting *pspC* of *S. pneumoniae* into *S. mitis*, we demonstrate that expression of PspC enabled *S. mitis* to then bind Factor H. Investigation of C3b/iC3b confirmed a decrease in opsonisation. Furthermore, survival in whole human blood of this modified strain showed an increase, when compared to the wild-type strain. These results suggest that an inability to bind factor H might underpin *S. mitis* sensitivity to opsonisation with complement and neutrophil killing compared to *S. pneumoniae*, and therefore contribute to the differences in virulence between these two commensal species.

Production of Shiga Toxin Type 1 (Stx1a) Attenuates the Virulence in a Mouse Model of an O26:H11 *Escherichia coli* Strain That Makes Stx1a and Stx2a

Author Block:

C. D. Petro, E. Trojnar, A. Melton-Celsa, A. O'Brien; Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD

Abstract Body:

Background: Stx-producing *E. coli* (STEC) cause food-borne outbreaks of diarrhea. The two major types of Stx produced by STEC are Stx1a and Stx2a. Although Stx1a is more toxic than Stx2a to Vero cells, Stx2a is more potent than Stx1a in mice. In addition, STEC strains that produce only Stx2a are more commonly linked to a serious sequela of disease, the hemolytic uremic syndrome (HUS), than isolates that make Stx1a or both Stx1a and Stx2a. In this study, we evaluated the virulence of an O26:H11 isolate that produces both Stx1a and Stx2a in a mouse model and determined the effect of passive immunization of the mice with neutralizing antibodies to either or both toxins.**Methods:** A clinical isolate of O26:H11 (stx_{1a}+, stx_{2a}+) was used for these studies. The level of cytotoxicity and degree of inducibility of toxin expression by the strain was measured on Vero cells without or with 15 ng/mL ciprofloxacin (Cip). *In vivo* studies were done in streptomycin (Str, 5g/L in drinking water)- or Str- and Cip- (5 ug/mouse administered by intraperitoneal injection) treated male BALB/c mice. Passive immunization of mice with antibodies against Stx1 or Stx2 was done by tail-vein or intraperitoneal injection.**Results:** *In vitro* toxin production was induced 10-fold from an overnight culture of bacteria grown in Luria Bertani broth supplemented with Cip. In the mouse model, Cip-treatment was required for the O26:H11 isolate to cause weight loss and mortality. Administration of neutralizing antibody against Stx2 to the Str- and Cip-treated and infected mice was protective. However, unexpectedly, when infected mice treated only with Str were given antibody to Stx1, weight loss and mortality was observed (in the absence of Cip).**Conclusions:** Our study shows that pathogenicity in a mouse model for this clinical O26:H11 isolate required Cip administration, most likely due to induction of toxin expression *in vivo*. However, when Stx1a was neutralized the strain became virulent in the absence of Cip, a finding that suggests Stx1a attenuates pathogenicity of this Stx1a+ Stx2a+ O26:H11 strain in mice. We hypothesize that in strains that produce both Stx1a and Stx2a, Stx1a functions to reduce the toxic effects of Stx2a.

Comparison of Virulence Factors between Mdr and Mds *Pseudomonas aeruginosa* Strains

Author Block:

K. Suzuki[1], Y. Mano[1], Y. Nozawa[1], C. Otsuka[1], S. Ishikawa[1], S. Ohtani[1], Y. Shiotani[1], H. Takoi[2], K. Fujita[2], Y. Saito[2], A. Gemma[2], N. Furuya[1]; [1]Bunkyo Gakuin Univ., Tokyo, Japan, [2]Nippon Med. Sch., Tokyo, Japan

Abstract Body:

Background: *Pseudomonas aeruginosa* is a major source of nosocomial infections, and the emergence of multidrug-resistant (MDR) *P. aeruginosa* is a serious problem in many countries. *P. aeruginosa* synthesizes several extracellular products which can act as virulence factors, possesses the flagellum and pili which mediate bacterial surface translocations known as motilities. In order to further clarify the association between magnitude of multidrug-resistance and its effect on *P. aeruginosa* virulence factors, we here compared the production of extracellular products, the bacterial motilities, between MDR *P. aeruginosa* and multidrug-sensitive (MDS) *P. aeruginosa*.**Methods:** Fourteen clinical *P. aeruginosa* strains were used in this study; 7 strains were MDR *P. aeruginosa* and 7 were MDS *P. aeruginosa*. Strains resistant to imipenem (MIC≧16μg/mL), amikacin (MIC≧32μg/mL), and ciprofloxacin (MIC≧4μg/mL) were defined as MDR *P. aeruginosa*, and strains sensitive to all these drugs were defined as MDS *P. aeruginosa*. Elastase and total protease activities, representatives of virulence factors, were determined using the elastin Congo red (Sigma) assay and the Remazol Brilliant Blue-Hide (Sigma) assay, respectively. Motilities of swimming, swarming and twitching were assessed using plate-based assay.**Results:** All mean values for production of elastase and total protease in MDR *P. aeruginosa* strains were significantly smaller than those in MDS *P. aeruginosa*. Mean spreading zones for swimming, swarming and twitching motilities in MDR *P. aeruginosa* strains were significantly smaller than those in MDS *P. aeruginosa* strains. Particularly significant difference was observed in twitching. The average (19.2mm) and median values (14.0mm) for the amounts of twitching in MDR *P. aeruginosa* strains were significantly greater than those (average 31.2mm; median 35.0mm) in MDS *P. aeruginosa* strains ($P<0.005$).**Conclusions:** Overall, this study demonstrates that the extent of multi-resistance in *P. aeruginosa* strains relates to the increase in amounts of the decrease in bacterial motilities, and the decrease in production of elastase and total protease.

***Borrelia burgdorferi* Bb059 Is a Virulence Factor Important for the Development of Lyme Arthritis**

Author Block:

x. xiang, T. Lin, S. Carrasco; Indianapolis Univ. Sch. of Med., Indianapolis, IN

Abstract Body:

Lyme disease is the most commonly reported arthropod-borne infectious disease in the United States and Europe. The causative agent, *Borrelia burgdorferi*, infects humans via tick bites. Lyme arthritis is the major clinical symptoms infected with *B. burgdorferi* in North America. Little is known about the factors in *B. burgdorferi* contributing to the development of Lyme arthritis. In effort to identify virulence factors of *B. burgdorferi*, we have been focusing on putative hemolysin genes predicted in the *B. burgdorferi* genome. One such gene is BB0059, which has homology to hemolysin C of other bacteria. To study the function of BB059 in the infectious cycle of *B. burgdorferi*, we generated a *bb0059* mutant (*bb0059mut*). We found that *bb0059mut* had reduced infectivity in C3H/HeN mice. Furthermore, *bb0059mut* could establish infection in immunocompromised SCID mice, but it could not trigger Lyme arthritis. These data suggest that BB0059 is a new *B. burgdorferi* virulence factor important for mammalian infection and for the development of Lyme arthritis. Further investigation will focus on elucidation of the mechanism of action of BB0059 that leads to the defect in infection and Lyme arthritis.

Detection Of The Spi-2 Type Iii Secretion System Needle And Rod Proteins By Mouse Naips

Author Block:

C. Vientos, E. A. Miao; Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract Body:

Type III secretion systems (T3SSs) are hollow, multiprotein molecular syringes that function to inject effector proteins, orchestrators of host signal modulation, into eukaryotic cells. Many Gram-negative bacterial pathogens encode a set of conserved, virulence genes that collaborate to construct this apparatus; however, *Salmonella typhimurium* possesses two pathogenicity islands (SPI-1 and SPI-2) that produce similar machines used at different points of infection. Host cells are equipped with Nod-like receptors (NLRs), as a defense mechanism, to survey the cytosol, and upon recognition of their cognate ligand, activate an innate immune pathway involving NLRC4 and caspase-1. Accidental injection of SPI-1 components, needle (PrgI) and rod (PrgJ) monomers, have been shown to activate NAIP 1 and 2. Here we further characterize the detection of the SPI-1 and SPI-2 rod and needle proteins by the NAIPs. We use a retroviral lethality screen with bone marrow derived macrophages of varying genotypes and transfections of purified protein. Our results will help lineate the complex nature of detection and evasion of inflammasomes by the *Salmonella* T3SSs.

Studying the Response of Alveolar Epithelial Cells in a Three-Dimensional Tissue-Equivalent Respiratory Model to Influenza A Virus Infections

Author Block:

R. Bhowmick, H. Gappa-Fahlenkamp; Oklahoma State Univ., Stillwater, OK

Abstract Body:

Influenza A virus (IAV) is the major agent for primary viral pneumonia and claims approximately 250,000 to 500,000 lives annually worldwide. Pathogenic IAV strains dysregulate cytokines in the lung alveoli, leading to a "cytokine storm", which results in a robust macrophage recruitment into the alveolar spaces. Currently, there are only a few *in vitro* models available for the study of alveolar immune responses during IAV infections. Monolayers of cultured cells (two-dimensional cell culture) is the most commonly used tool, however, this system does not recapitulate the *in vivo* pulmonary physiology, which requires intercellular communication occurring within a three-dimensional (3D) environment. Therefore, to study the immune responses of infected alveolar epithelial cells (AECs), macrophages and the transmigrating antigen presenting cell (APC) precursors, we have developed a novel tissue-equivalent respiratory model (TERM). The TERM is comprised of a 3D collagen-chitosan porous scaffold, seeded with human small alveolar epithelial cells (hSAECs). The hSAECs were maintained at an air-liquid interface (ALI) and were infected with either the highly pathogenic H1N1 or the mildly pathogenic H3N2 strains of IAV. Uninfected cells were included as controls. After infection, cytokine content in the conditioned media and the marker protein expression in the infected cells were measured. Our results show that H1N1 infections lead to a massive increase in cytokine expression of the hSAECs in the TERM. H1N1 infections also lead to a significant change in marker proteins in the hSAECs, while H3N2 infections did not result in a marked change in such marker proteins. The infected phenotype of hSAECs cultured in the TERM more closely resembled *in vivo* observations. Future work includes using the TERM to identify the key mechanisms associated with the ability of pathogenic strains of the influenza virus to attract and differentiate lung cells to a highly inflammatory phenotype. These mechanisms will provide new targets for preventative and therapeutic interventions of influenza infection that will be tested in the TERM.

Cytomegalovirus Blocks the Development of Inflammation Anergy in Intestinal Macrophages by Enhancing Myd88-Dependent Nf-κB Signal Transduction

Author Block:

E. A. Dennis, L. Smythies, M. Shimamura, W. Britt, P. Smith; Univ. of Alabama at Birmingham, Birmingham, AL

Abstract Body:

Background: Healthy intestinal lamina propria macrophages (LpMs) are profoundly down-regulated for cytokine production (inflammation anergy) which is the consequence of near-absent MyD88 expression and dysregulated down-stream NF-κB signaling. Paradoxically, in the setting of cytomegalovirus (CMV) mucosal infection, LpMs are markedly pro-inflammatory, most notably in persons with compromised immune function. **Methods:** We investigated the mechanism whereby macrophages are non-inflammatory in normal mucosa but pro-inflammatory in CMV mucosal disease using primary human LpMs, peripheral blood monocytes, and a clinical isolate of human CMV (TR). CMV infection and replication was assessed in cells by confocal and RT-PCR. Inflammation anergy in macrophages was determined by stimulating cells with TLR4/5 ligands, then measuring cytokine (IL-6, TNF-α, IL-8 or IL-1β) production with ELISA and/or RT-PCR. NF-κB signal pathway intermediates (MyD88, TRAF6, p-IκB-α, p-NF-κB) were measured by ELISA, Western Blot and/or RT-PCR. **Results:** CMV-infection of primary LpMs did not enhance cytokine production in response to TLR4/5 ligation compared to mock-infected LpMs, suggesting that CMV infection does not reverse inflammation anergy in differentiated LpMs. To investigate whether CMV infection prevents the development of inflammation anergy, we used an *in vitro* model of monocyte-to-LpM differentiation, in which monocytes cultured in de-cellularized normal intestinal stroma differentiate into macrophages nearly identical to primary LpMs. Monocytes infected with CMV prior to differentiation were significantly up-regulated for TLR4/5 ligand-induced cytokine production, resistant to stroma-driven development of inflammation anergy, resistant to stroma-driven MyD88 proteosomal degradation, and were significantly enhanced for NF-κB activation compared to mock-infected monocytes.**Conclusions:** Systemic infection of monocytes by CMV before recruitment into the intestinal mucosa strategically promotes the development of pro-inflammatory rather than inflammation anergic LpMs that are primed by CMV to interact with bacteria through TLR4/5, leading to enhanced MyD88-dependent NF-κB signal transduction and increasing the potential for exacerbated mucosal inflammation.

Human Cytomegalovirus Induces And Sustains Akt Activity Through A Unique Modulation Of Its Regulators To Mediate Monocyte Survival

Author Block:

O. Cojohari, M. A. Peppenelli, G. C. Chan; SUNY Upstate Med. Univ., Syracuse, NY

Abstract Body:

In a primary human cytomegalovirus (HCMV) infection, monocytes are responsible for spreading the virus systemically. However, monocytes have a short lifespan of ~48 hours (h) in the circulation, after which, in the absence of survival stimuli, they naturally undergo apoptosis. We previously showed HCMV manipulates monocytes to survive past this "48h-viability gate". We found that HCMV entry into monocytes induced a rapid activation of Akt (a major pro-survival protein) within 15 minutes post infection (mpi). Pre-treatment with an Akt inhibitor prevented the virus-induced cell survival, suggesting the rapid activation of Akt leads to induction of early monocyte survival. Moreover, inhibition of Akt 24 hpi also resulted in cell death, indicating that sustained Akt activity is required to maintain the viability of infected cells. However, the mechanisms by which HCMV induces and sustains Akt activity remain unknown. We found the virus activated Akt to a greater extent and with different kinetics compared to M-CSF, another myeloid survival factor, suggesting HCMV uses a unique mechanism of regulating Akt. We previously showed that HCMV stimulates PI3K, Akt's main positive regulator. We now identified that of the three PI3K isoforms, HCMV preferentially uses the p110β isoform to both induce and maintain monocyte survival, in contrast to non-infected cells, which use p110δ. However, to maintain high Akt activity, we hypothesized, the virus not only induces Akt's positive regulator, but also must modulate Akt's negative regulators, PTEN and SHIP-1. Indeed, we found HCMV rapidly inactivates PTEN through phosphorylation by 24hpi. Moreover, SHIP-1 inhibition resulted in a decrease in Akt activity rather than an increase, which was restored upon add-back of SHIP-1's product, PIP2, suggesting HCMV somehow uses SHIP-1 as a positive and not a negative regulator of Akt. Overall, our findings uncover a unique mechanism exploited by HCMV to induce and maintain an enhanced activation level of Akt: by inducing PI3K, inhibiting the activity of the negative regulator PTEN, and hijacking the biological function of SHIP-1, reversing it into a positive regulator, which allows monocytes to survive past the critical "48h-viability gate" and effectively disseminate the virus in the body.

Coxsackievirus B3 Containing Muscle-Specific MicroRNA Targets Induces Alleviative Inflammatory Cytokines Expression and T Cell Activation in Mice

Author Block:

F. He, Z. Xiao, Z. Liu, H. Yao, D. Cao, M. Feng, S. OuYang, Y. Li, Z. Liu; Capital Inst. of Pediatrics, Bei Jing, China

Abstract Body:

Background: Incorporation of cognate miRNA target sequences into viral genomes is an effective approach to attenuate viral tropism that has been applied to target several different viruses. In our previous study, CVB3 engineered to contain muscle specific miRNA targets were proved to have an attenuated replication capacity in the heart of mice, and high titer of neutralizing antibody were also induced. However, cellular immunity of mice immunized with engineered CVB3 were not known.**Methods:** In this study, mice were immunized with 10^4 PFU of engineered CVB3, wild-type and UV-inactivated CVB3, mice serum, heart and splenocytes on days 3,5,7,14 post immunization were collected , cytokines expression were detected by using Cytometric Bead Array method, T-cell activation and T-cell subset were detected by using Flow cytometry, histological analysis and T cell infiltration of the heart were also detected.**Results:** IFN-γ and TNF-α were found significantly decreased in the engineered CVB3 group than wild-type group on day 7(1.48±0.20 vs 8.03±4.70 for IFN-γ, 17.41±5.90 vs 40.31±11.05 for TNF-α, $p<0.05$), both cytokines were higher than the UV-inactivated group on day 5 (4.27±2.05 vs 1.36±0.94 for IFN-γ, 30.96±13.78 vs 7.49±5.23 for TNF-α). CD4+T and CD8+T cells in the splenocytes were detected to have a higher percentage than UV-inactivated CVB3 group on days 3(23.95±1.87 vs 17.59±3.53 for CD4+T and 11.25±1.84 vs 8.70±1.34 for CD48+T ,$p<0.05$), activated CD4+CD69+T and CD8+ CD69+T cells were lower than that of CVB3 wild-type group on day 5 (1.15±0.52 vs 3.02±0.70 for CD4+CD69+T and 0.93±0.49 vs 2.05±0.68 for CD8+CD69+T, $p<0.05$). Th1 and Th17 have a lower percentage than CVB3 wild-type group. We also detected histological and CD4+T and CD8+T cells infiltration in the heart of mice, and found that engineered CVB3 induced only minor dropsy and hemorrhage, and CD4+T and CD8+T cells infiltration were also decreased compared with CVB3 wild-type group.**Conclusions:** Overall, our results indicated that engineered CVB3 could induce a mild immune response that may help against the CVB3 infection in the early stage/acute stage, and further support the rationale for using miRNA-targeting approach to develop live attenuate virus vaccines.

Inflammasome Activation By Human Parainfluenza Virus Type 3

Author Block:

N. K. SHIL, S. M. Pokharel, S. Bose; Washington State Univ., Pullman, WA

Abstract Body:

Background: Human parainfluenza virus type 3 (HPIV3) is a RNA virus belonging to the paramyxovirus family that causes airway inflammation resulting in respiratory illness (croup, bronchiolitis and pneumonia) in children, elderly and immune-compromised individuals. Inflammasome activation results in maturation and production of pro-inflammatory cytokine interleukin-1β (IL-1β). Inflammasome is a oligomeric protein platform that cleaves pro-caspase-1 to yield enzymatically active caspase-1. Caspase-1 is involved in cleavage of pro-IL-1β into mature IL-1β. Although several RNA viruses are known to activate inflammasome, its activation status during HPIV3 infection is still unknown. In the current study we investigated whether HPIV3 activates inflammasome following infection of human macrophages. **Methods:** Human macrophage cell line THP-1 and ASC deficient THP-1 cells were infected with HPIV3. THP-1 cells treated with either caspase-1 inhibitor (Ac-YVAD-CHO), reactive oxygen species (ROS) inhibitor (Diphenyleneiodonium Chloride, DPI), and potassium efflux inhibitor (Glibenclamide) were also infected with HPIV3. Inflammasome activation was measured by - a) analyzing IL-1β levels (by ELISA) in the medium supernatant of HPIV3 infected cells, b) detecting cleaved IL-1β (p17 representing mature IL-1β) by Western blotting and c) examining cleaved portion of caspase-1 (p10 representing active caspase-1) by Western blotting. **Results:** Our studies demonstrated that HPIV3 activates ASC-inflammasome. We observed inflammasome activation in THP-1 cells infected with HPIV3. However, drastic reduction in inflammasome activation was noted in ASC deficient THP-1 cells. Inhibition of caspase-1 activation in THP-1 cells also led to loss of inflammasome activation. Inhibiting ROS production by DPI and blocking potassium efflux with Glibenclamide resulted in diminished inflammasome activation following HPIV3 infection. **Conclusion:** Our studies showed that HPIV3 activates ASC inflammasome in human macrophages. Furthermore, ROS and potassium efflux play an important role during HPIV3 mediated inflammasome activation. .

Respiratory Syncytial Virus Activates Tgf-β Signaling In Macrophages And Tgf-β Signaling Is Regulated By S100a9 Protein

Author Block:

S. M. Pokharel, S. Tsai, N. K. Shil, S. Bose; Washington State Univ., Pullman, WA

Abstract Body:

Background: Human respiratory syncytial virus (RSV) is the leading cause of lower respiratory tract infection and infant hospitalization. RSV infection manifest into two inflammatory diseases, pneumonia and bronchiolitis. Transforming growth factor-β (TGF-β) is an important cytokine regulating inflammation. RSV infectivity is regulated by TGF-β in epithelial cells. However, role of TGF-β during RSV infection of immune cells like macrophages is still unknown. Furthermore, activation of TGF-β pathway (i.e. SMAD2/3 pathway) has not been documented during RSV infection. In the current study we investigated whether - a) RSV triggers TGF-β production from macrophages, and b) RSV activates SMAD2/3 pathway in macrophages. Mechanism regulating TGF-β signaling during RSV infection is yet unknown. S100A9 is known to interact with TGF-β. Therefore, we also studied the role of S100A9 if any in regulating TGF-β production and TGF-β signaling following RSV infection. **Methods:** Mouse bone marrow derived macrophages (BMDMs) were infected with RSV. Active TGF-β and S100A9 protein production from infected cells was measured in medium supernatant by using ELISA assay. Cell lysates were used to assess activation of TGF-β pathway by Western blot analysis of phosphorylated SMAD2 (phospho-SMAD2). BMDMs were also treated with S100A9 blocking antibody (S100A9 Ab blocks extracellular S100A9 activity) during RSV infection. TGF-β production and TGF-β pathway activation in these cells were monitored as described above. **Results:** RSV infection of macrophages led to production of TGF-β and S100A9 proteins. RSV activated TGF-β pathway since we detected phospho-SMAD2 in infected cells. Although blocking S100A9 activity did not affect TGF-β production, S100A9 Ab diminished TGF-β signaling during RSV infection. Reduced levels of phospho-SMAD2 was detected in S100A9 Ab treated macrophages. **Conclusions:** Our studies demonstrated that RSV triggers TGF-β production from myeloid cells like macrophages. We also demonstrate for the first time that RSV activates TGF-β signaling (SMAD2/3 signaling) during infection. In addition, we have identified extracellular S100A9 protein as a positive regulator of TGF-β signaling during RSV infection.

P2X Purinergic Receptors Are Key Regulators of HIV-1 Infection and Inflammation

Author Block:

T. H. SWARTZ, M. O'Brien, N. Durham, N. Bhardwaj, B. K. Chen; Icahn Sch. of Med. at Mount Sinai, NEW YORK, NY

Abstract Body:

Background: HIV-1 infection is incurable and causes a chronic inflammation which causes multiple comorbidities, even with virologic suppression. The mechanism of this inflammation is not clearly understood. Purinergic receptors are known to be mediators of inflammatory responses and can contribute to pro-inflammatory cytokine production and lymphocyte cell death. Purinergic receptor signaling is important for HIV-1 infection and we have recently found that inhibition of the P2X subtype purinergic receptors potently blocks HIV-1 productive infection at the level of membrane fusion. This study examines whether virus-induced purinergic signaling is responsible for inflammatory cytokine release during HIV-1 infection.**Methods:** We use fluorescent constructs of HIV-1 to evaluate productive infection by flow cytometry in CD4 T cell lines and primary cells in the presence or absence of purinergic inhibitors. Infected supernatants can be subjected to multiplex bead capture assays to test for an array of human cytokines. We have tested the effect of HIV-1 infection on peripheral blood mononuclear cells and observed levels of pro-inflammatory cytokine production. **Results:** We observe that HIV-1 productive infection in CD4 T lymphocytes is potently blocked by P2X selective inhibitors. Exposure of peripheral blood mononuclear cells to HIV-1 results in induction of pro-inflammatory cytokines and levels are reduced with P2X inhibition. This suggests that P2X inhibitors can block both HIV-1 productive infection and associated inflammation.**Conclusions:** Our findings distinguish purinergic receptors, specifically P2X, as key signaling mediators of HIV-1 infection and inflammation. We believe that these drugs could be used as adjunctive antiretroviral therapy that could serve to reduce the morbidity and mortality associated with HIV-1 chronic inflammation.

Definition of the Hiv-1 Signalosome on Entry to Dendritic Cells

Author Block:

E. Khatamzas; Oxford Univ., Oxford, United Kingdom

Abstract Body:

Background: Scientific efforts to develop an effective HIV-1 vaccine have been hampered by the unprecedented genetic variability of the virus and its numerous strategies to subvert the function of immune cells, such as dendritic cells (DCs), allowing it to evade immune recognition, and persist in latent reservoirs. Here, DCs play a pivotal role in the initiation of immune responses and are one of the first cells to encounter HIV at mucosal surfaces. The mechanisms by which HIV avoids pattern recognition receptor mediated recognition in endosomes is unclear. **Methods:** Monocyte-derived DCs were infected with HIV-1 or mock for 10 minutes before purification of phosphoproteins. Phophoproteomics was used to identify proteins differentially phosphorylated by HIV-1. A secondary RNAi library was designed to assess the functional effect of these host proteins in transfer of HIV-1 from DCs to CD4+ T cells.**Results:** 340 proteins were differentially phosphorylated by HIV-1 within 10 minutes. These include proteins usually implicated in autophagy, neural synapse formation and trafficking. We identify a trafficking complex containing the biogenesis of lysosomal organelles 1, or BLOC-1, proteins that most strongly affect transfer of HIV-1 to CD4+ target cells. Mutations in BLOC-1 are responsible for Hermansky-Pudlak-Syndrome, a genetically heterogeneous disorder of intracellular vesicle biogenesis. We show that inhibition of Snapin, a component of BLOC-1, results in enhanced localization of HIV-1 in early endosomal (EEA1+) vesicles with TLR8 competent for cytokine and interferon responses. This effect of Snapin was not limited to HIV-1 sensing as removal of Snapin lead to enhanced TLR8 signaling and EEA-1/MyD88 localization following exposure to imidazoquinolones or single stranded RNA. Thus Snapin dissociates TLR8 from EAA1/MyD88 in a pathway utilized by HIV-1.**Conclusions:** Altogether, this suggests a mechanism by which HIV-1 virions hijack a physiological secretory pathway to evade lysosomal degradation and facilitate transfer to CD4+ T cells. Our findings reveal the complexity of the interaction of HIV-1 with the host cell machinery and identify novel mechanisms of the immune evasion tactics usurped by HIV-1 in DCs.

Impact of Antiretroviral Initiation on Cytokine Levels and During Immune Reconstitution Syndrome in Hiv Patients

Author Block:

Y. A. Vargas Infante, MD, J. I. Lezama Mora, P. M. Del Rio Estrada, V. H. Ahumada Topete, A. Y. Rivero Arrieta, C. E. Ormsby, Y. A. Luna Villalobos, G. Reyes Terán; Inst. Natl. de Enfermedades Respiratorias, Mexico, Mexico

Abstract Body:

Background: The aim of this study was to describe the levels of cytokines at baseline, after start antiretroviral treatment (ART), and at the time of inflammatory reconstitution syndrome (IRIS) in a cohort of HIV-infected patients. **Methods:** HIV-infected adults, ART-naïve, with CD4 count <200 cell/mm^3, who agreed to participate were evaluated at baseline, and after ART initiation on weeks 7, 12, 24. In case of IRIS, an additional sample was obtained. Subjects were recruited from Jul-12 to Jun-14. Demographic and clinical data were collected. Multiplex assays were performed on plasma to determine the serum levels of inflammatory cytokines. We analyzed the relationship between the cytokines, according to the time of exposure to ART, and the occurrence of IRIS. **Results:** Twenty-seven patients were included in the analysis, 21 (78%) were men with median age of 36 (IQR 30, 41) yrs-old. Baseline CD4-count was 37 (IQR 11, 77) cell/mm^3. Sixteen (59%) developed IRIS after a median of 9 [IQR 7,15] weeks of ART. Shingles was the main cause associated to IRIS (n=9/16, 56%). After ART initiation, levels of MIG, and IP-10 were higher in patients of the IRIS group compared to those in the non-IRIS group (Table 1). During the IRIS event, the levels of HGF, IFN gamma, EGF, IL-12 and IL-15 increased. These levels were higher to those observed at the entire evolution of patients within the non-IRIS group. **Conclusions:** Patients who developed IRIS showed higher levels of MIG, and IP-10 after ART initiation, compared to the non-IRIS group. Interestingly, significant differences in levels of HGF, IFN gamma, EGF, IL-12 and IL-15 only emerged during the IRIS episode.

Table 1. Median cytokine levels at baseline and during the follow-up, comparison between the IRIS and non-IRIS groups.

Porcine Circovirus Type 2 Activates Cammkβ to Initiate Autophagy in Pk-15 Cells by Increasing Cytosolic Calcium

Author Block:

Y. Gu, B. Qi, Y. Zhou, X. Jiang, X. Li, W. Fang; Zhejiang Univ., Hangzhou, China

Abstract Body:

Porcine circovirus type 2 (PCV2) has emerged as one of the most important pathogens in pigs since its initial recognition in 1998. It causes porcine circovirus-associated diseases (PCVAD) such as porcine dermatitis and nephropathy syndrome (PDNS), porcine respiratory disease complex (PRDC). PCV2 has a circular single-stranded DNA genome of about 1.7 kb that contains two major ORFs, ORF1 encoding the replicase protein (Rep and Rep') essential for transcription and ORF2 encoding the capsid protein (Cap) for genome packing. The pathogenic mechanisms underlying PCV2 infection remain largely unknown. Our early study shows that PCV2 induces autophagy via the AMPK/ERK/TSC2/ mTOR pathway in PK-15 cells and the autophagic response enhances viral replication. However, the mechanisms of AMPK activation in autophagy induction remain unknown. We used specific inhibitors and RNA interference of target signaling molecules in PCV2-infected cells in combination with Western blotting and flowcytometric and fluoresent calcium measurements. We provide clear evidence that that PCV2 infection upregulated CaMKKβ by increasing cytosolic Ca2+ via IP3R. Elevation of cytosolic Ca2+ did not seem to involve IP3 release from PIP2 by PLC-γ. The N-terminal two-thirds of PCV2 capsid protein played the major part in elevation of cytosolic Ca2+ and upregulation of CaMKKβ. CaMKKβ then activated both AMPK and CaMKI. PCV2 employed CaMKI and WIPI1 as another pathway additional to AMPK signaling in autophagy initiation. Our findings could help better understanding of the signaling pathways of autophagy induction as part of PCV2 pathogenesis. Further research is warranted to study if PCV2 capsid protein interacts directly with IP3R or indirectly with the molecules that antagonize IP3R activity responsible for increased cytosolic Ca2+.

Anti-Viral Immune Response in the Central Nervous System Decreases Proliferation of Neural Stem/Progenitor Cells

Author Block:

A. Kulkarni, T. Scully, L. O'Donnell; Duquesne Univ., Pittsburgh, PA

Abstract Body:

Viral infections in the central nervous system (CNS) are characterized by lymphocyte infiltration into the brain parenchyma and release of pro-inflammatory cytokines. Interferon-gamma (IFN) is a key anti-viral cytokine that is required for non-cytolytic clearance of many viruses from the CNS. Our lab has demonstrated that IFN induces cell type-specific signaling cascades that dictate neural cell survival and proliferation. Here, we address the effects of IFN signaling on the proliferation and differentiation of neural stem/progenitor cells (NSPCs). We hypothesized that IFN would inhibit NSPC proliferation and induce glial differentiation via the Janus activated kinase (Jak)/Signal Transducers and Activators of transcription (STAT) signaling pathways. Using primary wildtype and STAT1-KO NSPCs, we show that IFN inhibits NSPC proliferation in a STAT1-dependent manner as measured through neurosphere growth and BrdU incorporation. IFN exerted a cytostatic effect on NSPCs by blocking cell cycle progression at the late G1/S checkpoint, which was mediated by dephosphorylation of the retinoblastoma protein (pRb) at serine 795 and decreased cyclin E/cdk2 expression. In addition, IFN increased astrocytic differentiation and reduced neurogenesis in vitro. During a neuron-restricted measles virus infection in neonatal mice, IFN protected the NSPC pool, but could not protect young neurons or preserve neurogenesis. Through these studies, we defined the role of IFN-mediated inflammatory signaling in modulating NSPC activity. These studies will also identify potential new targets that could salvage the developing CNS from disruptive effects of an anti-viral immune response. Funding for this work is provided by the NIH (1R15NS087606-01A1) and Duquesne University’s Mylan School of Pharmacy.

Roles of Nipah Virus Attachment, Fusion, and Matrix Proteins on Viral Assembly and Budding

Author Block:

K. Matz, G. Johnston, H. C. Aguilar; Washington State Univ., Pullman, WA

Abstract Body:

Nipah Virus (NiV), in the family *Paramyxoviridae* and genus Henipavirus, is a bio-safety level 4 agent with a mortality rate of 40-90% in humans. Transmission is zoonotic and extends to many mammals. Symptoms of human infection include encephalitis and pneumonia caused by the formation of large multi-nucleated cells termed syncytia. NiV uses two transmembrane glycoproteins to induce viral-cell membrane fusion and viral entry: the attachment (NiV-G) and fusion (NiV-F) glycoproteins. Additionally, the matrix (NiV-M) protein promotes assembly of viral proteins to bud virus-like particles (VLPs). We hypothesized that these three proteins would interact and affect incorporation of each other into VLPs. Previous research indicated that NiV-F buds autonomously, thus we also hypothesized that the cytoplasmic tail (CT) of NiV-F would interact with host cell factors to modulate VLP budding. To test these hypotheses we used a viral budding assay to quantify the production of VLPs after human embryonic kidney 293T cells were transfected with different combinations of NiV proteins including NiV-F CT mutants. Following transfection, VLPs were purified from cell supernatants using sucrose-based ultracentrifugation and analyzed using SDS-PAGE. Flow cytometry and SDS-PAGE densitometry were used to compare the protein expression present in VLPs relative to that on cell surfaces and within cell lysates. A budding index was calculated from the ratio of relative viral protein levels between VLP isolates and cell lysates. Results showed NiV-G incorporation into VLPs increased significantly from single-expression of NiV-G (7%) as compared to co-expression of NiV-F and NiV-G (27%) or NiV-M and NiV-G (35%). Additionally, mutations in the NiV-F CT decreased budding by 60-90% as compared to wild-type NiV-F levels. Lastly, in the presence of mutant cellular factors thought to interact with the NiV-F CT, budding was substantially decreased along with syncytial formation. In conclusion, NiV-M and NiV-F increase NiV-G's incorporation into VLPs, and we uncovered a role for the NiV-F CT in viral particle budding. A greater understanding about characteristics of NiV budding and infection may aid in the development of novel targets for antiviral treatments.

Understanding Systems-Level Responses in *Clostridium ljungdahlii* through a Metabolic and Gene-Expression Model

Author Block:

J. Liu, A. Ebrahim, C. Lloyd, J-N. Kim, M. Al-Bassam, K. Zengler; Univ. of California, San Diego, La Jolla, CA

Abstract Body:

As an acetogen, *Clostridium ljungdahlii* can metabolize carbon monoxide (CO), carbon dioxide (CO_2), and hydrogen (H_2) (i.e. syngas) to produce multi-carbon organics. This ability, in addition to other attractive features such as its diverse substrate utilization, makes *C. ljungdahlii* an attractive organism for strain designed chemical production from cheap, renewable sources. To advance towards this goal, a constraint-based modelling method was used to systematize the biochemical, genetic and genomic knowledge of *C. ljungdahlii* into a mathematical framework, enabling a mechanistic description of metabolic physiology. This metabolic and gene expression model (ME-model) accounts for 961 ORFs that not only are responsible for the metabolic network, but also enable the production of transcriptional units, functional RNAs (i.e., tRNAs, rRNAs, etc.), prosthetic groups, and cofactors, as well as the formation and translocation of protein complexes. With this ME-model, we can now compute the molecular constitution of *C. ljungdahlii* as a function of genetic and environmental parameters. For instance, though low CO_2 uptake rate (i.e. low CO_2 partial pressure) may lead to a severe decrease in acetate production, the functional proteomic composition of *C. ljungdahlii* under high and low CO_2 partial pressure remains remarkably similar (Pearson $r = 0.98$, $P < 0.001$). In contrast, low and high fructose uptake rates lead to a more variable composition (Pearson $r = 0.80$, $P < 0.001$). Indeed, the ME-model provides a foundation for predicting and understanding the phenotype of *C. ljungdahlii*, which is vital for effective strain design.

Extensive Comparative Genomics Analysis of Epidemic and Reference Fish Isolates of *Aeromonas hydrophila S*trains

Author Block:

H. C. Tekedar, S. Kumru, A. Karsi, M. L. Lawrence; Mississippi State Univ., Mississippi State, MS

Abstract Body:

Aeromonas hydrophila is a Gram-negative, mesophilic bacterium that infects aquatic poikilothermic animals, mammals, and humans. Historically, *A. hydrophila* is an opportunistic pathogen of freshwater fish, but since 2009 the U.S. channel catfish industry has been affected by epidemics where *A. hydrophila* is a primary pathogen. To determine the genetic basis for this, we conducted genome sequencing of five *A. hydrophila* strains isolated from catfish pond epidemics (epidemic *A. hydrophila* or EAh) and five historical *A. hydophila* strains (reference *A. hydrophila* or RAh) using a Genome Analyzer IIx (Illumina, Inc., San Diego, CA) at the USDA ARS Catfish Genetics Unit. We recently reported completed genome sequencing of one EAh strain, ML09-119, which was isolated from diseased channel catfish during an outbreak of *A. hydrophila* in a commercial channel catfish pond. We also completed the sequence of one RAh strain, AL06-06, which was isolated from a goldfish in 2006 from the Auburn University Southeastern cooperative fish disease Laboratory in Greensboro, Alabama. We also improved the draft genomes from the other EAh and RAh strains. Results of genome comparisons indicated that only one of the RAh strains carries a full operon of the Type VI secretion system. None of the EAh strains carry plasmids, but three of the RAh strains carry plasmids. Moreover, EAh strains have a complete inositol catabolism pathway, while only one of the RAh strains has this pathway. Our findings will help elucidate the genetic mechanism for increased virulence of EAh strains compared to historical *A. hydrophila* isolates, which could enable improved diagnostics to distinguish EAh and vaccine development.

Transcriptomics-Based Genome Annotation of Penicillia

Author Block:

K. K. Pennerman, J. Akinsanya, P. Kurup, G. Yin, J. W. Bennett; Rutgers, The State Univ. of New Jersey, New Brunswick, NJ

Abstract Body:

Compared to plants, animals and bacteria, well-annotated genomic description of filamentous fungi is lacking. This dearth of knowledge limits our ability to understand fungal biology, even in well-known genera such as *Penicillium.* Collectively, the penicillia are fungi of major economic importance including plant pathogens, an opportunistic human pathogen, producers of antibiotics and contributors to a number of food fermentations. We used a bioinformatics approach to improve genome annotation of *Penicillium chrysogenum* (the species used for industrial production of penicillin) and *Penicillium digitatum* (a post-harvest pathogen of citrus fruits). We retrieved reference genomes and gene annotations from NCBI (http://www.ncbi.nlm.nih.gov/genome/) and JGI (http://genome.jgi.doe.gov/). *P. chrysogenum* RNA-seq data were obtained by our collaborators and published *P. digitatum* RNA-seq data were retrieved from the SRA database (http://www.ncbi.nlm.nih.gov/sra). Using gene prediction programs and other bioinformatics tools, we found over 300 previously unannotated, predicted gene sequences of many diverse functions for each genome. These predicted genes were found across the length of the genomes. Our results not only provide new candidates for genetic research, but also highlight the need for more evidence-based gene annotation.

VRprofile: A Web-Based Tool for *In silico* Profiling of Virulence and Antibiotic Resistance Traits Encoded within Genome Sequences of Pathogenic Bacteria

Author Block:

H. OU, J. Li; Shanghai Jiaotong Univ., Shanghai, China

Abstract Body:

Background: Throughout the entire bacterial domain, a vast repertoire of antibiotic resistance and virulence-associated traits has spread via horizontal gene transfer of various mobile genetic elements. Several bioinformatics tools and databases have been developed to mine the WGS data for the virulence and/or resistance-related genes. However, users frequently have to manually examine the broader context of these sequences to confidently define the gene clusters coding for the entire genetic elements. Here we report a user-friendly web server, called 'VRprofile', as a public resource for performing rapid homology searches and comparisons of virulence and antibiotic resistance-related gene clusters in bacterial genome sequences of various pathogens.**Methods:** The utilized back-end database MobilomeDB was built upon sets of known gene cluster loci of bacterial mobile genetic elements, including prophages, integrative and conjugative elements, class I integrons, IS elements, pathogenicity/antibiotic resistance islands, and type III/IV/VI secretion systems. With discovery of homologous gene cluster based on sequence similarity and gene order, VRprofile is able to recognize most known bacterial virulence factors, antibiotic resistance determinants, and MobilomeDB-archived transfer-related gene clusters in the genomic sequence of a bacteria pathogen within 15 minutes. The server also includes other individual tools with complementary functionality, including CDSeasy that rapidly identifies and functionally annotates protein-coding genes in a raw input contigs/scaffolds/complete sequence, and CGCfinder that quickly performs homologous gene cluster discovery across a user-defined search database of bacterial genomes.**Results:** VRprofile is freely available to all users without any login requirement at http://bioinfo-mml.sjtu.edu.cn/VRprofile.**Conclusions:** By ensuring ease of flexible input options, VRprofile may contribute to meet the increasing demands of bacterial variable region analysis, and aid in real-time definition of disease-relevant gene clusters in pathogenic bacteria of interest.

Identifying Functionally Important, Uncharacterized Genes in Microbial Communities

Author Block:

E. A. Franzosa[1], A. Shafquat[1], G. Rahnavard[1], E. P. Balskus[2], C. Huttenhower[1]; [1]Harvard T. H. Chan Sch. of Publ. Hlth., Boston, MA, [2]Harvard Univ., Cambridge, MA

Abstract Body:

Background: The prioritization of uncharacterized genes for further study is a challenging gap in microbial research. With thousands of microbial isolate genomes and metagenomes now sequenced each year, automated characterization is a must, isolate homology alone leaves many genes unannotated, and microbial community profiles provide a rich new resource for assigning putative functions for experimental follow-up. **Methods**: In this work, we present a computational method (PPANINI) for prioritizing genes for functional assignment based on their occurrence and properties within microbial communities, including population prevalence and abundance distributions. Our method complements existing approaches for prioritizing genes in the context of single isolate genomes, thus expediting microbial gene characterization efforts. **Results**: We applied PPANINI to collections of human (skin, vaginal, gut, and oral) and environmental (soil) metagenomes to 1) validate the method's performance and 2) identify important uncharacterized genes in these microbial communities. PPANINI correctly prioritized known essential genes as functionally important, while simultaneously downweighting putative lower-priority genes (e.g. non-biological ORFs and pseudogenes). In addition, PPANINI identified large numbers of putatively important but functionally uncharacterized genes, many of which were not prioritized by earlier methods (e.g. phylogenetic profiling). From among the prioritized genes we isolated 26 putative members of the glycyl radical enzyme (GRE) family, which catalyzes a range of important biochemical reactions in anaerobic metabolism. **Conclusions**: We are currently experimentally validating the GREs prioritized by PPANINI, thus demonstrating our method's utility in translating large volumes of gene sequence data to testable hypotheses. The open-source PPANINI software and documentation are available for download at http://huttenhower.sph.harvard.edu/ppanini.

Systematic Bioinformatics Analysis of Virulence Associated Factors of *Cryptococcus neoformans* Revisits Different Function of Osmolarity Pathway in Serotypes A and D

Author Block:

A. N. Malachowski, M. Yosri, Y. He, M. A. Olszewski; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

C. neoformans (C.neo) infection originates in the lungs from which it disseminates to CNS causing lethal pathologies. The cryptococcal survival in the lungs and its ability to disseminate into CNS is promoted by a large group of virulence associated factors (VAFs). To enhance comprehensive understanding of VAF roles and their possible relationships, we have gathered all of 284 reported VAFs of *C. neo.* from the scientific literature in a single database. Their relationships have been analyzed using protein sequence analysis tools and other bioinformatics resources: transmembrane localization software (TMHMM v 2.0), gene network mapping software (STRING), a gene pathway database (KEGG), intra-protein motif analysis software (GenomeNet) and the Broad Institute H99 database.Our study is the first to point out that Sho1, an osmosensor in the High Osmolarity Glycerol pathway (HOG), is present in *C. neo.* serotype A but not in serotype D. Analysis of KEGG diagrams and literature reveals that several proteins downstream from Sho1 were characterized in serotype D, suggesting that they may play different roles in either serotype. Furthermore, our network analysis indicates that the center of *C. neo.* virulence network is enriched in regulatory genes and especially kinases, consistent with their high potential for regulation. Finally, using the intra-protein motif analysis we confirmed the high frequency of kinase domains among the VAFs, and found other frequent domains such as the Major Facilitator Superfamily.Our analysis also revealed that the total genome contains 19.4% transmembrane proteins, while our VAF database 19%. While there was no enrichment in the proportion of transmembrane proteins, our results indicate VAFs tend to contain more transmembrane domains per protein than non-VAFs, suggesting larger and more complex proteins.In summary, this study generated a comprehensive database of *C. neo.* virulence factors and uncovered new information on the HOG pathway. It also revealed that *C. neo.* is a prime candidate for further bioinformatics studies, that will enhance understanding of virulence factor network in this and other pathogenic organisms.

Improving the Prediction and the Comparison of Genomic Islands in Draft and Complete Genomes

Author Block:

C. Bertelli, B. K. Dhillon, J. A. Shay, A. C. Lim, M. R. Laird, G. L. Winsor, F. S. L. Brinkman; Simon Fraser Univ., Burnaby, BC, Canada

Abstract Body:

Background: In bacterial and archaeal genomes, genomic islands (GIs) are commonly defined as clusters of genes with probable horizontal origins. They disproportionately encode medically important adaptations, including antimicrobial resistance (AMR) and virulence. Microbial genome sequencing has become rapid and inexpensive, but current computational methods for GI analysis are not amenable for rapid, accurate, user-friendly, and scalable analysis of the thousands of genomes being sequenced.**Material and Methods:** To improve the prediction of GIs, we have developed a new version of IslandPath-DIMOB, part of the IslandViewer suite of GI analysis tools, by implementing (i) a better score of dinucleotide bias to increase sensitivity, (ii) new HMM profiles to search for mobility genes, (iii) a better handling of pseudogenes and some bug fixes, and (iv) the concept of regions of GIs by considering closely positioned GIs as a single region. The performance of IslandPath-DIMOB was assessed against a dataset of GIs identified by comparative genomics. We have initiated the development of IslandViewer version 4 that facilitates expanded comparative visualization and analysis of a large number of genomes.**Results and Conclusion:** The new version of IslandPath-DIMOB has a notable increase in recall of greater than 10% for most genomes, while maintaining similar accuracy and precision. A novel IslandViewer interface extends circular and linear visualization of the GIs using interactive GenomeD3Plot. This web-based interface enables a smooth browsing of genome content and GI predictions, with overlaying annotation of genes and highlighted AMR and virulence factors. Genome analyses provided new insight into the evolution of AMR genes. The new features of IslandPath-DIMOB and IslandViewer will enable faster prediction and easier comparison of GIs in draft and complete genomes, facilitating direct use by biologists and clinicians.

Prokaryotic Sequence Analysis Resources In The Analysis Engine

Author Block:

S. Nadendla, S. C. Daugherty, R. S. Adkins, J. Crabtree, S. Agrawal, A. Shetty, O. White, A. A. Mahurkar, M. Giglio; Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract Body:

It is now relatively inexpensive and easy to acquire the genome sequence of a prokaryotic species. However, effective analysis of that sequence data is still a challenge for many researchers. To address this need, the Institute for Genome Sciences (IGS) has developed the Analysis Engine (http://ae.igs.umaryland.edu), a series of pipelines installed on publicly accessible cloud resources or as stand alone downloadable virtual machines.Here we describe ongoing work to add additional pipelines and tools to the resource as well as to increase the scalability and efficiency of existing pipelines. The analysis resources currently available in the Analysis Engine include: 1) automated structural and functional annotation of single genomes using the IGS Prokaryotic Annotation Pipeline; 2) comparative genomic analysis for up to 100 genomes at a time; 3) transcriptome analysis providing differential expression results; and 4) assembly of genomes. We provide the tool Manatee for visualization and curation of genome data, and Sybil for visualization of comparative analysis results that include ortholog groups and syntenic regions. We have recently created a Manatee virtual machine (VM) that allows users the option to have complete control of their genome data at their local site, allowing them to easily engage in continuous curation independent of IGS infrastructure. In ongoing work we will continue to incorporate additional pipelines and tools into the service and will strive for further integration between our tools and other resources. Finally, the Analysis Engine has a significant outreach component and provides training through workshops held both at relevant conferences and on-site at the Institute for Genome Sciences at the University of Maryland School of Medicine in Baltimore Maryland.

Statistical Evidence for a Relationship between Phage Isolation Location and Shared Gene Families

Author Block:

B. Q. Dang, D. Jacobs-Sera, W. H. Pope, D. A. Russell, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Mycobacteriophages are viruses that infect mycobacteria, including the causative agent of tuberculosis, *Mycobacterium tuberculosis*. As such, research in characterizing mycobacteriophage genomes may lead to insight for novel techniques for treatment of tuberculosis. From a data set of 767 sequenced and annotated mycobacteriophages that included GPS coordinates of where the phages were isolated, we investigated whether there was a relationship between geographical isolation location and gene content. The density-based spatial clustering of applications with noise (DBSCAN) algorithm was used to organize closely-isolated phages into groups, with a 1 mile search radius and a 3 neighboring-points requirement. After establishing these "geogroups" of phages isolated in close proximity, each geogroup's CLASP index was calculated. The CLASP index stands for Cluster Average Shared Phams, where phams refers to genes belonging to the same gene family. The CLASP index is a representation of how closely related a group of genomes are, and is calculated by averaging the percent of shared phams between all possible pairwise combinations within a cluster or group. The genomes and coordinates were then randomly shuffled, and a statistical t-test revealed that the average of all CLASP indices were significantly (pvalue: 0.00152) different than the average of all CLASP indices of the original, unshuffled data set. Being that the t-test identifies the data sets as significantly different, it implies that CLASP indices are nonrandom and are attributed to the specific, closely-isolated mycobacteriophages for a given geogroup.

Mathematically Modeling the Biodistribution Kinetics of *Acinetobacter baumannii* Infection

Author Block:

S. E. Miller, C. S. Bell, M. McClain, T. Cover, T. D. Giorgio; Vanderbilt Univ., Nashville, TN

Abstract Body:

A multicompartmental pharmacokinetic model was developed to study the biodistribution of *Acinetobacter baumannii* in bacteremia. The model includes parameters to represent physical and immunological interactions, bacterial net growth, transport among tissues (lungs, spleen, liver, blood), antibiotic treatment, and extracorporeal blood cleansing. Five first-order homogenous ordinary differential equations were developed as a model representation of the physiological system. This dynamic systems analysis approach was used to explore the impact of extracorporeal blood cleansing based on magnetophoretic separation of nanoparticle-bacteria complexes from the blood in combination with antibiotic treatment. Previously published empirical data was used to assign values to model parameters. The validity of the model was confirmed through comparison with experimental data from scientific literature. This is the first multicompartmental model of bacteremia that includes extracorporeal elimination of bacteria from the bloodstream and antibiotic treatment. This kinetic model provides an approach to quantitatively assess bacterial clearance in complex living systems. The new addition of an extracorporeal circuit reduces the time of total bacteria clearance from the blood of an immunocompromised mouse model by 35 hours, compared to antibiotic treatment alone. Our results suggest that extracorporeal blood cleansing in combination with antibiotic treatment may significantly reduce *A. baumannii* concentration in blood and reduce the transport of bacteria to distant organs. These factors are critical contributors to disease progression, and thus, this combination treatment has the potential to significantly improve patient outcomes.

Detection of an Unusual Plasmid in Spm-1 Producing *Pseudomonas aeruginosa*

Author Block:

A. Nascimento[1], **W. Martins**[2], L. Fehlberg[2], M. Munoz[3], N. Lincopan[3], A. Vasconcelos[1], A. Gales[2]; [1]Lab. Natl. de Computação Científica, Petrópolis, Brazil, [2]Univ.e Federal de São Paulo, São Paulo, Brazil, [3]Univ.e de São Paulo, São Paulo, Brazil

Abstract Body:

Background: Plasmids are extra chromosomal DNA, which normally harbor genes involved in bacterial adaptability. However, due to high capacity of P. aeruginosa isolates incorporate into its genome the genes that confer great selective advantage, the detection of plasmids in this species is not common. Our aim was to evaluate if the presence of this unusual plasmid would confer any virulence advantages to the SPM-1-producing P. aeruginosa (SPM-1-PSA) ST277 clone.**Methods:** After studying the genomes of SPM-1-PSA recovered from the Brazilian territory, we identified two isolates harboring an unusual plasmid (pPSABr). Plasmid assembly was performed using Newbler v 3.0. SABIA pipeline was used for gene prediction and automatic annotation. The curing of plasmid using acridine orange and consecutive passages onto LB agar was carried out as previously described. The ability of bacteria to initiate biofilm formation on polystyrene plastic was evaluated. Virulence experiments were performed testing six isogenic SPM-1-PSA isolates previously sequenced including two strains carrying pPSABr. To assess the virulence of was SPM-1-PSA isolates in vivo using the Galleria mellonella model of infection.**Results:** Assembly of the plasmids showed that strains 3448 and 7790 carried an identical plasmid, pPSABr, with 49 Kb size and 58.89% GC content. A total of 61 ORFs were present in pSPM-1. Interestingly, 50 of 61 (≈ 82%) ORFs were annotated as hypothetical proteins without known function. No resistance genes were detected in pPSABr. Genes encoding for secretion systems types III and IV were detected in this plasmid. SPM-1-PSA not harboring pPSABr killed all *G. mellonella* (5 larvae) approximately in sixteen hours, while strains harboring pPSABr did it at 22 hours. Cure of pPSABr failed despite many attempts. All isolates were weakly adherent in the biofilm formation test.**Conclusions:** Despite carrying genes encoding secretion systems, the acquisition of pPSABr seems to decrease the pathogenicity of SPM-1-PSA clone ST277. Although pPSABr codifies proteins of unknown function, they may be important for the P. aeruginosa cell since pSPM-1 was stable. However, more studies are necessary to determine the function of proteins encoded by pSPM-1 genes.

Bacterial Proteins and Complexes: Evolution, Function, and Perturbations

Author Block:

J. H. Caufield, P. H. Uetz; Virginia Commonwealth Univ., Richmond, VA

Abstract Body:

Bacterial diversity reveals the colossal scale of genetic flux, especially among seemingly well-conserved proteins. The functions of many of these protein components remain unclear. Even the most well-studied *E. coli* strains contain genomes with hundreds of open reading frames of unclear function. Just 1% of published bacterial protein sequences have annotations from experimental results. With the goal of finding novel functional context, we studied thousands of uncharacterized bacterial proteins with a bifurcated strategy: we used more than 300 *E. coli* model protein complexes to predict the presence of complexes across bacteria and combined published interactions into meta-interactomes of orthologous groups (OGs). We have also used bacteriophage proteins to illustrate protein relationships often missing from interactome studies but crucial to protein evolution.Computational analyses of more than 1,000 bacterial species and their protein complexes revealed how nearly all complexes deviate from the *E. coli* model in other species. Only 14 out of 285 model protein complexes are fully conserved across 95% of the ~1,000 genomes investigated. We then used a set of more than 50,000 protein interactions, combined into a meta-interactome, to focus on protein interaction conservation outside protein complexes. Our meta-interactome contains more than 43,000 distinct OG vs. OG interactions involving proteins from more than 250 bacterial species yet only 68 OG-OG interactions have evidence from than two species. This approach provides evidence for interaction predictions beyond what existing experimental data sets provide. The meta-interactome provides evidence for interactions for 951 of 4175 *Bacillus subtilis* proteins and 509 of 843 *Rickettsia prowazekii* proteins, both species without experimental protein interactomes.Together, these methods place proteins of unknown function in the context of well-conserved proteins and their interactions. We have explored the function of selected bacterial proteins, using a variety of studies, including the expression of a bacteriophage protein to perturb the host. We have developed methods to express phage proteins as sources of interactome disturbance and phenotype change. Identifying functions for bacterial proteins, whether they interact with phage proteins or not, may reveal novel physiological activities or potential antibiotic targets.

Heat Shock Protein 90 Shapes *Candida albicans* Genome Architecture

Author Block:

K. Dong[1], A. Forche[2], S. Milne[1], L. Alaalm[1], J. Berman[3], S. Diezmann[1]; [1]Univ. of Bath, Bath, United Kingdom, [2]Bowdoin Coll., Brunswick, ME, [3]Tel Aviv Univ., Tel Aviv, Israel

Abstract Body:

Hsp90 regulates the emergence of novel traits in animals, plants and fungi. It does so by stabilizing up to 10% of the eukaryotic proteome. In *Candida albicans*, Hsp90 is a key regulator of virulence and drug resistance. Since *C. albicans* does not engage in canonical meiosis to generate genetic variations, it has evolved a repertoire of alternative routes to diversify its genome. Forche *et al*. (mBio, 2011) demonstrated that Loss-of-Heterozygosity (LoH) provides a mechanism for generating genetic variation aiding in the response to environmental stresses and possibly adaptation. Indeed, stressors such as H_2O_2 or fluconazole altered rates and types of LoH events in *C. albicans*, suggesting that LoH generates genetic diversity thereby facilitating adaptation and ultimately evolution. We hypothesize that Hsp90 affects LoH rates and events in *C. albicans* and thus genome integrity and phenotypic variation. To test this hypothesis, we created reporter strains and conducted fluctuation assays measuring rates of LoH at 9 genomic loci located on 4 chromosomes. We were able to demonstrate that both, pharmacological inhibition and genetic depletion of Hsp90, increase LoH rates. Subsequent SNP-RFLP genotyping analyses at 2 loci indicated that reduced Hsp90 function not only alters LoH rate but more importantly the types of LoH events when compared with standard growth conditions. Pharmacological inhibition of Hsp90 increases local recombination like gene conversion or break-induced recombination events. Growth at high temperature results in increased whole-chromosome homozygosis. The emergence of different types of LoH in response to Hsp90 stress suggests that *C. albicans* may utilize distinct forms of LoH in response to different stressors. To characterize types of LoH with higher granularity than SNP-RFLP, we are currently conducting ddRAD sequencing, which facilitates the identification of karyotypic changes across the entire genome. We furthermore complement our genotyping efforts with fitness assays and measurements of drug resistance to establish a functional relationship between Hsp90, LoH and fitness. This would have theoretical and clinic implications and further our knowledge of how Hsp90 shapes an organism's genome structure with consequences for antifungal drug resistance and fungal virulence.

Mcrx, A Novel Modification- Dependent Restriction Enzyme In *e.Coli* B

Author Block:

A. Fomenkov[1], D. K. Dila[2], B. P. Anton[1], Z. Sun[1], R. J. Roberts[1], E. A. Raleigh[1]; [1]New England Biolabs, Ipswich, MA, [2]Univ. of Wisconsin-Milwaukee, Sch. of Freshwater Sci., Milwaukee, WI

Abstract Body:

Modification-dependent restriction enzymes (MDE) play two interconnected major roles in prokaryote evolution. First, they protect cells from phage infection, particularly from virulent phage with nonstandard nucleotides such as T4. Second they promote stability of genome lineages by restricting incorporation of genomic DNA from lineages with different DNA modification patterns. At least 10 families of such enzymes have been described, although for many families the mechanism of action is not clear. Understanding the diversity, distribution and mechanisms of action of these remarkable enzymes is critical to understanding microbial populations: how prokaryotic lineages are established, how the breakdown of the protections relates to acquisition of pathogenic potential, and how the interplay of MDE with phage, plasmids and transforming DNA affect microbiome functions.The earliest genetically-defined MDE was identified in *E. coli* B in the 1960s. Initially designated r_6, and later $rglA_B$ or $mcrA_B$, it has remained biochemically uncharacterized. It has been clear for many years that the gene is not related to the $mcrA_K$ ($rglA_K$, $r6_K$) gene found in *E. coli* K-12, and thus is here renamed *mcrX* to avoid confusion.McrX was characterized here genetically and biochemically. To develop expression strains for conventional restriction enzymes, establishment of protective cognate modification methyltransferases is required. The widely-used host BL21(DE3) could not be used for this purpose due to expression of three MDE. In the process of developing a usable derivative, ER2566, we characterized inactivating mutations in *mcrX* that allowed methyltransferase establishment. The genome sequence of ER2566 revealed that the *mcrX* gene is located in a genomic island with variable contents in different wild *E. coli* isolates. *In vitro* characterization of the wild type BL21(DE3) activity followed. As expected from its genetic properties, the enzyme digests DNA with 5-hydroxymethylcytosine (from phage T4) or with 5-methylcytosine in particular sequences. Unlike most MDE, the recognition sequence is fairly well-defined, and the position of cleavage is fixed within the recognition site.

Transcriptomic Study of Currently Circulating Immunogen Deficient *Bordetella pertussis* Strains

Author Block:

C. Lam, Y. Peng, M. Williams, M. Tondella, L. Pawloski; CDC, Atlanta, GA

Abstract Body:

The development of an inactivated whole cell vaccine (wP) against *Bordetella pertussis* was instrumental in reducing mortality against pertussis disease (whooping cough). In the 1990s, acellular vaccines (aP) with fewer adverse side effects, replaced the original wPs. These aPs only contain 3-5 components of the original wP, specifically pertussis toxin (Ptx), pertactin (Prn), and filamentous haemagglutinin (Fha) and in some vaccine formulations, two fimbrial proteins (Fim2/3). Since then, pertussis has steadily been increasing to levels last observed in the 1950s. Previous genomic analysis of the vaccine strains has revealed a very different genome from currently circulating strains. Furthermore, ongoing molecular surveillance of *B. pertussis* has identified isolates which do not express one or more of these vaccine immunogens, and the occurrence frequency of such strains is also increasing steadily across the US. It is imperative to understand the changes occurring at both the genomic and transcriptomic level that may be contributing to the perceived increased fitness of the currently circulating strains. In this study, we performed RNA sequencing on a representative sample of modern isolates to reveal the different transcriptome profiles compared to old vaccine strains. Total RNA was isolated from six strains deficient in Ptx, Prn or Fha. For comparison, RNA was also isolated from two vaccine strains (Tohama I and CS) and two recently isolated wild type strains, respectively. RNA samples were also depleted of ribosomal RNA and DNA before constructing cDNA libraries. Illumina MiSeq was used to sequence the cDNA libraries and expression analysis was performed using CLC Genomic Workbench (8.5). Comparative transcriptomic analysis was between immunogen deficient isolates and wild type strains, as well as recent isolates and legacy vaccine strains; and the strain specific expressing genes were identified. Preliminary analysis showed that immunogen deficient strains produce transcripts of unique genes that were not identified in the vaccine strains. Further investigation of these genes revealed functions involved with protein transport and secretory systems, which may be compensating for the loss of function as a result of antigen non-expression.

Dynamics of *Escherichia coli* from Human Populations in Tanzania

Author Block:

T. S. Richter[1], T. H. Hazen[1], D. Lam[1], C. L. Coles[2], J. C. Seidman[2], Y. You[2], E. K. Silbergeld[3], C. M. Fraser[1], **D. A. Rasko**[1]; [1]Univ. of Maryland Sch. of Med., Baltimore, MD, [2]Dept. of Intl. Hlth., Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD, [3]Dept. of Environmental Hlth., Johns Hopkins Bloomberg Sch. of Publ. Hlth., Baltimore, MD

Abstract Body:

The stability of non-pathogenic bacterial populations in the human gastrointestinal tract is not fully appreciated and represents a significant knowledge gap regarding gastrointestinal community structure, resistance to incoming pathogenic bacterial introductions, as well as antibiotic treatment. The current study examines the genomic content of *Escherichia coli* isolates from individuals in Tanzania at three time points spanning a six month time period with or without antibiotic treatment. The findings in this study highlight the dynamic nature of the *E. coli* population in the human gastrointestinal tract, as during the six-month interval, no one individual contained phylogenomically related isolates at all three time points. Additionally, while the majority of the isolates at any one time point were phylogenomically similar, the majority of individuals did not contain phylogenomically similar isolates in more than two time points. This suggests that at any one time point there is a dominant clone of *E. coli* within the gastrointestinal tract of an individual, but that this dominance was transient. Examination of canonical *E. coli* virulence factors and antimicrobial resistance genes identified similar, but distinct patterns when compared to the phylogenomic analysis. There is a greater variability in the gene presence and absence patterns being observed among the antimicrobial resistance genes. Gene content analyses emphasized the diversity among *E. coli* isolates and identified gene presence/absence differences between isolates from hosts of different age, sex, antibiotic exposure, or gastrointestinal disease state. Interestingly, there was a lack of correlation with genes associated with diarrhea and the clinical presentation of diarrhea. This is the first study of the dynamic nature of the population structure of *E. coli* in the human host.Keywords: *Escherichia coli*, microbial genomics, population dynamics

Shared Alleles Among Group-A, -C and -G *Streptococci* Exist Due to Molecular Trans-species Polymorphism Rather Than Asymmetric Horizontal Gene Transfer

Author Block:

V. Bahrambeigi, A. M. Bolivar, H. Du, X. Li, X. Shi, K. Khanna, V. Varghese, P. C. Hu, E. J. Thompson, **A. KALIA**; The UT MD Anderson Cancer Ctr., Houston, TX

Abstract Body:

Background: β-hemolytic isolates of Lancefield group C and group G Streptococci (GCS-GGS) identified as *Streptococcus dysgalactiae* subsp. *equisimilis* can infect humans and other mammals. GCS and GGS now approximate or surpass group A streptococci (GAS) as the predominant cause of invasive β-hemolytic streptococcal infection. The transfer of genes from GAS into GCS-GGS genomes via horizontal gene transfer (HGT) is common. The dynamics of HGT between GAS and GCS-GGS are complicated. Some HGT events are asymmetric (aHGT), which can further be categorized as additive- or replacing-type aHGT. The mechanisms of replacing-type aHGT remain elusive. It is unclear (i) how replacing-type aHGT may shape diversity in the global GCS-GGS gene pool, and (ii) whether aHGT dynamics differ spatially and temporally.**Methods**: Whole genome sequences of 10 GCS-GGS isolates that caused invasive disease using the Illumina MiSeq platform were determined. Draft assemblies were generated via the Seqman NGen or the Velvet assembler. Genome annotation was performed with the RASTtk and Blast2Go. To elaborate on the global extent and nature of aHGT, we performed pairwise comparisons between GCS-GGS genomes (N = 23; 13 genomes were obtained from the NCBI) and 25 complete GAS genomes.**Results**: Estimated genome size of the six sequenced isolates ranged from 2 – 2.2 Mb. Intraspecific analyses revealed extensive heterogeneity in genome content, and strains differed in terms of phage and other mobile element content, presence or absence of CRISPRs and other strain-specific features. Interspecific comparisons with 25 complete GAS genomes representing multiple *emm*-types revealed that *all GCS-GGS genomes* harbored genes that were identical to those in diverse GAS strains. Strikingly, the extent and nature of identical genes shared between GCS-GGS and GAS genomes was largely similar, mostly neutral, and independent of the GAS *emm*-type thereby precluding any single GAS donor.**Conclusion**: Data suggest that identical gene content between GAS and GCS-GGS is not due to aHGT (or replacement HGT). We propose that identical gene content between GAS-GGS-GCS reflects molecular trans-species ancestral polymorphisms indicating very recent speciation.

Analysis of Intergenic Repeat Sequences of *Clostridium botulinum* and *Clostridium sporogenes*

Author Block:

C. Nasongkla; Cal Poly Pomona, Pomona, CA

Abstract Body:

Clostridium botulinum is a spore-forming, Gram-positive bacteria that belongs to the phylum Firmicutes. It produces botulinum neurotoxin, the most poisonous neurotoxin known to man. The genomes of several *Clostridium botulinum* strains have been sequenced and annotated, which provides a great tool for mining this bacterial species. Comparative analysis of gaps between *Clostridium botulinum* Hall A and ATCC 3502 identified interspersed DNA repeats. Additionally, the repeats have been found in other closely related species, including *Clostridium sporogenes*, a highly homologous genome to *C. botulinum* without the botulinum toxin, providing a surrogate model system. Repeats have been found throughout eukaryotes and prokaryotes. Previously considered "junk DNA", these repeats are thought to have stable, secondary RNA structures suggesting their roles in gene expression. This study focuses on a repeat sequence designated "Intergenic Repeat 1". Analysis of Repeat 1 sequences identified six subgroups of repeats named 1A, 1B, 1D, 1Q, 1T, 1U, and 1V, whose size ranges from 85 bp to 241 bp and frequency of each repeat ranges from 1 to 21 sequences per genome. Repeat sequences run in both directions on the genome of *Clostridium botulinum* ATCC 3502 and Hall A. The genomes of *C. sporogenes* are not sequenced, with *C. sporogenes* 15579 the only strain that is partially sequenced. PCR cloning and sequencing of the repeat sequences in *C. sporogenes* showed some similar and a novel repeat (designated as 1W) when compared to the repeats of *C. botulinum*. RNA isolation and reverse transcription revealed that the repeats are transcribed into RNA in *C. sporogenes* 15579. The sequences of all repeats are flanked by direct repeats of TTTAT, which also occurred in bcr1-bcr3 repeats of *Bacillus cereus*. BLAST analysis of 1A repeat showed various degrees of similarities to sequences in 5 other *Clostridium* species and 9 other strains of Group I *Clostridium botulinum*. Phylogenetic relationships among the organisms based on the repeats are different from the phylogeny based on functional profile indicating the repeats have a slightly different evolutionary relationship as compared to the host genome.

Comparative Genomics and Evolution of Amylase-Binding Proteins of Oral Streptococci

Author Block:

E. M. Haase[1], Y. Kou[2], A. Sabharwal[1], Y-C. Liao[3], H-H. Lin[3], T. Lan[1], C. Lindqvist[1], F. A. Scannapieco[1]; [1]Univ. at Buffalo, Buffalo, NY, [2]China Med. Univ., Shenyang, China, [3]Univ. at Buffalo, Miaoli County, Taiwan

Abstract Body:

Many oral streptococcal species bind salivary amylase by expressing a diverse range of amylase-binding proteins (ABPs). The aim of this study was to identify ABPs from a collection of streptococcus strains, and use sequence and bioinformatic analyses to explore their evolutionary relationships.Sixty-two strains from 14 oral streptococcus species were grown overnight in TSBY. Cells were collected by centrifugation and DNA was isolated. Concentrated culture supernatants were used for the detection of ABPs by the amylase-ligand binding assay. ABPs of diverse size were selected for N-terminal sequencing from 18 strains. Whole genome sequencing was performed to identify the genes associated with the ABPs. After sequencing, assembly and annotation, AbpA-like sequences were searched for using size and 'amylase binding protein', and confirmed using the N-terminal sequence. AbpB-like sequences were identified using the sequence obtained from primer-walking of *abpB* performed using degenerate primers. Other novel ABPs were identified using the N-terminal sequence. Alignment and phylogenetic analyses ascertained the evolutionary relationships among ABPs of these strains and database homologs.Nineteen strains from 6 oral streptococcal species expressed ABPs. N-terminal sequencing was performed on 36 ABPs. Among them, 14 ABPs matched amylase-binding protein A (AbpA) with identities ranging from 75-100%, and 6 ABPs matched protein B (AbpB) with 75-100% identity. Eleven unique ABPs were identified as peptidoglycan-binding proteins, hypothetical proteins or choline-binding proteins. AbpA-like sequences could be divided into five subgroups based on the N-terminal sequence and shared high similarity in the signal sequence, C-terminal sortase-binding motif and stop codon. While AbpB-like sequences were highly similar to peptidase C69 from several streptococcal species, they were functionally different from the inter-related AbpAs. The sequence of the novel groups also diverged from AbpA and AbpB.ABPs have the ability to bind amylase, but have divergent functions. There is no evidence that one group evolved from another. A combination of sequence alignment and synteny plot analysis suggests random uptake of *abpA* by horizontal gene transfer.

Identification of Essential Genes of *Pseudomonas aeruginosa* for It Is Growth in Airway Mucus

Author Block:

m. abdo, **S. Yoon**; Yonsei Univ., Seoul, Korea, Republic of

Abstract Body:

Pseudomonas aeruginosa has been identified as an important causative agent for airway infection mainly in cystic fibrosis. This disease is characterized by defective mucociliary clearance induced in part by mucus hyper-production. Mucin is a major component of airway mucus and is heavily *O*-glycosylated with a protein backbone. Airway infection is known to be established with bacterial adhesion to mucin. However, genes involved in mucin degradation or utilization still remains elusive. In this study, we thought to provide a genetic basis of *P. aeruginosa* airway growth by identifying those genes.First, we compared genome-wide expression profiles of PAO1, a prototype *P. aeruginosa* laboratory strain, grown in M9-mucin (M9M) and M9-glucose (M9G) media by RNASeq analyses. *PA2939* and *PA0122* genes encoding putative aminopeptidase and a hemolysin homologue were among top 5 genes, whose expression were increased >100-fold in M9M-grown PAO1. Second, a PAO1 transposon (Tn) insertion mutant library was screened for mutants defective in growth in M9M media. Six mutants with Tn insertion in *trpC* (*PA0651*), *trpD* (*PA0650*), *trpF* (*PA3113*), *leuA* (*PA3792*), *leuD* (*PA3120*), *purF* (*PA3108*) genes were determined to exhibit faulty growth in M9M. These genes are involved in the synthesis of leucine and tryptophan. Importantly, all of these mutants were incapable of establishing mouse airway infection, suggesting that these gene functions are required for *P. aeruginosa in vivo* infectivity.Our results indicate that *P. aeruginosa* possesses a unique genetic repertoire and regulatory mechanisms for establishing competitive respiratory infection. Further mechanistic dissection of this particular process will reveal new drug targets, inhibition of which could control recalcitrant *P. aeruginosa* infections.

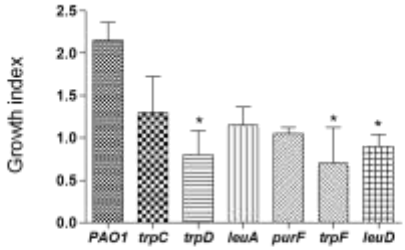

Figure 2: *Pseudomonas aeruginosa* selected mutants in M9Mucin media. PAO1 and mutants in M9M. The cell viability calculated using growth index (growth index= log(CFU $_{\text{after 16 hours}}$/ CFU $_{\text{at 0 time}}$ in M9Mucin media). Three independent experiment were done with mean and ± SD (error bar). P value calculated using ANOVA test.

Genome-Wide Identification Of Genes That Are Essential For Non-Replicating Mycobacterium Tuberculosis

Author Block:

Y. Minato, A. D. Baughn; Univ. of Minnesota, Minneapolis, MN

Abstract Body:

Most anti-tubercular drugs are effective against actively replicating populations of *Mycobacterium tuberculosis* but have limited efficacy against non-replicating populations of bacilli. The presence of such drug tolerant populations of bacilli require protracted treatment times for the eventual clearance of latent and active tuberculosis (TB). To comprehensively identify essential genes for non-replicating *M. tuberculosis*, we utilized a Next-Gen Sequencing (NGS)-based approach, transposon sequencing (Tn-seq). We generated a transposon library of *M. tuberculosis* H37Rv on a custom made defined nutrient rich (TB rich) agar medium. Approximately 3 x 10^6 colonies were collected (TB rich plate sample). A portion of the TB rich plate sample was washed twice with 10 mM Tris-Cl (pH.6.8) and resuspened in the same buffer and then spotted onto 0.22 µm membrane filter. The membrane filter was placed on 10 mM Tris-Cl (pH6.8) agar plate and incubated at 37°C for a month both aerobically and anaerobically. The membrane filters were then transferred onto the TB rich agar plate and incubated at 37°C for at least six generations of bacterial growth (TB starvation - O_2, and TB starvation + O_2 samples). Genomic DNA were purified from the three samples, fragmented, ligated to adaptors for Illumina sequencing, and amplified transposon junction by PCR. The amplified transposon junction region was sequenced by Illumina Hi-seq 2500 at the University of Minnesota Genomics Center. The Tn-seq data was analyzed by ARTIST, a recently developed Matlab-based pipeline for identifying essential genomic regions (1). We identified at least 25 genes that were essential for *M. tuberculosis* survival in starvation - O_2 but not in starvation + O_2. Among these genes, we have confirmed that the mutant strain of *gltB*, the gene encoding the large subunit of the ferredoxin- dependent glutamate synthase, showed a survival defect under anaerobic conditions.

Involvement of Exopolysaccharide in *Stenotrophomonas maltophilia* Biofilm Formation

Author Block:

G. ANDERSON; Indiana Univ. Purdue Univ. Indianapolis, Indianapolis, IN

Abstract Body:

The Gram-negative pathogen *Stenotrophomonas maltophilia* causes numerous serious human infections, including respiratory, urinary tract, skin, bloodstream, soft tissue, and wound infection. Mortality reaches 70% in some cases. Due to innate antibiotic resistance, this microbe is increasing in incidence and is currently the 11th most common isolate from nosocomial infections. However, our understanding of *S. maltophilia* pathogenesis is in its infancy. Several studies have suggested a role for biofilm in infection, but the molecular details of *S. maltophilia* biofilm formation are unknown. Reasoning that polysaccharide secretion is vital for biofilm formation of many microorganisms, we screened a *S. maltophilia* transposon mutant library for strains with reduced binding to the polysaccharide-binding stain Congo red. We found that mutation of the gene *gpmA* resulted in colonies that were paler than wild type on plates with Congo red, suggesting reduced polysaccharide secretion. *gpmA* encodes for phosphoglycerate mutate, a key glycolysis/gluconeogenesis gene, and as such it impacts polysaccharide metabolism. Importantly, *gpmA* mutation also reduced biofilm formation, while growth was unaffected. Using genetic and biochemical assays, we are identifying polysaccharide pathways involved in *gpmA*-mediated polysaccharide production as well as the composition of the secreted biofilm polysaccharide. We are also exploring *gpmA*-mediated biofilm formation on biotic and abiotic surfaces, as well as in an *in vivo* infection model. These experiments reveal one of the first factors known to be involved in *S. maltophilia* biofilm formation. Exploitation of biofilm polysaccharide pathways could lead to new avenues for treatment of this recalcitrant microbe.

Interspecies Electron Transfer Enables Photosynthesis of *Prosthecochloris aestuarii*

Author Block:

P. T. Ha, Stephen R. Lindemann, Liang Shi, James K. Fredrickson, Michael Mardigan and Haluk Beyenal; Washington State Univ., Pullman, WA

Abstract Body:

Recent studies have provided evidence suggesting that direct electron transfer (DIET) is one of the mechanism for electron exchange in syntrophic consortia. Many studies have focused on the DIET in methanogenic communities. Although it is known that phototrophs are the major primary energy providers that generate organic substrates via photosynthesis for heterotrophs in the phototrophic community, far less is known if the phototrophic community can also use DIET to exchange electrons. In this study, we report the evidences suggesting phototrophic bacteria also function as the electron accepter that obtain energy, as the form of electrons, directly from heterotrophs for their photosynthesis. Here we show that the phototrophic bacterium *Prosthecochloris aestuarii* can accept electrons directly from a metal reducing bacterium *Geobacter sulfurreducens* for photosynthesis. *P.aestuarii* and *G. sulfureducens* cannot grow individually using acetate as electron donor but can grow in co-culture. We found that *P. aestuarii* can use solid electrode as electron donor for photosynthesis. Both the DIET between *G. sulfurreducens* and *P. aestuarii* and the electron uptake from electrode by *P. aestuarii* were light-dependent processes under which the photosynthesis occurs. As the phototrophic microbial community have big potential application for wastewater treatment, bioremediation and fuel conversion from light and CO_2. This finding contributes the important knowledge for further engineering of synthetic microbial community for our desires.**Keywords:** direct electron transfer, cytochrome c, photosynthesis, *Geobacter sulfurreducens*, *Prosthecochloris aestuarii*

The Dna Damage Response May Regulate Bacterial Multicellularity

Author Block:

K. Gozzi, C. Ching, S. Paruthiyil, I. Lin, V. G. Godoy, Y. Chai; Northeastern Univ., Boston, MA

Abstract Body:

Bacillus subtilis is a gram-positive bacterium that is capable of forming multicellular communities, known as biofilms. Biofilm formation in *B. subtilis* is a well-studied process that incorporates multiple signals and regulatory pathways. Here, we present evidence showing the impact of DNA damage and the SOS response on bacterial biofilm development. In *B. subtilis*, the SOS response is triggered by DNA damage and mediated by RecA, a recombinase that, upon formation of nucleoprotein filaments with single-stranded DNA, acts as a co-protease and induces autocleavage of LexA. LexA is a master repressor for dozens of genes involved in the SOS response. Here we demonstrate that a knockout of *lexA* resulted in significant repression of biofilm formation, indicating a role of DNA damage sensing in biofilm formation. We further identified the ability of the protein product of *sda*, a LexA-controlled gene, to strongly negatively regulate biofilm formation. To elucidate the impact of the SOS response on biofilm formation, static biofilms grown in LB supplemented with glycerol and manganese were examined over time. A *B. subtilis* P_{yneA}-gfp (SOS gene) and P_{yqxM}-mKate2 (matrix gene) dual transcriptional fusion reporter was constructed and gene expression of biofilm cells was tracked over time using single-cell fluorescent microscopy. An inverse relationship between the SOS response and matrix production in cells within the biofilm was observed over time. To further investigate this relationship, *B. subtilis* biofilm cultures were treated with hydrogen peroxide, an endogenous reactive oxygen species and source of DNA damage. Biofilms treated with hydrogen peroxide demonstrated delayed and less robust biofilm formation, suggesting that DNA damage and thus the SOS response negatively regulate biofilm formation. In addition, we show that SlrR, a key regulator for biofilm formation and a LexA-like protein, autocleaves itself when exposed to long filaments of RecA nucleoproteins during the SOS response using *in vitro* cleavage assays. Interestingly however, when exposed to shorter RecA filaments, the autocleavage of SlrR is much less efficient, indicating that SlrR may only cleave itself and thus further inactivate biofilm formation when there are high levels of DNA damage. These findings imply a putative linkage between biofilm formation and DNA damage signals in *B. subtilis*.

Loss of Type IV Pilus Retractive Force Generates Spatiotemporal Patterns in *Neisseria gonorrhoeae* Microcolonies

Author Block:

K. Eckenrode[1], I. Spielman[1], K. Alzurqa[1], C. A. Weber[2], W. Poenisch[2], V. Zaburdaev[2], N. Biais[1]; [1]Brooklyn Coll. of the City Univ. of New York, Brooklyn, NY, [2]Max-Planck Inst. for the Physics of Complex Systems, Dresden, Germany

Abstract Body:

As antibiotic resistant bacteria steadily increase their global prevalence, new targets to curb bacteria virulence become increasingly important. *Neisseria gonorrhoeae* (GC) produce extracellular protein filaments named type IV pili (tfp), which can possess a variety of functions such as cellular adherence, DNA uptake, electron transfer, and twitching motility. Due to GC's pathogenic nature, it is critical to understand the role of the polymeric appendage during microcolony—a biofilm precursor—formation. When tfp retract from extracellular space into periplasmic space a mechanical force is produced. Pilus retractive forces are fueled by an intracellular ATPase, pilT. When the pilT gene is deleted (ΔpilT), pili are still produced and present in the extracellular space but cannot retract and thereby apply force. A ΔpilT mutant will produce viable microcolonies, even without retractive force, due to the lateral sticky binding of the tfp. The current study aims to understand the role of physical forces during GC tfp bacterial aggregation. Here, we present a set of microcolony formation assays, in which fluorescent ΔpilT GC strains and wild type (WT) GC strains were mixed in equal numbers. Spatiotemporal fluorescent patterns are observed for ΔpilT cells in ~30-50 μm microcolonies at single cell resolution after 3 hours of incubation. Resultant fluorescent microscopy images demonstrate that ΔpilT consistently localized to the outer perimeter of the microcolony when mixed with non-fluorescent WT GC. The experimental results are compared to the results of in silico simulations. These results suggest that upon loss of tfp retractive forces, these retraction-deficient cells, through interactive with WT cells are unable to integrate normally into the microcolony and are subsequently segregated away from the center on the microcolony.

Investigating the Role of Quorum Sensing in Overall Biofilm Formation During the Epibiotic-parasitic Relationship Between *Actinomyces odontolyticus* (Xh001) and Its Epibiont, a Tm7 Phylotype (Tm7x)

Author Block:

J. Bedree[1], B. Bor[1], J. S. McLean[2], X. He[1], W. Shi[1]; [1]Univ. of California-Los Angeles, Los Angeles, CA, [2]Univ. of Washington, Seattle, WA

Abstract Body:

Background: We observed enhanced biofilm formation ability in the TM7x associated XH001 background compared to XH001 as monospecies. To elucidate the genetic basis of the observed phenotype, meta-transcriptomic profiling was implemented, revealing a set of differentially regulated genes in the TM7x-associated XH001 background versus XH001 as mono-species. The most highly expressed gene, an *lsrB* homologue, encodes a putative periplasmic binding protein for the auto inducer (AI) 2 signaling molecule. The primary focus of this study was to establish a genetic system for XH001 to elucidate the role of AI-2 quorum sensing in biofilm formation dictated by the epibiotic-parasitic relationship between XH001 and TM7x.**Methods:** We established a genetic system in XH001 enabling the successful construction of an XH001*lsrB* defective mutant. This mutant was subjected to phenotypic analyses, including growth kinetics and biofilm formation. Meanwhile, the impact of the *lsrB* mutation on the establishment and maintenance of the epibiotic parasitic interaction between XH001 and TM7x was further investigated. Utilizing a developed TM7x re-attachment method, we monitored this relationship using phase contrast microscopy and Fluorescence *in situ* Hybridization (FISH). The biofilm formation capability of TM7x-associated XH001 and the XH001*lsrB* mutant was investigated. Confocal microscopy was employed to evaluate changes in biofilm formation.**Results:** Under planktonic growth conditions, the XH001*lsrB* mutant did not display noticeable phenotypic variation as mono-culture in comparison to XH001 wild type. Strikingly, phase contrast microscopy and FISH analysis revealed significantly less micro-aggregates in liquid culture as TM7x establishes association with the XH001*lsrB* mutant compared to XH001 wild type. We evaluated this mutation in the context of biofilm formation and observed equal biofilm formation capability between XH001 wild type and XH001*lsrB*. Intriguingly, the *lsrB* mutation greatly reduced duo-species biofilm formation of XH001 and TM7x as they establish physical association.**Conclusions:** AI-2 quorum sensing likely plays a significant role in modulating duo-species biofilm formation as XH001 establishes its epiparasitic relationship with TM7x.

Udp-Galactose - Signal and Toxin in *Bacillus subtilis*

Author Block:

C. W. Habib, Y. Chai; Northeastern Univ., Boston, MA

Abstract Body:

Uridine-diphosphate-galactose (UDP-Gal) is a sugar metabolite generated from glucose by the highly conserved Leloir pathway. Though production of UDP-Gal is a standard cellular function, accumulation of this metabolite causes unexpected toxicity in both prokaryotes and eukaryotes, the molecular mechanism for which is unclear. In the model organism *Bacillus subtilis*, toxicity is presented as rapid cell death, and occurs when a mutation or deficiency is present in the last of the three Leloir pathway genes, *galE*. Herein, using a screen of second-site suppressor mutations and next generation sequencing techniques, we identify several potential targets for the toxicity of UDP-Gal. We additionally identify a catalyst for the production of UDP-Gal, *yhxB*, as well pathways for the production of biofilm and inhibition of secondary sugar uptake mechanisms which serve as rescue mechanisms for the reduction of toxicity. We propose a mechanism for the toxicity in *Bacillus* involving the incorrect incorporation of UDP-Gal in to cell wall synthesis, leading to cell wall stress and structural deformities.Further, we identify the function of UDP-Gal as an intracellular signaling molecule involved in both biofilm production and cell size determination. Biofilms are complex extracellular matrixes consisting of secreted proteins and polysaccharide components, formed in response to environmental stresses as a survival mechanism. We show that the expression of *galE*, and thereby levels of UDP-Gal, is independent of the Leloir pathway and closely regulated with that of the polysaccharide component of the biofilm. We further show that cell size and UDP-Gal production are closely regulated, with formation of UDP-Gal serving to titrate out UDP-Glucose, which has known roles in cell size signaling. As many of these genes and pathways are highly conserved, these findings are wide reaching to both gram positive and negative organisms, with implications possible in the understanding of eukaryotic disease.

Degradation of Phage Transcripts by Crispr-Associated Rnases Enables Type III Crispr-Cas Immunity

Author Block:

W. Jiang, P. Samai, G. W. Goldberg, L. A. Marraffini; The Rockefeller Univ., New York, NY

Abstract Body:

Clustered, regularly interspaced, short, palindromic repeats (CRISPR) loci and their associated (*cas*) genes encode an adaptive immune system that protects prokaryotes from viral infection. Immunity is achieved through small-RNA-directed recognition and degradation of the viral genome. CRISPR-Cas systems can be classified into three types based on their *cas* gene content. Type III CRISPR-Cas immunity is achieved through the co-transcriptional cleavage of DNA targets and their transcripts. Whereas DNA cleavage is essential for immunity, the function of RNA targeting is unknown. Here we show that transcription-dependent targeting results in a sharp increase of viral genomes in the host cell when the target is located in a late-expressed phage gene. In this targeting condition, mutations in the active sites of the type III-A RNases Csm3 and Csm6 lead to the accumulation of the target phage mRNA and abrogate immunity. Csm6 is also required to provide defense in the presence of mutated phage targets, when DNA cleavage efficiency is reduced. Our results show that the degradation of phage transcripts by CRISPR-associated RNases ensures robust immunity in situations that lead to a slow clearance of the target DNA.

Characterization of the Polyamine-Specific NspS-MbaA Signaling Pathway Controlling *Vibrio cholerae* Biofilm Formation from Polyamine Input through to Phenotypic Output

Author Block:

R. Sobe, E. Karatan; Appalachian State Univ., Boone, NC

Abstract Body:

Biofilm formation plays a major role in the *Vibrio cholerae* infectious cycle by enhancing environmental persistence and shielding members of the biofilm from acidic pH of the stomach during infection. Two polyamines, norspermidine and spermidine, have opposite effects on *V. cholerae* biofilm formation. Norspermidine is self-generated and enhances *V. cholerae* biofilm formation. Spermidine is encountered within the human host and diminishes biofilm formation. These effects are abolished in mutants lacking either component of a two-protein signaling system: the periplasmic binding protein, NspS, and the transmembrane c-di-GMP phosphodiesterase, MbaA. Interestingly, mutation of several NspS binding cleft amino acids predicted to play a role in polyamine binding result in severe defects in biofilm formation. The goal of this project was to characterize the NspS-MbaA signal transduction pathway from polyamine input through to biofilm output. Biofilm and Vibrio polysaccharide (*vps*) transcription assays were used to determine how norspermidine and spermidine influence these phenotypes in NspS ligand-binding pocket mutants. Thermal shift assays (TSAs) were used to investigate the capacity of NspS mutants to bind various concentrations of norspermidine and spermidine *in vitro*. Here we show that, in response to norspermidine and spermidine, NspS ligand-binding pocket mutants have altered capacity to influence *vps* gene transcription and biofilm formation *in vivo*. However, purified NspS mutants maintain the ability to bind these polyamines as well as the wild-type protein *in vitro*. Our results suggest that the effect of norspermidine and spermidine on *vps* gene transcription and biofilms is a consequence of an interaction between NspS with MbaA to alter phosphodiesterase activity of the latter rather than polyamine binding to NspS. Altogether, this work provides further characterization of the first polyamine-based signaling system controlling biofilm formation identified in bacteria.

Single-Base Change by Laboratory-Driven Evolution Eliminates Biofilm Formation in *Desulfovibrio vulgaris* Hildenborough

Author Block:

K. B. De Leon[1], G. M. Zane[1], G. P. Krantz[2], A. P. Arkin[3], P. D. Adams[3], M. W. Fields[2], J. D. Wall[1]; [1]Univ. of Missouri, Columbia, MO, [2]Montana State Univ., Bozeman, MT, [3]Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract Body:

Desulfovibrio vulgaris Hildenborough (DvH) is a sulfate-reducing bacterium present in heavy-metal and radionuclide contaminated sites, often as a biofilm. Yet, the genetic requirements of DvH biofilm formation have not been determined. Our goal is to determine the mechanisms and genetic requirements of biofilm formation in DvH. In pursuing this goal, inter-laboratory collaboration has led to the discovery that two wild-type DvH strains, both originally from ATCC 29579, have diverged in biofilm formation due to laboratory-driven evolution. Our wild-type DvH (DvH-MO) is partially deficient in biofilm formation as compared to data published for what should have been the same strain used in Matthew Fields' lab at Montana State University (DvH-MT). The genomes were re-sequenced from planktonic cultures of DvH-MT and DvH-MO, and DvH-MO steady-state biofilm. In DvH-MO, a single nucleotide polymorphism (SNP) in the ABC transporter (DVU1017) of a type I secretion system (T1SS) has resulted in an Ala635 to Pro change in a conserved α helix near the ATP-binding site. However, after DvH-MO forms a biofilm, a secondary SNP predominates and results in Leu635. We hypothesized that this Ala to Pro change inhibits protein transport by the T1SS and the secondary SNP resulting in a Leu restores transport. This was confirmed by introduction of the SNPs into DvH-MT. Therefore, protein transport via the T1SS is required for biofilm formation in DvH and a single nucleotide change due to laboratory-driven evolution is sufficient to stop biofilm formation. Proteins encoded in DVU1012 and DVU1545 both contain T1SS export motifs and are abundant in the DvH biofilm matrix. Inhibited transport of these proteins may have caused biofilm deficiency in DvH-MO. The double deletion mutant is deficient in biofilm formation similar to ΔDVU1017. As either DVU1012 or DVU1545 is sufficient to form biofilm, these biofilm structure proteins likely require DVU1017 for export. These findings have led to a proposed mechanism for biofilm formation in DvH and emphasize the importance of monitoring laboratory-driven evolution, especially between collaborating laboratories.

Size Distribution and Predatory Characteristics of *Pseudomonas aeruginosa* Outer Membrane Vesicles Isolated from Biofilms

Author Block:

A. C. Cooke, J. W. Schertzer; Binghamton Univ., Binghamton, NY

Abstract Body:

Gram-Negative bacteria produce Outer Membrane Vesicles (OMVs) in planktonic cultures and in biofilms. Differences between planktonic and biofilm OMVs suggest that OMVs may have different functions in different environments. Previous studies used electron microscopy and proteomic analyses to conclude that *P. aeruginosa* OMVs isolated from biofilms are smaller than planktonic OMVs, and that the two types of OMVs differ in protein content. We characterized planktonic OMVs and biofilm OMVs isolated from *P. aeruginosa* strains PAO1 and PA14. Using single particle tracking technology, we calculated the size of OMVs in solution based on Brownian motion. We also assessed the predatory ability of the OMVs against planktonic *Staphylococcus epidermidis*, as well as *S. epidermidis* grown on solid medium using a filter disk assay. Contrary to previous studies, size distributions between the OMV samples overlapped with one another, and differences between the average diameters of the OMVs tested were not statistically significant. Regardless of how they were tested, PA14 OMVs were more predatory against *S. epidermidis* than the PAO1 OMVs. However, the differences in predation between biofilm OMVs and planktonic OMVs of the same strain were not statistically significant. Our results suggest that the physical differences between biofilm OMVs and planktonic OMVs do not contribute to a difference in OMV predation, and that further investigation is required in order to conclude whether biofilm OMVs and planktonic OMVs differ in size. Future studies should investigate other characteristics to better elucidate how physical differences contribute to functional differences between OMVs in planktonic and biofilm cultures.

Identification and Analysis of Genes Responsible for Penicillin Tolerance in Group A *Streptococcus* Biofilms

Author Block:

J. A. Freiberg[1], Y. Le Breton[2], K. S. McIver[2], M. E. Shirtliff[1]; [1]Univ. of Maryland Sch. of Dentistry, Baltimore, MD, [2]Univ. of Maryland, Coll. Park, College Park, MD

Abstract Body:

Group A *Streptococcus* (GAS) is an important human pathogen that causes a number of diseases with a wide range of severity. The ability of GAS to form biofilms, complex microbial communities that adhere to a surface and secrete an extracellular matrix, has been demonstrated both *in vitro* and *in vivo*. It has been hypothesized that clinical failure of antibiotic treatment of GAS may be due in part to the formation of biofilms. However, little is known about the genes involved in GAS biofilm growth. In order to globally identify those genes and their products, we took a comprehensive approach using both transcriptomic and proteomic analyses to compare *in vitro* grown planktonic and biofilm cultures. Using both high-throughput RNA sequencing and liquid chromatography-tandem mass spectrometry (LC-MS/MS) shotgun proteomics, were able to identify 94 genes and 47 proteins whose expression differed between planktonic and biofilm cultures at multiple time points. Furthermore, the biofilm-upregulated proteins accounted for a majority of the proteins that were subsequently identified through immunoproteomics as being expressed *in vivo* in an animal model of a biofilm-mediated GAS infection.In order to study the role that certain biofilm-upregulated proteins play during biofilm growth, insertion mutants were constructed to abrogate expression of specific genes. Knocking out gene expression in the *arc* operon, which encodes genes important for pH homeostasis, caused a significant increase in susceptibility to penicillin when compared to the parent strain. After 4 hours of penicillin exposure (20 μg/ml), there was a 0.58 log-fold reduction in CFUs in the parent strain biofilm compared to a 1.41 log-fold reduction in the *arc* mutant biofilm ($p<0.01$). This difference was also seen after exposing WT and *arc* mutant biofilms to penicillin for 24 hours (0.82 vs 3.44 log-fold reduction, respectively, $p<0.0005$). This difference in penicillin sensitivity was not seen in planktonic cultures after 4 hours (3.25 vs 3.52, respectively; $p=0.73$) or 24 hours (6.99 vs 4.32, respectively; $p=0.1093$) of antibiotic treatment. This is the first report of a genetic component of penicillin resistance in GAS biofilms, and may lead to a better understanding of how to treat complex Group A *Streptococcus* infections.

Links between Anr and Quorum Sensing in *P.aeruginosa* Biofilms

Author Block:

J. H. Hammond[1], E. F. Dolben[1], W. P. Hebert[1], K. Ray[2], P. Lalitha[3], D. A. Hogan[1], M. E. Zegans[1]; [1]Geisel Sch. of Med. at Dartmouth, Hanover, NH, [2]Univ. of California, San Francisco, San Francisco, CA, [3]Aravind Eye Hosp., Madurai, India

Abstract Body:

Pseudomonas aeruginosa (*Pa*) is capable of causing acute and chronic infections at multiple body sites, and persistent *Pa* infection in the airways of cystic fibrosis (CF) patients is correlated with decreasing lung function and increased mortality. In established infections, *Pa* cells reside primarily within multicellular biofilms that are oxygen-depleted environments, and it is not yet well understood how oxygen limitation impacts *Pa* virulence. The cellular response to low oxygen or anoxia in *Pa* is controlled by the transcription factor Anr, and our analyses of *Pa* RNA harvested directly from CF patient sputum or bronchoalveolar lavage have revealed that Anr-regulated transcripts are abundant *in vivo*. Based on our finding that Anr is necessary for normal biofilm development both *in vitro* and on human CFBE cells, as well as for persistence in a model of acute lung infection, we hypothesize that Anr controls biological processes that are important for infection. To gain further insight into the Anr-regulon, we analyzed the transcriptome of two strains and their Δ*anr* derivatives, after growth as biofilms in 1% O_2. The two strains were the laboratory strain strain PAO1 and a clinical isolate with a loss of function mutation in the master regulator of quorum sensing *lasR*, a type of mutant frequently isolated from infections. We found that Anr regulated the expression of multiple pathways known to be involved in virulence, including iron acquisition and storage, CupA fimbriae, type VI secretion, and production of the 4-hydroxy-2-alkylquinolines. Additionally, these data and subsequent analyses found an inverse relationship between LasR-mediated quorum sensing and Anr activity in six pairs of constructed or naturally occurring *lasR* mutants. In a survey of 101 *Pa* clinical isolates from keratitis infections collected during the Steroids for Corneal Ulcers Trial (SCUT), we identified 22 isolates with loss-of-function mutations in *lasR*. We determined that these strains had high-level expression of Anr-regulated pathways, and a retrospective analysis showed that the presence of *lasR* mutants was correlated with poorer patient outcomes in this study.

A Novel Function for Comk in Regulating Differentiation During *Bacillus subtilis* biofilm Development

Author Block:

E. Hunter, Y. Chai; Northeastern Univ., Boston, MA

Abstract Body:

Bacillus subtilis is a Gram-positive, soil-dwelling bacterium that is commonly used to study biofilm development. Under conditions of high cell density, nutrient limitation, and hypoxia, *B. subtilis* will form highly-structured multicellular communities by secreting a self-produced polymeric substance. Biofilm cells differentiate and serve various functions in the community, therefore genetic regulatory networks are necessary to ensure cells fulfill only their designated responsibilities. López et al. (2009) demonstrated that during biofilm development, *B. subtilis* cells differentiate into surfactin- and matrix-producing subpopulations; this illustrates that differentiation into certain cell fates is often mutually exclusive. Environmental stresses can also induce expression of ComK, the master transcription regulator of genetic competence. ComK has positive and negative regulatory functions, and activates genes for DNA uptake and integration. Recently, the consensus sequence for ComK-DNA binding has been identified in the promoter for *sinI*, a key gene in biofilm development. This suggests that ComK binds the *sinI* operator to repress matrix production. In this research, we propose that competent and matrix-producing cells belong to distinct populations in the biofilm community. We demonstrate that ComK overexpression by an IPTG-inducible promoter inhibits biofilm development in *B. subtilis*. Furthermore, beta-galactosidase assays were used to show that ComK overexpression leads to downregulation of matrix genes. This added layer of regulation is a strategy to prevent competent cells from producing biofilm matrix, most likely because the matrix would interfere with DNA uptake.

Characterization of a New Ap41-Like Pyocin from *Pseudomonas aeruginosa* Isolated from Human Microbiota

Author Block:

H. Turano, F. Gomes, L. Netto, N. Lincopan; Univ. of São Paulo, São Paulo, Brazil

Abstract Body:

Bacteriocins produced by *P. aeruginosa* (pyocins) exhibit bactericidal activity against related species, including multidrug-resistant (MDR) strains. To date, three different types of pyocins have been identified based on their structure (i.e., R-type, F-type and S-type). While R and F-type pyocins are high-molecular-weight protein complexes that resemble phage tails, S-type pyocins are binary protein complexes consisting of a large protein killing and a smaller immunity protein. This study aimed characterize a new pyocin produced by a commensal *P. aeruginosa* strain (named ET02) recovered from a human patient in Brazil. From an initial screening performed on a collection of clinical and environmental *P. aeruginosa* isloates, pyocins produced by *P. aeruginosa* strain ET02 were selected for further investigation due to their wide spectrum activity against multidrug-resistant (MDR) *P. aeruginosa* strains. Antimicrobial activity of pyocins was evaluated by the Gillies and Govan method of pyocin typing. The pyocin synthesis was induced by adding mitomycin C and pyocins molecules were then precipitated by ammonium sulfate. The high-molecular weight R and F-type pyocins were sedimented by ultra-centrifugation while the S-type pyocins remained in supernatant this ultracentrifugation. The fraction containing the S-type pyocins from ET02 strain displayed the highest killing activity against carbapenemase (SPM-1, GIM-1, VIM-1, IMP-1, KPC-2 and GES-5)-producing *P. aeruginosa* strains. Analysis of mass spectrometry this fraction identified the presence of an S-type pyocin belonging the subtype AP41 (GenBank accession number: D12705.1). In this regard, further sequencing of DNA fragments containing the encoded genes of this pyocin (PyoAP41-ImuAP41) revealed a new AP41 variant (92% similarity), which showed differences in the catalytic domain. In summary, we hereby describe a new isoform of the AP41 pyocin presenting a wide spectrum activity against carbapenemase-producing *P. aeruginosa* strains. The clinical therapeutic potential of this new pyocin is worthy of further investigation.

Axenic Biofilm Formation by the Cyanobacterium *Synechocystis* PCC 6803 Requires Cell Surface Structures and Occurs Under Nutrient Limitation

Author Block:

R. C. Allen[1], B. E. Rittmann[1], W. Vermaas[1], R. Curtiss, III[2]; [1]Arizona State Univ., Tempe, AZ, [2]Florida State Univ., Gainsville, FL

Abstract Body:

Phototrophic biofilms are key to nutrient cycling in natural environments and engineered bioreactors. The literature on mixed-species phototrophic biofilms is extensive, but there are few studies describing biofilm formation by a single (axenic) species of phototrophic microbe. The cyanobacterium *Synechocystis* PCC 6803 is a model organism for the study of oxygenic photosynthesis and a promising candidate for microbial biofuel production. We hypothesize that phototrophic bacteria such as *Synechocystis* are able to form axenic biofilms, and use cell surface structures such as pili to attach and adhere to surfaces, similar to other biofilm-forming heterotrophic bacteria. Using microscopy and the crystal violet biofilm assay, we have found that *Synechocystis* forms biofilms of cells and extra-cellular material when shifted to nutrient-depleted medium. Axenic wild-type (WT) *Synechocystis* does not form biofilms in nutrient-replete medium (BG11). *Synechocystis* mutants lacking genes required for synthesis of cell surface structures such as pili and the S-layer do not form biofilms under nutrient limitation. We conclude that pili and the S-layer are necessary but not sufficient for biofilm formation by WT *Synechocystis*: an additional adhesion factor must be induced, such as through nutrient limitation, in order for pili and S-layer to facilitate biofilm formation by WT cells.To further elucidate the molecular mechanisms of adhesion by *Synechocystis*, we compared outer membrane fractions of WT and mutant cultures under induced (nutrient-limited) and uninduced conditions. SDS-PAGE of these OM proteins showed that nutrient-limited WT cultures experience a shift in the S-layer protein band; additionally, a second band is present in induced, aggregated cultures that is not in uninduced, unaggregated cultures. These data support that the molecular mechanism for aggregation by WT *Synechocystis* is synthesis and/or modification of cell surface structures in response to environmental stimuli such as nutrient limitation. We will perform RNA sequencing of *Synechocystis* cultures and also mass spectrometry of OM protein bands to further elucidate the genetic and molecular mechanisms of induction and subsequent aggregation by *Synechocystis*.

Gbpa Promotes Resistance of Nt*hi* 86-028np to Antibiotics and Oxidants within Biofilms *In Vitro* and Persistence *In Vivo*

Author Block:

B. Pang, W. Swords; Wake Forest Sch. of Med., Winston Salem, NC

Abstract Body:

Nontypeable *Haemophilus influenzae* (NT*Hi*) is a common human airway commensal that can cause respiratory tract diseases including otitis media (OM). During colonization and infection, NT*Hi* persists within surface-attached biofilms to resist environmental stress and host clearance. Our lab and others have shown that oxidative stress responses are related to persistence of NT*Hi* within biofilms. Recently we found that a chimeric antioxidant enzyme, peroxiredoxin-glutaredoxin (PgdX), was related to NT*Hi* resistance to oxidative stress and host clearance in chronic OM infections. Glutathione (GSH) is the essential intracellular reductant of the PgdX. However NT*Hi* cannot synthesize GSH and has to import it from environment via GSH binding protein (GbpA). In this study, we sought to define the factors of GbpA in stress responses and persistence of NT*Hi* within biofilms.An NT*Hi* 86-028NP *gbpA* null mutant was generated and compared to the parental strain. We measured the GSH level within whole cell lysates and observed that GSH in the *gbpA* mutant was not detected. It confirmed that GbpA was essential for the GSH uptake in NT*Hi* 86-028NP. Using a static biofilm system, we found that the *gbpA* mutant formed thinner and rougher biofilms compared to the parental strain. Using COMSTAT software to quantify biofilm properties, we observed that the thickness and biomass of the *gbpA* mutant biofilm were decreased. Although there was no survival defect in the mature biofilms of the *gbpA* mutant strain within the general condition, the *gbpA* mutant biofilm was more sensitive to multiple antibiotic and oxidative stresses. The role of GbpA in persistence *in vivo* was tested using the chinchilla infection model for OM. Animals were infected with ~1000 CFU of bacteria. Bullae and effusion fluids were harvested for bacterial counts at 7, 14, and 21d post infection. The results showed that the *gbpA* mutant had decreased resistance to clearance compared to the parental strain and the incidence rate of the *gbpA* mutant biofilms observed in the chinchilla upper bulla was significantly less than that of the parental strain at the late time point post infection.We conclude that GSH uptake mediated by GbpA promotes resistance of NT*Hi* 86-028NP to antibiotics and oxidants within biofilms and bacterial persistence in chronic OM infection.

Investigation of Surface Sensing and Response Mechanisms by P. Aeruginosa

Author Block:

S. L. Kuchma, G. O'Toole; Geisel Sch. of Med. at Dartmouth, Hanover, NH

Abstract Body:

Biofilms are surface-attached microbial communities. We are interested in understanding how microbes transition from a free-swimming to a surface-associated lifestyle. The gram-negative bacterium *Pseudomonas aeruginosa* displays a number of surface-associated behaviors, including biofilm formation as well as surface motility. The challenge for this microbe is to effectively coordinate these different behaviors to respond appropriately to prevailing surface conditions.Results from our recent studies of early cell-surface interactions indicate that *P. aeruginosa* utilizes a step-wise regulatory cascade involving successive signaling events via two distinct second messengers to control surface interaction events. Initial growth on surfaces leads to an increase in levels of the second messenger cAMP. This burst of cAMP requires a chemotaxis-like protein PilJ with its cognate chemosensory protein (Chp) complex and the type IV pilus (TFP), leading to production of cAMP via the adenylate cyclase, CyaB. cAMP and its receptor protein Vfr, together with the FimS/AlgR two-component system up-regulate expression of the TFP protein, PilY1, upon surface growth. PilY1 is subsequently secreted to the cell surface via the TFP whereby it then signals via the TFP alignment complex (PilMNOP) and the diguanylate cyclase, SadC, to promote production of the second messenger c-di-GMP. Increased levels of c-di-GMP promote biofilm formation and repress surface motility. Thus, this hierarchical regulatory cascade allows *P. aeruginosa* to coordinately regulate its surface behaviors upon surface interaction and growth.Current studies are focused on determining the precise molecular mechanisms governing the early surface stimulation of cAMP. Using the bacterial two-hybrid assay as a first step in assessing protein interactions, we have identified an interaction network between PilJ, CyaB, FimS and PilA, all of which are predicted or have been shown to reside in the inner membrane of *P. aeruginosa*. We are exploring the possibility that these protein-protein interactions are involved in the regulation of cAMP synthesis upon surface interaction.

Tfp Mediated Retraction Force Modulates Antibiotic Resistance in *Neisseria gonorrhoeae*, the Causative Agent of Gonorrhea

Author Block:

B. E. Ford, N. Biais; Brooklyn Coll. of the City Univ. of New York, Brooklyn, NY

Abstract Body:

The potential emergence of multi antibiotic-resistant *Neisseria gonorrhoeae* strains is a clear and imminent threat. Previous work has demonstrated that mechanical forces generated by the retraction of Type IV pili (Tfp) borne by *Neisseria* bacteria play a direct role in many aspects of *Neisseria* biology and in particular, microcolony formation. Microcolonies are precursors to biofilm formation and, as biofilms have been implicated in both antibiotic resistance and pathogen persistence in the environment, could be an important step in the gain of antibiotic resistance. Here we aim to assess whether the Tfp generated mechanical force crucial in microcolony formation also plays a role in antibiotic resistance. Wild-type *Neisseria gonorrhoeae*, as well as its derivative ΔpilT (mutant lacking the pilT gene—coding for an ATPase motor protein—and thereby incapable of retractive forces), were grown for 1 h in the presence of either growth media or growth media supplemented with one of six different antibiotics—Erythromycin (Erm; 50 μg/ml), Chloramphenicol (Chl; 250 μg/ml), Nalidixic acid (NA; 30 μg/ml), Kanamycin (Kan; 80 μg/ml), Ciprofloxacin (Ci; 0.12 μg/ml) and Cephalexin (Ce; 50 μg/ml); the first three being bacteriostatic and the latter three bactericidal—at the minimum inhibitory concentration (MIC), either with or without disruption of microcolonies, and subsequently assessed for viability. Preliminary results suggest that the formation of microcolonies is protective against antibiotic action for the wild type bacteria only; for mutants incapable of producing mechanical forces (e.g. the ΔpilT strain), loose microcolony aggregation leads to an increase in cell death under all tested antibiotic selection (save for Kanamycin selection as Kan resistance is also the selective marker for that mutant). These findings suggest that Tfp generated mechanical forces do indeed play an important role in modulating bacterial antibiotic susceptibility.

Cell Division Regulator Mipz in "Caulobacter Crescentus"

Author Block:

Y. Refes, B. He, M. Thanbichler; Philipps Univ. of Marburg and Max Planck Inst. for Terrestrial Microbiol., Marburg, Germany

Abstract Body:

Caulobacter crescentus is a Gram-negative bacterium that divides asymmetrically and serves as a well-established model to study the bacterial cell cycle. Each division of a *C. crescentus* cell gives rise to two morphologically and physiologically different cells: one motile cell called “swarmer cell”, and a non-motile cell called “stalked cell”. In *C. crescentus*, proper cell division requires the formation of a bipolar gradient of the regulatory ATPase MipZ that ensures the establishment of the cytokinetic FtsZ ring (Z ring) at midcell. Although the basic function of the MipZ system has been worked out, several issues remain to be clarified, including the mode of interaction between MipZ and different interaction partners, such as FtsZ, the origin-bound chromosome partitioning protein ParB, and the nucleoid. An important objective of this project is to identify the FtsZ-, ParB-, and DNA-binding regions of MipZ and thus understand how ATPase-driven changes in the oligomerization state of MipZ affect its interaction pattern. To this end, we systematically exchanged surface-exposed residues of MipZ by alanine-scanning mutagenesis. Analyzing the subcellular distribution of the mutant proteins and their ability to support division site placement, we then identified mutations that likely affect the interaction with FtsZ, DNA or ParB. The different MipZ variants were purified and further characterized *in vitro* to verify the initial, phenotype-based categorization. We found that ParB- and DNA-binding regions are overlapping and that the DNA-binding and FtsZ-binding interfaces of MipZ comprise residues located on opposite sides of the dimer. This result is consistent with the previous finding that the regulatory effect of MipZ is specific for its dimeric form and that only the dimeric form binds DNA and FtsZ. We also found that the DNA-binding region consists mainly of positively charged arginine and lysine residues lining the subunit interface, suggesting that the binding of MipZ to DNA is mainly mediated through interaction of positively charged residues with the negatively charged DNA phosphate backbone. These results provide the first detailed analysis of the interaction determinants of MipZ and, thus, deepen our knowledge of the molecular mechanism underlying the function of this intriguing cell division regulator.

Identifying Sites on MinC Important for Cell Division by Mutagenesis and Phenotypic Screening

Author Block:

C. J. LaBreck, J. L. Camberg; Univ. of Rhode Island, Kingston, RI

Abstract Body:

The Min system in *Escherichia coli*, including MinC, MinD, and MinE, controls the spatiotemporal placement of the FtsZ-ring and prevents FtsZ assembly near the cell poles. MinC is the effector of the Min system and antagonizes FtsZ polymerization through interactions at the MinC N- and C-terminal domains. MinC destabilizes FtsZ polymers by an interaction that is stimulated by MinD, which binds to the MinC C-terminal domain. To gain mechanistic insight into how MinC interacts with both FtsZ and MinD and identify the specific interaction sites important for function, we expressed MinC mutant proteins to native levels from the chromosome and performed a phenotypic screen to identify mutants with functional defects. Mutations in MinC were constructed by both random and site-directed mutagenesis of *minC*. Copies of *minC* from the mutant library were reinserted at the native locus by selective recombination into a *minC* deletion strain. We screened isolated recombinants for cell morphology and overall length distribution. Strains deleted for *minC* and those expressing defective MinC mutant proteins form anucleate minicells and short filaments in liquid culture. Using this strategy, we identified several single amino acid substitutions that inactivate MinC and mapped mutations to both the N- and C-domains of MinC. To determine if mutations in *minC* impair direct interactions with FtsZ or MinD, we purified MinC mutant proteins from *E. coli* and analyzed protein interactions in biochemical assays and assessed MinC dimerization in vitro. We tested MinC mutant proteins for inhibition of FtsZ polymerization and identified several mutations that impair the activity of MinC to inhibit GTP-dependent polymerization of FtsZ. We identified two regions on the predicted surface of MinC, one on the MinC N-terminal domain and one on the C-terminal domain, as important for FtsZ interactions. To determine if MinC mutant proteins form a complex with MinD, we used a sedimentation assay to detect ATP-dependent copolymers assembled by MinC and MinD. Several MinC mutant proteins show reduced copolymer formation with MinD, indicating that they are impaired for a direct interaction with MinD. These experiments provide important insight for the identification of surface exposed regions of MinC that mediate interactions with FtsZ and MinD and are important for cell division.

Mraz Is a Transcriptional Repressor of the *ftsz* Cluster in the Model Organism *Mycoplasma genitalium*

Author Block:

C. Martínez-Torró, S. Torres-Puig, M. Huguet-Ramón, C. Muñoz-Navarro, E. Querol, J. Piñol, O. Q. Pich; Univ.t Autònoma de Barcelona, Cerdanyola del Vallès, Spain

Abstract Body:

Cell division in bacteria is a complex process involving the coordinated participation of many proteins. In *Escherichia coli*, the division and cell wall cluster consists of sixteen genes implicated in peptidoglycan biosynthesis and assembly of the cell division apparatus. Genome reduction in mycoplasmas prompted the loss of many genes related to cell division and accordingly, in the cell wall-less bacterium *Mycoplasma genitalium*, the cell division cluster (known as the *ftsZ* cluster) contains only four genes: *mraZ* (MG_221), *mraW* (MG_222), MG_223 and *ftsZ* (MG_224). The MG_225 and MG_226 genes, located immediately downstream and in the same orientation as the *ftsZ* gene cluster, code for two putative amino acid permeases apparently unrelated to cell division. In a previous study, we demonstrated that *ftsZ* was dispensable for *in vitro* growth in *M. genitalium*. This finding highlights the unique nature of *M. genitalium* as the *ftsZ* gene is essential for survival in most bacteria. In the current study, we obtained null mutants of *mraZ*, *mraW* and MG_223 by allelic exchange, demonstrating that the four genes of the *ftsZ* cluster are non-essential in *M. genitalium*. Transcriptional analysis of the *mraZ* mutant revealed a significant upregulation (~12-fold) of the *mraW*, MG_223 and *ftsZ* genes, indicating that MraZ is a transcriptional repressor of the cell division cluster in this model organism. Transcription of the MG_225 gene was also upregulated in the *mraZ* mutant. In contrast, transcription of the *ftsZ* gene cluster was essentially unaltered upon deletion of the *mraW* gene. The repressor role of the MraZ protein is in agreement with recent work in *E. coli* and *Corynebacterium glutamicum*. Remarkably, a putative binding site for MraZ was also identified in the upstream region of the *ftsZ* cluster. On the other hand, we created fluorescent fusions of the four proteins encoded in the *ftsZ* cluster at their respective native loci. We did not observe any fluorescence when these mutants were obtained in a wild-type strain background. However, fluorescent cells were apparent in an *mraZ* mutant as well as in non-adherent mutant backgrounds. This result reinforces the repressor role of MraZ in *M. genitalium* and advocates an important role for the cell division apparatus in non-adhering populations of this bacterium.

Protein Interactions at the Conserved C-Terminus of FtsZ Affect the Dynamic Exchange of Subunits in the Z-Ring During Cell Division in *Escherichia coli*

Author Block:

M. G. Viola, C. J. LaBreck, J. Conti, J. L. Camberg; Univ. of Rhode Island, Kingston, RI

Abstract Body:

The highly coordinated process of bacterial cell division enables the separation of a mother cell into two daughter cells. FtsZ, an essential cell division protein, assembles into a dynamic ring (Z-ring) at the site of constriction. The Z-ring is composed of a bundled network of overlapping filaments, which are stabilized and/or destabilized by many cell division proteins. As the Z-ring assembles, the nucleoid associated protein SlmA binds FtsZ to prevent Z-ring assembly over the nucleoid, while the Min system, including MinC, MinD and MinE, establishes a polar gradient of MinC to inhibit Z-ring assembly at the poles. The ATP-dependent protease ClpXP and the putative ATPase ZapE have also been shown to destabilize FtsZ polymers in vitro, however the in vivo roles for these activities are unclear. To determine if proteins that destabilize FtsZ polymers in vitro also modulate the dynamic exchange of subunits in the Z-ring during division, we bleached a small region of fluorescence from Z-rings containing Gfp-FtsZ and monitored recovery in wild type and deletion strains. Cells deleted for *minC*, *slmA*, *clpX*, *clpP* or *zapE* contain Z-rings that exchange subunits 50-80% more slowly than Z-rings in wild type cells. FtsZ contains a conserved region near the C-terminus that is important for interactions with many division proteins, including MinC, SlmA, and ClpX. Expression of an FtsZ mutant protein with a C-terminal substitution, Gfp-FtsZ(R379E), in wild type cells causes cell filamentation, impaired Z-ring formation and slow Z-ring dynamics, similar to the rate of subunit exchange in cells expressing the FtsZ GTP hydrolysis mutant FtsZ(G105S). Expression of the double mutant Gfp-FtsZ(G105S, R379E) causes aberrant, membrane-associated Z-rings and severe mislocalization defects in a strain containing chromosomal *ftsZ(G105S)* at the permissive temperature, indicating that both GTP hydrolysis and C-terminal protein interactions are critical for Z-ring assembly. Together, these results demonstrate that the fast rate of subunit exchange in the Z-ring is mediated by FtsZ GTP hydrolysis and by proteins that modulate FtsZ polymerization through direct interactions at the FtsZ C-terminus.

Functional Analysis of the Bacterial Cell Division Atpase Zape

Author Block:

E. DiBiasio, M. G. Viola, A. Velasquez, J. L. Camberg; Univ. of Rhode Island, Kingston, RI

Abstract Body:

When bacterial cells divide, a large cytoskeletal structure called the Z-ring assembles at the division site. The major protein in the Z-ring is FtsZ, a tubulin homolog and GTPase that assembles into polymers and organizes into the Z-ring. In *Escherichia coli*, many cell division proteins interact with FtsZ and direct Z-ring assembly, while others may modulate constriction or direct cell wall insertion and remodeling. Several accessory proteins that interact with FtsZ are called Z-ring associated proteins (ZAPs). The Zaps (ZapA, ZapB, ZapC, ZapD, and ZapE) are recruited to the divisome and may influence Z-ring assembly or stability. ZapE was recently identified to be an ATPase that accumulates during late constriction in Gram-negative bacteria, including *E. coli*, and is important for bacterial growth under low-oxygen conditions and high temperatures (Marteyn, et al., 2014, *mBio*, 5(2):e00022-14). In vitro ZapE destabilizes FtsZ polymers suggesting that it may promote Z-ring disassembly in vivo. To investigate the role of ZapE during division, we constructed a *zapE* deletion strain to determine if the absence of *zapE* leads to a change in average cell length indicating impaired cell division. Cells deleted for *zapE* are similar in length to wild type cells and have normal Z-rings by microscopy using the fluorescent Z-ring reporter Gfp-FtsZ. However, strains deleted for *zapE* and *minC* are extensively filamentous, with the majority of cells longer than 10 μm. Synthetic cell division phenotypes have also been observed when the *minC* gene is deleted in combination with *slmA* and *clpX*. MinC spatially regulates placement of the Z-ring in vivo by preventing Z-ring assembly near the cell poles. These results demonstrate that when division site selection is impaired by deletion of *minC*, other FtsZ-assembly regulators including ZapE are important for promoting division. To further evaluate ZapE function and interactions in vivo, we are using random and site-directed mutagenesis to construct a library of *zapE* mutants. The library will be inserted into the chromosome at the native *zapE* locus by selective recombination, and isolated recombinants will be screened for overall cell length to identify loss of function mutations. These results will provide important insight for understanding the role of ZapE in cell division.

FtsEX Regulates Divisome Activity by Interacting with FtsA in *E. coli*

Author Block:

S. Du, J. Lutkenhaus; Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract Body:

Background: Cytokinesis in *E. coli* is mediated by a ring-shaped multi-protein complex called the divisome. The divisome is activated by FtsN, the last essential division protein localizing to the division site . FtsN is a bitopic membrane protein and it does this by activating FtsA in the cytoplasm (^{N}FtsN) and relieving the inhibition of peptidoglycan synthesis by the FtsQLB complex in the periplasm (^{E}FtsN) (5, 6) . Interestingly, these ATP lesion mutants of FtsEX allow divisome assembly, suggesting that ATP hydrolysis of FtsEX is necessary for divisome activation.**Methods and Results:** Using one of the ATP lesion mutants of FtsEX (FtsE^{D162N}X), we confirmed that overexpression of FtsE^{D162N}X blocks cell constriction but not assembly of the divisome. Overexpression of FtsN counteracts the division inhibitory activity of FtsE^{D162N}X, suggesting that FtsE^{D162N}X has opposite function of FtsN (blocks divisome activation). Hyperactive mutants of FtsB and FtsL are also resistant to overexpression of FtsE^{D162N}X. However, hyperactive mutants of FtsA become more sensitive to overexpression FtsE^{D162N}X, indicating that FtsE^{D162N}X blocks divisome activation in the cytoplasm. Screening for extragenic mutations that provide resistance to FtsE^{D162N}X revealed mutations in FtsB, FtsL and FtsW as well as mutations in FtsA. Characterization of these mutations suggested that the isolated mutations in FtsB, FtsL and FtsW are similar to the previously isolated hyperactive mutations of FtsB and FtsL, while the mutations on FtsA impair the interaction between FtsA with FtsX. We further identified a region on FtsA that is important for FtsA interaction with FtsX and showed that this interaction is important for cell constriction to occur but not divisome assembly.**Conclusions:** These results together suggest that FtsEX uses the energy of ATP hydrolysis to regulate divisome activity by interacting with FtsA. As FtsEX governs cell wall hydrolysis at the division site, our findings thus provide a mechanism by which cell wall synthesis (divisome activation) and hydrolysis are coupled at the division site in *E. coli*.

Effect of Essential Oils Compounds on Bacterial Cell Division

Author Block:

M. Albano[1], I. C. da Silva[1], A. Savietto[1], F. C. Bérgamo Alves[1], L. Nunes Barbosa[1], B. F. Murbach Teles Andrade[1], A. Marques Pereira[1], H. Ferreira[2], A. Fernandes Júnior[1]; [1]Univ.e Estadual Paulista "Júlio de Mesquita Filho", Botucatu, Brazil, [2]Univ.e Estadual Paulista "Júlio de Mesquita Filho", Rio Claro, Brazil

Abstract Body:

Background: The rise of drug resistance has prompted pharmaceutical industry to develop new antimicrobial drugs and bacterial cell division is a interesting new target. FtsZ is the central protein of bacterial cell division that forms the Z-ring at midcell, which enables septation. The aim of this study was to investigate plant essential oil compounds as inhibitors of bacterial cell division. **Methods:** Mutant cells of *X. citri* subsp. *citri* expressing GFP-ZapA were cultivated until the OD at 600 nm reached ~0.3 and then subjected to treatments with cinnamaldehyde, eugenol and carvacrol at concentrations corresponding to MIC_{70} (previously determined) for 3h at 30°C and immobilized on agarose-covered slides for observations by fluorescence microscopy. Control treatment was carried out with cells cultivated in the presence of 1% DMSO. Cells were visualized by using an Olympus BX-61 microscope and documented with a monochromatic XM-10 camera. Image processing and analyses were conducted by using Cell-F (Olympus). **Results:** Cinnamaldehyde and carvacrol reduced the frequency of Z-ring occurrence in X. citri subsp. citri and perturbed the Z-ring morphology. In the absence of compounds, the normal pattern of divisional septum was observed in the midcell. Eugenol did not affect the divisional septum.**Conclusions:** Our results suggest that cinnamaldehyde and carvacrol can inhibit bacterial cell division, apparently by perturbing the cytokinetic of Z-ring assembly. This could be an alternative to new treatments of infection diseases.

Role of Amidase in Cell Morphogenesis: New Insights from C*aulobacter crescentus*

Author Block:

A. DUBEY, R. Priyadarshini; Shiv Nadar Univ., Greater Noida, India

Abstract Body:

Growth and division of bacterial cell is intimately linked to remodeling of the peptidoglycan layer. Separation of daughter cells during bacterial cell division requires hydrolysis of septal peptidoglycan by peptidoglycan hydrolases. Hydrolases are the enzymes capable of cleaving the covalent bonds in peptidoglycan. One such enzyme is *N*-acetylmuramyl -L-alanine amidase that removes the peptide side chain from peptidoglycan and plays crucial role in septum cleavage. While wealth of knowledge is available about the enzymatic activity and structure of amidases, not much is known about their regulation in bacterial cell. *Caulobacter crescentus* is an eminent model system for studying cell morphogenesis. It is a dimorphic bacterium that divides asymmetrically giving rise to two different types of cells; swarmer cells and stalked cells which are genetically identical but morphologically different. Genome analysis reveals that in *C. crescentus* there is one annotated amidase homolog and this enzyme is the focus of our study. To study the localization of amidase, we created C-terminus mCherry fusion and our preliminary data showed that amidase-mCherry is localized at the cell division site and this medial localization is dependent on FtsZ in *C. crescentus*. Covisualization of amidase and FtsN in synchronized cells revealed that amidase is recruited to cell division site after FtsN, suggesting that it is a part of late cell division machinery. To more precisely assess the role of amidase, we determined the effect of amidase over activity by expressing it from plasmid (pJS14) under the control of xylose inducible promoter. In presence of xylose cell exhibited chaining indicating that over-expression of amidase leads to defects in cell division and separation. Based on these results we conclude that amidase plays a crucial role in morphogenesis of *C. crescentus.*

Variability of Thickness in Individual Cable Bacteria

Author Block:

T. Yang, L. P. Nielsen; Aarhus Univ., Aarhus C., Denmark

Abstract Body:

Cable bacteria stretch their multicellular filaments from the oxic surface sediment, through the suboxic zone and into the sulfidic zone centimeters below. They transport electrons from sulfide to oxygen, presumably via strings in a periplasmic space shared by all the cells. In developing, mixed populations of cable bacteria the average thickness of filaments has been found to increase with time and depth in the sediment. By more detailed examination we found that this was a character of single bacteria, and eventually the sulfide exposed end of a filament could be more than two times thicker and have eight times bigger cell volumes compared to the oxic end. High frequencies of dividing cells, 7% in the thin end and 11% in the thick end, showed that cells in both ends were actively dividing and not in a diseased stage.We propose that the thickness flexibility is an adaption to competition among cable bacteria for more and more distant and depleted electron donors and acceptors: Under some conditions thinning is most advantageous by allowing more efficient substrate uptake and increased filament length relative to biomass. Other conditions makes thickening more advantageous as it enhances strength and electron conductivity provided the number or thickness of periplasmic strings increases accordingly. How the morphological changes are regulated and the role of motility, energy storages, and carbon sources will also be discussed.

Role of Peptidoglycan Remodeling Machinery Components in Regulating Engulfment and Coat Localization During *Clostridium difficile* Spore Formation

Author Block:

J. Ribis, K. Fimlaid, A. Shen; Univ. of Vermont, Burlington, VT

Abstract Body:

Clostridium difficile is a major nosocomial pathogen that is the leading cause of healthcare associated diarrhea worldwide. In order for this obligate anaerobe to transmit infection, it must form metabolically dormant spores through a developmental pathway known as sporulation. A critical step during sporulation is the engulfment of the forespore by the mother cell, which in the model spore former *Bacillus subtilis* depends on the peptidoglycan hydrolases SpoIID and SpoIIP in complex with the transmembrane protein SpoIIM. Disruption of any one of the genes encoding the *B. subtilis* DPM complex prevents engulfment and thus spore formation. While homologs of these proteins exist in *C. difficile*, their role in engulfment has not been characterized. In addition, the *C. difficile* protein, SpoIIQ, likely has endopeptidase activity and is required for engulfment as well as proper coat localization in contrast with *B. subtilis*. In this study, we use allelic exchange to construct deletions of genes encoding putative engulfment-related proteins and are evaluating engulfment and coat localization in the resulting single, double, triple, and quadruple mutants. Deletion of *spoIID, spoIIP,* and *spoIIQ* resulted in engulfment and coat localization defects, with the latter phenotype being distinct from observations in *B. subtilis,* Loss of SpoIIM had minimal impact on *C. difficile* spore formation, suggesting that SpoIIM may not complex with SpoIID and SpoIIP in *C. difficile* unlike in *B. subtilis*. These analyses suggest that diverse mechanisms may control engulfment in spore-forming organisms and could inform the development of strategies for inhibiting *C. difficile* engulfment and thus disease transmission.

Mreb Regulates Polar Geometry and Stalk Elongation in *Caulobacter crescentus*

Author Block:

M. A. Bamimore[1], B. P. Bratton[2], E. A. Klein[1]; [1]Rutgers Univ.-Camden, Camden, NJ, [2]Princeton Univ., Princeton, NJ

Abstract Body:

The variety of bacterial cell shapes and sizes found in nature are largely determined by the structure and composition of the peptidoglycan cell wall. *Caulobacter crescentus*, a Gram-negative bacterium, synthesizes a long thin stalk appendage at one pole that elongates in response to phosphate limitation. Though we and others have recently uncovered the mechanisms underlying stalk localization and the establishment of stalk diffusion barriers, the mechanism of stalk synthesis remains unknown. The cytoskeletal protein MreB is known to regulate peptidoglycan synthesis in the cell body and is required for stalk synthesis. Furthermore, we have shown that MreB localizes to the stalk pole in response to phosphate starvation. Based on recent reports that the motion of MreB filaments along the cell body mediates cell width, we hypothesize that polar MreB similarly can guide stalk diameter. Using a series of MreB point mutants with unique cell shapes, we have begun to correlate polar curvature with stalk diameter. Using transmission electron microscopy (TEM), we have measured stalk diameters in the mutant collection. When compared to wild-type cells, 7/9 mutants had statistically significant changes in stalk diameter ($p<0.05$) ranging from 88-121% of wild-type.To correlate stalk diameter with polar curvature, we are expressing cytoplasmic GFP in each of the mutants and generating 3-D reconstructions of the cells using confocal microscopy. We are currently developing tools to quantitatively describe polar geometry to determine whether it is linked to stalk diameter. Our findings in this project will help to establish a basis for further characterization of the mechanisms underlying stalk biogenesis.

Characterization of a Novel Lethal Mutation in *E. coli* Gtpase Era

Author Block:

A. Weaver, X. Zhou, N. Costantino, D. Court; Natl. Cancer Inst., Frederick, MD

Abstract Body:

Purpose: The highly conserved *E. coli* GTPase Era has a known role in 30S ribosomal subunit biogenesis but also affects cell division by an unknown mechanism. We have generated an Era mutant with a multi-residue change in the G domain, Era647, that leads to lethal cell filamentation and the inability to form colonies under certain conditions. Once characterized, this mutant may be useful in identifying *E. coli* cell division factors with which Era interacts. **Methods:** To study the effects of expression level and temperature on the lethality of Era647, we have placed the mutant allele on the chromosome under the native Era promoter P_{rnc} or under a temperature inducible version of the strong bacteriophage lambda promoter P_L as well as under the arabinose induced promoter P_{BAD} on a pUC derived plasmid. Viability of these strains, in terms of the ability to form colonies, was determined by growing strains at 32°C in liquid LB media with aeration overnight, then titering on LB agar plates at 32°C and 42°C. Ampicillin and arabinose were added to maintain and induce expression from plasmids. **Results:** Expression of Era647 from the native chromosomal locus does not reduce cell viability when compared to WT Era similarly expressed at 32°C or 42°C. Expression of Era647 from chromosomal P_L or from the fully induced pUC plasmid does reduce viability by roughly 10^4x at 42°C when compared to WT Era similarly expressed while expression of Era647 from the pUC plasmid does not reduce viability of cells at 32°C. **Conclusions:** We have determined that the lethality of Era647 is dependent upon both high temperature and high expression.

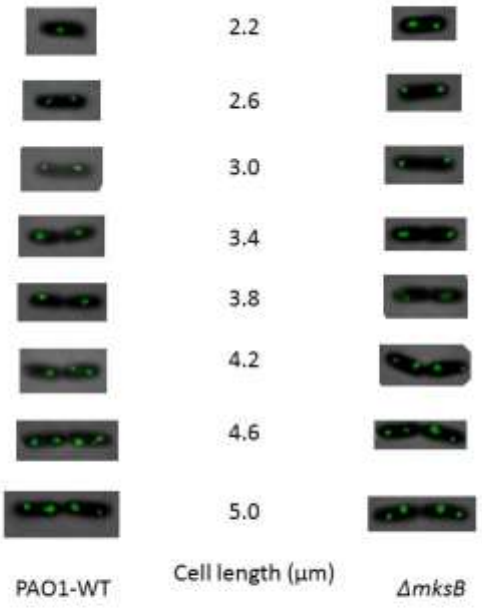
On the Contribution of Mksbef to Chromosome Segregation in *Pseudomonas aeruginosa*

Author Block:

B. K. BHOWMIK, V. V. Rybenkov; Univ. of Oklahoma, Norman, OK

Abstract Body:

Background: Condensins play a crucial role in global chromosome organization in both prokaryotes and eukaryotes. Pseudomonas aeruginosa expresses two condensins, the canonical SMC-ScpAB and the unconventional MksBEF. This study investigates the influence of MksBEF on chromosome segregation in *P. aeruginosa*.**Methods:** PAO1 condensin mutant, *ΔmksB* was constructed through homologous recombination. Several *tetO* repeats were cloned into specific loci of PAO1 chromosome and used as a target for *tetR*-CFP chimera expressed from a plasmid under an IPTG inducible promoter. Chromosomal loci were then observed using fluorescence microscopy to investigate their localization. **Results:**When grown in minimal media (doubling time 1 hr), the *oriC* and *dif* proximal regions were located towards the opposite poles of the newly born cells. The *oriC* region readily relocated towards mid-cell, following replication, splits into two foci, and remained at the cell quarters for the rest of the cell cycle. Separation of the chromosomal arms occurred later, followed by the separation of the *dif* region which splits at the very end of cell cycle and remained close to the newly formed poles of daughter cells. When grown in rich media (doubling time 52 mins) chromosome segregation followed the same pattern. However, the next round of replication began before the completion of cell division. As a result, the daughter cells contain two separate *oriC* foci. Significant differences could be observed between *ΔmksB* and PAO1-WT cells.



Segregation of oriC region in PAO1-WT and ΔmksB cells in grown in minimal media supplemented with citrate

Conclusions: Our findings indicate that the chromosomes are longitudinally organized both in PAO1-WT and *ΔmksB* cells and that MksBEF has marked effect on chromosome segregation. Conditions that support faster growth rates promote faster replication initiation without significant changes in the pattern of chromosome segregation.

Intrinsic Role of *Helicobacter pylori* min Proteins

Author Block:

Y. Nishida, H. Takeuchi, N. Morimoto, M. Kira, A. Okazaki, Y. Mastumura, T. Sugiura; Kochi Med. Sch., Kochi Univ., nankoku city, Japan

Abstract Body:

Background: Bacterial cell division is coordinated by many molecules, including FtsZ and Min proteins. In *Escherichia coli*, FtsZ forms a Z-ring structure at the division site. Min proteins (MinC, D and E) are responsible for the Z-ring formation at midcell. *Helicobacter pylori* conserves *min* genes with less than 50% homology to *E. coli*, thus the mechanisms are still unknown. Our aim is to analyze the function of *H. pylori* Min proteins and the interactions between FtsZ and Min proteins.**Methods:**A wild-type HPK5 and its derivative mutants (ΔMinC, D, E, CD and DE) disrupted by a Km^r and Cm^r cassette, were used. Bacteria were cultured in Brucella Broth supplemented with 10% horse serum with shaking at 37°C under microaerophilic condition (10% CO_2). Cells were examined by the absorbance, CFU, and Gram's stain whenever appropriate times. The cellular localization of FtsZ was detected by immunofluorescent (IF) staining. The interactions between FtsZ and Min proteins were examined by immunoprecipitation (IP)-western blotting (IP-WB) using *H. pylori* specific polyclonal antibodies were prepared with His-fusion proteins.**Results:**Except two strains (ΔMinCD and ΔMinDE), four strains showed no significant difference for cell growth and division. Gram-stain demonstrated that all disruptants became filamentous cell with different degree. The appearance rate of coccoid was obviously decreased in ΔMinE strain, consisting with high CFU count. IF staining showed FtsZ localized out of the center except HPK5 and ΔMinE. Especially in ΔMinD, FtsZ dispersedly distributed irrespective of the nucleoid position. Each Min protein interacted with FtsZ by IP-WB assay.**Conclusion:**Min proteins are involved in morphological shape determination by functional cooperation of FtsZ during cell division. Specifically, MinD plays a key role in the nucleoid occlusion system. MinE affects the morphological conversion to coccoid. Min functions were different between *E. coli* and *H. pylori*. We showed the unique characteristics of *H. pylori* Min proteins.

Role of the Semi-Conserved Histidine Residue in the Light-Sensing Domain of LitR, a MerR-Type Photosensory Transcriptional Regulator

Author Block:

H. Takano; Nihon Univ., Fujisawa, Japan

Abstract Body:

The LitR/CarH protein family transcriptional regulator is a new type of photoreceptor based on the function of adenosyl B_{12} ($AdoB_{12}$) as a light-sensitive ligand. Here, we studied the structure and function of the light-sensing ($AdoB_{12}$-binding) domain at the C-terminus (LitR-CTD) of LitR from a thermophilic gram-negative bacterium, *Thermus thermophilus* HB27. We identified a semi-conserved histidine residue (His^{132}) involved in the function of LitR, and revealed the X-ray structure of the LitR-CTD in complex with hydroxocobalamin (OHB_{12}). The *in vivo* mutation of His^{132} within LitR caused a reduction in the rate of carotenoid production in response to illumination. BIAcore analysis revealed that the illuminated-$LitR_{H132A}$ possesses high DNA-binding activity compared to the wild-type protein. The crystal structure of the OHB_{12}-bound LitR-CTD was determined at 2.52 Å, which was closest to that of monomethylamine corrinoid protein from *Methanosarcina barkeri*. The OHB_{12} bound to LitR was tucked with His^{177}, a conserved residue of the B_{12}-binding motif, and His^{132} from both sides. The ability of $LitR_{H132A}$ to associate with $AdoB_{12}$ was reduced compared with that of the wild-type protein in an equilibration dialysis experiment. Overall, these results suggest that His^{132} of LitR-CTD is involved in the association with $AdoB_{12}$ as well as the light-sensitive DNA-binding activity.

Molecular Analysis of *glnR* and the *vicRKX* Two-Component System in the pH-Dependent Expression of the *Streptococcus salivarius* 57.I Urease Operon

Author Block:

S-C. Huang, Y-Y. M. Chen; Chang Gung Univ., Taoyuan, Taiwan

Abstract Body:

Ureolysis by *Streptococcus salivarius* is critical for pH homeostasis of dental plaque and prevention of dental caries. The expression of *S. salivarius* urease is enhanced by acidic pH and excess amounts of glucose. The differential expression is regulated mainly at the transcriptional level on the promoter 5' to *ureI*, p_{ureI}. Our previous study demonstrates that CodY directly represses p_{ureI} expression and the repression is more pronounced at pH 7 compared to cells grown at pH 5.5. The expression of p_{ureI} remains sensitive to pH and glucose concentration in the *codY*-deficient background, suggesting that additional regulator is involved in the urease regulation. Recent sequence analysis revealed a putative VicR box and two GlnR boxes 5' to the CodY box. The results of DNA affinity precipitation assay, electrophoretic mobility shift assay (EMSA), and chromatin immunoprecipitation-PCR indicated that both VicR and GlnR interacted with the predicted binding boxes on p_{ureI}. By establishing a p_{ureI}-chloramphenicol acetyltransferase gene (*cat*) fusion system in *S. salivarius*, it was found that mutations in the VicR box upregulate p_{ureI} expression, whereas mutations in the GlnR boxes downregulate p_{ureI} expression. Isogenic mutant strains (*vicRKX*- and *glnR*-null) and complemented strains (harboring *S. salivarius vicRKX* and *glnR*) were generated in the recombinant *Streptococcus gordonii* host harboring a wild-type p_{ureI}-*cat* fusion on *gtfG* to investigate the regulatory function of VicR and GlnR. The recombinant strains were grown in a chemostat under glucose-excess (100 mM) and -limiting (20 mM) conditions, at pH 7 and 5.5. Results of p_{ureI}-*cat* activity indicated that the repression by VicR was more pronounced at pH 7 whereas GlnR was more active at pH 5.5. Furthermore, the results of EMSA and promoter analysis indicated that the C-terminal domain of the RNA polymerase α subunit interacted with the VicR box to enhance p_{ureI} expression in the absence of VicR. The overall regulation by CodY, VicR and GlnR in response to pH ensures optimal expression of urease in *S. salivarius* when the enzyme is most needed.

Application of *Pseudomonas aeruginosa* as a Genetic Tool for the Molecular Study of *Corynebacterium glutamicum*

Author Block:

J-H. Lee, Y-J. Kim, H-S. Shin, H-S. Lee, U-H. Ha; Korea Univ., Sejong, Korea, Republic of

Abstract Body:

Background: We previously identified a putative acyltransferase encoded by NCgl0350 of *Corynebacterium glutamicum*, which is induced by cell-free culture fluids obtained from stationary-phase growth of both *C. glutamicum* and *Pseudomonas aeruginosa*, providing evidence for interspecies communication. However, upstream regulators responsible for the autoinduction have not been elucidated yet.**Methods:** A growth-permissive assay and β-galactosidase assay were conducted to determine the transcriptional expressions. To identify the upstream regulators, we used *P. aeruginosa* as a genetic model to substitute for *C. glutamicum*.**Results:** The putative acyltransferase expression was induced by culture fluids obtained from diverse Gram-negative and -positive bacterial strains. A homologous acyltransferase encoded by PA5238 of *P. aeruginosa* was identified and found to be induced by those culture fluids, as observed for NCgl0350 of *C. glutamicum*. Because *C. glutamicum* is difficult to study using transposon mutagenesis approaches, the homologous gene PA5238 was used to identify PA5309 as an upstream regulator of expression. A homologous D-amino acid dehydrogenase encoded by NCgl2909 of *C. glutamicum* was cloned based on amino acid similarity to PA5309, and its role in the regulation of NCgl0350 expression was confirmed.**Conclusions:** We successfully applied *P. aeruginosa* to substitute for the molecular study of *C. glutamicum*, resulting in identifying a D-amino acid dehydrogenase as an upstream regulator of the autoinduction of a putative acyltransferase in *C. glutamicum*.

ampM*, a Member of L2-*ampM* Operon, Involved in the *mrcA* Inactivation-Mediated β-Lactamase Expression in *Stenotrophomonas maltophilia

Author Block:

Y-W. Huang, C-J. Wu, Y. Wang, T-C. Yang; Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract Body:

The L2 β-lactamase gene of *Stenotrophomonas maltophilia* has been shown to be involved in β-lactams resistance and its expression is regulated by the *ampR* gene, which divergently locates upstream of the L2 gene. In this study, L2 and its downstream gene, designated as *ampM* hereinafter, were shown to be an operon, as revealed by Quantitative Real-Time PCR (QRT-PCR), and Reverse Transcriptase PCR (RT-PCT). The expression of the *ampM* gene depended on the *ampR*-regulated L2 promoter (P_{L2}) and its own promoter (P_{ampM}). The *ampM* gene previously annotated as a putative Na^+/H^+ antiporter in the genome project of *S. maltophilia* was found to be less involved in the sodium homeostasis. Since *ampM* and *L2* form an operon, we assessed the involvement of AmpM in the β-lactamase expression. An *ampM* isogenic deletion mutant, *ΔampM*, was constructed, and the basal- and induced- β-lactamase activities between WT and *ΔampM* were evaluated. Inactivation of *ampM* little affected the basal and induced β-lactamase activities. In our previous study, we have demonstrated that the *ampD*$_I$, *mrcA*, and *mltD1* deletion mutants, *ΔampD*$_I$, *ΔmrcA*, and *ΔmltD1*, display a similar phenotype of basal-level β-lactamase upexpression; therefore we further assessed the involvement of AmpM in this phenotype. The *ΔampM* allele was introduced into the chromosomes of *ΔampD*$_I$, *ΔmrcA*, and *ΔmltD1,* respectively, yielding double mutants of *ΔampD*$_I$*ΔampM*, *ΔmrcAΔampM*, and *ΔmltD1ΔampM*. The basal-level β-lactamase activities of these double mutants and their parental strains were comparatively determined. Inactivation of *ampM* partially decreased the basal-level β-lactamase activity of *ΔmrcA* mutant, but hardly affected those of *ΔampD*$_I$ and *ΔmltD1* deletion mutants.

The Global Regulator WetA Governs Fungal Development and Secondary Metabolism

Author Block:

M-y. Wu, J-H. Yu; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Background: The genus *Aspergillus* represents the most common fungi in the environment and can serve as a model system for genetic study of filamentous fungi. The main reproductive mode of aspergilli is the formation of asexual spores called conidia. BrlA, AbaA, and WetA are proposed as the central regulators of asexual development (conidiation) in aspergilli. BrlA and AbaA are transcription factors, yet the WetA-mediated regulatory mechanism is still unknown. Here, we characterized WetA's functions and further investigated the underlying molecular regulatory mechanism.**Methods:** We characterized WetA's functions in *A. nidulans* (FGSC4) and *A. flavus* (NRRL3357) by generating *wetA*-null mutants. For genome-wide expression studies, RNA-seq was carried out using RNA samples extracted from *A. nidulans* WT and *wetA*-null mutant conidia. The library was sequenced (PE100bp) using the Illumina HiSeq2500 generating final of over 10^7 reads/sample. For in vivo WetA-DNA interaction studies, ChIP-PCR was performed using MAGnify Chromatin Immuno-precipitation System (Invitrogen) with anti-WetA antibody. Samples were collected from *A. nidulans* and *A. flavus* WT conidia. The enriched DNA were confirmed by PCR.**Results:** The *wetA*-null mutants form wet and white conidia, which display deficient structure and autolyze in 3 days. Loss of *wetA* leads to decreased levels of conidial trehalose, the major protectant for thecellular integrity. Consistently, the *wetA*-null conidia show reduced viability under normal and stressed conditions. WetA also regulates conidiation timing in a species-specific manner. The growth rate and aflatoxin production data indicated that WetA is not only involved in asexual development, but also in vegetative growth and secondary metabolism. Northern analysis shows that WetA is a negative regulator of its upstream regulators and exerts feed-back control for development in both species. RNA-seq data show that WetA plays a global regulatory role in conidiogenesis. The ChIP-PCR results show that WetA binds to the upstream region of *brlA*, indicating the direct repressive role of WetA on *brlA* expression.**Conclusions:** WetA is an evolutionary conserved central developmental regulator in certain groups of Ascomycetes. This is the first study demonstrating that WetA is a DNA-binding protein, which plays a global regulatory role on asexual development, vegetative growth and secondary metabolism.

Determining the Architecture of a Succinate-Mediated Catabolite Repression Controlled Promoter in *Sinorhizobium meliloti*

Author Block:

J. Johnson, C. Mirarchi, M. Arif, L. Ngaba, C. Arango; St. Joseph's Univ., Philadelphia, PA

Abstract Body:

Sinorhizobium meliloti, a Gram negative soil bacterium that fixes nitrogen when in symbiosis with legumes, exhibits succinate-mediated catabolite repression (SMCR), where the presence of succinate controls expression of a number of genes. The regulatory mechanisms of SMCR in *S. meliloti* are not well understood, and, although it is known that a phosphotransferase system is involved, a global regulator has not been identified. Uncovering the architecture of SMCR-regulated promoters may shed light on the presence of such regulator and help identify the members of the SMCR regulon. The purpose of this study is to identify sequences that are critical for regulation of gene expression in the model SMCR-controlled operon *agp-melA*. This operon, induced by raffinose but repressed in the presence of succinate, codes for proteins for raffinose utilization and is under the control of the local activator AgpT. To determine the promoter architecture, a 400 bp region upstream of *agp-melA*, P*melA*, was identified as necessary for proper regulation. This region was used to investigate the binding site of the activator ApgT, using radio-labeled wild-type and mutant DNA, and crude protein *S. meliloti* extracts in an Electrophoresis Mobility Shift Assay. Additionally, a P*melA*:*gfp* reporter plasmid was used to find other regulatory sequences, using two approaches: the promoter was subjected to random point mutations through error-prone PCR, and 3'- and 5'- shortened promoters were constructed. The library of random and shortened mutant P*melA* was screened for altered *gfp* expression in colonies grown on raffinose plates in the presence and absence of succinate using low-magnification fluorescence microscopy. Eighty random P*melA* mutants and four 5'end-shortened promoters that exhibited reduced expression were identified. The phenotypes of a subset were confirmed monitoring fluorescence in liquid culture. Sequencing of two of the random P*melA* mutants, and analysis of the 5' end shortened ones revealed a 26-bp region that is critical for expression. We are conducting EMSA assays to elucidate if this is the binding site of AgpT. Sequencing of the remaining random mutants is ongoing and may reveal the location of other regions critical for SMCR regulation of the *agp-melA* operon.

A New Regulatory Cascade Controlling *ompF* Expression with Temperature

Author Block:

V. Duval, S. B. Levy; Ctr. for Adaptation Genetics and Drug Resistance, Tufts Univ. Sch. of Med., Boston, MA

Abstract Body:

In *Escherichia coli*, OmpF is an important outer membrane protein, which serves as a passive diffusion pore for nutrients and antibiotics, and for excretion of toxic products. Regulation of OmpF expression is well documented and is known to involve a network of transcriptional and translational regulators responding to osmolarity, stress and temperature. However, the detailed mechanism leading to increased OmpF levels at ambient temperature (25°C) versus 37°C is still unknown. Using RT-qPCR, we quantified OmpF mRNA levels and showed that two mutations in *lon* (coding for the Lon protease) and in *bluR* (coding for a MerR-like regulator) prevented high expression of *ompF* at ambient temperature. Using a chromosomal fusion of *ompF* promoter region and *lacZ* (*ompFp-lacZ*), we measured similar activity of *ompF* promoter at 37°C for both wild-type and *lon bluR* mutant, while a decreased activity was observed in the *lon bluR* mutant at 25°C. Deletion of the *ycgZ-ymgABC* operon in the *lon bluR* mutant, known to be regulated by BluR, restored wild-type like expression of OmpF at 25°C. The stability of YcgZ, YmgA, YmgB and YmgC proteins was then analyzed in both wild type and *lon* strains using the vector pBAD for expressing the proteins. Our results showed that YcgZ protein was highly unstable in the presence of Lon (wild type background) while a high amount of YcgZ was observed in the *lon* mutant. The quantity of YmgA, YmgB and YmgC was similar in wild type and *lon* strains indicating that these proteins were not degraded by the Lon protease. Furthermore, overexpression of YcgZ at 25°C significantly decreased *ompFp-lacZ* activity in a strain carrying mutations in *lon, bluR and ycgZ-ymgABC*. In summary, our study identified a new regulatory cascade that controls levels of OmpF with temperature. This pathway involves BluR, which controls expression of YcgZ, a repressor of OmpF transcription and a substrate of the Lon protease. As *Enterobacteriaceae* may transit through many different locations encountering shifts to lower temperatures, an understanding of how these microorganisms adaptto temperature changes is particularly important in medical and food industry where the prevention of bacterial contamination is imperative.

Structure-Function Studies of the *Schizosaccharomyces pombe* Ell-Eaf Transcription Elongation Complex

Author Block:

N. Sharma[1], P. Dabas[1], K. Sweta[1], S. Gopalan[2], K. Jain[1], R. Conaway[2], J. Conaway[2];
[1]G.G.S.Indraprastha Univ., New Delhi, India, [2]Stowers Inst. for Med. Res., Kansas City, MO

Abstract Body:

Transcription is an important step in the control of gene expression in eukaryotic cells. Research over the past few decades has primarily focussed on the preinitiation and initiation stages of transcription. However, recent studies have shown that transcription elongation also constitutes a major step of transcription regulation. A plethora of elongation proteins have been discovered, and elucidating the roles of each of these proteins is a challenge. The ELL (Eleven Nineteen Lysine Rich Leukemia) and EAF (ELL associated factor) family of proteins suppress transient pausing of the RNA polymerase II enzyme along the DNA template in *in vitro* transcription assays. However, the structure and function(s) of these proteins still await a detailed characterization. A single homologue of ELL and EAF proteins is present in *Schizosaccharomyces pombe*. In this study, we have used different approaches to elucidate the functional and structural properties of these proteins in *S. pombe*. Our results show that deletion of either ELL or EAF causes slow growth of cells under optimum growth conditions. Moreover, exposure to DNA damaging agents reduces the viability of ELL and EAF null mutants. In comparison, no growth defect was observed under a variety of environmental stress conditions tested. To determine if both these proteins act in the same pathway, we have also looked at the effect of deleting both these genes on different phenotypes. Truncation mutants have also been constructed to delineate the regions of these proteins important for the observed phenotypes, as well as required for transactivation and transcription elongation. Yeast two-hybrid and co-immunoprecipitation assays have been used to map the domain required for interaction between ELL and EAF proteins. Localization of these proteins has also been studied. Our yeast two hybrid analysis has revealed that the *S. pombe* and human ELL-EAF proteins do not heterodimerize. We have also used CD spectroscopy to gain insights into the structure of the EAF protein. In summary, our results provide novel insights into the structure and functions of these proteins.

Protein-Protein Interaction of *Campylobacter jejuni* Post-Transcriptional Regulator CSRA and Putative Flagellar Chaperone Fliw

Author Block:

J. Li[1], **C. A. Fulmer**[1], A. Upchurch[1], L. K. H. Tran[1], P. M. H. Tran[1], J. S. Fiedler[1], G. Gutierrez-Sanchez[2], S. A. Thompson[1]; [1]Augusta Univ., Augusta, GA, [2]Univ. of Georgia, Athens, GA

Abstract Body:

Campylobacter jejuni is a leading causative agent of bacterial gastroenteritis and is attributed to as much as 40-80% of cases of Guillain-Barré syndrome. We showed that the homodimeric post-transcriptional regulator CsrA is involved with biofilm formation, motility, and host cell invasion, each of which require functional flagella. While *Escherichia coli* CsrA activity is regulated by interactions with small non-coding RNAs, we demonstrated that *C. jejuni* CsrA activity is likely regulated by protein-protein interactions between CsrA and FliW, a putative flagellar chaperone. Using pulldown assays, protein-protein crosslinking, and surface plasmon resonance, we demonstrated binding of CsrA to FliW. *C. jejuni* CsrA notably differs from *E. coli* CsrA in the C-terminal region of the protein, both in amino acid sequence and in length. PHYRE[2] analysis of *C. jejuni* CsrA predicts that this region lies on the outside of CsrA homodimers, leading to the hypothesis that this is the site of protein-protein interactions between CsrA and FliW. Deletion analysis of the CsrA C-terminus showed that the region of -16 to -28 amino acids (relative to the CsrA C-terminus) was required for FliW binding. We are currently using site-directed mutagenesis of this region of the CsrA protein to identify amino acids that are required for *C. jejuni* CsrA-FliW protein-protein interaction. These results suggest a model that binding of FliW near the CsrA C-terminus destabilizes the second CsrA RNA binding domain and thereby modulates its regulatory activity, linking flagellar synthesis with CsrA regulation of metabolic and other pathogenesis-related features of *C. jejuni*.

Lambdoid Phages Modulate Regulation of the Pathogenicity Island Locus of Enterocyte Effacement (Lee) on Pathogenic *Escherichia coli*

Author Block:

J. D. Hernandez-Doria, V. Sperandio; Univ. of Texas Southwestern Med. centre, Dallas, TX

Abstract Body:

Enterohemorrhagic *Escherichia coli* (EHEC) causes bloody diarrhea and hemolytic uremic syndrome (HUS) worldwide. HUS is caused by Shiga toxin (Stx), and the genes encoding this toxin are carried within the late genes of a lambdoid bacteriophage. The stx phage can be either lysogenic or lytic. Another important pathogenicity island is the locus of enterocyte and effacement (LEE) that encodes for a type three secretion system, and adhesin and its receptor that are necessary to form attaching and effacing (AE) lesions on epithelial cells. Here we show that there is regulatory "cross-talk" between the LEE and the stx phage. The phage transcription factor Cro activates expression of the LEE genes and promotes AE lesion formation. Cro directly binds to the regulatory region of *ler*, which encodes the activator of all LEE genes. The Cro protein differs among different Stx-phages, suggesting that modulation of LEE expression may vary among different EHEC strains.

Transcriptional Regulation of Quinate Metabolism in *Listeria monocytogenes*

Author Block:

S. M. Prezioso, D. Christendat; Univ. of Toronto, Toronto, ON, Canada

Abstract Body:

The shikimate pathway is an essential metabolic pathway in bacteria, plants, and fungi, which leads to the synthesis of the three aromatic amino acids among other important aromatic compounds. Quinate is an abundant plant derived compound that can be catabolized by some bacteria through a branch of the shikimate pathway to generate energy, although little is known about the regulation of quinate utilization in bacteria. The genome of *Listeria monocytogenes* includes an operon that contains quinate utilization enzymes (shikimate/quinate dehydrogenase and dehydroquinate dehydratase), and a LysR type transcriptional regulator (named QuiR1) that is upstream and divergently transcribed. Using differential scanning fluorimetry and electrophoretic mobility shift assays, we have shown that QuiR1 binds to shikimate in order to modulate its activity at this divergent promoter. Data from *lacZ*-promoter fusion experiments demonstrate that QuiR1 functions as an activator of quinate operon transcription in the presence of shikimate and an auto-repressor of its own transcription. Additionally, the crystal structure of the QuiR1 effector binding domain was determined to a resolution of 2.5 Å in complex with its effector, shikimate. Since Listeria does not have the familiar downstream enzymes involved in quinate catabolism, the role of quinate metabolism in *L. monocytogenes* is also intriguing.

Investigating the Effect of the Calr Transcription Factor on Expression of Calcium-regulated Genes *In Vibrio* Parahaemolyticus

Author Block:

R. Manges, L. Post, K. Bies, L. Swanson, J. Enos-Berlage; Luther Coll., Decorah, IA

Abstract Body:

Background: Although calcium is known to influence gene expression in some bacteria, the mechanisms and physiological benefits of this regulation are not well understood. *Vibrio parahaemolyticus* is a ubiquitous marine bacterium and major cause of seafoodborne illness. Notably, this organism experiences varying calcium levels in its ocean, estuary, and human GI tract habitats. Previous isolation of Tn5*lux* gene fusions identified over 40 distinct *V. parahaemolyticus* loci whose expression was influenced by calcium. CalR, a LysR-type transcription factor, was initially found to repress calcium-dependent swarming and Type III secretion in *V. parahaemolyticus*. We hypothesized that CalR might also be involved in the regulation of other calcium-regulated genes. To test this idea, we examined the effect of overexpressing or knocking out *calR* on expression of calcium-regulated genes. **Methods and Results**: A CalR overexpression vector was introduced into the collection of calcium-regulated Tn5*lux* fusions, and twelve loci were identified whose expression was altered by increased levels of CalR. Six of these loci were chosen for further analyses based on their potential to increase understanding of the CalR regulon. A *calR* knockout mutation was introduced into each of these strains, and gene expression was examined in triplicate in both $calR^+$ and $calR^-$ strains grown under varying calcium conditions. Lack of CalR resulted in elevated gene expression in five Tn5*lux* fusions and decreased gene expression in one fusion, with $calR^-/calR^+$ fold changes ranging from three to over 20-fold. Genes whose expression was regulated by CalR had established or predicted functions in motility, amino acid transport, extracellular polysaccharide transport, iron acquisition, hemolysis, and protease activity. For all loci, the phenotypic impact of the *calR* mutation was most pronounced under low calcium conditions. **Conclusion:** These data serve to expand the CalR regulon in *V. parahaemolyticus* and support the idea that CalR is repressing expression of multiple genes under low calcium conditions. The existence of one locus whose expression is enhanced by CalR suggests additional regulatory complexity. Collectively, these data provide useful clues to further our understanding of calcium regulation in bacteria.

Crystal Structure of Dimerization/Oligomerization Domain of an Mvat Homolog in *Pseudomonads*

Author Block:

C. Suzuki-Minakuchi[1], K. Kawazuma[1], J. Matsuzawa[1], D. Vasileva[1], Z. Fujimoto[2], T. Terada[1], K. Okada[1], H. Nojiri[1]; [1]The Univ. of Tokyo, Tokyo, Japan, [2]Natl. Inst. of Agrobiological Sci., Tsukuba, Japan

Abstract Body:

Background: H-NS family proteins, one of the nucleoid-associated proteins, repress genes acquired through horizontal gene transfer. MvaT homologs in *Pseudomonas* have almost negligible amino acid sequence identity with H-NS but can complement an *hns*-related phenotype of *Escherichia coli*. It remains unknown whether the molecular mechanisms for their function are the same between MvaT and H-NS homologs. Here, we solved the crystal structure of the dimerization/oligomerization domain of TurB (TurB_nt$_{61}$), an MvaT homolog in *Pseudomonas putida* KT2440, to get an insight into functional manner of MvaT homologs.**Methods:** To obtain oligomerization-deficient derivatives of TurB_nt$_{61}$, we introduced the alanine substitutions at seven residues, which were predicted to be involved in homo-oligomerization from the previous study [1]. Among them, TurB_nt$_{61}$-R8A was crystallized using a precipitant solution containing ammonium acetate. Initial structural determination was conducted by the single-wavelength anomalous diffraction using the selenium absorption peak. Crystal structure of the native TurB_nt$_{61}$-R8A was determined by the molecular replacement.**Results:** The structure of TurB_nt$_{61}$-R8A was determined at 2.3 Å resolution. The crystal contained one dimer molecule per asymmetric unit, in which two subunits were interlocked at the C-terminal region. This “dimerization site” was stabilized by a hydrophobic core and hydrogen bonds, and was similar to that of H-NS. N-terminal region of TurB_nt$_{61}$ missing the above “dimerization site” still formed homo-dimers but not homo-oligomers, suggesting that TurB has additional “dimerization site” in its N-terminus. The fact that two dimerization sites are necessary for oligomerization is similar to that of H-NS. But, N-terminal “dimerization site” in TurB_nt$_{61}$ was predicted to be formed by a coiled-coil motif, whereas the corresponding “dimerization site” in H-NS is interlocked by additional two small helices.**Conclusions:** We found that TurB and H-NS have partly similar but different oligomerization mechanisms. The results can shed light on the evolutionary pathway of H-NS family proteins.

Uncovering Structural Determinants Associated with Ligand and Dna Binding Specificity in a Conserved Subfamily of Arac Transcription Regulators

Author Block:

G. G. Willsey, E. L. English, M. J. Wargo; Univ. of Vermont, Burlington, VT

Abstract Body:

Catabolism of glycine betaine in *Pseudomonas aeruginosa* is regulated by two transcription factors, SouR and GbdR. GbdR induces genes encoding all steps in the pathway in response to GB and dimethylglycine, while SouR only induces the genes for sarcosine demethylation in response to sarcosine. GbdR and SouR are members of the glutamine amidotransferase1-like subfamily of AraCt transcription regulators (GATRs), and their sequence homology and phylogenetic distribution suggest common ancestry and extensive gene transfer. Despite their widespread distribution among proteobacteria, little is known about these regulators aside from their basic two domain architecture. The close phylogenetic similarities between SouR and GbdR and their partially overlapping regulons provide us with a powerful system to understand the molecular basis of the ligand binding and promoter specifies for the GATR subfamily. To gain insight into the ligand recognition mechanism of GATR's we have devised a gain-of-function genetic screen coupling the random mutagenesis of *souR* with sarcosine anaologs ethylglycine and dimethylglycine as potential inducing ligands with the goal of identifying residues influencing activation specificity. Through this process we have identified numerous mutants exhibiting either sarcosine hyper-responsive, sarcosine-repressive, ethylglycine-responsive, or constitutive phenotypes, and are currently characterizing the genotypic signatures of each. Additionally, we are in the process of performing a second gain of function screen to identify signatures within the promoter region that direct the differential DNA binding specificities of SouR and GbdR. Together, data collected from these screens will provide the first insight into the GATR activation mechanism, and will generate the information necessary to guide future structure-function studies.

Quorum-sensing Gene Regulation by *Vibrio harveyi* luxr Requires an Activity in Addition to Dna Binding

Author Block:

J. A. Healy, **J. C. van Kessel**; Indiana Univ., Bloomington, IN

Abstract Body:

Quorum sensing is a method of cell-cell communication that allows bacteria to sense and respond to changes in population density. Bacteria use quorum sensing to control processes that are more beneficial when performed by groups of cells acting together, such as virulence factor production, biofilm formation, competence, and bioluminescence. In vibrios, quorum-sensing gene expression is controlled by the master transcription factor LuxR, which controls >600 genes, including those that produce bioluminescence. *Vibrio harveyi* LuxR is classified as a member of the TetR superfamily of transcription factors but is unique because it both activates and represses transcription. We isolated three mutants of LuxR that are defective for transcription activation of the bioluminescence genes but retain wild-type transcription repression of other promoters. Each of these mutations lies outside the N-terminal DNA binding domain and instead are located closer to the C-terminus on alpha-helix 7. The LuxR L139P mutant does not show any defects in DNA binding activities at any tested binding site *in vitro*. Thus, we hypothesized that another activity - in addition to DNA binding - is required for transcription activation of the bioluminescence genes. We developed a reporter assay in *Escherichia coli* to monitor LuxR transcription activation and repression simultaneously: activation of the bioluminescence genes (*gfp*) and repression of a hydrolase gene (*mCherry*). Using the LuxR L139P mutant and this reporter, we performed a suppressor screen via EMS mutagenesis to isolate *E. coli* mutants with increased activation of the bioluminescence genes. Several *E. coli* mutants increased activation two- to four-fold, suggesting that another factor in *E. coli* plays a role in transcription activation together with LuxR. Surprisingly, we also isolated several *E. coli* mutants that decreased repression activity. Characterization of these mutants will enable us to identify possible interaction partners or other *trans*-acting elements that regulate transcription activation of quorum-sensing genes with LuxR. Because LuxR proteins are the central regulators of quorum sensing in all vibrios, this research will uncover novel functions and interactions that are required for quorum-sensing gene regulation.

The Involvement of Nucleoid-associated Proteins in Luxr-directed Transcription *In Vibrio* Harveyi

Author Block:

R. Chaparian, S. G. Olney, J. C. van Kessel; Indiana Univ., Bloomington, IN

Abstract Body:

Quorum sensing is a cell-cell communication process in which bacterial cells produce, release and respond to extracellular chemical signaling molecules to evaluate local population density. Bacteria coordinate group activities such as bioluminescence, virulence factor production, and biofilm formation via quorum sensing. In *Vibrio harveyi*, the master quorum-sensing transcription factor LuxR activates and represses >600 genes. However, the mechanistic details by which this is achieved are unclear; we have identified 7 LuxR binding sites within the promoter region and will characterize their individual contributions to transcription. Using biochemical and genetic approaches we identified the nucleoid associated proteins IHF, Fis and H-NS as regulators of the *luxCDABE* operon, a model LuxR-dependent promoter. IHF bends the *luxCDABE* promoter DNA ~90° *in vitro*, and binding of IHF *in vivo* is required for precise timing and levels of activation of this operon. Conversely, H-NS functions solely as a repressor of transcription, and we have shown that H-NS inhibits transcription of the *luxCDABE* operon *in vivo*. To gain insight on the mechanistic details regarding LuxR-driven transcription activation, we will utilize *in vitro* transcription assays to monitor the formation of transcriptionally competent nucleoprotein complexes. We performed gel-shift assays in the presence of LuxR and IHF in which we observed synergistic binding. Furthermore, using RNA-Seq we demonstrated that the LuxR and IHF regulons overlap at 18 promoters. Collectively, our data implicate nucleoid-associated proteins in LuxR-dependent gene regulation in the *Vibrio* clade.

Irf-3 Regulates Rig-I Expression in Ifn-Independent Manner in Response to Dsrna

Author Block:

R. Hayakari, T. Matsumiya, F. Xing, H. Yoshida, T. Imaizumi; Hirosaki Univ. Grad. Sch. of Med., Hirosaki, Aomori, Japan

Abstract Body:

The innate immune system is the first line of host defense against invading pathogens. Retinoic acid-inducible gene-I (RIG-I) plays an important role in the innate immune responses. Upon viral infection, RIG-I senses viral RNA in cytoplasm triggering the activation of antiviral signaling to produce type I interferon (IFN). In this cascade, IFN regulatory factor-3 (IRF-3) is known to be a crucial molecule. Although RIG-I contributes to the antiviral signaling, RIG-I itself is known to be one of IFN-inducible genes. However, the mechanism wherein viral infection stimulates the expression of RIG-I has not been completely elucidated. We transfected the cells with polyinosinic-polycytidylic acid (poly I:C), a synthetic double-stranded (ds)RNA, to mimic viral infection. Using IFN-α/β receptor-null U5A cells and their parental 2fTGH cells, we previously reported that a part of RIG-I expression is regulated in an IFN-independent manner in response to dsRNA. To elucidate what factor(s) regulates the RIG-I expression, we generated a series of luciferase reporter constructs containing RIG-I promoter and analyzed the promoter activity. Although a number of consensus sequences of transcriptional factors were identified in the RIG-I promoter region by computational analysis, deletion of putative IRF binding site abolished its transcriptional activity. This result suggests that IRF regulates RIG-I gene expression through the activation of the RIG-I promoter. We further tested the influence of IRF-3 on the expression of RIG-I using IRF-3-specific RNAi and found that the knockdown of IRF-3 significantly decreased the RIG-I expression level in poly I:C-transfected U5A and 2fTGH cells. Our results suggest that a part of the expression of RIG-I is regulated directly by IRF-3 in an IFN-independent manner. IRF-3 may be one of the key molecules in antiviral signaling-mediated RIG-I expression.

A Repurposed Repressor: The *Salmonella* typhimurium Counter-silencer, Slya

Author Block:

W. R. Will, S. J. Libby, F. C. Fang; Univ. of Washington, Seattle, WA

Abstract Body:

Counter-silencing is a mechanism of transcription regulation in which the activity of a repressor protein bound in the vicinity of a bacterial promoter is disrupted by additional proteins. Counter-silencing has fewer architectural requirements than canonical transcriptional activation and therefore plays an important role in facilitating the regulatory integration of horizontally-acquired bacterial genes. To examine the features that characterize an effective counter-silencer, we performed a molecular and genetic characterization of the SlyA protein, a MarR-family transcriptional regulator that represses the expression of a drug efflux pump and counters the silencing of multiple virulence genes in Salmonella Typhimurium. Using in vitro transcription and footprinting assays, we have demonstrated that SlyA lacks activation activity and functions as a repressor of its own transcription. Furthermore, SlyA exhibits relatively weak target specificity, binding to high-affinity sites and subsequently spreading outwards to form an oligomeric nucleoprotein complex. Notably, like other MarR regulators, SlyA activity is modulated by aromatic carboxylates such as salicylate. SlyA-mediated repression and counter-silencing are inhibited by aromatic carboxylates, whereas its ability to bind DNA is not, suggesting that salicylate interactions alter the conformation of SlyA. In contrast to Salmonella, SlyA plays a minor regulatory role in Escherichia coli despite a high degree of homology (89.6%) between the two species. Genetic analyses revealed that the E. coli and S. Typhimurium slyA alleles are interchangeable, but the promoter regions exhibit considerable divergence, resulting in substantially higher slyA expression levels in S. Typhimurium. This suggests that mutations altering the Salmonella slyA regulatory circuit have been critical for the evolution of SlyA from a minor transcriptional repressor to a counter-silencer that plays an essential role in virulence.

Regulation of *yidC2* in *Streptococcus mutans*

Author Block:

S. Palmer; The Ohio State Univ., Columbus, OH

Abstract Body:

Background: The universally conserved YidC/Oxa/Alb family of integral membrane chaperones-insertases has diverse functions in the assembly and insertion of respiratory chain complexes in bacteria, mitochondria, and chloroplasts, respectively. Enteric bacteria generally have one essential YidC, while streptococci and most Gram-positive bacteria encode two YidC paralogs. In the cariogenic bacterium *Streptococcus mutans*, deletion of *yidC1* has only minor effects, whereas *yidC2* mutants are severely impaired in growth, biofilm, and stress tolerance. Importantly, deletion of either gene results in reduced virulence in a rat caries model. In *Bacillus subtilis yidC2* is differentially expressed in response to YidC1 function, through ribosome stalling on the upstream gene *mifM*. However, streptococci do not have *mifM*, and very little is understood about the regulation of the *yidC* genes. It's been proposed by others (1) that the LiaSR two-component system (TCS), which regulates the cell-envelope stress response, regulates *yidC2* expression in *S. mutans*, however molecular data supporting this theory is limited. **Methods:** 5' RACE was used to map the promoter of the *yidC2* gene from *S. mutans*. Promoter-reporter gene fusions were constructed between the *yidC2* promoter and a chloramphenicol acetyltransferase (*cat*) gene from *Staphylococcus aureus*, and point mutations were introduced into the predicted LiaR binding site. The promoter-reporter constructs were inserted in single copy into the mannitol PTS operon of the wildtype strain, and various LiaFSR mutant backgrounds. Reporter strains were grown under different conditions (pH 5.0, oxygen, 50 μg/ml bacitracin, and various growth domains) and CAT activity measured. **Results:** *YidC2* promoter activity was decreased in stationary phase compared to exponential, and increased in the presence of bacitracin. While deletion of *liaR* had no effect on *yidC2* promoter activity, point mutations in the predicted LiaR binding site reduced activity by 3-fold. Deletion of *liaS* and *liaF* increased *yidC2* promoter activity by 1.5-fold and 3-fold, respectively, while deletion of *liaSR* or *liaFSR* had no effect. **Conclusions:** Collectively, our results indicate the *yidC2* gene is transcribed from a sigma 70 type promoter that is differentially regulated (either directly or indirectly) by the LiaFSR TCS through a predicted LiaR-binding motif located just 5' of the -35 promoter element.

Preference of Glucose over Mannitol in *Escherichia coli* Is Independent of Enzyme Iia^{glc}

Author Block:

m. choe, K. Heo, H-Y. Lee, Y-R. Kim, Y-J. Seok; Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract Body:

Carbon catabolite repression (CCR) is generally regarded as a regulatory mechanism to ensure sequential utilization of carbohydrates in various microorganisms. The regulatory mechanisms underlying the preferential use of glucose over other sugars have been intensively studied in *Escherichia coli* since the discovery of the *lac* operon by Jacque Monod. Previous studies on CCR suggest the model based on 'inducer exclusion' and 'induction prevention', especially for the case of glucose and lactose. Both of 'inducer exclusion' and 'induction prevention' are regulated by the phosphorylation state of EIIA^{Glc}. However it is still under debate how CCR is controlled in other cases and preferential utilization among PTS sugars cannot be explained based on inducer exclusion and induction prevention. In this study, we found that the preferential use of glucose over another PTS sugar mannitol is independent of the phosphorylation state of EIIA^{Glc}. Our data suggests that the regulatory mechanism of glucose/mannitol CCR is far different from that of glucose/lactose. Unlike in the glucose/lactose model, EIIA^{Glc} is not the major factor in the regulatory mechanism of the preferential use of glucose over mannitol. Even in the absence of EIIA^{Glc}, glucose is preferred over mannitol. Interestingly, however, preference of glucose is abolished in a mannitol operon repressor 'MtlR' deletion mutant. The mannitol operon is composed of 3 genes, *mtlA*, encoding mannitol PTS permease, *mtlD*, encoding mannitol-1-phosphate dehydrogenaseand *mtlR*, encoding putative mannitol operon repressor, and its expression is known to be negatively regulated by MtlR. In summary, unlike the model proposed for the preferential utilization of glucose over lactose, where the phosphorylation state of EIIA^{Glc} is known to play a central role, MtlR is likely to be the key factor for the preferential utilization of glucose over mannitol as a carbon source.

Specificity of a Sphingosine Induced Protective and Metabolic Cassette of *Pseudomonas aeruginos*a

Author Block:

L. Hinkel, M. J. Wargo, A. E. LaBauve, J. A. Meadows; Univ. of Vermont, Burlington, VT

Abstract Body:

Sphingolipids are abundant in cell membranes and their breakdown products, ceramide and sphingosine, are frequently encountered by bacterial pathogens during infection. Sphingosine is an antimicrobial and it contributes to bacterial growth control on skin and in the lungs. Pseudomonas aeruginosa can detect sphingosine via the AraC-family regulator SphR to induce genes involved in sphingosine resistance (sphA) and metabolism (sphBCD). sphA encodes a ß-barrel protein involved in sphingosine resistance and uptake, while sphBCD encode for a putative periplasmic cytochrome C, putative sphingosine oxidase, and putative sphingosine aldolase, respectively. Here we report on studies aiming at understanding the ligand/substrate specificity of these proteins using genetic and biochemical methods. Using a variety of sphingosine analogs we have established the ligand requirements for SphR as including the primary amine in the head group of sphingosine, while the presence and length of the hydrocarbon tail and trans double bond are not as critical for sphingosine detection by SphR. We are in the process of determining the importance of the hydroxyl groups to SphR ligand specificity. We are using similar techniques to characterize these requirements for the sphingosine resistance (SphA) and metabolism (SphBCD) components. This study adds to current knowledge concerning mechanisms that bacteria use to detect, protect against, and metabolize sphingosine.

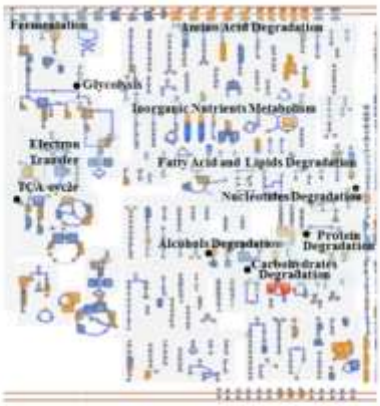
Significance of an 8-Bp Variation in a Global Regulator, *mext, S*equence in *Pseudomonas aeruginosa*

Author Block:

A. Correia[1], J. Malone[2], A. Desbois[3], L. Crossman[1], J. Wain[1]; [1]Univ. of East Anglia, Norwich, United Kingdom, [2]John Innes Ctr., Norwich, United Kingdom, [3]Univ. of Stirling, Stirling, United Kingdom

Abstract Body:

The global transcriptional regulator *mexT*, a mutational hotspot; has two sequence variants that commonly co-exist within the *P. aeruginosa* population: drug susceptible PAO1 and the norfloxacin non-susceptible and reduced motility *nfxC* mutant (selected for on chloramphenicol agar). The conversion between PAO1 and *nfxC* phenotypes is associated with an 8 bp sequence **(CGGCCAGC)** in *mexT*. Using isogenic mutants, we examined the effects of the 8 bp deletion on the *mexT* regulon and central metabolism. This is critical to understanding the response of *P. aeruginosa* in different environments and its adaptive mode of survival e.g. biofilm formation.PAO1 (8 bp, two copies) and it isogenic mutant PAO1*Δ8-bp* (8 bp, one copy) were phenotypically characterised using phenotypic microarrays (Biolog), motility and antibiotic susceptibility tests (broth dilution). Virulence testing was performed in *Galleria* models (University of Stirling) and transcriptome analysis using RNA-seq (Illumina).**Phenotypic microarray tests showed differences in central metabolism between PAO1 and** PAO1*Δ8-bp* (Figure). **PAO1 swarming and swimming behaviour were two and three times greater compared to** PAO1*Δ8-bp*, respectively. PAO1 was significantly more virulent than PAO1*Δ8-bp* in the *Galleria mellonella* infection model. Transcriptome analysis revealed that reads after the *mexT* 8-bp insertion declined across the gene in PAO1 yet 169 genes were upreglated by this strain as opposed to 22 upreglated by PAO1*Δ8-bp*. These data suggest that *mexT* remains active despite the 8 bp duplication and has effects on central metabolism, chemotaxis and cell adhesion. We are currently investigating the molecular mechanism.



Section of the Kegg map showing central metabolism overlaid with RNA transcriptome and phenotypic microarray data

Based on RNA-seq data, differences in metabolism between PAO1 and PAOL*18-bp* are colour coded and graded from 0.1 (blue) -22 (red) Log_{10}. Pathways indicated with ● illustrate differences found using phenotypic microarray data. Analysis of the area under the curve (AUC) showed that growth rates of PAO1 exceeded that of PAOL*18-bp* by two fold, in the presence of specific carbohydrate and nucleotide based substrates. PAOL*18-bp* however was more metabolically active on peptide-nitrogen based sources producing AUCs ≥ 2.

Acid Induced Overexpression of the *Mycobacterium tuberculosis Rv3488* Gene Effects Pigment Production in *Mycobacterium smegmatis*

Author Block:

B. Saviola; Western Univ. of Hlth.Sci., Pomona, CA

Abstract Body:

Mycobacterium tuberculosis continues to be a threat and difficult to treat. Mycobacterial antibiotic resistance is also on the rise especially in regions of the world such as Africa. During infection, *M. tuberculosis* bacilli invade and enter phagosomes of macrophages where they persist and are exposed to a variety of stressors, including reactive oxygen species and acididty. The *lipF* gene encodes a lipase or esterase within the mycobacterial genome and a promoter upstream of this gene has been shown to be upregulated by acidic stress. The minimal acid inducible promoter region of *lipF* is upregulated by acidity from pH as low as 4.3 to as high as 6.4, pH's that can be encountered within phagosomes of macrophages. We have engineered a plasmid to use the *mpr* promoter to drive expression of proteins at acidic pH, thus creating a tightly controlled expression vector for mycobacteria. *Rv3488* a gene upstream of *lipF* and divergently transcribed is situated close to the minimal acid inducible promoter of *lipF* in the *M. tuberculosis* genome. We used this acid inducible minimal promoter region (*mpr)* to make a construct in which *mpr* drives expression of the *Rv3488* gene, thus making this gene highly acid inducible which does not normally occur in wild type *M. tuberculosis*. It has yet to be established what induces *Rv3488* expression in wild type *M. tuberculosis*. We hypothesized that Rv3488, being a DNA binding protein, may regulate some gene responses, and may also be involved in acid stress responses as it is placed so close to the acid induced *lipF* gene. *Rv3488*, encoding a DNA binding protein, could be tightly regulated by *pMPR-RV3488* with no expression at pH 7.0 and robust expression at pH 4.5. Upon acid induced over expression of *Rv3488* with acid exposure it was determined that in *Mycobacterium smegmatis* acid induced pigment production was inhibited, while acid induced over expression of *gfp* did not result in a similar inhibition of acid induced pigment production. Acid induced pigment production was previously established in *M. smegmatis* and *Rv3488* appears to participate in its stress induced regulation in this mycobacterium.

Culturing *Coccidioides:* Optimizing *In Vitro* Culture Media to Reflect Nutrient Availability *In Vivo*

Author Block:

H. L. Mead, B. M. Barker; Translation Genomics Res. Inst.-North, Flagstaff, AZ

Abstract Body:

Background: The pathogenic soil dwelling fungi, *Coccidioides immitis* and *C. posadasii* can be found in arid desert regions and cause an estimated 150,000 cases of coccidioidomycosis, also known as valley fever, in the United States each year[i]. The current media for culturing spherules is not nutritionally representative of a mammalian respiratory system or conducive to *in vitro* immunology experiments. Supplemented RPMI media was used to produce the spherule form in a previous study[ii]. RPMI media is routinely used in cell culture applications making it useful for *in vitro* immunology experiments. **Methods:** Using the supplemented media and an attenuated biosafety level two (BSL2) *Coccidioides,* preliminary trials were conducted to determine which factors, such as cell density, temperature, time, CO_2 and O_2 concentration, would affect spherule development. Potential conditions were identified, reproduced in triplicate, and compared to determine the most successful method of growth.**Results:** The BSL2 strain cultured in the supplemented RPMI media successfully grew spherules at several conditions similar to the host environment. Temperature ranged between 37-39°C and CO_2 concentration between 5-15%. The supplemented RPMI media produced both spherule and mycelial morphology under normoxic conditions. Spherule development between the two media types was relativity equivalent, and the highest percentage of parasitic morphology occurred at 15 % CO_2. Hypoxia impaired the growth of mycelial structures while allowing for growth of spherules. Additionally, hypoxic conditions inhibited growth in the control, Converse media, while only slowing growth in the supplemented RPMI.**Discussion:** The supplemented RPMI media is an excellent candidate for culturing *Coccidioides* spherules and can be applied to future research in the BSL3 laboratory. The components of the media provide the organism with nutrients that are similar to those found in a host respiratory system and the conditions of growth are favorable for mammalian immune cells allowing *in vitro* immunology experiments.

Effects of Pyoverdine for the Growth Suppression of Diverse Microbes

Author Block:

Y. Lee[1], Y-J. Kim[1], J-H. Lee[1], H. Yu[2], K. Lee[1], S. Jin[3], U-H. Ha[1]; [1]Korea Univ., Sejong, Korea, Republic of, [2]Hyundai Pharmaceutical Co., Yongin, Korea, Republic of, [3]Univ. of Florida, Gainesville, FL

Abstract Body:

Background: Interspecies interactions play a role in altering the composition of communities in terms of the course and severity of infections. However, little is known about the mechanism of interspecies interactions in microbial coinfections. **Methods**: We applied a technique of transposon mutagenesis to screen mutants with defects in growth suppression. To identify responsible components for the growth suppression, HPLC was used to analyze secreted metabolites. **Results**: Cell-free culture supernatants obtained from *P. aeruginosa* suppressed the growth of a number of bacterial strains such as *Corynebacterium glutamicum*, *Bacillus subtilis*, *Staphylococcus aureus* and *Agrobacterium tumefaciens*, but had little effect on the growth of *Escherichia coli* and *Salmonella typhimurium*. By performing transposon mutagenesis, TatC encoded by PA5070 of *P. aeruginosa* was identified, and the supernatant of its mutant did not suppress the growth. Molecular analysis of supernatants showed that pyoverdine was a secondary metabolite present in culture supernatants of the wild-type strain, but not in those of the PA5070 mutant. Supplementation of $FeCl_2$ as a source of iron compromised the growth suppression effect of supernatants, indicating that pyoverdine-mediated iron acquisition is responsible for the growth suppression. **Conclusions**: Thus, this study provides the action of TatC-dependent pyoverdine translocation for the growth suppression, and it might aid understanding of the impact of *P. aeruginosa* in the complex community of bacterial species upon coinfection.This research was supported by Basic Science Research Program (NRF-2013R1A1A2059846) and the BK21 plus program of the Ministry of Education, Korea.

Post-translational Modification by Acetylation Regulates *Vibrio cholerae* Virulence in a *Drosophila melanogaster* Model of Infection

Author Block:

K. Liimatta, **A. E. PURDY**; Amherst Coll., Amherst, MA

Abstract Body:

The pathogen *Vibrio cholerae* can infect eukaryotic organisms by deploying toxins, proteases, and other secreted effectors. *V. cholerae* may also affect host physiology and health by altering the metabolic milieu of the host's gastrointestinal (GI) tract. Recent work by Hang and colleagues (2014) demonstrated that *V. cholerae* lethally infects *Drosophila* by manipulating levels of acetate, a shared central metabolite, in the fly GI tract. By expressing acetyl-CoA synthetase (Acs), the key enzyme required for converting acetate to acetyl-CoA, *V. cholerae* causes intestinal steatosis in the fly, contributing to its death. Acs is carefully regulated transcriptionally and post-translationally in *E. coli* and *Salmonella*. However, our understanding of its regulation in *V. cholerae* is incomplete. While transcription of Acs may be controlled by novel signaling pathways in *Vibrio*, post-translational modification by acetylation may be widely conserved. *V. cholerae* carries copies of the *patZ* and *cobB* genes that are required for acetylation and deacetylation of Acs and other proteins, but their role in *V. cholerae* physiology or virulence are unknown. The goal of this project is to test the hypothesis that proper acetylation of central metabolic enzymes, including Acs, is required for (i) utilization of acetate as a carbon source, and (ii) *V. cholerae* virulence in a *Drosophila* model. We have demonstrated that an in-frame deletion of *cobB*, required for activation of Acs by deacetylation, in *V. cholerae* behaves similarly to a strain carrying a deletion in *acs.* The *cobB* mutant is incapable of growing on acetate as a sole carbon source but displays no growth defect in rich media. As expected, virulence towards *Drosophila* is significantly reduced, although not completely abrogated, in the *cobB* mutant. These results suggest, for the first time, that acetylation may be an important regulator of *V. cholerae* physiology and virulence during infection, and we are currently undertaking both biochemical and genetic approaches to test the hypothesis that targeted acetylation of Acs is mediating these phenotypes. Future work will explore mechanisms that regulate activity of the acetylase and deacetylase enzymes, and proteomics approaches will reveal the extent to which acetylation modifies proteins important to *V. cholerae* survival and infection.

Integration ofCarbon Metabolism and Quorum Sensing Through the Bara/Sira-csra And LsrRegulatory System in *Salmonella typhimurium*

Author Block:

E. V. Gart[1], R. C. Laughlin[2], C. C. Hung[3], S. Myers[1], K. E. McWhinney[1], C. Altier[3], S. D. Lawhon[1]; [1]Texas A&M, College Station, TX, [2]Texas A&M Kingsville, Kingsville, TX, [3]Cornell Univ., Ithaca, NY

Abstract Body:

Salmonella Typhimurium uses autounducer-2 (AI-2) signaling molecule to regulate the *Salmonella* pathogenicity island-1 (SPI-1) Type 3 Secretion System (T3SS), flagellar gene expression, and biofilm formation. AI-2 is sensed and internalized by the *lsrACDB*-encoded transporter. Following intracellular phosphorylation, AI-2 represses the transcriptional repressor protein LsrR, allowing the transcription of *lsr*- and SPI-1 - encoded genes. The BarA/SirA two-component system also controls SPI-1 T3SS through the RNA-binding protein CsrA which affects mRNA stability and translation. However, the interaction between the BarA/SirA-CsrA regulatory cascade and the *lsr* operon is unknown. The goal of this study was to determine whether the BarA/SirA-CsrA regulatory cascade regulates *lsr* expression and AI-2 transport in *S.* Typhimurium. Extracellular AI-2 was measured in mutant (*sirA, barA, csrA, csrBC* and *barA-ackA-pta*) and parent (WT) strains of *S.* Typhimurium using the luminescent response of reporter *V. harveyi* to *Salmonella* AI-2. The *β*-galactosidase activity of *lsrR-lacZ* and *lsrD-lacZ* transcriptional fusions was assayed at early-, mid-, and late-log phase in parent and mutant strains. Mobility shift assays were performed to determine whether CsrA-His binds to *lsrR* and *lsrD* mRNA. Analysis of variance followed by Tukey's test ($P<0.05$) was used to determine the differences in the extracellular AI-2 and *β*-galactosidase activity. The mid-log phase expression of *lsrR* is positively regulated by BarA/SirA and CsrBC. CsrA suppresses *lsrR* expression at the mid-log phase and suppresses *lsrD* expression at the early-, mid- and late-log phase. Additionally, CsrA binds to *lsrR* and *lsrD* mRNA. Our results demonstrate the cross-talk between the BarA/SirA-CsrA and *lsr* regulatory systems in regulating AI-2 quorum sensing in *S.* Typhimurium. Therefore we propose a model where *lsrD* expression, and therefore AI-2 internalization, is constantly suppressed by CsrA and LsrR. This is counteracted at the mid-exponential phase by CsrA binding to the *lsrR* transcript and relieving the repression of the AI-2 transporter.

Brnq1 in *Staphylococcus aureus* is a Leu/Val Transporter Required for Determining Branched-chain Membrane Fatty Acid Content

Author Block:

J. C. Kaiser[1], S. Sen[2], B. J. Wilkinson[2], D. E. Heinrichs[1]; [1]Univ. of Western Ontario, London, ON, Canada, [2]Illinois State Univ., Normal, IL

Abstract Body:

The branched-chain amino acids (BCAAs; Ile, Leu, Val) are important nutrients for the metabolism and growth of the human pathogen *Staphylococcus aureus*, as in addition to their role in protein synthesis they are precursors for the branched-chain fatty acids (BCFAs). The BCFAs constitute ~50% of membrane fatty acids and are necessary for environmental adaptation and resistance to membrane stresses. We have found that *S. aureus* represses Leu and Val synthesis, and instead prefers to acquire these nutrients from the extracellular milieu via two BCAA transporters; BrnQ1 and BcaP. We therefore hypothesized that BCAA transporters are necessary to supply the precursors for BCFA synthesis, and that mutation of such transporters would result in altered BCFA content in the cellular membrane. Membrane composition analysis revealed that the membrane of a *brnQ1bcaP* mutant was completely devoid of Leu- and Val-derived iso-BCFAs, corresponding with the role of these genes in Leu and Val transport. The membrane of the *brnQ1* mutant also lacked Leu- and Val-derived iso-BCFAs, implicating BrnQ1 as the predominant Leu and Val transporter. Confirming this, we determined that BrnQ1 is the higher affinity transporter and is essential for the growth of *S. aureus* under BCAA limiting conditions, whereas BcaP plays a secondary role in growth. Paralleling the absence of Leu- and Val-derived BCFAs, we observed an increase of Ile-derived anteiso-BCFAs from 45% to 90% of total membrane fatty acids, which we surmise is dependent on Ile acquisition via the Ile-specific transporter, BrnQ2. Ile-derived anteiso-fatty acids increase membrane fluidity, and we found that *S. aureus* compensates for compromised membrane fluidity by incorporating more staphyloxanthin, a pigmented carotenoid that reduces membrane fluidity. These data demonstrate the importance of BCAA acquisition for supplying the BCAAs for BCFA synthesis, and thus for maintaining the appropriate membrane content for environmental adaptation of *S. aureus*.

Branched-Chain Fatty Acids (Bcfas) In The *staphylococcus Aureus* Membrane And Their Physiological Significance

Author Block:

R. P. Ring[1], S. Sirobhushanam[2], C. Gatto[2], B. Wilkinson[2], V. Singh[1]; [1]A. T. Still Univ. of Hlth. Sci., Kirksville, MO, [2]Illinois State Univ., Normal, IL

Abstract Body:

Background: Maintenance of membrane fluidity is critical for *Staphylococcus aureus* to overcome diverse environmental conditions and to a large extent is governed by BCFA content. While branched-chain α-keto acid dehydrogenase (BKD) is the key enzyme in BCFA synthesis, a *S. aureus* BKD-deficient mutant still produces substantial levels of BCFAs. The pyruvate dehydrogenase (PDH) complex was hypothesized to contribute the BCFA production as PDH and BKD both belong to the α-ketoacid dehydrogenase complex family. This study investigated the role of PDH in conjunction with BKD in BCFA metabolism and its significance in *S. aureus.* **Methods:** This study was carried out using BKD, PDH, and BKD-PDH deficient derivatives of methicillin resistant *S. aureus* (MRSA) strain USA300 (WT). Differences in growth kinetics at 37°C were evaluated spectrophotometrically by measuring OD_{600}. Membrane BCFAs were analyzed using gas chromatography and membrane fluidity by fluorescence polarization. Carotenoid levels were estimated by measuring the A_{465} of methanol extracts from 48h cultures. MIC values were determined for oxacillin (OXA), vancomycin (VAN), daptomycin (DAP), bacitracin (BAC), and D-cycloserine (DCS) by broth microdilution in duplicate.**Results:** The BKD and PDH deficient strains grew slower than WT, while the BKD-PDH double mutant grew much slower than WT. BCFAs made up 50% of membrane lipids in WT, but only 31% in the BKD-deficient strain. In contrast, the BCFA level was ~80% in the PDH-deficient strain and 38% in the BKD-PDH double mutant. Of all strains tested, the BKD mutant showed decreased membrane fluidity. Compared to WT (100±9.1%), the BKD-deficient strain produced more staphyloxanthin (141±7.6%, $p = 0.03$) and the PDH-deficient strain produced lower levels of carotenoids than WT (47±5.6%, $p = 0.007$). In MIC studies, the BKD-deficient strain showed reduced OXA and DAP resistance. There was no difference in resistance to BAC, VAN, or DCS among these strains.**Conclusions:** The BCFA composition of the cell membrane in *S. aureus* seems to significantly impact cell growth, membrane fluidity, and resistance to certain antibiotics. Carotenoid production appears inversely correlated with BCFA content and may be key for *S. aureus* membrane fluidity under BCFA-deficient conditions.

***Staphylococcus aureus* Uses Proline and Arginine as Primary Carbon Sources When Grown on Defined Media Lacking Glucose**

Author Block:

C. Halsey[1], S. Lei[2], M. K. Lehman[1], V. Eckrich[1], R. Powers[2], P. D. Fey[1]; [1]Univ. of Nebraska Med. Ctr., Omaha, NE, [2]Univ. of Nebraska Lincoln, Lincoln, NE

Abstract Body:

S. aureus has the ability to establish an infection in a wide variety of unique metabolic niches within the human host. However, it is unclear what specific carbon and nitrogen sources are available to *S. aureus* in specific host niches and how these specific growth conditions may affect virulence factor expression and subsequent invasion, metastasis or quiescence. We hypothesize that *S. aureus* encounters niches within the host where proteins, peptides, or free amino acids are the only carbon source available. To assess which amino acids are important for growth in media lacking glucose, *S. aureus* JE2 and mutants were grown aerobically (250 rpm, 37 degrees, 10:1 flask to volume ratio) in complete defined medium lacking glucose (CDM) and particular amino acids. It was first determined that JE2 grown in CDM is auxotrophic for arginine, valine and leucine. Use of mutants that do not have functional pathways generating glutamate from either arginine or proline were unable to grow in this media. Furthermore, a mutation in glutamate dehydrogenase (*gudB*), which generates 2-oxoglutarate from glutamate, abrogated growth in CDM suggesting that glutamate derived from arginine and proline serves as the major carbon source in this media. Nuclear Magnetic Resonance (NMR) studies using uniformly ^{13}C-labeled glutamate, arginine and proline confirmed this observation. Lastly, a mutation in acetate kinase (*ackA*) also abrogated growth of JE2 in CDM suggesting that ATP generation via substrate level phosphorylation from pyruvate generating amino acids (e.g. alanine, serinine, glycine) is also critical for growth. In conclusion, our data suggest that *S. aureus* uses arginine and/or proline as primary carbon sources to generate glutamate when *S. aureus* is grown on media lacking glucose. Furthermore, the glucogenic amino acids that generate pyruvate may serve as a primary energy source to generate ATP via the PTA/AckA system. These data may suggest that pathways important for glutamate catabolism or ATP generation via PTA/AckA are important for growth in niches where glucose is not abundant such as abscesses within skin and soft tissue infections.

***Staphylococcus aureus* Nitric Oxide Synthase (SANOS) Modulates Respiratory Metabolism and Cell Physiology**

Author Block:

A. B. Mogen[1], R. K. Carroll[2], J. Culver[3], C. Petucci[3], L. N. Shaw[4], K. C. Rice[1]; [1]Univ. of Florida, Gainesville, FL, [2]Ohio Univ., Athens, OH, [3]Sanford Burnham Prebys Med. Discovery Inst. at Lake Nona, Orlando, FL, [4]Univ. of South Florida, Tampa, FL

Abstract Body:

S. aureus is a notorious human pathogen that can be resistant to multiple antibiotics. A promising target for drug development in this organism is saNOS, as a link between this enzyme's inhibition and increased antimicrobial efficacy has been previously established. Although the mechanism is currently unknown, saNOS contributes to *S. aureus* virulence, as well as protection against exogenous oxidative stress and antimicrobials. However, little is known about the potential effects of this enzyme on *S. aureus* physiology in the absence of exogenous stress. When grown aerobically, endogenous reactive oxygen species (ROS) levels, including the respiratory by-product superoxide, were elevated in a *S. aureus nos* mutant, independent of catalase activity. Multiple transcriptional and metabolic changes were also observed in the *nos* mutant, as assessed by RNAseq and targeted metabolomics analyses, respectively. Specifically, expression of genes associated with oxidative and nitrosative stress responses, anaerobic/lactate metabolism, and cytochrome biosynthesis were increased in the *nos* mutant relative to wild-type, whereas expression of several virulence factor genes was decreased. Metabolites utilized to produce reducing equivalents by the right arm of the TCA cycle were depleted in a *nos* mutant, whereas fumarate and malate levels were increased relative to wild-type. A significant reduction in intracellular lactate levels was also observed in the *nos* mutant. Collectively, these results support a model in which the absence of saNOS results in increased respiration and endogenous ROS accumulation, which may signal a switch to an alternative lactate-based respiratory metabolism. These results build upon previously-published observations that NO can limit cellular respiration in bacteria and mitochondria, and suggests that bacterial NOS is a previously-unappreciated modulator of bacterial respiratory metabolism.

Mapc, but Not Mapa Is Essential to the Viability of *Mycobacterium bovis*, and Is a Potential Drug Target

Author Block:

M. Vanunu, D. Barkan; Koret Sch. of Vet. Med., Rehovot, Israel

Abstract Body:

Background: *Mycobacterium tuberculosis* (Mtb) kills more than 1.5 million people each year, and 1/3 of the global population is estimated to be latently infected. The recent emergence of drug-resistant strains emphasizes the need for new treatments, and thus for new drug targets. The search for new drug targets led us to investigate the Methionine aminopeptidase (MAP) pathway, a post-translation modification in most newly synthesized proteins in all living cells, including mycobacteria. Mtb, and its attenuated strain BCG, possess two variants of the gene - *mapA* (Rv0734) and *mapC* (Rv2861c). The essentiality of these genes was investigated in recent studies but is still unclear. Olyleye et al (2009) suggested by chemical inhibition that *mapA*, but not *mapC*, was essential. On the other hand, analysis of a transposone mutant-library (Griffin 2011) suggested the opposite. A targeted deletion of neither gene was performed, thus leaving the question of their essentiality unanswered. **Methods:** We decided to delete the genes *mapA* and/or *mapC* by specialized transduction, based on TM4 phage. Because these genes may be essential, we first pre-complemented the bacteria with a second copy of the gene at the *attB* site. After obtaining a mutant deleted in the native gene and confirming the deletion using several PCR reactions, we attempted to remove the complementing copy from the *attB* site by exchanging for another *attB*-integrating cassette, carrying a different selection marker. This way, a decisive proof of essentiality for each of these genes can be obtained. **Results:** The first gene we investigated was *mapC*. We pre-complemented BCG with an extra copy of the gene. After deleting the native gene by phage infection we exchanged the second copy with an empty cassette, an extra copy of *mapA*, or another copy of *mapC*. We obtained no colonies where the complementing *mapC* gene was removed, showing *mapC* is essential for *in-vitro* growth. To investigate *mapA*, we created a pre-complemented mutant, and a deletion of the native *mapA* is underway. **Conclusion:** Our results confirm the essentiality of the methionine amino-peptidase pathway to the viability of BCG (and thus, Mtb). Contrary to previous reports, of the two genes *mapC* is the essential one, and is a legitimate target for future drug development. The essentiality of *mapA* will be determined in the next few months.

The Developmental Inhibitor Hetn is Produced from an Internal Translational Start Site within the Filamentous Cyanobacterium *Anabaena* sp. Pcc 7120

Author Block:

O. S. Rivers[1], P. Videau[2], S. M. Callahan[1]; [1]Univ. of Hawaii Manoa, Honolulu, HI, [2]Oregon State Univ., Corvallis, OR

Abstract Body:

Formation and maintenance of a periodic pattern of terminally differentiated nitrogen-fixing cells called heterocysts by the filamentous cyanobacterium *Anabaena* sp. PCC 7120 is dependent on the developmental regulators PatS and HetN. HetN is annotated as a 287 aa protein, but the mature HetN-derived signal that is transferred between cells, likely via SepJ-mediated intercellular channels, is yet to be defined. Similar signal ranges produced by a wild-type allele of *hetN* and one encoding a HetN-YFP fusion protein that is not exchanged between cells suggests that the full-length protein is not the mature signal. Mutants containing variants of *hetN* in which the annotated and/or potential internal start methionines were changed to leucine were created to assess the possible use of one or more of these potential translational start sites in creation of the HetN developmental signal. The mutant phenotypes suggest an internal translational start site at position M119 relative to the annotated start site. The data is consistent with the theory that a smaller peptide within the sequence of HetN is the inhibitory signal produced by heterocysts and transported to vegetative cells within the *Anabaena* sp. PCC 7120 developmental system.

CSPA and CSPC are Required in Germination of Spores *Clostridium perfringens* Strain SM101

Author Block:

P. K. Talukdar, M. R. Sarker; Oregon State Univ., Corvallis, OR

Abstract Body:

Clostridium perfringens is a Gram-positive, anaerobic, spore forming bacterium resides in different environmental niches including gastrointestinal tracts of humans and animals. The spores of *C. perfringens* are resistant morphotype and metabolically inactive until it sense signals from molecules termed germinants and going back to its metabolically active vegetative form via germination process. In recent years, a plethora of information has been gathered regarding the germination of *C. perfringens* spores, but still several questions remains unanswered. Different germinant receptors have been identified that sense the signals from germinants and activate other protein functions. Cortex hydrolysis is one of the major events in germination process, as the hydrolysis of cortex allows the spores' core to uptake water and thus quickens the germination process. The major cortex lytic enzyme SleC is being processed by the activation of CspB, a serine protease. Although we know that in *Clostridium difficile*, CspA and CspC have roles in the activation of CspB, but the role of these two proteins in *C. perfringens* is still yet to be determined. In this study, we showed by promoter expression assay that *cspA-cspC* is organized as a bicistronic operon and expressed only during sporulation. To investigate the role of CspA and CspC, we constructed a single Δ*cspA* or Δ*cspC* mutant derivative in *C. perfringens* strain SM101. The germination assay with different germinants showed that both mutants have deficiency in germination. These results are in agreement with the DPA release data, as both Δ*cspA* and Δ*cspC* spores released less DPA than wild-type spores during germination. The outgrowth assay and the colony forming efficiency also confirmed the germination defects in spores of both mutants. The Western blot analysis with SleC antibody showed that during germination, SleC processing was blocked in spores of both mutants. In summary, our study showed that both CspA and CspC serine proteases play major roles in spore germination by directly activating the SleC and/or CspB.

Regulation of Spore Germination in *Clostridium difficile* by Csp Family Proteases

Author Block:

Y. Kevorkian, A. Shen; Univ. of Vermont, Burlington, VT

Abstract Body:

Clostridium difficile Infection (CDI) is a major healthcare-associated disease that is transmitted by *C. difficile*'s metabolically dormant spore form. Upon entering the gut, spores germinate, resuming metabolism and leading to release of toxins. In *C. difficile*, germination depends on the Csp family of subtilisin-like serine proteases and the cortex hydrolase SleC. The pseudoprotease CspC acts as the primary germinant receptor that initiates germination upon binding specific bile salts. CspC activates CspB, which in turn removes an inhibitory pro-peptide from SleC. Active SleC degrades the protective cortex layer, allowing dormant spores to resume metabolism and growth. We previously investigated the role of CspA, a pseudoprotease domain fused to CspB prior to interdomain processing. Mutational analyses revealed that the CspA domain controls CspC germinant receptor levels in mature spores and is required for optimal spore germination, particularly when CspA is fused to the CspB protease. However, study of the individual Csps was complicated by the polar effects caused by the TargeTron mutagenesis method and the requirement for multi-copy plasmid complementation, which may cause experimental artifacts. To overcome these limitations, we now use allele coupled exchange to create individual deletions of the genes encoding CspB, CspA, and CspC, as well as to complement these mutations in single copy on the chromosome. These individual deletion mutants exhibit significant decreases in germination efficiency. Since their germination defects are similar, our preliminary data are consistent with the hypothesis that direct interactions between Csp family proteases are vital for maintaining efficient germination.

Characterization of the Early Events of Germination of *Clostridium difficile* Spores

Author Block:

T. Kochan, P. Hanna; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Clostridium difficile (*Cd*), a Gram-positive anaerobe, is a leading cause of both hospital- and community- acquired antibiotic associated diarrhea. *Cd* infection (CDI) typically occurs after treatment with broad-spectrum antibiotics disrupts the normal gut microbiota, allowing for *Cd* colonization. While CDI is a toxin-mediated disease, its capacity for transmission and, therefore, disease is dependent on spore formation and germination. *Cd* spores become metabolically active (germinate) when receptors packaged within the spore recognize host-specific molecules (e.g., bile salts, glycine) known as germinants. Currently, the mechanism of germination in *Cd* is not completely understood. Many of the genes required for germination in other spore forming bacteria, including the known germinant receptors, are not encoded by sequenced *Cd* strains. The receptor for the bile salt taurocholate, CspC, has been identified. However, the receptor(s) for the necessary co-germinant, glycine, remains unknown. Although it is known that glycine is required for efficient germination of *Cd* spores, the mechanism controlling this requirement remains to be elucidated. In this work, we provide evidence that glycine plays a role in the release of calcium-dipicolinic acid (Ca-DPA) from the spore core. While both taurocholate (Tc) and glycine are required for efficient germination, supplementation with exogenous Ca-DPA can eliminate the requirement for glycine. Germination was measured by loss of optical density. Tc-Ca-DPA induced germination leads to direct activation of SleC (cortex lytic enzyme) and requires CspC, indicating that Tc-Glycine and Tc-Ca-DPA induced germination function through a similar pathway. We have also identified an outer membrane associated protein that may facilitate access of germinants into the spore. A mutant lacking this protein germinates slowly in response to BHIS+Tc, indicating that germinants may have restricted access within the spore. These data strongly suggest that glycine induces the release of Ca-DPA from the spore core, and Ca-DPA transmits the germination signal to activate cortex hydrolysis via SleC.

Protein Composition of Infectious Spores Reveals Novel Sexual Development and Germination Factors in *Cryptococcu*s

Author Block:

M. Huang, A. S. Hebert, J. J. Coon, C. M. Hull; Univ. of Wisconsin-Madison, Madison, WI

Abstract Body:

Spores are an essential cell type required for long-term survival across diverse organisms in the tree of life and are a hallmark of fungal reproduction, persistence, and dispersal. Among human fungal pathogens, spores are presumed infectious particles, but relatively little is known about this robust cell type. Here we used the meningitis-causing fungus *Cryptococcus neoformans* to determine the roles of spore-resident proteins in spore biology. Using highly sensitive nanoscale liquid chromatography/mass spectrometry, we compared the proteomes of spores and vegetative cells (yeast) and identified eighteen proteins specifically enriched in spores. The genes encoding these proteins were deleted, and the resulting strains were evaluated for discernable phenotypes. We hypothesized that spore-enriched proteins would be preferentially involved in spore-specific processes such as dormancy, stress resistance, and germination. Surprisingly however, the majority of the mutants harbored defects in sexual development, the process by which spores are formed. One mutant in the cohort was defective in the spore-specific process of germination, showing a delay specifically in the initiation of vegetative growth. Thus, by using this in-depth proteomics approach as a screening tool for cell type-specific proteins and combining it with molecular genetics, we successfully identified the first germination factor in *C. neoformans*. We also identified numerous proteins with previously unknown functions in both sexual development and spore composition. Our findings provide the first insights into the basic protein components of infectious spores and reveal unexpected molecular connections between infectious particle production and spore composition in a pathogenic eukaryote.

Role of Petrobactin in *Bacillus anthracis* Outgrowth from Spores

Author Block:

A. Hagan[1], A. Tripathi[2], D. Sherman[2], P. Hanna[1]; [1]Univ. of Michigan Med. Sch., Ann Arbor, MI, [2]Univ. of Michigan Life Sci. Inst., Ann Arbor, MI

Abstract Body:

Bacillus anthracis, a Gram-positive spore forming bacterium, is the causative agent of anthrax. Anthrax, a highly lethal disease, is accompanied by growth to high titers in the blood following germination and outgrowth of the spore in the iron-limited host. Iron is an important nutrient required for multiple cellular processes including DNA replication and ATP generation. As a result, iron acquisition by bacterial pathogens in the iron-limited host environment is critical for pathogenesis. One method of iron acquisition employed by many bacteria is the production of siderophores, small molecules with high binding affinities for iron. Siderophores are secreted into the environment under iron-limited conditions to acquire iron for growth. Siderophore biosynthesis is an energetically costly process involving expression of multiple biosynthetic enzymes when vegetative cells encounter iron-limited conditions. *B. anthracis* has multiple methods of acquiring iron but the siderophore petrobactin (PB) is the only system involved in murine models of anthrax virulence. While much is known about PB biosynthesis and import, little is known about the role of PB in early outgrowth of *B. anthracis* from spores. As *B. anthracis* is capable of infecting the iron-limited host environment from the transcriptionally dormant spore, we sought to identify the role of PB in this process. Outgrowth of spores in iron-depleted medium (IDM) as compared to iron-replete medium (IRM) revealed that wildtype and a mutant deficient for production of the siderophore bacillibactin (Δ*dhb*) achieved outgrowth in both conditions. Spores of PB biosynthesis (Δ*asb*) or import (Δ*fpuA*) mutants outgrew in IRM but failed to achieve detectable levels of outgrowth in IDM. The exogenous supplementation of purified PB to Δ*asb* spores rescued outgrowth in IDM. These data indicate a requirement for PB in early spore outgrowth in iron-limited conditions. As the spore begins in a transcriptionally dormant state, we hypothesized that PB is biosynthesized during sporulation and packaged within the spore, ready for export and iron retrieval upon germination. Mass spectrometry confirms the presence of PB in wildtype but not Δ*asb* spores. Future work will identify the location of PB in the spore and parse the role of pre-packaged PB from PB *de novo* synthesis during *B. anthracis* outgrowth from spores.

Determination of Cyclic Dimeric Gmp Targets in *Streptomyces coelicolor* Using Rna Sequencing

Author Block:

M. A. Stark, J. A. Bennett; Otterbein Univ., Westerville, OH

Abstract Body:

The second messenger molecule cyclic dimeric GMP (c-di-GMP) regulates a myriad of processes in gram-negative bacteria. However, little is known about the roles it plays in gram-positive bacteria. The second messenger molecule has been shown to regulate biofilm formation, motility, cell cycle progression, and virulence. Differential gene expression in two strains of the gram-positive bacterium, *Streptomyces coelicolor*, was studied using RNA sequencing to determine direct and indirect gene targets of c-di-GMP signaling. RNA was collected in triplicate from the double mutant and wild-type strain of *S. coelicolor* for use in the RNA sequencing experiment carried out on an Illumina Hi-Seq instrument. The *rmdA rmdB* (regulator of morphology and development) double mutant was compared to the wild-type strain known as MT1110. It is known that there is increased intracellular pooling of c-di-GMP in the double mutant which means that c-di-GMP is not being broken down. The *rmdA* and *rmdB* genes are needed for the formation of aerial mycelium, an important step in the life cycle of *S. coelicolor*. The RNA sequencing experiment implicated many known developmental genes in *S. coelicolor* as targets of c-di-GMP including the *chaplins*. The eight *chaplin* genes which are known to play a role in the formation of aerial mycelium by coating them in a hydrophobic sheath that enables them to break the surface tension of the substrate were all downregulated in the double mutant compared to the wild-type. Many additional known developmental genes were shown to be differentially regulated compared to the wild-type. Excitingly, many novel genes were also implicated as potential targets of c-di-GMP regulation in this RNA sequencing study. The study gained needed information about c-di-GMP signaling and its effect on various developmental genes in *S. coelicolor*. *S. coelicolor* is a model organism for the group of soil-dwelling bacteria that produce anti-tumor agents, immunosuppressant drugs, and over two-thirds of commercially used antibiotics.

Characterization of Random Transposon Insertion Mutants Defective for Development in a Filamentous Sporulating Bacterium

Author Block:

S. G. Kirk[1], J. A. Bennett[1], J. R. McCormick[2]; [1]Otterbein Univ., Westerville, OH, [2]Duquesne Univ., Pittsburgh, PA

Abstract Body:

Streptomyces coelicolor is a filamentous, sporulating bacterium commonly found in soil and is a model system to study for microbial cell biology and development. Streptomycetes produce many commonly medically utilized antibiotics. The purpose of this study was to identify new developmental mutants. In this study, ten random transposon insertion mutants with interesting developmental defects were identified by visual analysis on solid media. Preliminary characterization was done by microscopy to further understand the mutant phenotypes. Using Inverse PCR and DNA sequencing, the transposon insertion sites were identified to further analyze the mutants. Insertions were identified in both known and novel developmental genes. One of the identified insertion mutants, with a spore shape defect, has a transposon insertion in a gene that codes for protein of unknown function. Another mutant has a segregation defect as judged by DNA staining using confocal microscopy. This strain has a transposon insertion in a gene that codes for a putative membrane protein. Genetic complementation of the insertion mutations and/or PCR-targeted deletions are currently being performed to determine if the mutant visual and microscopic phenotypes are linked to the insertion mutation.

Signaling and Activating the *Streptomyces coelicolor* Response Regulator Ramr Involved in Cell Differentiation

Author Block:

J. Girouard, T. Perkins, R. S. Greenwell, Jr.; Worcester State Univ., Worcester, MA

Abstract Body:

The soil-dwelling actinomycete bacterium *Streptomyces coelicolor* has been studied for both its complex developmental life cycle and production of secondary metabolites. The life cycle of these filamentous bacteria begins as emergence from spores to form vegetative hyphae as they colonize the nutrient layer of soil, and then eventually breach the surface as aerial hyphae and finally form spores. In order to transition from vegetative to aerial growth, the cells must escape from the colony aqueous environment by secreting biosurfactants such as the small lantibiotic peptide SapB. SapB has previously been shown as an important molecule in aerial hyphae development.Production of SapB is regulated by the response regulator RamR. We are investigating the mechanism by which RamR is activated. Cells expressing RamR proteins with amino acid substitutions generated at potential sites of phosphorylation are being analyzed for mature SapB production. Substitutions at those amino acids important for RamR function will create cells unable to produce mature SapB, detected via Western blot analysis.The signal molecule that stimulates production of SapB transduced through RamR has not been identified. Additionally, the kinase that activates RamR activities has not been isolated, as the *ramR* gene is not located in an operon with an encoded signal kinase. This work seeks to determine the identity of both the signal molecule and the activating kinase. There are 19 orphan kinases in the genome of *S. coelicolor*, of which we have 11 distinct kinase-null mutants that are being tested for mature SapB production via Western Blot. These experiments will provide insight into the function of RamR in production of SapB.

Characterization of a Conserved Multi-gene System Regulating Developmentally-associated Gene Expression in *Streptomyces coelicolor*

Author Block:

J. W. Sallmen, J. R. McCormick; Duquesne Univ., Pittsburgh, PA

Abstract Body:

Streptomyces coelicolor is a Gram positive, filamentous soil dwelling bacterium that exhibits a complex life cycle including the transition from a vegetative mycelium to a sporulating, aerial mycelium. Early genetic studies identified two classes of genes that resulted in developmental blocks, bald and white. The bald (*bld*) phenotype occurs when colonies cannot produce aerial hyphae. White (*whi*) colonies exhibit incomplete sporulation and/or loss of production of the concurrently produced grey pigment. While some of the original mutants have been explored, the developmental functions of many of the identified genes are not well understood. Of particular interest is a multi-gene regulatory system, with multiple homologues of each gene present in *S. coelicolor* chromosome and are well conserved among other streptomycetes and other morphologically complex actinomycetes. Two of these genes encode a predicted helix-turn-helix protein (WhiJ-like proteins) and a small, acidic protein of unknown function (BldB-like proteins). In order to explore the roles of these genes in development, one such system involved in the regulation of the spore-associated protein (*sap*) operon, *sapCED*, was analyzed. *sapR* and *sapS* are *whiJ* and *bldB*-like genes, respectively, and are a multi-gene regulatory system that is divergently transcribed from *sapCED*. In order to investigate the potential roles of this gene system in regulation of this operon, null mutants were isolated by recombineering. Single and double null mutants were isolated and the effects on expression were analyzed by the extraction of spore-associated proteins using a nonlethal detergent wash and were fractionated on a Coomasie Blue stained SDS-PAGE. Analysis shows an increase in the production of the *sapCED* encoded spore-associated proteins in both single mutants and double mutants of *sapR* and *sapS* with no obvious effect on other Saps. This phenotype was confirmed by genetic complementation of the *sapR* and *sapS* mutants. In addition, *sapR* and *sapS* were cloned into the Bacterial Two-Hybrid system based on the reconstitution of adenylate cyclase. Preliminary analysis suggests an interaction between SapR and SapS, and SapS with itself. These results together suggest a role for SapR and SapS in negatively regulating the development-associated *sapCED* operon.

Natural Products Alter the Rates of Physiological Differentiation or Antibiotic Production in *Streptomyces* Species

Author Block:

R. S. Greenwell, Jr.; Worcester State Univ., Worcester, MA

Abstract Body:

Microorganisms coexist in nature by forming complex communities of a wide variety of species actively engaging with one another via various forms of communication. It was recently proposed that natural product compounds, such as antibiotics, may be produced as signals for cellular communication that modulate microbial behavior, morphology, and physiology. The effects of these natural products on microbial communities are of great importance for understanding how these organisms contend with each other in nature.We are examining the capacity of the soil bacterium *Streptomyces coelicolor* and other Streptomycetes to have their complex developmental life cycles altered when exposed to other environmental microbes and natural products. We have identified numerous environmental bacterial isolates that can inhibit or accelerate morphological differentiation of *S. coelicolor* and/or alter the expression of the pigmented antibiotics undecylprodigiosin (Red) or actinorhodin (Blue). Environmental microbes that alter Streptomycete differentiation allow us to monitor interspecies interactions that influence complex developmental processes of actinomycetes and gain perspective on the dynamics of the soil microbiome. The products secreted by these environmental microbes are currently being isolated to determine their mechanism of action.We have also demonstrated that a number of naturally-produced antibiotic compounds can influence *S. coelicolor* development when present in sub-lethal concentrations. Of the natural products tested, we identified that erythromycin and bacitracin can trigger *S. coelicolor* to more rapidly transition to aerial hyphae and form spore chains. These two antibiotics trigger independent pathways that allow *S. coelicolor* to form aerial hyphae, as observed by the ability of these compounds to bypass the morphological defects of various *S. coelicolor* developmental mutants. The ability of antibiotic compounds to trigger differentiation and spore formation in *S. coelicolor* provides evidence that these organisms recognize and contend with these compounds in nature via alternative resistance mechanisms, such as antibiotic indifference.

Temperature Regulation of Capsule and Biofilm Development in *Klebsiella pneumoniae*

Author Block:

S. Haxhi, C. O'Connor, R. Girresch; Maryville Univ., St. Louis, Saint Louis, MO

Abstract Body:

Background: *Klebsiella pneumoniae* is a pathogenic bacterium commonly found in clinical settings, as well as the environment. Research has demonstrated that certain factors contribute to this species' relative pathogenicity, two of which are explored in this study: 1) its polysaccharide capsule and 2) its ability to form biofilms on medical instruments. With growing concern over antibiotic resistance, research into the development and transmission of pathogenic organisms is critical. **Methods:** Capsule staining Cells were stained with India ink and observed under fluorescent microscope. Capsule size was quantified at various points in the growth curve (2, 4 and 6 hours incubation) through the program ImageJ.Biofilm formation Bacteria was inoculated for 24 hours and then transferred to the biofilm assay the next day where they were incubated for another 24 hours. Biofilm staining was made using crystal violet and quantification of the biofilm was made using iMark microplate reader at 550nm. (Protocol by US National Library of Medicine National Institutes of Health, 2011, George A. O'Toole.**Results:** No significant difference was found in capsule size at 26 and 37 degrees Celsius. A greater number of capsules were present at 37 degrees than at 26 degrees Celsius agar 24 hrs incubation. Capsule development demonstrates a similar growth curve to that of the standard bacteria growth at 37 degree celsius. No significant difference was found in biofilm formation at 26 or 37 degree celsius **Conclusions:** From the capsule staining and biofilm analysis we found out that the temperature does not have a significant effect on this bacterium's pathogenicity. Future work could be done by altering other effectors including humidity or nutrient availability in different stages of the growth.

Role of *wzi* Gene in Capsule Development in *Klebisella pneumoniae*

Author Block:

R. Girresch, C. O'Connor; Maryville Univ., St. Louis, MO

Abstract Body:

Klebsiella pneumoniae is a pathogenic bacterium commonly found in clinical settings. Research has demonstrated that certain factors contribute to this species' relative pathogenicity, including its polysaccharide capsule. The literature identifies several genes involved in capsule development in *Klebsiella*, most notably the *wzi* gene. This research sought to quantify *wzi* gene expression levels at critical points in *Klebsiella*'s growth curve. These critical points of capsule development were observed during a 6-hour incubation period of cultured Lennox nutrient broth. Optical density was observed hourly and dramatic increases at 3, 4 and 5 hours of incubation at 37 degrees Celsius. For this reason, these time points in *Klebsiella*'s growth curve were used for study of *wzi* gene expression and its role in capsule development. At each time point (3, 4 and 5 hours incubation), 2 milliliters of cultured broth was centrifuged and cellular DNA was extracted using the Qiagen extraction kit. Samples were stored overnight at -20 degrees Celsius. RNA was extracted from each sample using the Qiagen extraction kit. Samples were then stored at -80 degrees Celsius. Success of extraction was determined by gel electrophoresis. cDNA was synthesized from RNA using the Qiagen kit. Primers for the *wzi* gene were then developed and gene was amplified through PCR, establishing cDNA synthesis was successful. While cDNA synthesis was successful, quantification of *wzi* gene expression was not fully determined because Real-Time PCR was not successful. Each sample demonstrated expression of *wzi*. These results make it difficult to tease out the significance of *wzi* gene in capsule development, specifically at these time points determined to be critical. Future work will include generating a *wzi* gene knockdown strain for comparison to wild-type *Klebsiella* to better elucidate the gene's role in capsule development. Similarly, other genes noted to contribute to capsule development will be included in the assay to better understand the interaction of these genes during the bacterium's growth curve.

The *Aspergillus flavus fluP*-Associated Polyketide Metabolite Promotes Production of Sclerotia

Author Block:

P-K. Chang[1], L. L. Scharfenstein[1], K. C. Ehrlich[1], J. D. Di Mavungu[2]; [1]Southern Regional Res. Ctr., Agricultural Res. Service, U. S. Dept. of Agriculture, New Orleans, LA, [2]Faculty of Pharmaceutical Sci., Ghent Univ., Ghent, Belgium

Abstract Body:

Aspergillus flavus is able to produce a variety of polyketide-derived secondary metabolites, including the hepatocarcinogenic aflatoxin. The fungus reproduces and disseminates predominantly by production of conidia. It also produces sclerotia, which are hardened mycelia aggregates used to cope with unfavorable growth conditions. In the present study, we examined the role of the polyketide synthase gene, *fluP*, of secondary metabolite gene cluster 41 on fungal development by gene deletion and overexpression approaches. The *fluP* deletion strain grew and produced aflatoxin normally, but it produced a much lower amount of sclerotia than the wild type. In contrast, the *fluP*-overexpressing strain produced a higher amount of sclerotia than the wild type. When the *fluP*-overexpressing strain was co-cultured with the wild type and the deletion strain, it elevated their sclerotial production at edges of contact. Acetone extracts of the *fluP*-overexpressing strain but not of the deletion strain exhibited the same effect on promoting sclerotia production of the wild type. These results suggest that FluP polyketide synthase is involved in the synthesis of a diffusible metabolite that serves as a signal molecule to regulate sclerotial production.

Tests for Coevolution in a Microbial Mutualism

Author Block:

S. G. Wallen Jr, V. Bravman, I. Stroynyy, S. Rhothisen, A. Macarulay, Y. Demissie, C. Feng, K. Hillesland; Univ. of Washington Bothell, Bothell, WA

Abstract Body:

Coevolution, where one species adapts to the evolutionary changes of another, can increase the rate of evolution, cause species diversification, and can give rise to complex adaptations. It is unclear, however, whether these effects apply to mutually beneficial interactions between species commonly found in microbial communities. We tested whether the bacteria *Desulfovibrio vulgaris* and the archaea *Methanococcus maripaludis* coevolved during 1000 generations of evolution in laboratory conditions that forced them to cooperate with each other to survive. If *D. vulgaris* adapted to the evolving *M. maripaludis* population, then it should have higher fitness when paired with *M. maripaludis* from its past, and lower fitness with *M. maripaludis* that it did not evolve with. To test this, we revived frozen communities of *D. vulgaris* and *M. maripaludis* from generations 0, 300, 780, 1000, 1500, and 2000 of the laboratory evolution experiment, used antibiotics to separate *D. vulgaris* and *M. maripaludis* populations, and then paired *D. vulgaris* from the 1000 generation timepoint (D1000) with *M. maripaludis* populations from each past and future timepoint. To control for overall evolutionary changes in *M. maripaludis*, the growth rate and yield of each mixed-history community was compared to a control pairing of the cognate *M. maripaludis* population and ancestral *D. vulgaris*. All communities containing D1000 grew faster and had higher yield than communities containing only ancestral *D. vulgaris*, regardless of how long the *M. maripaludis* population had previously evolved. This result shows that 1000-generation *D. vulgaris* was compatible with both past and future partners. In addition, the growth rate and yield of D1000 communities with past *M. maripaludis* was not significantly different from those with future *M. maripaludis*. Thus, if *D. vulgaris* coevolved with *M. maripaludis* during 1000 generations in obligate mutualism, the resulting mutations did not impact community growth rate or yield.

The Role of Rpob Mutation 526 in *Mycobacterium tuberculosis* Virulence *In Vitro* & *In Vivo*

Author Block:

V. L. Campodonico, D. Rifat, J. A. Miller, P. C. Karakousis; Johns Hopkins Univ., Baltimore, MD

Abstract Body:

Background: Over 90% of *Mycobacterium tuberculosis* (Mtb) rifampin resistance is due to mutations in the *rpoB* gene encoding the β-subunit of RNA polymerase. Most mutations occur in an 81-bp fragment of the *rpoB* gene spanning codons 507-533, with the majority of clinical isolates containing point mutations in codons 531, 526 and 516. In the current study, we hypothesized that *rpoB* is required for full Mtb virulence. **Methods:** Bacterial strains used included wild-type Mtb CDC1551, an *rpoB* H526D mutant, isolated from Mtb CDC1551 grown on 1µg/ml rifampin-containing plates and confirmed by DNA sequencing, and the *rpoB* complemented strain by reintroduction of the native *rpoB* gene and confirmed by Southern blot. The growth of each strain was studied in nutrient-rich broth, and during nutrient starvation and progressive hypoxia at 37°C. Fixed phosphotungstate negative stains were used to determined bacterial morphology and to measure the longitudinal axis of each strain by transmission electron microscopy. Female BALB/c mice were aerosol-infected with Mtb. On Days 1, 14, 28, 56, 98 and 135 post-infection, the lungs and spleens of mice (n=4-5) were homogenized, diluted and plated on Middlebrook 7H11 agar plates for CFU counts. The upper lobe of the left lung was processed for histological examination. **Results:** No obvious differences in growth and survival were observed between the mutant and the WT strain during nutrient starvation or progressive hypoxia. The mean length of *rpoB* mutant bacilli was shorter during progressive hypoxia relative to that of wild-type and complement bacilli ($p<0.01$), but longer during nutrient starvation ($p=0.04$). Deficiency of *rpoB* was associated with reduced Mtb survival in mouse lungs following infection, as bacillary burden in lungs of mice infected with rpoB mutant was 1.8, 1, 1.4 and 0.7 $\log_{10,}$ lower than that of WT infected mice on days 14, 28, 56 and 98 respectively and with a lower percentage of lung area affected by granuloma (4% in lungs of mice infected with rpoB mutant versus 25% in mice infected with WT strain on day 135) **Conclusions:** Our data suggest that the H526D mutation is relatively dispensable for Mtb survival during various physiologically relevant stress conditions *in vitro*, but is required for full virulence in mouse lungs.

Toxin YafQ Reduces *Escherichia coli* Growth at Low Temperatures

Author Block:

T. K. Wood, Y. Zhao; Pennsylvania State Univ., University Park, PA

Abstract Body:

Toxins of toxin/antitoxin (TA) systems have several roles in cell physiology with reduction in metabolism being the clearest. Under stress, toxin YafQ of the YafQ/DinJ *Escherichia coli* TA system alters metabolism by associating with ribosomes and cleaving transcripts with in-frame 5'-AAA-G/A-3' sites. Antitoxin DinJ is a global regulator that represses its locus as well as influences the level of the stationary sigma factor RpoS. Here, we investigated the influence temperature on activation of toxin YafQ. We found that deletion of the gene for the antitoxin, *dinJ*, resulted in both reduced metabolism and slower growth at 18^{o}C but not at 37^{o}C. The reduction in growth could be complemented by producing DinJ from a plasmid. Using a transposon screen to reverse the effect of the absence of DinJ, two mutations were found that inactivated the toxin YafQ; corroborating this result, a clean deletion of *yafQ* in the Δ*dinJ* ΔKm^{R} strain restored both metabolism and growth at 18^{o}C. In addition, production of YafQ was more toxic at 18^{o}C compared to 37^{o}C. Therefore, YafQ is more effective at reducing metabolism at low temperatures.

Mutational Analysis of the Periplasmic Sensor Domain of the *Porphyromonas gingivalis* Fims Histidine Kinase

Author Block:

K. Nishikawa; Aichi Gakuin Univ., Nagoya, Japan

Abstract Body:

Porphyromonas gingivalis (Pg) is a Gram-negative oral anaerobe closely associated with adult periodontitis. Known virulence factors of this organism include FimA fimbriae which are important for colonization in the gingival sulcus and evasion of the host immune system. The biogenesis of the fimbriae is positively regulated at the transcriptional level by FimS-FimR two-component system (TCS). The FimS histidine kinase comprises a putative periplasmic sensor domain containing multiple TPR motifs, which are often identified in the surfaces responsible for protein-protein interactions. The environmental signal that the TCS responds to is still unknown. In this study, a FimS random mutant library was constructed to identify the critical amino acids within the periplasmic domain for its sensory function. An error-prone PCR method was used to introduce random mutations in the sensor coding region of the wild-type *fimS*. The mutant *fimS* fragments were cloned into a pT-COW-based, novel expression vector, and introduced into a *fimS*-knockout Pg strain by electroporation. More than fifty transformants were found to be complemented with exogenous *fimS* genes, and further analyzed by direct sequencing to identify the mutation sites in the periplasmic domain-coding region. Their phenotypes in terms of the production of FimA were also examined by western blot using an anti-FimA peptide antibody. Interestingly, at least five clones had a single missense mutation within one of the TPR motifs that was sufficient for the FimA-deficient phenotype, indicating that these amino acids in the TPR motifs are critical for the sensory function of FimS. These results support the idea that the unknown environmental signal for FimS-FimR TCS could be a kind of protein/peptide molecule.

Thioredoxin Protects *Salmonella* Against Oxidative Stress of the Nadph Phagocyte Oxidase Independently of Thiol-Disulfide Oxidoreductase Enzymatic Activity

Author Block:

J-S. Kim, M. Song, L. Liu, M. Husain, A. Vázquez-Torres; Univ. of Colorado, Sch. of Med., Aurora, CO

Abstract Body:

The thiol-disulfide oxidoreductase CXXC catalytic domain of thioredoxin contributes to antioxidant defense in organisms as phylogenetically distant as humans and bacteria. We indicate that the oxidoreductase activity of thioredoxin-1 protects *Salmonella enterica* serovar Typhimurium against the bacteriostatic activity of hydrogen peroxide *in vitro*, but does not seem to add to antioxidant defenses of this enteropathogen *in vivo*. Nonetheless, thioredoxin-1 defends *Salmonella* from the oxidative stress emanating from the NADPH phagocyte oxidase expressed in the innate response of macrophages and mice in a thiol-disulfide oxidoreductase-independent fashion. Thioredoxin-1 binds to and stabilizes the SPI2 master regulator SsrB independently of the canonical CXXC catalytic motif. Thus, thioredoxin-1 activates intracellular SPI2 gene transcription that is needed for resistance of *Salmonella* to both reactive oxygen species generated by the NADPH phagocyte oxidase and oxygen-independent host defenses of lysosomes. These investigations indicate that the horizontally-acquired virulence determinant SsrB is under post-translational regulation by ancestral thioredoxin.

Redox Status Affects Biofilm Formation and Pyocyanin Synthesis in *Pseudomonas aeruginosa*

Author Block:

T. A. Van Laar, T. J. Birges, J. Thomas, B. Hazen, M. Rawat; California State Univ., Fresno, Fresno, CA

Abstract Body:

Low molecular weight (LMW) thiols are involved in protection against oxidative stress through the detoxification of reactive oxygen species (ROS). One of the most important LMW thiols is glutathione (GSH), which is able to reduce ROS, becoming oxidized to glutathione disulfide (GSSG) in the process. GSSG can be recycled to GSH through the activity of glutathione reductase, a critically important step for the regeneration of GSH and thus protection against ROS. *Pseudomonas aeruginosa* is a Gram-negative bacterium normally found in soil and water that can cause opportunistic infections, particularly in the lungs of cystic fibrosis (CF) patients. Previous work has shown that a mutant in GSH synthetase (*gshB*) has increased sensitivity to antibiotic therapy, indicating that GSH may play a role in tolerance of antibiotic treatment. To further study the role of GSH in *P. aeruginosa*, we obtained mutants in numerous genes responsible for GSH biosynthesis and recycling. We found that the *gshA* mutant does not produce any GSH and has a slight growth delay when compared to wild type. The *gshA* mutant is also defective for biofilm formation, supporting the idea that the redox state of *P. aeruginosa* is important for biofilm formation. We noted that the GSH mutant has reduced levels of swarming motility and pyocyanin (an important secreted virulence factor) production when compared to wild type. Finally, the *gshA* mutant has increased sensitivity to oxidative stressors. Taken together, these data suggest that an imbalance in the redox state of *P. aeruginosa* may decrease its virulence. We are in the process of further characterization of a mutant disrupted in *gor*, a glutathione reductase responsible for recycling GSH, to understand how GSH contributes to the redox balance in *P. aeruginosa*.

Glutathione Synthesis Protects *Streptococcus agalactiae* against Hypochlorous Acid and Hydrogen Peroxide Oxidative Stresses

Author Block:

T. George, L. Grant, Y. Dhindsa, A. Patel, P. Desai, M. Schwabe, S. Patel, B. Janowiak; Saint Louis Univ., St. Louis, MO

Abstract Body:

Background: *Streptococcus agalactiae*, or Group B Streptococcus (GBS), is a leading cause of neonatal meningitis. GBS maintains high levels of an antioxidant known as glutathione, which is produced by a gamma-glutamylcysteine synthetase - glutathione synthetase encoded by the *gshAB* gene. The hypothesis was that GBS produces large quantities of glutathione in order to protect itself from the harsh oxidants produced by the host immune system during infections. **Methods:** In order to test the hypothesis, the *gshAB* gene was knocked out and complemented back in three clinically relevant GBS strains, GBS Ia A909, GBS III COHI, and GBS V 2603V/R. The bacteria were exposed to two immunologically relevant stresses, hypochlorous acid (HOCl) and hydrogen peroxide (H_2O_2), and differential killing by HOCl & H_2O_2 were compared between wild type, glutathione-deficient, and *gshAB*-complemented GBS for all three clinically relevant strains. The comparisons were performed in both exponentially-growing bacteria as well as GBS grown to stationary phase.**Results:** For all three clinically relevant strains, the killing by both HOCl and H_2O_2 were statistically similar between the wild type and complemented strains. However, for all three strains, glutathione-deficient GBS were more efficiently killed by HOCl than H_2O_2, when compared to either wild type or complemented GBS. These results were observed for both the exponentially- and stationary- grown GBS.**Conclusion:** Based on these results, it does appear that GBS relies on production of glutathione for the protection against immunologically relevant oxidative stresses such as HOCl and H_2O_2. Future studies will focus on other relevant stresses to GBS such as pH, osmotic, and metal stresses.

Persistent *Mycobacterium Bovis*-Bcg is Resistant to Glutathione Induced Reductive Stress Killing

Author Block:

N. Patel, R. Lawrence, **R. Yancey**, E. Gianacopoulos, K. Parker, M. Peteroy-Kelly; Pace Univ., NY, NY

Abstract Body:

The global incidence of tuberculosis has been slowly declining since 2003. Despite this, approximately nine million individuals contracted the disease with mortality rates approaching 20% in 2013. Therefore, there is still a great need to better understand how mycobacteria respond to the environments they may encounter within the host to develop effective therapies and vaccines. This study focuses on the redox stress response in mycobacteria elicited by a host-derived, thiol-based detoxification molecule, glutathione (GSH). Although the growth and viability of *M. bovis*-BCG (BCG) was hampered by exposure to 8 mM GSH, oxygen depleted, persistent BCG (NRP BCG) resisted GSH-mediated killing. Fast growing mycobacteria also resisted GSH-mediated killing. To determine the mechanisms behind these observations, we evaluated the levels of intracellular ATP in both BCG and NRP BCG exposed to 8 mM GSH. Intracellular ATP levels increased from 0.13 to 2.3 uM in BCG upon exposure to GSH. The levels of ATP remained low and unchanged when NRP BCG was exposed to GSH. Using both HPLC and a cell-based thiol detection assay, it was determined that GSH stimulates the production of mycothiol (MSH) by BCG approximately 5.7 fold. The levels of MSH did not change upon exposure of NRP BCG to GSH. MSH is an alternative, thiol-based detoxification molecule employed by mycobacteria. Changes in the cytoplasmic concentrations of this molecule are suggestive of redox imbalances. Together, GSH and MSH may introduce excess reducing equivalents into the mycobacterial cytoplasm; leading to reductive stress. The modulation of NAD^+ levels through alterations in ATP metabolism can enhance the cells ability to bind excess reducing equivalents and serve as a mechanism to restore the cellular redox balance when cells experience reductive stress. These results are corroborated by RNAseq data that suggests that pathways involved in regenerating NAD^+ (such as fatty acid biosynthesis) are activated in BCG exposed to GSH. An evaluation of NRP BCG RNAseq data is ongoing. Taken together, these data suggest that killing of BCG by GSH may result from reductive stress that cannot be controlled. NRP BCG appears to be resistant to GSH-induced reductive stress.

Glutathione Protects *Synechococcus* pcc 7942 Against Environmental Stress

Author Block:

M. Rawat, A. Strankman, M. Abou-Naoum, J. Thomas, B. Hazen, S. Hartanto, T. Johns, T. Brooks, A. Rajkarnikar- Singh; California State Univ.-Fresno, Fresno, CA

Abstract Body:

Glutathione (GSH), a major low molecular weight thiol in cyanobacteria, protects the cell from oxidative stress caused by reactive oxygen species produced as by-products of photosynthesis and aerobic respiration. GSH contributes to the reducing environment within the cell by acting as an electron donor, becoming oxidized to glutathione disulfide (GSSG) in the process. While the functions of GSH are widely investigated in higher plants, not as much is known about the role of GSH in cyanobacteria. To investigate the role of GSH and GSH dependent enzymes in protecting cyanobacteria from oxidative and other environmental stresses, *Synechococcus* PCC 7942 transposon mutants disrupted in *gshB*, coding for the enzyme catalyzing the second step of glutathione synthesis, *gor*, coding for the glutathione reductase that maintains the glutathione in a reduced condition, and *gscR*, coding for the nitrosoglutathione reductase/ formaldehyde reductase, were analyzed. Growth of mutants and the complemented strains was measured under a variety of stresses, including oxidative and nitrosative metal stress. While the growth of the *gshB* mutant was adversely affected under several different stresses, the *gor* mutant behaved like wildtype and still contained substantial GSH. However, activity assays with recombinant Gor validated its function as a glutathione reductase. Intriguingly, RNAseq analysis of the *gor* mutant indicated that the mutation resulted in the expression of phage genes, which was not observed in the *gshB* mutant. Both *gscR* and the *gshB* mutants were more susceptible to nitrosative stress and formaldehydes than wildtype and activity assays with recombinant GscR demonstrated that GscR is able to act as a nitrosothiol reductase and formaldehyde dehydrogenase. Proteomic analysis of *S*-nitrosylated proteins in the wildtype and the *gscR* mutant and *S*-glutathionylated proteins in the wildtype and the *gshB* mutant revealed that multiple processes are affected by nitrosylation and glutathionylation of cysteine residues in *Synechococcus* PCC7942. Our data thus indicates that GSH plays an important role in protection against a number of stresses in *Synechococcus* PCC7942.

Copper Resistance in Acinetobacter Baumannii

Author Block:

C. L. Williams[1], J. J. Gilbreath[1], S. L. Tyner[2], A. C. Jacobs[2], D. V. Zurawski[2], D. S. Merrell[1]; [1]Uniformed Services Univ. of the Hlth.Sci., Bethesda, MD, [2]Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract Body:

Acinetobacter baumannii is an important emerging pathogen that is capable of causing many types of severe infection, especially in immunocompromised hosts. Since *A. baumannii* rapidly acquires antibiotic resistance and infections are on the verge of being untreatable, novel therapies are desperately needed. Recently, the antimicrobial properties of copper against various bacterial pathogens have been described, and clinical studies have shown that copper coated surfaces can reduce microbial burden and rates of infection in the hospital setting. To investigate the utility of copper-based antibacterial strategies against *Acinetobacter* infections, we characterized copper resistance in a diverse panel of *A. baumannii* strains. Exposure to increasing concentrations of copper in liquid culture and on solid surfaces resulted in dose-dependent and strain-dependent effects; levels of copper resistance varied broadly across strains, and were more pronounced in liquid culture. Examination of the growth phase dependent effect of copper on *A. baumannii* revealed that resistance to copper increases dramatically in stationary phase. Moreover, exposure of cultures to sub-inhibitory concentrations of copper allowed the bacteria to adapt to and grow in high concentrations of copper; this 'copper tolerance response' is likely achieved via increased expression of copper resistance mechanisms. Indeed, genomic analysis revealed numerous putative copper resistance proteins that share amino acid homology to known proteins in *Escherichia coli* and *Pseudomonas aeruginosa*. Transcriptional analysis revealed significant up-regulation of these putative copper resistance genes following brief copper exposure. To our knowledge, this is the first investigation into the copper resistance mechanisms of *A. baumannii*. Characterization of copper resistance mechanisms may aid in the search for novel antibiotics against *Acinetobacter* and other highly antibiotic resistant pathogens.

Identification of Reduction-independent, Tellurite Resistance Determinants in Antarctic Bacteria

Author Block:

C. Muñoz, F. Cornejo, M. Figueroa, C. Pinto, E. Morales, F. Arenas, C. Vásquez; Univ. de Santiago de Chile, Santiago, Chile

Abstract Body:

Microorganisms can tolerate metals and others toxics because their genomes encode resistance determinants that are relatively specific and have been described in a variety of bacteria. There are several general metal resistance mechanisms including metal volatilization, metal chelation (intra- and extracellular), increased efflux, decrased uptake, and enzymatic detoxification, among others (Lemire et al., 2013). For the oxyanion tellurite, one of the best described resistance mechanisms is the reduction to elemental tellurium by proteins like flavoproteins (Castro et al., 2008). Furthermore, proteins encoded in the *ter*, *kil*A*Tel*AB, and *teh*AB operons, are implicated in tellurite resistance, although the mechanism of this process remains to be elucidated- and does not seem to be related to tellurite reduction. With the goal of finding novel mechanisms of tellurite resistance, we isolated bacteria from Antarctica, an environment that naturally imposes many types of stress that have been related to the toxicity of tellurite, including ROS. Specifically, we isolated a strain of *Staphylococcus haemolyticus* carrying 3 plasmids, and found that the larger one (pBNF01A) increases the resistance of *E. coli* to tellurite ~ 100 fold. Sequencing of plasmid revealed the presence of ORFs involved in metal resistance, glutaredoxin and hypothetical proteins. The *E. coli* wild type strain carrying or not pBNF01A showed similar physiological responses to tellurite exposure, including no differences in ROS production, activity of antioxidant enzymes, levels of intracellular thiols or in tellurite reductase activity. In addition, we isolated a strain of *Psychrobacter glacincola* with a high resistance to tellurite (MIC 2.3 mM). Sequencing of the genome showed the presence of genes involved in metal resistance, response to oxidative stress and tellurite resistance (*ter* genes). Surprisingly, *E. coli* carrying plasmid pBNF01A as well as *P. glacincola* did not show increased resistance to other metals and/or oxidizing agents, indicating that the resistance determinants are specific for tellurite.

Identification of Zinc-Regulated but Zur-Independent Genes in *Francisella*

Author Block:

G. Moreau, B. Mann; Univ. of Virginia, Charlottesville, VA

Abstract Body:

Francisella tularensis has been classified as a Tier 1 select agent by the Centers for Disease Control because it has a low infectious dose, is easily aerosolized, and infection is potentially lethal. Zinc is an essential nutrient for all cells, and one mechanism host cells use to control bacterial growth is to limit pathogen access to zinc. As *Francisella* grows effectively intracellularly, it must have efficient mechanisms of acquiring zinc from host cells, but these mechanisms have not been well characterized. Many bacteria use a zinc-responsive transcriptional regulator, Zur, to control expression of genes required for zinc uptake. We performed RNAseq with a wildtype and Zur transposon mutant of *Francisella novicida* to identify Zur-regulated genes. We identified only four genes that were differentially regulated in the *zur* mutant strain. Of the identified genes, only two are thought to encode functional proteins in the virulent *Francisella tularensis* ssp. *tularensis* Schu S4 strain, and none were predicted to encode for transporter proteins. These results suggest that the virulent Schu S4 strain must have mechanisms of responding to zinc-limiting conditions that are Zur-independent. To identify genes involved in the uptake of zinc in zinc-limiting conditions, we performed RNAseq with both *Francisella novicida* and *Francisella tularensis* Schu S4 that were either untreated or treated with TPEN, a zinc-chelating agent. Our future directions are to identify and characterize genes that are important for zinc acquisition and survival in the zinc-limiting environment of the host.

Control of Antibiotic Resistance and Virulence is Coupled in *Acinetobacter baumannii*

Author Block:

M. J. Gebhardt, H. A. Shuman; Univ. of Chicago, Chicago, IL

Abstract Body:

Acinetobacter baumannii is a serious human health threat because many currently circulating, highly virulent strains have acquired multiple antibiotic resistance determinants. In addition, our understanding of the molecular mechanisms that underlie *A. baumannii* pathogenesis and innate resistance to antibiotics and environmental stresses is incomplete. In particular, the transcriptional networks that govern the expression of genes involved in virulence and antibiotic resistance remain largely uncharacterized. We recently performed a large scale, unbiased forward genetic screen to identify genetic elements required for *A. baumannii* to grow within the larvae of the insect, *Galleria mellonella*, an established infection model for microbial pathogens. The screen identified 300 genes required for survival and/or growth within *G. mellonella* larvae. Interestingly, we also discovered that several genes required for virulence are also required for antibiotic resistance, suggesting a link between virulence and antibiotic resistance in this emerging pathogen.Two genes of particular interest are *gigA* and *gigB* (for *G*rowth *i*n *G*alleria), which show a defect for both growth within and killing of *Galleria* larvae. The *gigA* gene encodes a predicted two-component response regulator protein while *gigB* is predicted to encode a hypothetical protein containing a STAS domain (Sulphate Transporter and Anti-Sigma factor antagonist). Interestingly, mutant strains harboring a deletion of either *gigA* or *gigB* display a survival defect in the presence of several environmental stressors, including low pH, heavy metals and antibiotics. Finally, suppressor analysis identified a connection between *gigA*/*gigB* with the Nitrogen Phosphotransferase system (PTS^{Ntr}). These findings suggest that GigA and GigB, possibly in conjunction with the PTS^{Ntr} system, comprise a signal transduction pathway that controls not only adaptation to environmental stresses, including antibiotic exposure, but also virulence in *A. baumannii*.

Phenotypic Response Of Bacteria To Antibiotics At Single Minute Time Scales

Author Block:

K. Babcock, C. Schneider, P. Harris, S. Markakis, S. Strenn; Affinity Biosensors, Santa Barbara, CA

Abstract Body:

Clinical tests of the response of bacteria to antibiotics monitor growth over many hours. It is well documented, however, that the stress response in a bacterial cell can occur within minutes after exposure. We tested a method for measuring the phenotypic changes in bacteria at time scales down to one minute, and monitored very short-term changes in bacteria cultures in real time when exposed to antibiotics.We used mechanically resonant microchannels (ref Burg) to measure the masses and concentrations [#/ml] of individual microbes drawn from broth microdilution cultures. Fluidics were designed to maximize throughput, so that up to 1,000 microbes could be measured in one minute. A number of microbe species were tested in the presence of bactericidal and bacteriostatic antibiotics. A typical test protocol grew the microbes from low concentrations ($<1x10^6$/ml) until they reached their growth phase, then added the antibiotic. Throughout this process the culture was sampled once per minute and quantified *via* number concentration and the distribution of individual microbe masses. Bacteriostatic antibiotics could then be diluted away and the culture monitored for resumption of growth.For ampicillin added to *E. coli* K12 (ATCC 10798) at a concentration four times the minimum inhibitory concentration, the mean microbe mass was observed to increase within three minutes. The number concentration began to decrease at the same point, apparently caused by decay into small-mass debris which appear simultaneously in the mass distribution. For tetracycline, replication ceased within two minutes, while there were no significant changes in mass distribution. After diluting the tetracycline 100-fold, replication resumed after 40 minutes. At high enough concentrations of tetracycline, growth did not resume for several hours, if at all, indicating a transition to bactericidal action. This transition can be studied in detail as a function of antibiotic exposure time and concentration. Response time to antibiotic exposure varied by strain, with some showing rapid growth of filamentous forms.The results demonstrate that phenotypical response can be detected down to the one-minute timescale, enabled by the combination of high number throughput and the measurement of individual microbe masses. Among numerous potential applications are antibiotic discovery, dosing, and modes of action.

Novel Genes Involved in the Generation of Persister Cells in Ampicillin-exposed Cultures of Uropathogenic *Escherichia coli* (Upec)

Author Block:

R. C. Molina-Quiroz[1], D. Lazinski[2], S. B. Levy[1]; [1]Ctr. for Adaptation Genetics and Drug Resistance, Tufts Univ., Sch. of Med., Boston, MA, [2]Tufts Univ., Sch. of Med., Boston, MA

Abstract Body:

Uropathogenic *E. coli* (UPEC) is the main ethiologic agent of urinary tract infections worldwide, generating aproximatelly 80% of the clinic cases every year. Most of these infections are chronic and recurrent and represent a global health threat. Relapsing infections have been associated with the generation of persister cells. This subpopulation is characterized by a transient non-hereditary state with the ability to survive lethal concentrations of different antibiotics. To date it has been shown that these subpopulations are generated by stocastic processes and a role for toxin-antitoxin modules (TA), stringent response among others, has been described. We used a high-throughput genetic screen to identify mutants with an increased fitness after exposure to Ampicillin. To do this, we used a transposon library containing ~360.000 mutants in the CFT073 genetic background and we mapped the insertions in the bacterial chromosome by Illumina-sequencing. This library was exposed to a lethal concentration of Ampicillin during 6 hours and survivors were enriched by overnight growth in LB medium. This approach allowed us to identify 30 mutants under positive selection in Ampicillin-exposed cultures, most of them metabolic and membrane proteins. Construction and evaluation of bacterial persistance of mutants corresponding to *dsbA* (thiol:disulfide interchange protein *dsbA* precursor), *cyaA* (adenylate cyclase) and *udhA* (pyridine nucleotide transhydrogenase) validated our screen. These results suggest a role –non-described to date- of novel metabolic genes associated with persister cell generation.

Daptomycin Exposure Selects for Novel Mutations Resulting in Enhanced Pigmentation in Methicillin-resistant *Staphylococcus aureus*

Author Block:

A. D. Berti[1], H. M. Turner[1], I. R. Monk[2], S. L. Baines[2], B. P. Howden[2], R. A. Proctor[1], W. E. Rose[1]; [1]Univ. of Wisconsin - Madison, Madison, WI, [2]Univ. of Melbourne, Melbourne, Australia

Abstract Body:

Background: *Staphylococcus aureus* exposed to daptomycin (DAP) frequently demonstrates increased carotenoid pigment production. The major carotenoid produced by staphylococci, staphyloxanthin, is biosynthesized by the *crtMNOPQ* pathway. Here we characterize the carotenoid content of *S. aureus* containing individual targeted mutations outside of the *crt* locus based on a panel of sequence variations identified following serial *in vitro* DAP exposure. **Methods:** Whole genome sequencing was performed on 25 experimental replicates of *S. aureus* strain J01 exposed to DAP with-or-without adjunctive antibiotics *in vitro* over a period of 28 days. Genetic loci containing mutation in at least 10% of the 25 replicates were selected for further study. Mutations in loci thus identified were introduced in isolation back into the original strain J01 via pIMAY-based allelic replacement. Carotenoid extracts were quantified spectrophotometrically and confirmed via chromatography and mass spectrometry. Membrane fluidity was determined using polarized spectrofluorometry with 1-6 diphenylhexatriene as a lipid-partitioning probe. Susceptibility to reactive oxygen species was assessed via peroxide tolerance assay. Minimum inhibitory concentration (MIC) to DAP was assessed by broth microdilution. **Results:** Nine loci were identified that contained mutation in at least 10% of replicates. Targeted mutation in *gerCC* (nt925 del A) or *rsh* (L68F) significantly increased carotenoid production. These genes encode a medium-chain length polyprenyl synthase and a GTP pyrophosphokinase, respectively. No other targeted mutations significantly altered carotenoid production. Mutation in either *gerCC* or *rsh* resulted in more rigid membranes. Strains with mutation in *rsh, but not gerCC,* were less susceptible to hydrogen peroxide-mediated killing. No mutation resulted in increases to the DAP MIC. **Conclusions:** Mutation in *gerCC* or *rsh* results in phenotypes frequently observed in both DAP nonsusceptible isolates and clinically persistent strains. While no mutation identified in this work significantly alters the DAP MIC, they likely play a role in survival under stress conditions including those induced by antibiotic exposure.

Loss of Antibiotic Resistance in Benzoate-Evolved *E. coli*

Author Block:

E. S. Ditmars, P. Basting, K. Creamer, S. Acero, I. Hamdallah, E. Eder, J. L. Slonczewski; Kenyon Coll., Gambier, OH

Abstract Body:

We conducted experimental evolution over 2000 generations on *Escherichia coli* K-12 to isolate clones with increased fitness under benzoate stress. 24 populations of *E.coli* were grown in semi-aerobic microplate wells and sub-cultured with increasing levels of benzoate in LBK at pH 6.5. 16 benzoate-evolved clones were selected based on growth rate in benzoate and on chloramphenicol sensitivity. Clones isolated from this experiment showed a number of mutations that suggested that benzoic acid stress could result in a decrease of antibiotic resistance, such as a 6,000-bp deletion that includes the entire Mar (multiple antibiotic resistance) operon. Benzoate-evolved clones were phenotyped in 8 ug/ml chloramphenicol 5 mM benzoate 100 mM MOPS pH 7 LBK. Phenotyping revealed a number of clones sensitive to chloramphenicol. Certain clones showed greater chloramphenicol sensitivity than a MarA knockout strain. One highly sensitive clone, G5-2, was selected for further phenotyping; its resequenced genome showed only one mutation known to be linked to antibiotic resistance in the gene for mar regulator, *rob*. By replacing this mutated gene with its ancestral allele, we determined that the G5-2 clone's decrease in antibiotic resistance was not *rob* mediated, implying that there is a secondary, uncategorized aromatic acid-induced antibiotic resistance system. Salicylate, the main inducer of the Mar regulon and the main circulating product of aspirin, conferred an even greater fitness advantage than benzoate in our evolved clones. By contrast, acetate and sorbate had no effect on division time. Our results may model evolutionary trends seen in the gut of individuals taking aspirin. This model suggests that there could be a connection between the health of the microbiome and the selective pressure of aspirin derivatives such as salicylate in individuals who take aspirin on a regular basis.

Abstract Body:

Glutaredoxins (Grxs), also known as thioltransferases (TTases), are thiol oxidoreductases that regulate cellular redox state in a variety of organisms. In the budding yeast *Saccharomyces cerevisiae*, Grx1 and 2 are cytosolic dithiol Grxs, while Grx3, 4 and 5 are monothiol Grxs. A gene encoding a new monothiol Grx, Grx6, was previously cloned from the genomic DNA of *S. cerevisiae* by PCR. The *S. pombe* cells harboring plasmid pFGRX6 containing the Grx6 gene could grow much better, after the shifts to the fresh medium with cadmium chloride (25, 50 and 100 μM), than the vector control yeast cells. They were identified to contain the lower reactive oxygen species (ROS) and nitrite content, an index of nitric oxide (NO), in the presence of cadmium, than the vector control cells. In the absence or presence of cadmium, changes in glutathione content, superoxide dismutase and glutathione peroxidase activities were also compared. In brief, the *S. cerevisiae* Grx6 participate the defense against cadmium toxicity in *S. pombe*.**:**

***Staphylococcus aureus* Persisters Form Due to a Drop in ATP**

Author Block:

B. P. Conlon, **E. A. Zalis**; Northeastern Univ., Boston, MA

Abstract Body:

Background: We sought to examine the mechanism of persister formation in *Staphylococcus aureus*. *S. aureus* is responsible for a variety of difficult to treat biofilm associated infections. Persister cells are antibiotic tolerant sub-populations of cells believed to be responsible, at least in part, for the antibiotic tolerance of the biofilm. We hypothesized that persisters in an exponential phase population are cells entering the stationary phase before the bulk of the population**Methods:** We compared antibiotic tolerance of stationary phase and exponential phase populations. We used fluorescence activated cell sorting (FACS) of cells with stationary phase specific promoters (P*capA* and P*arcA*) downstream of GFP. We also measured ATP and examined its role in antibiotic tolerance.**Results:** We found that indeed stationary phase specific promoters fused to GFP facilitated sorting of persister cells from the population and generated a 1000 fold enrichment of persisters. We also found that persister formation and expression of these persister markers was dependent on ATP.**Conclusions:** ATP is the major energy currency of the cell. ATP drives the activity of major cell processes targeted by antibiotics. Our results demonstrate that ATP levels in a population are heterogeneous and a drop in ATP results in persister formation, presumably due to inactivity of antibiotic targets. This finding has major implications for the development of new treatments to kill persister cells and eradicate, not just for *S. aureus* but also other important, difficult to treat bacterial infections.

Metal Resistance Patterns in *Enterococcus spp.* Isolated from Irrigation Water

Author Block:

A. A. Ramos, L. A. Navedo, M. Díaz-Camacho, N. M. Rodriguez-Bonano, L. B. Mendez; Univ. del Este, Carolina, PR

Abstract Body:

Background: *Enterococcus spp.* are gram-positive commensal bacteria found in the GI tract of humans and animals. Resistance to antibiotics and heavy metals has been reported in environmental strains of *Enterococcus spp.* Their presence in the environment is of public health concern since enterococci are a common cause of community-acquired and foodborne diseases, causing approximately 800,000 infections per year in USA. The purpose of this study was to determine metal resistance patterns in environmental strains of *Enterococcus spp.* isolated from irrigation water. **Methods:** *E. faecalis* and *E. faecium* were isolated from water samples obtained in a farm in Puerto Rico, which uses well water for irrigation. The minimum inhibitory concentration for 8 metals (i.e. arsenic, cadmium, copper, iron, lead, nickel, and vanadium) was determined using the micro-broth dilution technique. Briefly, enterococci were incubated with increasing concentrations (0.03-1.6 mg/mL) of the metals dissolved in brain heart infusion broth supplemented with 0.5% nalixidic acid. The absorbance (595 nm) was measured after 24 hours of incubation.**Results:** Results showed differences in metal resistance patterns among *E. faecalis* and *E. faecium* isolates. Most of the strains showed resistance to As (III) while only two were resistant to Pb. Metal resistance correlated with previously observed antibiotic resistance patterns determined for the same strains. Specifically, lead-resistant isolates showed higher resistance to the previously tested antibiotics.**Conclusions:** These results are important to public health since in many instances foodborne diseases are associated with contaminated water used for irrigation.

Molecular Mechanism of Bacterial Killing by Plasmid-Encoded Two-Component Bacteriolysin Bac41 in *Enterococcus faecalis*

Author Block:

J. Kurushima, H. Tomita; Gunma Univ., Gunma, Japan

Abstract Body:

Background: For decades, plasmid-mediated acquisition of drug resistances has increased severity of bacterial infection. Proteinaceous bacteriocin (bacteriolysin) Bac41 is encoded on plasmid of clinical strains of *Enterococcus faecalis* that is a causative agent of several opportunistic infections. Since Bac41 system selectively kills bacterial cells not carrying Bac41-coding plasmid, it is supposed to contribute propagation of Bac41-coding plasmid among *E. faecalis* population. Bac41 lytic effectors, $BacL_1$ and BacA, are secreted proteins responsible for specific bacteriolysis on *E. faecalis*. Here, we reported frequency of Bac41 in *E. faecalis* clinical strains and molecular functions of the Bac41 effectors, $BacL_1$ and BacA. **Materials and Methods:** Epidemiologic study for Bac41 was performed by PCR detection of Bac41-related genes and bacteriocinogenic activity against *E. faecalis*. Bactericidal assay was performed by soft-agar method using bacterial supernatant or recombinant protein prepared from *E. coli* expression system. For fluorescent imaging, *E. faecalis* cells were incubated together with the fluorescence-labeled recombinant proteins in THB broth and chemically fixed, following by analysis under the fluorescent microscopy. **Results:** Among 327 *E. faecalis* clinical isolates, 195 strains (59.6%) were Bac41 positives, showing that Bac41 is extensively propagated through *E. faecalis* in clinical environment. Mixture of $BacL_1$ and BacA recombinants induced bacteriolysis on *E. faecalis*. In contrast, single treatment of $BacL_1$ or BacA did not show any lytic activity, indicating that these effectors need each other to exert the bacteriolytic activity. Both $BacL_1$ and BacA have peptidoglycan hydrolase-like domains. Actually, $BacL_1$, but not BacA, showed an endopeptidase activity to degrade *E. faecalis* cell wall. Fluorescent imaging revealed that $BacL_1$ specifically localized in cell division loci of the target *E. faecalis* cell surface independently of BacA. BacA also localized the same region only when catalytic mutant of $BacL_1$ coexisted. However, the BacA targeting was not detected when coexistence of wild-type $BacL_1$ or BacA alone. **Conclusion:** These observations suggested working model that $BacL_1$ primarily attacked to target cell wall independently of BacA, and then BacA follows $BacL_1$ to rapidly trigger the bacteriolysis.

The Essential Role of Stress Induced Sigma Factor E in Gram Negative Bacteria

Author Block:

A. M. Zappas; The Pennsylvania State Univ., University Park, PA

Abstract Body:

Background: Due to increasing antibiotic resistance, new antibiotic development has become essential research. Sigma factor E is a potential new target for antibiotic development. The alternative sigma factor E is activated when stress is induced on membrane or periplasmic proteins within most gram-negative bacteria. Though sigma E was found to be essential in the cell, mutations known as suppressors may allow cells to grow in absence of sigma E[1]. These suppressor mutations give insight to the role of sigma E in the cell and help to understand how sigma E could be targeted with an antibiotic. The project involves connecting a mutation known as prlF1 to the sigma E pathway, and analyzing if the mutation may replace or bypass the function of sigma E. This mutation was found to relieve hybrid jamming in outer membrane protein secretion in *Escherichia coli*[2]. **Methods:** To test the suppression effect of prlF1, the gene *rpoE* coding for sigma E is removed by gene knockout.In order to remove any other mutations from creating a suppression effect prlF1 was marked by a chloramphenicol marker. The marked strain was used to create a P1 lysate and then used for a phage transduction to transduce prlF1 into two wild type strains. The final strain was used to test the suppression effect of prlF1, the gene *rpoE* coding for sigma E is removed by gene knockout. The overexpression of the gene *prlF* has also shown a similar suppression effect as prlF1. The overexpression is done by an expression plasmid containing an IPTG promoter.**Results:** Sigma E is more easily removed in prlF1 strains than wild type, showing its suppression. The overexpression of *prlF* allows more growth of sigma E gene knockout products than in wild type strains**Conclusions:** Suppression is shown by both prlF1 and the overexpression of prlF. Identifying the connection of prlF1 and prlF to sigma E will help to understand how the envelope is being maintained by sigmaE, leading to better understanding of sigmaE as an antibiotic target.

Fnr Regulates Important Virulence Factors in Apec (Avian Pathogenic *Escherichia coli*)

Author Block:

N. L. Barbieri, A. R. Baker, G. Li, C. M. Logue, L. K. Nolan; Iowa State Univ., Ames, IA

Abstract Body:

Avian pathogenic *Escherichia coli* (APEC) is the etiologic agent of colibacillosis, an important cause of morbidity and mortality in poultry. Though many virulence factors associated with APEC pathogenicity are known, their regulation remains unclear. FNR (fumarate and nitrate reduction) is a well-known global regulator that works as an oxygen sensor and has previously been described as a virulence regulator in bacterial pathogens. The goal of this study was to examine the role of FNR in the regulation of such APEC virulence factors and processes as adherence and invasion, type I fimbriae, type VI secretion, survival during oxidative stress, and growth in iron-restricted environments. To accomplish this goal, APEC O1, a well characterized, highly virulent strain of APEC with multiple virulence mechanisms, was compared to its FNR mutant for expression of various virulence traits. Deletion of FNR was found to affect APEC O1's adherence and invasion and expression of *ompT*, a plasmid-encoded outer membrane protein; type I fimbriae; and *aatA*, an autotransporter system. Indeed, the *fnr*$^-$ mutant showed an 8-fold reduction in expression of type I fimbriae and a highly significant reduction in expression of *fimA*, *ompT* (plasmid-borne) and *aatA* ($P<0.0001$). FNR also was found to regulate expression of the type VI secretion system, affecting the expression of *vgrG* and *clpV*. Further, FNR was found to be important to APEC O1's growth in iron-deficit media and survival during oxidative stress with the mutant showing a 4-fold decrease in tolerance to oxidative stress, as compared to the wildtype. Thus, our results suggest that FNR not only mediates APEC adaptation to anaerobic metabolism but also functions as an important regulator of APEC virulence.

Novel *Acinetobacter baumannii* Strategy to Regulate the Response to Dna Damage

Author Block:

C. Ching, K. Gozzi, B. Heinemann, V. G. Godoy; Northeastern Univ., Boston, MA

Abstract Body:

Acinetobacter baumannii (Ab) is an emerging multidrug-resistant, opportunistic pathogen. *Ab* survives desiccation, remaining on the surfaces of hospital equipment, reaching immunocompromised individuals. *Ab* antibiotic resistance acquisition has been linked to its DNA damage response (DDR) and DDR genes are involved in DNA damage and desiccation-induced mutagenesis. In *Escherichia coli*, RecA, the cells' main recombinase, binds single stranded DNA, the signal of DNA damage, to form the nucleoprotein (RecA*). Co-protease activity of RecA* promotes autocleavage and inactivation of LexA, the global DDR repressor, resulting in expression of DDR genes. In *Ab*, this well-known circuitry does not exist, in part because *Ab* lacks LexA. We have shown that conserved DDR genes in *Ab* form two phenotypic subpopulations in response to DNA damage: one with low and another with high expression. Bimodal DDR gene expression may provide a strategy for survival and plasticity in an ever-changing environment.We aim to elucidate the regulation of *recA* in *A. baumannii* as we hypothesize it underlies the bimodal DDR. We have found that the *recA* gene contains a *cis*-acting element in its 5' untranslated region (UTR) unlike any other known DDR gene in *A. baumannii* or other bacteria. *In-vitro* transcription demonstrated that this 5'UTR is structured. A plasmid-borne fluorescent reporter was constructed in which mKate is regulated by the UTR. Mutants of the UTR that delete repeated sequences or changes predicted stem and loop secondary structures were constructed using site-directed mutagenesis. Fluorescence microscopy experiments using the parental and mutant strains with and without DNA damage treatment have shown that the *cis*-acting regulatory element and its structure are important for *recA* regulation. Remarkably, the UTR senses DNA damage not only in *Ab* but also in other bacterial species. These findings provide insight into the evolution of a fundamental DDR regulation and how *Ab* is able to quickly acquire antibiotic resistances.

Identification of Sigma / Anti-Sigma Factor Regulatory Pairs in the Cyanobacterium Nostoc Punctiforme

Author Block:

A. Amir Ali; California State Univ. Northridge, Glendale, CA

Abstract Body:

The filamentous cyanobacterium Nostoc punctiforme grows using plant-like oxygenic photosynthesis and can differentiate into spore-like akinetes, nitrogen-fixing heterocysts, or motile hormogonia in response to stress. Under optimal growth conditions, the genes involved in environmental stress are inactive but under stressful conditions, transcription of stress-responsive genes is induced. A subset of these stress responses are hypothesized to be regulated by the 12 alternative sigma factor subunits of RNA polymerase, previously identified in the genome, which belong to groups 1-4. Anti-sigma factors are hypothesized to sequester these alternative sigma factors until stress induces their release, but little is known about these specific interactions. Seven putative anti-sigma factors were identified in Nostoc punctiforme by sequence homology. We screened for the interaction of all sigma factors with these putative anti-sigma factors using a bacterial 2-hybrid assay and found 23 interactions. These interactions were then quantified by using β-galactosidase assays and 12 of the interactions were shown to have significant β-galactosidase activity. 2 of the 12 interactions with the highest β-galactosidase activity have been confirmed using GST-pulldown assays and Western Blotting, and 5 have yet to be confirmed. These data support the conclusion that multiple anti-sigma factors function in Nostoc punctiforme to regulate gene transcription. A putative anti-sigma factor antagonist belonging to the STAS (sulphate transporter and anti-sigma factor antagonist) superfamily has also since been identified using sequence homology. We hypothesize that the anti-sigma factor antagonist will interact with the putative anti-sigma factors. We plan to screen these interactions using bacterial 2-hybrid assays, quantify these interactions using β-galactosidase assays, and confirm them using GST-pulldown assays and Western Blotting. Larger implications of these findings will help our understanding of complex regulatory events involved in cellular differentiation and adaptation to stress in cyanobacteria and eventually increase our understanding of sigma/anti-sigma interactions and anti-sigma/anti-sigma factor antagonist interactions in all bacteria.

Fitness Cost Associated With The Loss Of Major Porins In *klebsiella Pneumoniae*

Author Block:

A. Fajardo-Lubian, A. Agyekum, J. Iredell; The Westmead Inst. for Med. Res., the Univ. of Sydney and Westmead Hosp., Westmead, Australia

Abstract Body:

It has been suggested that the loss of certain porins could significantly affect the bacterial fitness and the susceptibility to antibiotics. Porins form water-filled channels that allow the passive transport of small molecules across the bacterial membrane, a vital process to cell survival. *Klebsiella pneumoniae* encodes two major porins, OmpK35 and OmpK36. In order to fully understand the role of porins in bacterial adaptation and antibiotic resistance, mutants in five porins (OmpK35, OmpK36, OmpK37, OmpK26 and PhoE) of *K. pneumoniae* wild-type strain ATCC 13883 were obtained by complete deletion or interruption of the gene. Antibiotic resistance tests and competition experiments were performed to evaluate the consequences of the loss of porins for antimicrobial susceptibility and bacterial fitness. The levels of expression of porins were measured in *K. pneumoniae* mutants by real time RT-PCR and compared with those in the wild type strain. Our data reveal that the loss of OmpK36 affects the metabolic fitness. The adaptation of the bacteria to external conditions in the absence of its major porins is a complex process that includes the up-regulation and down-regulation of "secondary" porins (*ompK37, ompK26, phoE* and l*amB*) depending on the environmental circumstances and bacterial growth phase.

Integrating Microbial Genome Annotation Research into the Undergraduate Biology Curriculum

Author Block:

K. Moitra; Trinity Washington Univ., Washington DC, DC

Abstract Body:

Background: The process of linking biological information to gene sequences is called genome annotation. It involves annotating predicted genes and connecting these genes to protein functions. The integration of microbial genomics research into the undergraduate biology curriculum provides students with the opportunity to become familiar with state-of-the-art bioinformatics tools and answer original research questions. Our central hypothesis is that by upscaling and integrating undergraduate research within the classroom experience we would enable larger numbers of students to have access to authentic research, which would, in turn have a high impact on student engagement, learning outcomes and student interest in pursuing future scientific research careers. **Methods:** Students in Introductory Genetics classes and Cell Biology classes over a period of 3 years annotated over 60 predicted ABC (ATP Binding Cassette) genes of 2 microbes: *Methanothermobacter thermautotrophicus* and *Methanobacterium sp. SWAN-1* utilizing the Genomics National Initiative- Annotation Collaboration Toolkit (GENI-ACT) developed by the Joint Genome Institute (JGI) to annotate microbial genomes. A number of pre-course and post-course tests and surveys were conducted to assess if the project engaged students, impacted student learning outcomes, and generated interest in scientific research. **Results:** Our results suggest that the project had a high impact in all three targeted areas. The post-course student surveys indicated that 93% of students acknowledged that genome annotation was a very positive and engaging experience. We also discovered from directed testing and grading of the gene annotations that the students exhibited a tremendous gain in knowledge of genome annotation and research skills over the semester. Finally, 81% of students agreed that they had more interest in pursuing an advanced degree/following a scientific research career, based on their experience with the genome annotation project. **Conclusions:** This suggests that the project has fulfilled its desired outcomes and can be instrumental in engaging students in undergraduate research and in encouraging them to pursue future scientific research careers.

Using the Sea-Phages Program to Integrate Undergraduate Research Experience in Freshman Science Lab Courses

Author Block:

H-M. Chung; Univ. of West Florida, Pensacola, FL

Abstract Body:

Background: The SEA-PHAGES (Science Education Alliance-Phage Hunters Advancing Genomics and Evolutionary Science) program has been implemented nationwide to promote course-based undergraduate research experience. It is jointly administered by Graham Hatfull's group at the University of Pittsburgh and the Howard Hughes Medical Institute's Science Education division. The prototype of the program is a two-semester research course that begins with students digging in the soil to isolate, purify new phages and follows with sequencing the genome of newly purified phage genome and genome annotation. In the past nine years, the program has successfully increased undergraduate interest and retention in the biological sciences through the courses mostly offered by the Biology department or Honors programs in participating schools. UWF joined the SEA-PHAGES Program in 2015; we aim to engage students' interest in biological science with an inter-discipline approach that enables students to truly appreciate chemistry in biological science. **Methods:** With this in mind, we offered the SEA-PHAGES research project by integrating General Chemistry I - and II - and Biology I - and II laboratory courses in fall 2015 and spring 2016. Our goals are to identify novel phage(s) and annotate their genomes in the Bio I and II lab sessions in fall 2015 and spring 2016 semesters, and to explore experiments (and projects) of general chemistry that can be directly linked to microbiology, genetics, genomics and ecology through General Chemistry I and II lab activities in fall 2015 and spring 2016, and "Exploring Santa Rosa Island" projects occurring in Bio II lab session in spring 2016. **Results:** We will present the newly identified phages: Slimphazie and DarthP, novel elements of our course design, hurdles encountered when integrating biology and chemistry lab activities, as well as feedback from students in regard to the good and bad of the program. **Conclusions:** The findings of our endeavor will support the course-based undergraduate research model as the more effective platform for success in introductory biology.

Publishing Title:

Introducing a Mini-Course-Based Undergraduate Research Experience into a Microbiology Laboratory in Order to Identify Plants with Antimicrobial Properties and Help Students Identify as Scientists

Author Block:

P. J. Baynham; St. Edward's Univ., Austin, TX

Abstract Body:

The US faces a growing need for diverse Science Technology Engineering and Math (STEM) professionals with a shrinking pipeline for such individuals. A current threat in healthcare in the US and abroad is the growing resistance of bacteria to current antibiotics, with associated infections sickening 2 million people, and killing more than 23,000 people in the US annually. To address both of these situations, an abbreviated course-based undergraduate research experience (mini-CURE) was introduced into a junior level undergraduate microbiology lab required for biology and biochemistry majors at St. Edward's University (SEU) in spring 2015 (n=32). Over half the students in the sciences at SEU are from groups under-represented in STEM disciplines and 35% are Pell eligible. After gaining basic skills, students analyzed plant extracts from various countries obtained from the National Cancer Institute for antimicrobial properties using a Kirby-Bauer disk diffusion assay for three weeks. Students examined the literature to determine their solvent of choice and which bacterium they would test for inhibition of growth and/or quorum sensing. As they tested their samples they maintained an electronic laboratory notebook on Blackboard. The impact of this project on students was analyzed using David Loppato's pre and post CURE surveys (2008). Of 352 extracts tested 21 showed growth inhibition. The promising extracts will be further analyzed by future students. According to the surveys my students had large gains in "understanding how scientists work," "skill in interpretation of results" and "tolerance for obstacles faced." In the overall assessment of the course students indicated that the course was a good way to learn about the subject, about the process of scientific research and that it had a positive effect on their interest in science. Anecdotally, students seemed more engaged in the activities associated with the mini-CURE and raved about these in course evaluations compared with other lab assignments. These data suggest that this mini-CURE was successful in helping students learn, fostering their confidence while helping them to identity as scientists and in finding promising samples for further work. In spring 2016, this project is being expanded to include the entire semester.

Genomic and Phenotypic Characterization of *Epilithonimonas diehli* Sp. Nov., Isolated from a Freshwater Creek

Author Block:

K. T. Jacobs; Lycoming Coll., Williamsport, PA

Abstract Body:

A Gram-Staining-Negative, yellow-orange pigmented bacterial strain, designated FH1 was isolated from Fox Hollow in Williamsport, PA during an undergraduate microbiology course. The 16S rRNA sequences of strain FH1 was most similar to that of *Epilithonimonas lactis* (98.1%) and *Epilithonimonas ginsengisoli* (97.1%) in the family *Flavobacteriaceae*. The genomes of FH1 and *E. lactis* were sequenced, assembled, annotated and compared to each other and the type species of the genus, *E. tenax*. The estimated DNA-DNA hybridization value between FH1 and *E. lactis* was 33.1 as calculated by the DSMZ Genome-Genome Distance Calculator. The Average Nucleotide Identity (ANI) was 85.6. Both values are well below the threshold for separate species. Comparison of annotated gene sets identified. The 4.0 Mbp genome of FH1 contained 632 genes not found in either of the other *Epilithonimonas* sequenced genomes. Phenotypic comparisons identified a several distinguishing characteristics that support the hypothesis that isolate FH1 represents a novel species in the genus *Epilithonimonas* for which the name *Epilithonimonas diehli* sp. nov. is proposed.

Cloning Of Unique β-Lactamases from *Elizabethkingia miricola* and *Elizabethkingia anopheles, E*xperiments in a Freshman Course

Author Block:

J. A. Matts, P. J. Canaan, **N. J. Torres**, J. E. Gustafson; Oklahoma State Univ., Stillwater, OK

Abstract Body:

The genus *Elizabethkingia* contains emerging human pathogens that express multiple antimicrobial resistance and are linked to water source outbreaks in hospitals. Modern genomics in combination with traditional approaches has demonstrated that there are at least five unique species of *Elizabethkingia*. The analysis of *Elizabethkingia* genomes also indicates these organisms harbor greater than 10 chromosomally-located β-lactamases genes, which makes treating *Elizabethkingia* infections with -lactams impossible. To date, only 2 unique metallo-β-lactamases and an extended-spectrum β-lactamase have been cloned from *Elizabethkingia meningoseptica* and characterized. We now report the cloning of additional *Elizabethkingia miricola* and *Elizabethkingia anopheles* β-lactamases which was carried out to provide a course-embedded research experience to freshman biochemistry students. Initially, amplicons of the putative β-lactamase genes were generated from genomic DNA with primers with *BamHI* (5') and *SacI* (3') restriction sites. These amplicons were then cloned into pSKB3 and transformed into *Escherichia coli* DH5α. Following sequence confirmation, the plasmids were then transformed into *E. coli* BL21 to characterize β-lactamase activity following induction with IPTG. For a positive control, the previously characterized β-lactamase BlaB3 was cloned from *E. meningoseptica*. As expected, BlaB3 overexpression in *E. coli* led to the hydrolysis of nitrocefin, a chromogenic β-lactamase substrate. Out of 15 putative serine- and metallo-β-lactamases examined, 7 hydrolyzed nitrocefin similar to BlaB3 (in 30 min) and 4 demonstrated slight nitrocefin hydrolysis (in 45 min). We have therefore identified 6 functional β-lactamases in *E. miricola* and 5 in *E. anopheles*. In addition, we have identified 3 β-lactamase genes identified by gene annotation in *E. anopheles* and 1 in *E. miricola* that do not express β-lactamase activity in a heterologous system. Furthermore, we provide evidence that this course embedded research was met with great enthusiasm by the students in our class.

Publishing Title:

A Student-Led Investigation Exploring Bacterial Presence in Water Distribution Systems to Teach High School Microbiology Students About Scientific Writing and the Peer-Review Publication Process

Author Block:

K. Gonzalez; Lowell High Sch., Lowell, MA

Abstract Body:

Inquiry based learning allows students to develop knowledge of scientific concepts and ideas by allowing them to ask questions, seek answers, collect and analyze data, and communicate and defend their findings using evidence. An effective way to demonstrate learning gained from inquiry based science is to have the students conduct independent (although guided) research, and develop a manuscript of their work for publication.Microbiology students explored whether or not bacteria were present in different types of water distribution systems at our high school. Water samples (9-12) were collected from the three different water distribution systems on different days. One milliliter of each sample was pipetted onto nutrient agar and incubated at 35^{O}C for 24 hours. Colonies were counted after 24 hours to calculate Colony Forming Units (CFUs)/mL. A statistical difference among the mean CFUs/mL of the three water distribution systems was observed (p<0.021; Kruskal-Wallis ANOVA). These findings indicate that bacteria remain in drinking water after purification, however, more elaborate purification mechanisms appear to improve upon the removal of bacteria from the drinking water supply. Students divided the portions of the paper they would write based on the journal specifications. The lead author assembled and finalized the document for submission. The manuscript was submitted to the Journal of Emerging Investigators, a high school peer-reviewed science journal, in December 2015. This process has led to a self-reported increase in confidence performing scientific research, as well as a developing identity as a scientist. This experience has also led to two additional investigations being pursued. The students are currently determining whether or not yogurt affects the numbers of *Bacteroides thetaiotaomicron* in culture, and whether or not a nutritional supplement containing honey and ginger is an effective antimicrobial agent against *Escherichia coli* and *Staphylococcus epidermidis.* This research opportunity will continue to be offered to the microbiology students and may be incorporated into the core biology and microbiology curriculum at our school.

Personal Microbiome Portraits: Using Next-Generation Sequencing for Inquiry-Based Learning

Author Block:

M. Hartman, H. DeBaets, K. Harrington, M. Fierman, D. Slonim, D. R. Walt; Tufts Univ., Medford, MA

Abstract Body:

Microbiomes are an excellent entry point to engage K-12 students in the life sciences and introduce a variety of subjects including microbiology, human health, and ecological communities. Recently, the study of microbiomes has been revolutionized by developments in next-generation sequencing (NGS) technology. Despite the relative simplicity and low cost offered by NGS, experience with microbiomes remains out of reach for most high school students due to the limited availability of specialized equipment and knowledge. To bridge this access gap, we have developed an inquiry-based module that uses NGS to bring microbial ecology to high-school classrooms as part of our larger BioSeq project (http://ase.tufts.edu/chemistry/walt/sepa/index.html). Our classroom-based project, the "Microbiome Portrait Experiment", emphasizes the personal aspects of the human microbiome. In this module, students sample microbial communities on their hard palate and retroauricular crease (behind the ear) and ask the basic research question: "will the microbiome from one site on my body be more similar to the microbiome on the other part of my body, or will it be more similar to the microbiome on the same body part of another person?" The specific result of this experiment is not pre-determined and will vary between students and classrooms, representing a more realistic scientific research experience. We have run the Microbiome Portrait experiment in seven local high school classrooms and reached over 100 students. Students were tested pre- and post-intervention, and results indicated consistent knowledge gains in the areas of genetics, bioinformatics, and laboratory protocols. Based on our assessment outcomes, we conclude that the Microbiome Portrait Experiment has been very successful in engaging high school students and demonstrating the personal relevance of science. As our program expands to more schools, we plan to continue refining our methods to address a broader range of research questions.

Public Health's Pit Crew: A Look Inside the Indiana State Public Health Laboratory

Author Block:

S. Matheson, J. Madlem, M. Glazier; Indiana State Dept. of Hlth.Lab., Indianapolis, IN

Abstract Body:

Laboratory science is a fundamental component of the public health infrastructure and is critical in responding to novel strains of disease, chemical spills, and other health emergencies. However, it is facing a serious workforce shortage. One major cause for this manpower crisis is laboratory science is a “faceless” profession and is invisible to the general public. In an attempt to showcase the Indiana public health laboratory and expose middle school students and their parents to professions available in public health laboratory science, the Indiana State Department of Health (ISDH) Laboratory kicked off the 2015 Association of Public Health Laboratories (APHL) annual meeting with an open house student event targeting grades 5-8 on May 17, 2015.The ISDH Laboratory student event in Indianapolis, entitled “Public Health’s Pit Crew”, was planned by the ISDH Laboratory and APHL. The event was marketed through local middle schools, ISDH, and through the Indiana Laboratory System database. Student activities ranged from solving an outbreak with staff laboratorians to performing Pulsed-Field Gel Electrophoresis. Students met members of the local 53rd Civil Support Team and toured their mobile laboratory to learn how they respond to biological and chemical incidents. Parents were invited to the event and were given a tour of ISDH Laboratories. They watched their children participate in various laboratory activities and viewed several public health documentaries. They were also introduced to Jerome Adams, MD, the ISDH Health Commissioner.Approximately, 40 middle school students attended “Public Health’s Pit Crew”, along with 30 parents. Feedback from attendees was positive, students displayed genuine interest in laboratory science, and requests for future events were received.Public health laboratory science protects our lives and must become visible and apparent to our youth. The extent to which public health laboratories can continue to make improvements in public health greatly depends on assuring a sufficient and competent workforce. “Public Health’s Pit Crew” was extremely successful, and the ISDH Laboratory will continue its outreach efforts to address the rapidly approaching workforce shortage in public health laboratory science. Future student events and open houses will be planned in Indiana.

A Microbiological Platform for Investigation

Author Block:

J. Redfern, J. Verran; Manchester Metropolitan Univ., Manchester, United Kingdom

Abstract Body:

The Museum of Science and Industry (http://msimanchester.org.uk/) located in Manchester, UK hosts a contemporary science programme called Pi: Platform for Investigation. The platform provides a space for scientists to demonstrate their work and research to members of the public. The event typically attracts over 400 visitors, mainly families with children between 7 and 14 years of age attend on a single Saturday once a month.Microbiology researchers from Manchester Metropolitan University have delivered three Pi events in recent years; The Very Small World of Viruses (2012), Fuelling the future (2015) and Antimicrobial resistance (AMR, 2016). Each activity was designed to discuss and convey specific microbiological messages that were relevant to people's lives, and incorporated a range of hands-on activities designed to engage families. The Very Small World of Viruses aimed to convey three messages: the nature and size of viruses; treatment and antibiotics stewardship; and prevention of viral infection. Activities included drawing, microscopy, making models of viruses with clay to scale in comparison with a large cell floor covering, and the creation of a virus Christmas decoration (the event was held on World AIDS Day). Fuelling the Future focused on the importance and prevalence of fermented foods, touching on the gut microbiome and probiotics. Activities included an introductory guesstimate exercise on the percentage of 'good' bacteria; a ''Myths or Medicine' board, videos, a display of world fermented food (including foods to sample), and a map, encouraging additional contributions. The 2016 AMR event conveyed messages about bacterial infection, treatment (antibiotics), the origin of antibiotics, and antibiotic stewardship. This event was based on the Yale University Small Worlds Initiative, in collaboration with the UK Microbiology Society. Participants plated out soil they bought from home. A follow-up viewing and interpretation session was carried out at the University microbiology lab. Discussion with scientists was embedded in every activity. Each event was evaluated using a range of methods (counting outputs, ad-hoc conversations, written feedback). Each event was well attended and very successful, and evaluation strategy enabled better analysis and interpretation of success, as well as indicating strategies for future events.

Teaching Microbiology Applications and Poster Presentations in Environmental Week Event

Author Block:

A. M. N. KORRES, F. B. Aponilário, J. R. Bringhenti; Inst. Federal de Educação, Ciência e Tecnologia do Espírito Santo, Vitoria, Brazil

Abstract Body:

This work reports an activity performed with 17 Environmental and Sanitary Engineering undergraduate students during Applied Microbiology discipline classes. Students were challenged to develop a theme in Microbiology associated with environmental and, or sanitary application to expose during the 2015 Environment Week of Campus Vitória, held between days 2 and 4 July. The event focused on "Four thousand dreams. One School. Consume with care", in reference to the United Nations campaign. Themes developed were biodigestor and biogas production, aseptic techniques, and virus in biological control. Themes were discussed for four weeks during and out of the classes. Students prepared posters, flies and other visual and printed materials to present during the technique-scientific exposition of Environment Week event in the Institution. Projects were followed by the teachers since early preparation to the presentation. One group prepared a plastic 20 L bioreactor to produce biogas using organic wastes 10 days before the presentation and a miniature of a bacteria to explain the exposition visitors the importance of this group of microorganism in the process. Other group prepared informative material about microorganism control in food and aseptic techniques to distribute among the show attendees and also provided a public utility service. The other group prepared a poster to explain an example of the use of virus in biological control of caterpillars *Spodoptera frugiperda* with Baculovirus, what can avoid or reduce the use of chemical control. The exposition occurred from 9 am to 7 pm during the poster show of the Environment Week of Ifes. Considering the importance of the issues studied, the involvement and dedication of students in the activity and the contribution of this participation to the professional life, the teachers concluded that the proposal of challenges that lead students to actively take part in the learning process should be valued and encouraged in the Engineering teaching. In addition, teachers considered the methodology used easy to replicate and enable the students a practical experience.

Integrating a Unique Microbiology Educational Platform Highlighting Interactive Puppets: "The Culture Plate Gang"

Author Block:

J. G. Thomas; Allegheny Hlth.Network, Pittsburgh, PA

Abstract Body:

Background: The challenges continue in educating various audiences, magnified in clinical microbiology. In the past 51 years, we have integrated a variety of novel teaching techniques, initially focusing on post graduate education in medicine/dentistry. Here, we describe our most recent platform highlighting the use of 7 topic-selected 36-44 inch puppets addressing microbial phenotype, antibiotic resistance, probiotics, infection prevention, and history. **Methods:**Seven microbial/ infectious disease topics with matching puppet names were selected: first, by academic coursework at WVU Schools of Medicine/Dentistry; second, by invitation to ancillary medical/dental CE programs; third, public health interest including civil service organizations; and fourth, political and religious societies. Each topic was linked to 4-6 lectures depending on depth and breadth, emphasizing appropriate additional platform tools including: 3-D PowerPoints/ 3-D glasses, motion, sound, and 5 minute visual introduction based on author international travels, highlighted by representative clothing.**Results:** The seven topics with matching puppets included: 1) Biofilm Bradford, 2) Planktonic Phylis, 3) Antibiotic Resistant Rachel and CAT scan, 4) Probiotic Buster, 5) Infection Control Claire, 6) Candy Candida, and 7) Historical Louis. They were referred to as the "Culture Plate Gang"; only Candy Candida (Number 6) was species specific highlighting our VAP research and most recently Historic Louis (Number 7), a French speaking microbial personality . One hour lectures were best suited to 1/ 2 puppets, while 2/3 hour CE courses could accommodate 4-6. Most gratifying was growth in infection prevention and use in 'Ronald McDonald House-like' residences, or ICU's with adolescent patients, explaining cleanliness; Most surprising was growth in civil service, adult education and political meetings . To date, greater than 200 lectures have been evaluated. Success has been marked by a variety of significant awards received from universities, national and international organizations. **Conclusions:**Today's society is driven by visual and entertaining electronics; we harnessed this approach by incorporating standing puppets, matching infectious disease/microbial topics and lectures, unmasking a broad interest in microbiology, drawing parallels between human behavior and microbes.

Testing an Application Based Service Learning Pedagogy

Author Block:

M. G. ANDERSON[1], J. M. Engle[1], R. Lamendella[2], J. M. Senko[3], G. E. Rowe[4], S. Grubb[5], S. K. Woodley[6], N. Trun[6]; [1]Mount Aloysius Coll., Cresson, PA, [2]Juniata Coll., Huntingdon, PA, [3]Univ. of Akron, Akron, OH, [4]La Roche Coll., Pittsburgh, PA, [5]Univ. of Pittsburgh, Pittsburgh, PA, [6]Duquesne Univ., Pittsburgh, PA

Abstract Body:

Background: Eight institutions have collaborated over three years to implement Application Based Service Learning (ABSL), a pedagogical approach engaging students in responding to community concerns. Disciplines include microbiology, geochemistry, physiology, chemistry, architecture, and communication.**Methods:** ABSL emphasizes five practices documented as having a high impact on student learning: learning communities, writing-intensive courses, collaborative projects, undergraduate research, and service learning. These practices are incorporated into courses in which students address a community-based problem, such as the possibility that feral cats carry pathogenic microbes, or that areas impacted by mining or manufacturing practices might have altered water quality or issues associated with their redevelopment for other uses. As part of their course work, students collect and analyze samples, and their findings are shared not only within the class but with other ABSL classes and the community at large.**Results and Conclusions:**Three years of assessment data using the Classroom Undergraduate Research Experience Survey (CURE), Student Assessment of Learning Gains (SALG), and the Critical Thinking Assessment Test (CAT) will be reported, indicating gains in scientific understanding and communication, gains in student learning and attitudes, improved technical skills, and increased motivation to work. Additionally, there was an increase in the quantity and quality of undergraduate research and honors theses completed.

Linking a Capstone Project in Microbial Physiology with Service Learning at Secondary School

Author Block:

C. Rios-Velazquez[1], B. Cabrera[2]; [1]Univ. of Puerto Rico at Mayaguez, Mayaguez, PR, [2]Residential Ctr. of Educative Opportunities of Mayagüez (CROEM), Mayaguez, PR

Abstract Body:

There are diverse emerging challenges for the students' transition processes from school to an academic community, especially the importance of team work and service learning. Also, there are opportunities for faculty and teachers to team and collaborate to guide these processes. A special capstone project (CP) was assigned to students in the Microbial Physiology class, to combine and link as a team, the knowledge acquired in class with service learning by developing microbial models as pedagogical instruments for secondary school. After choosing the school, the university professor and the science school teacher chose Microbial Physiology Structure and Morphology as the CP topic. A total of five teams of 5-6 students were organized and a month given for the task completion. The models prepared included: a gram-negative (GN), gram-positive (GP), Mycobacteria (MY), an Archaea (AR), and a fungus (FU). A rubric was designed to evaluate the projects in general terms, creativity, clarity, pedagogical functionality, and overall evaluation. The teams prepared an index card summarizing the model explanation and described it orally to the evaluators, which included the class professor, school teacher, class cohort, and visitors. A teams-self and project evaluation was also done. The Residential Center of Educative Opportunities of Mayagüez (CROEM) was the chosen secondary school. Considering all the individuals evaluations, the project scores ranged from 84% (GP) - 100% (AR and FU). Once averaged, the models ranked as follow: AR (98%), FU (98%), GN (95%), MY (92%) and GP (91%). The percentages in the ranking coincided with teams-self-evaluations. By categories: the GN and AR were the more creative (96%); the FU showed more clarity (96%), while pedagogically, the GN was the best (98%). Finally, the GN was chosen as the best in general terms (98%). Some of the written comments focused on ways to improve the models (better ID, size, materials used), and oral presentations. The teacher, evidenced by an educational plan, the use of the models in the classroom. This activity represent a creative way to support collaboration among different educational centers and could be implemented in any class, once a link between the faculty-teacher is done and an agreement of the topics is established.

Virtual Virus, a Semester-Long Interdisciplinary Project on the Crossroads of Creativity and Knowledge Integration

Author Block:

B. MARINTCHEVA; Bridgewater State Univ., Bridgewater, MA

Abstract Body:

Virtual virus is a semester-long interdisciplinary project offered as a part of upper level elective course in Virology. Students are challenged to apply key concepts from multiple biological subdisciplines to "synthesize" a plausible virtual virus. The project is executed as a scaffolded series of hands-on sessions and mini-projects during which students built physical models of their viruses and developed scenarios for viral life cycles and virus-host interactions on the cellular and organismal level. The outcomes of individual projects were integrated into continuous story via mock conference presentation and comprehensive report modeling article publication. Instructor and peer feedback were used as tools to prompt reflection and guide revisions of the final report. Student learning gains and attitudes toward the approach were studied by evaluating project work product and end of the semester survey. Outcome analysis demonstrated that students exit the course with elaborated conceptual understanding of viruses and ownership of their work. The project can be viewed as an approach to model the process of scientific discovery in fast-forward mode by combining active learning, creativity and problem solving to assemble and communicate a virtual virus story.

Improving Civic and Scientific Literacy through Student Reading with Scaffolded Thematic Classroom Research Experiences

Author Block:

D. S. SMYTH[1], J. But[2]; [1]Mercy Coll., Dobbs Ferry, NY, [2]New York City Coll. of Technology, Brooklyn, NY

Abstract Body:

Our assessments to date have shown that for many of students the major hurdle to learning basic scientific content is their lack of one basic skill - reading. This has led to the establishment of Reading Effectively Across the Disciplines (READ), aimed at improving reading skills through faculty training, peer led team learning, student training in strategic reading and dissemination of the materials via a website.At Mercy College, READ has been expanded to include an additional focus, the inclusion of research experiences to encourage civic and scientific literacy. Whereas most authentic research experiences target the laboratory, we have targeted the lecture component of two sequential courses, Introductory Biology, and Microbiology. To encourage reading, students were given textbook surveys, strategic reading assignments and instructed in concept mapping. The classroom experience included think-pair-share moments. Students in both classes were assigned teams and engaged in research of civic import in both classes. In biology, students were tasked with developing a poster, in an area of civic and scientific importance. The posters were printed at the end of the semester and displayed publically in the library. The microbiology students utilized social media to generate an ePortfolio of a microorganism to understand bacterial classification. The second microbiology project involved a presentation and pitch for grant funding from the NIH for an area of importance in microbiology chosen by the students.Through these literature-based projects, students were able to take their first steps towards understanding and immersing themselves in the scientific method using authentic student-driven discovery. Student feedback was positive as measured using student feedback forms. Students enjoyed participating in the activities. Many students found concept mapping to be the most useful reading technique. Our students were not familiar with the generation of posters or bibliographies prior to the biology experience. The ePortfolio and engaging atmosphere of the debate was found to be the most exciting aspect of the microbiology experience. This pilot has shown the feasibility of intervening in the lecture to enhance civic engagement and scientific literacy and exposing all students to research and the scientific method.

Active Learning for Undergraduate Medical Students: A First Encounter with Evidence-Based Medicine in the Microbiology Laboratory

Author Block:

N. A. Castillo, O. Candolfi, A. Davila, L. Arzamendi; Univ. Autónoma de Baja California, Tijuana, Mexico

Abstract Body:

Active learning is essential in the training of medical students. In the microbiology laboratory at the Autonomous University of Baja California we use project-based learning so that students acquire skills in the diagnosis and treatment of infectious diseases applying clinical practice guidelines, laboratory diagnosis protocols and evidence-based medicine. This proposal aims to strengthen the understanding of microbiology and diagnostic techniques, develop critical thinking skills, cultivate students' interest in scientific research and encourage collaborative work by conducting a project for the resolution of a case of infectious disease and case report. Medical students (n=75) were organized in teams to resolve a case of an infectious disease. Prior to the biosafety training students obtained a specimen with the quality criteria. As a hypothesis, students established a differential diagnosis based on clinical practice guidelines and evidence-based medicine. They identified the causative organism and antimicrobial susceptibility test was performed referring laboratory diagnostic procedures. The results were discussed and a diagnosis with a proposed therapy was established. Information was integrated into a clinical case report. The case report and the student's perception were assessed with a questionnaire. Students apply evidence-based medicine and clinical practice guidelines to establish a diagnosis with the set of clinical variables. Questionnaire results show that most students know the application of evidence-based medicine, clinical practice guidelines and laboratory diagnosis procedures. The majority of students are motivated to pursue research and agree on the importance of knowing all the steps in the diagnosis of infectious disease. Through project-based learning, students build their knowledge by a specific task to generate products for learning, applying the scientific method and quantitative reasoning, they learn to communicate collaboratively and understand the importance of science in medical practice.

Modeling of Cancer System Pathogenesis with *H. pylori*: A Novel Approach

Author Block:

S. Perez; Coll. of Med.- Univ. of Arizona at Phoenix, Phoenix, AZ

Abstract Body:

Background: Modeling behaviors of gastric cancer system with a H.Pylori co-morbidity allows scientists to describe pathogenesis through the lens of a system approach. Microscopic natural systems in the human body such as cellular structures exhibit behaviors that show it has elements of a systems approach such as inputs, processes, output feedback that occur.**Methods:** Insightmaker.com is a simulation and modeling program used to create the stock and flow models. This system based approach allows a user to create primitives such as stock and variables and add connections using link and flow elements. A simulation run provides a visualization of the defined stock against a timeline on a dynamic graph.**Results:** A generalized pathogenesis model was first generated in insightmaker.com. An organ specific model was also created to model how cancer cells interact with the different organs and cells in the human body. The organ specific model will help the scientist determine if new chemical pathways and relationships can be discovered to help explain organ specific cancer pathogenesis.**Conclusion:** The successful implementation of a system approach is the packaging of the instructional activity and its supporting content in bite size and incremental approach and explicit description of the activity's deliverables. The drag and drop interface and intuitive icon driven menu of Insightmaker is ideal for lowering the learning curve for a systems thinking instructional activity. The initial instructional activity was designed with an easy to follow demo of an actual working systems model in systems biology or population ecology. This allows for the content to be familiar to the student. A team of 4 students constructed a systems model of a portion of the cancer pathogenesis cycle such as tumor formation, tumor metastasis or tumor aptosis. An evaluation rubric was used to guide the development of the group created student model with evaluation categories such as narrative of the system model, attributes of the system, data flow and values used and a personal reflection of their experience.

Virtual Biotech: The Meat in the Sandwich?

Author Block:

D. Cameron, F. Holmwood, A. McElroy, **C. Craig**; The Res. Network Ltd, Sandwich, United Kingdom

Abstract Body:

There is an urgent clinical need to discover and develop novel approaches to treat infectious diseases (IDs). Innovative target validation and early drug discovery is increasingly available from academic institutions. Pharma companies can complete development, manufacture and distribution of therapies, but are primarily interested in external projects only after demonstration of clinical safety and efficacy. Optimized management of early stage discovery through to successful uptake by Pharma is key to efficient prosecution of new treatments. Networks of Pharma experienced scientists, united through flexible virtual biotech entities (VBs), can enable projects to bridge this gap with collaborations to gain access to grant and investment resources and through VB based project management of the lead generation and optimization, translational activities and early clinical trials.University and research institute business development departments publish projects seeking external 'bench to bedside' support. To quantify, qualify and identify those ID projects that would benefit most from VB support, a systematic regional survey of 1272 projects was carried out. Of these projects 154 targeted IDs (non-exclusive: 61 antibacterial; 73 antiviral; 20 anti-parasite, 5 antifungal). Additional major therapeutic areas represented included oncology (328), cardiovascular (210) and CNS (170) with 410 others. Antibacterial and antiviral approaches included respectively small molecule (31 and 28) vaccine (8 and 11) and other platform or diagnostic approaches (30 and 34). Antiviral approaches included HIV (n=24), with 2 specifically looking at HIV cure, influenza virus (n=8) HCV (n=6) and other viruses (n=14). Pan-antiviral approaches including immunomodulation were also common (n=21). Triage was performed and ID projects meeting criteria of high clinical need with available expertise and resource have become substrate for VBs and the establishment of consortia to facilitate further project development.VB companies providing Pharma based expertise can enable progression of discovery and development projects to attain Pharma support to enter the clinic. This form of bridging can effectively and efficiently provide the required expertise for managing and progressing scientific projects suitable for clinical development and treatment of patients.

Cost Analysis of Implementing Maldi-Tof with Real-Time Antimicrobial Stewardship Intervention for Bloodstream Infections

Author Block:

R. Kaakeh, T. Patel, **J. Nagel**, D. Newton, J. Stevenson; Univ. of Michigan, Ann Arbor, MI

Abstract Body:

Background: Studies evaluating rapid diagnostic testing with stewardship intervention have consistently demonstrated improved clinical outcomes for patients with bloodstream infections. However, the cost of implementing new rapid diagnostic testing can be significant, and usually does not generate additional revenue. There is minimal data evaluating the financial impact on total hospital costs following implementation of MALDI-TOF for rapid organism identification and allocating antimicrobial stewardship pharmacy resources. **Methods:** A cost analysis was performed utilizing patient data generated from the hospital cost accounting system, and factoring in additional costs of MALDI-TOF equipment, supplies and personnel, and the cost associated with allocating pharmacist time for blood culture review and antimicrobial therapy intervention. The cost analysis was performed from a hospital perspective for 3-month blocks before and after implementation of MALDI-TOF plus stewardship intervention. **Results:** A total of 480 patients with blood stream infections were included in the analysis: 247 in the pre-intervention group and 233 in the intervention group. Mortality was significantly improved in the intervention group (21% vs. 12%, $p<0.01$), and mean length of stay was numerically shorter (13 ± 16.5 vs. 12 ± 10.4 days). The total hospital cost per bloodstream infection was lower in the intervention group ($45,018 vs. $42,580). Intensive care unit costs accounted for the largest share of the total costs in each group and were also lower in the intervention group ($13,727 vs. $10,833). **Conclusion:** Implementing MALDI-TOF with real-time stewardship review and intervention decreased mortality for patients with bloodstream infections. Despite the additional costs of implementing MALDI-TOF and dedicating additional personnel time, the total hospital costs decreased by $2,438 per bloodstream infection, for an approximate annual cost savings of $2.34 million.

Microbial Community Response and Crude Oil Biodegradation in Different Deep Oceans

Author Block:

J. Liu[1], J. Fortney[1], S. Techtmann[2], D. Dominique[1], T. Hazen[1]; [1]Univ. of Tennessee, Knoxville, Knoxville, TN, [2]Michigan Technological Univ., Houghton, MI

Abstract Body:

Many studies have shown that microbial communities can play an important role in oil spill clean up. However, very limited information is available on the oil degradation potential and microbial community response to crude oil contamination in deep oceans. Therefore, we investigated the response of microbial communities to crude oil in various deep-sea basins from around the world where oil exploration is anticipated (Eastern and Central Mediterranean Sea, Great Australian Bight and Caspian Sea). In this study, microcosms were set up aerobically with three different treatments: seawater, seawater + oil and seawater + oil + oil dispersant. Samples were taken at three time points for the analysis of oil degradation by fluorescence and GC-MS, and microbial community changes by16S rRNA sequencing. CO_2 evolution followed a similar pattern among off the basins. The treatment of seawater + oil + dispersant had the highest CO_2 production. The amendment of oil lead to a more CO_2 accumulation than seawater treatment. However, it's much higher in the Gulf of Mexico (GOM) than other oceans. What's more, the dissolved organic mater analysis revealed that application of oil dispersant lead to better oil degradation, which was consistent with the GC-MS results. Oil biodegradation appears to occur rapidly in all of the sites. In addition, there was a clear succession of microbial communities during degradation of oil. The microbial diversity decreased in all of the microcosms over time. Oil amendment affected how quickly the diversity decreased. The relative abundance of *Proteobacteria* increased drastically while the relative abundance of archaea decreased. In particular, the percentage of *Betaproteobacteria* increased in samples from the Central Mediterranean Sea. However, *Gammaproteobacteria* increased in abundance in the microcosms from the Eastern Mediterranean Sea and Great Australian Bight, which was very similar to GOM.

Dimethylsulphoniopropionate Catabolism by Bacteria Isolated from the East China Sea

Author Block:

J. Liu[1], S-H. Zhang[1], J. Liu[1], H-H. Zhang[1], J. D. Todd[2], G-P. Yang[1], **X-H. Zhang**[1]; [1]Ocean Univ. of China, Qingdao, China, [2]Univ. of East Anglia, Norwich, United Kingdom

Abstract Body:

Marine bacteria play a central role in the production of the environmentally important gas dimethylsulfide (DMS) from dimethylsulfoniopropionate (DMSP), an abundant compatible solute made by many marine phytoplankton. Here bacterial communities from four seawater samples in the East China Sea (ECS) were characterized by both culture-dependent and molecular techniques. Of 91 marine bacterial isolates screened, 37 and 2, respectively, had the ability to catabolise DMSP generating DMS or methanthiol (MeSH), with only a few isolates able to use DMSP or acrylate as sole carbon source for growth. Many of DMS-producing bacteria (32.4%) were Roseobacters, some of which have not been reported to catabolise DMSP. Genes homologous to *dddD*, *dddL* and *dddP*, previously implicated in DMSP degradation, were also characterized from some of these strains. The existence of *ddd* gene(s) of one *Labrenzia* strain and one *Ahrensia* strain were confirmed by gene cloning and expressing. For the first time, some Gram-positive *Actinobacteria*, closely related to species in *Agrococcus*, *Brevibacterium*, *Kytococcus*, *Microbacterium*, *Micrococcus* and *Phycicoccus* genera were found to make DMS. These results highlight the phylogenetic diversity of various DMS-producing bacteria. 16S rRNA gene clone libraries indicated that uncultured bacteria affiliated to Roseobacter were predominant in the sampling sites with higher DMSP concentration, such as the coastal site and surface seawaters. Both of the Roseobacter bacterial abundance and the proportion of DMS-producing bacteria in all cultivated bacteria showed positive correlations with DMSP and DMS concentration, indicating that the concentration of DMSP in seawater is likely to play a role in structuring bacterial communities and also confirming that bacterial cleavage of DMSP is probable a major source of DMS in seawater.

Seasonal Dynamics Of A Phototrophic Microbial Mat In An Intertidal Marine Environment

Author Block:

U. Lopez, G. Flores; California State Univ. Northridge, Northridge, CA

Abstract Body:

Photosynthetic microbial mats are complex, stratified microbial ecosystems that can be found in a variety of environments including intertidal regions of salt marshes. Generally, phototrophic organisms dominate the top layers, while diverse heterotrophic organisms can be found throughout a well-developed mat. This study focuses on how seasonally fluctuating environmental factors (salinity, temperature, and pH) influence the diversity and composition of an intertidal microbial mat located in Southern California, USA. Using high-throughput sequencing of the 16S rRNA gene and the ITS1 region of fungi, we characterized the microbial communities of the top (0 - 0.5cm) and bottom layers (0.5 - 1.0cm), and the underlying sediments of a mat system. To date, field measurements and microbial samples have been collected and analyzed over six seasons (summer 2014 & 2015, fall 2014 & 2015, winter 2015, and spring 2015). Over the observation period, salinity (3.7% - 5.9%), temperature (18.0°C - 30.4°C) and pH (7.8 - 8.4) were variable, revealing a dynamic environment influenced by seasonal changes in tide height, solar radiation, and precipitation. Microbial communities were compared for changes in phylogenetic diversity and in community composition. The top layer of the mat was composed primarily of oxygenic-photosynthetic Cyanobacteria, purple sulfur bacteria, and aerobic heterotrophs, but the relative abundance of each varied seasonally. In the bottom layers of the mat, the depletion of oxygen and filtering of light selected for anaerobic heterotrophs, primarily sulfate reducing bacteria. Fairly consistent conditions within underlying sediments maintained a relatively constant microbial community. Similarly, fungal communities throughout the layers of the mat varied seasonally in the abundance of each lineage. Ongoing seasonal characterization of this mat system will provide foundational data that will allow us to identify factors structuring this mat system and will ultimately lead to a better understanding of how photosynthetic microbial mats contribute to carbon cycling within salt marsh environments.

Diversity of Methane Associated Microorganisms in the Columbia River Estuary

Author Block:

K. Jenkins[1], M. Kim[1], D. Fachko[1], T. Peterson[2], G. Nyerges[1]; [1]Pacific Univ., Forest Grove, OR, [2]Oregon Hlth.& Sci. Univ., Portland, OR

Abstract Body:

Methanogens and methanotrophs play crucial roles within the global methane cycle. Methanotrophic activity is the most effective biological methane sink in the environment, and methanogenic activity contributes significantly to atmospheric methane levels. The diversity of these microbes is well studied in many environments, however, estuarine methanogens and methanotrophs are not well characterized, even though estuaries contribute significantly to the global methane budget. This study investigates methanogen and methanotroph diversity of water and sediment from the Columbia River estuary (CRE). 14 water filter and 13 sediment samples collected from three locations throughout the CRE were subjected to PCR using gene-specific primers targeting the mcrA gene in methanogens and the pmoA gene in methanotrophs. PCR products were cloned and sequenced. Sequences were analyzed using NCBI BLAST, then trimmed, translated, and aligned using CLC Main Workbench. Neighbor-joining amino acid phylogenetic trees were created using Geneious. The mcrA tree, with reference sequences from a peat bog and M. kandleri as the outgroup shows clustering of half of our samples with the reference sequences. The tree reveals a wide diversity of the mcrA genes, with matches to sequences mainly from river sediment, rice paddy soil, and wetland sediment. The pmoA tree, with reference sequences from the Newport Bay estuary, CA and N. oceani as the outgroup shows one large clade with a bootstrap value of 97 containing 24 of our samples and sparse clustering with reference sequences. The tree indicates limited diversity of pmoA sequences with all but six matching to sequences from river and lake sediment, and remaining sequences matching to sludge, oil field soil, and a coal mine. The trees indicate little similarity between methanogens and methanotrophs from the CRE and the referenced locations. With low percent identity matches revealed by BLAST, one *pmoA* sequence and six of our *mcrA* sequences are likely novel. The majority of sequences showed similarity to sequences from freshwater environments, indicating that the methanogenic and methanotrophic communities in the CRE are dominated by freshwater representatives.

Investigating Microbial Carbon Cycling in Sediments Using Natural Isotope Respirometry in a Novel, Carbon-Free Bioreactor

Author Block:

N. Mahmoudi[1], S. Beaupre[2], A. Pearson[1]; [1]Harvard Univ., Cambridge, MA, [2]Stony Brook Univ., Stony Brook, NY

Abstract Body:

Aquatic sediments are carbon-rich environments that harbor complex and diverse microbial communities which mediate the rate and extent of organic matter degradation. In order to gain insight into microbial carbon utilization and carbon cycling, we constructed a bioreactor system to measure carbon isotopes during microbial degradation of complex organic matter. Using sediments collected from Salt Pond (Falmouth, MA), we observed a successive pattern of microbial respiration such that several peaks appear over a 7-day time-series experiment. $\Delta^{14}C$ signatures of CO_2 fractions collected during incubation indicated that the microbial community is primarily respiring labile organic matter from fast cycling pools. The observation of different rates of respiration - corresponding to multiple peaks of CO_2, each with different $\Delta^{14}C$ signatures - suggest that the community may be using different suites of carbon compounds in succession. High-throughput DNA sequencing was carried out on daily samples to determine if organic matter was degraded by a succession of taxa or by a single dominant group. Bacilli were found to be the dominant group observed throughout the experiment. Within Bacilli, Planococcaceae accounted for over 90% of assigned sequences during days 1 to 4, when the majority of total carbon was respired. This suggests that the observed CO_2 peaks on these days are a result of changes in enzymatic activities rather than changes in community structure. During days 5 to 7, there was a steady increase in sequences assigned to Panenibaillaceae, coinciding with prominent CO_2 peak observed at this time. Concurrent enzymatic analyses are being carried out to determine the metabolic pathways that correspond to each peak.

Microbial Interactions with Natural Organic Matter Extracted from the Oak Ridge FRC

Author Block:

X. Wu[1], S. Jagadamma[2], T. C. Hazen[2], N. Justice[1], A. P. Arkin[1], S. Jenkins[1], T. R. Northen[1], M. W. Fields[3], P. Fox[1], P. Nico[1], R. Chakraborty[1]; [1]Lawrence Berkeley Natl. Lab., Berkeley, CA, [2]Oak Ridge Natl. Lab., Oak Ridge, TN, [3]Montana State Univ., Bozeman, MT

Abstract Body:

Natural organic matter (NOM) is central to microbial food webs; however, little is known about the interplay between the physical and chemical characteristics of NOM and its turnover by microbial communities. Microbial activity changes structure and properties that influence further bioavailability of NOM. To date, our understanding of these interactions is insufficient, and it is critical to identify the important role NOM characteristics play to the structure and composition of microbial communities and to the metabolic potential of that community. In this study, we aimed to study the interactions between microbial communities and native NOM in background well FW305 at Oak Ridge Field Research Center, Oak Ridge, TN. The NOM was obtained by extracting FW305 sediment samples using MilliQ-water via shaking and sonication. The total organic carbon and inorganic carbon in these sediment samples were 0.071% and 0.011%, respectively. The extraction efficiencies were 3.2% for organic carbon and 1.6% for inorganic carbon. Results from UV and FTIR tests showed that the extracted NOM mainly contained polysaccharides and there were very few aromatic and unsaturated compounds. The NOM was then provided as the carbon source for microbes from FW305 groundwater. Analysis of the enriched microbial community, and transformed NOM metabolites was carried out. 16S rRNA sequencing and metatranscriptomics were performed to identify the changes of microbial communities. Several fine-scale chemical techniques including FTIR, LC-TOF-MS, and Orbitrap were also used to characterize the metabolites.

Genomic Sequence of *Enterococcus* Phage KKAS003-1

Author Block:

A. Gomez[1], C. Lyons[2], M. Shiaris[2]; [1]Cornell Univ., Ithaca, NY, [2]Univ. of Massachusetts, Boston, Boston, MA

Abstract Body:

Bacteriophages infecting bacteria in the genus *Enterococcus* are widespread and have been isolated from a variety of sources. There is growing interest in their use for phage therapy since strains in this genus are major nosocomial pathogens. Despite their abundance, these phages are not well characterized and only eight complete genome sequences are available. A plaque assay was used to isolate and *Enterococcus faecalis* phage from active sludge from an urban sewage treatment plant. Using Illumina paired-end next generation DNA sequencing, we characterized the novel *Enterococcus* phage. Sequencing yielded 128 scaffolds with a total length of 109,365 bp. Quality of the sequence data was low to assemble a complete genome. The assembly contains 148 putative open reading frames (ORFs). Of these, 120 match sequences in the NCBI database, with putative functions identified for 40. Most of the protein-encoding ORFs are structural or involved in capsid assembly or DNA processing. The phage lysed a variety of species in the genus *Enterococcus.* Phylogenetic analysis showed that ΦKKAS003-1 is a member of the *Spounavirinae* subfamily of the *Myoviridae* family. Therefore, the phage likely has a double-stranded DNA genome with an isometric capsid, long contractile tail and is an obligate lytic phage. It is most closely related to *Enterococcus* phages EFDG1, ΦEF24C, and ECP3. Higher quality sequence data is needed to validate and expand upon these results.

Prophages Related to Lytic Nontailed Viruses Are Widespread in Marine *Vibrio*

Author Block:

F. A. Hussain, K. M. Kauffman, M. F. Polz; Massachusetts Inst. of Technology, Cambridge, MA

Abstract Body:

The surface ocean is dominated by nontailed viral morphotypes (1), yet tailed viruses are most abundant in viral culture collections. Previous bioinformatic analyses identified putative Corticovirus-like prophages as widespread in the Proteobacteria (2) and suggested that they may contribute to the nontailed viruses. Here, we show these elements to also be prevalent in diverse *Vibrio* genomes, and further, that they are able to naturally excise from their host genome and occur protected in the extracellular milieu. By concentrating, nuclease treating, and then sequencing the supernatants of putative lysogenic cultures we find that active prophages excise during both mid-exponential and late-stationary phases, indicating continuous release during growth. Using a comparative genomics approach, we find that in their major capsid protein and packaging ATPase, these prophages show homology to those of their lytic counterpart, the Corticovirus PM2. Out of 849 fully sequenced *Vibrio* genomes, 401 (49%) harbor a prophage, and of these, 36% contain more than one prophage. The elements are themselves diverse, and cluster into at least 6 distinct groups based on sequence similarity of the major capsid protein. Similar elements are not necessarily found in closely related hosts, suggesting that the elements have a broad host range. Sequencing data suggest the prophages use a site-specific recombinase to integrate into the host genome directly upstream to a tRNA dihydrouridine synthase, and the surrounding genes, upstream and downstream of the integration site, may determine host specificity. Additionally, for several genomes with the element, we identify a partner strain that has identical upstream and downstream regions, but that is missing the element, leading us to believe these may be potential hosts for the corresponding element. The widespread distribution and observed natural continuous induction of these elements suggests that they play a significant role in the ecology of marine *Vibrio* and may contribute to the nontailed viral majority.

Vector-Borne Viruses of Human Interest in Southern Ukraine

Author Block:

O. O. Yurchenko[1], D. O. Dubina[1], N. O. Vynograd[2]; [1]SB «Mechnikov Ukranian Anti-Plague Res. Inst. of the Ministry of Hlth.of Ukraine», Odesa, Ukraine, [2]Danylo Halytsky Lviv Natl. Med. Univ., Lviv, Ukraine

Abstract Body:

Background: Sporadic cases of vector-borne viral diseases - tick-borne encephalitis (TBE), Crimean-Congo hemorrhagic (CCHF) and West Nile (WNF) fevers have been registered in Ukraine. However, very little is known about natural vectors and hosts of the arboviruses or their prevalence among humans in the country. The goal of this study was to determine a spectrum and abundance of arboviruses circulating in natural foci and among humans in southern Ukraine.**Methods:** We examined 21,674 ixodid ticks, 45,652 mosquitoes, 515 avian brain tissue samples, 6 small mammals, and 813 human sera collected in southern Ukraine in 2000-2007. Arthropods and brain tissue suspensions were tested for arboviruses by intracerebral inoculation of newborn mice, in enzyme-linked immunosorbent assay (ELISA) or reverse-transcription polymerase chain reaction. Human sera were tested for antibodies by hemagglutination inhibition test and ELISA. The Envelope (E) protein gene of 7 tick-borne encephalitis virus (TBEV) strains, isolated from ticks in southern Ukraine in 1988-90, were sequenced by the Sanger method.**Results:** TBEV, Uukuniemi (UUKV), CCHF viruses were detected in ticks - the minimum infection rates (MIR) were 0.48%, 0.27% and 0.03%, respectively. Mosquitoes were infected with West Nile (WNV) and Sindbis (SINV) viruses - the MIRs were 0.16% and 0.09%, respectively. The main vectors of TBEV and UUKV were *Ixodes ricinus* ticks, WNV and SINV - *Culex pipiens* mosquitoes. TBEV, UUKV, WNV, SINV, Tahyna (TAHV) and Inkoo viruses were found in birds, while snowshoe hare virus (SSHV) - in hares. In humans, seroprevalence rate for WNV was up to 28.75%, and for TBEV - up to 11.17%. Antibodies to SINV, TAHV and SSHV were detected in single cases. WNF cases were serologically confirmed for 33 humans. All studied TBEV strains belonged to European genotype (TBEV-Eu) and had 4 marker amino acid replacements in E protein.**Conclusions:** In summary, WNV and TBEV are the most important vector-borne viruses regarding possible infection of humans in southern Ukraine. The circulation of TBEV-Eu may determine milder course and better outcome of the infection.

Molecular Phylogeography of Foot and Mouth Disease Virus in Bangladesh

Author Block:

M. Sultana, H. Ullah, M. A. Siddique, A. Rahman, S. T. Towhid, **M. A. Hossain**; Univ. of Dhaka, Dhaka, Bangladesh

Abstract Body:

Foot-and-Mouth Disease Virus (FMDV), etiological agent of FMD, causes an endemic animal disease in Bangladesh. Here we report circulatory FMDV serotypes and its genome-wide analysis to develop strategies of trans-border disease control and containment.RT-PCR was employed to amplify VP1 gene of viral RNA from blister tissue samples of infected animals collected from 24 districts of Bangladesh since 2011 to 2015. Bioinformatics analyses of cultured FMDV isolates' whole genomes and retrieved VP1 sequences was done along with Bayesian MCMC method to predict phylogeography of circulatory FMDV.FMD was predominant in female animals (55.87%) than males (44.13%) with increased susceptibility in aged cattle (51.17%) than the young animals (38.97%) and calves (9.86%). FMDV serotypes O, A and Asia 1were circulatory in Bangladesh with predominant serotype O (~80%) within the lineage ME-SA/Ind-2001. Within the Ind-2001 clade, the type O complete genome sequences were clustered with those of type O of Uttarkhand, India 2010; Assam, India 2012 and Karnataka, India 2013. FMDV type O from pig formed a sub-clade homologous to 2013 sequences of cattle. Sequences of serotype A retrieved from samples of Chittagong and Gazipur districts, belonged to genotype VII under topotype Asia clade. Serotype Asia 1 re-emerged in 2012 after last out breaks in 1996 and was confined only in certain areas of Jessore and Gazipur districts with sequences clustered within genetic lineage C. The Phylographic analysis confirmed the cross-border movement of FMDV from India to Bangladesh. VP1 sequences of Bangladesh-FMDV detected a notable 8 nucleotide substitutions in the immune-dominant epitope located in GH loop conferring antigenic heterogeneity; most likely the reason behind vaccination failure using imported vaccine.Unrestricted unidirectional animal movement from India is the main source of intrusion of FMDVs in Bangladesh. Presence of significant positive selection pressure within the VP1 antigenic sites implicates evolution of VP1 under high immune surveillance. Regular monitoring is necessary for checking genotype turnover and emergence of new antigenic types that might lead to new outbreaks.

Classification Of Bacteriophage Isolated From The Great Salt Lake Using Electron Microscopy

Author Block:

B. D. Nelson[1], M. J. Domek[1], D. M. Belnap[2]; [1]Weber State Univ., Ogden, UT, [2]Univ. of Utah, Salt Lake City, UT

Abstract Body:

Bacteriophage lyse bacteria and play crucial role in the recycling of nutrients in a halophilic environment such as the Great Salt Lake (GSL). A previous study showed that the bacteriophage CW02, isolated from the GSL, was a dsDNA bacteriophage with icosahedral head and a short non-contractile tail and belonged to the bacteriophage family podoviridae. CW02 was also shown to share a conservative protein fold in a capsid protein originally identified in bacteriophage HK97. Very few bacteriophage isolated from the GSL have been assigned within the bacteriophage classification scheme. In this study we attempt to classify recently isolated bacteriophage from the GSL based on morphology using transmission electron microscopy (TEM) and molecular techniques. Bacteriophage were isolated from water and soil in or near the GSL. Bacterial lysate containing bacteriophage were centrifuged and filtered to remove bacterial debris. The sample was concentrated using 100,000 molecular weight cut-off filters. Samples were further purified by CsCl density gradient ultracentrifugation. Six bacteriophages have been imaged using TEM. TEM has shown all bacteriophage infecting Salinivibrio costocola bacterium SA-39 to be icosahedral with no detectable tail while bacteriophage infecting Salinivibrio costicola bacterium SA-40 having a circular head with a long tail. This suggests that the structure and shape of the bacteriophage capsid play an important role in the specificity of the bacteriophage to host. Based on shapes found using TEM, the bacteriophage infecting SA-39 likely belongs to the Podoviridae group while bacteriophage infecting SA-40 possibly belong to either long-tailed bacteriophage families Myoviridae or Siphoviridae. Further characterization using cryogenic electron microscopy should enable us to determine the 3D characterization of the capsid.

What And Where Are The Native American Begomoviruses?

Author Block:

N. Jacko, S. Duffy; Rutgers Univ., New Brunswick, NJ

Abstract Body:

Begomoviruses are economically and socially important ssDNA plant viruses that are transmitted by the whitefly *Bemisia tabaci* and cause severe commercial crop losses which contribute to famine in developing countries. This project seeks to determine what specific begomoviruses are present along the eastern seaboard of the United States and where these viruses are located. Such information is imperative from an epidemiological standpoint in order to better control the spread of these dangerous plant pathogens. It has been previously determined that *B. tabaci* populations can over-winter outdoors as far north as South Carolina. However, we propose that increasing temperatures evident in the northeastern region of the United States have enabled *B. tabaci* populations to migrate further north. A comprehensive literature review and samples collected during the summer of 2014 revealed that *B. tabaci* populations have not reached New Jersey. Thus, samples of whiteflies were collected from states south of New Jersey and north of Florida as the begomoviruses in Florida have been studied extensively. To test for the presence of begomoviruses, methods similar to those used for vector enabled metagenomics were utilized and whitefly samples were analyzed via PCR with degenerate begomovirus detection primers. Protocols were tested using a model ssDNA virus, bacteriophage φX174, or total DNA from begomovirus-infected plants before implementing on begomovirus samples. Whitefly samples have so far been virus-free. Continued screening could prove very useful in the prevention of the spread of begomoviruses and the subsequent destruction of commercial crops along the eastern seaboard of the United States.

Isolation of Polyvalent Bacteriophages Using Sequential Multiple Host Approaches

Author Block:

P. Yu, J. Mathieu, M. Li, Z. Dai, P. J. Alvarez; Rice Univ., Houston, TX

Abstract Body:

Many studies on phage biology are based on isolation methods that may inadvertently select for narrow host-range phages. Consequently, broad host-range phages, whose ecological significance is largely unexplored, are consistently overlooked. To enhance research on such polyvalent phages, we developed two sequential multi-host isolation methods and tested both culture-dependent and culture-independent phage libraries for broad infectivity. Lytic phages isolated from activated sludge were capable of interspecies or even interorder infectivity without a significant reduction in the efficiency of plating (0.45 to 1.15). Two polyvalent phages (PX1 of the *Podoviridae* family and PEf1 of the *Siphoviridae* family) were characterized in terms of adsorption rate (3.54×10^{-10} to 8.53×10^{-10} ml/min), latent time (40 to 55 min), and burst size (45 to 99 PFU/cell), using different hosts. These phages were enriched with a nonpathogenic host (*Pseudomonas putida* F1 or *Escherichia coli* K-12) and subsequently used to infect model problematic bacteria. By using a multiplicity of infection of 10 in bacterial challenge tests, >60% lethality was observed for *Pseudomonas aeruginosa* relative to uninfected controls. The corresponding lethality for *Pseudomonas syringae* was 50%. Overall, this work suggests that polyvalent phages may be readily isolated from the environment by using different sequential hosts, and this approach should facilitate the study of their ecological significance as well as enable novel applications.

Biological Characterization of a Library of Mycoviruses Detected in Marine Fungi Isolated from *Posidonia oceanica* (L.)

Author Block:

L. Nerva[1], G. C. Varese[1], G. Gnavi[1], M. Ciuffo[2], M. Turina[2]; [1]Univ. of Turin, Torino, Italy, [2]Inst. for Sustainable Plant Protection (CNR), Torino, Italy

Abstract Body:

Previously we characterized molecularly 12 new viral species[1] in 6 different marine fungal isolates from *Posidonia oceanica*[2,3] present in the *Mycotheca Universitatis Taurinensis* (MUT) collection. These new viral species are distributed among different dsRNA and ssRNA taxa. Scope of our work is the dissection of biological impact of these viruses on their fungal host comparing cured or partially cured isolates to the original virus-infected ones. Curing was obtained with a mix of techniques comprising single spore colonies, hyphal tipping, and use of anti-viral drugs (ribavirin and cycloheximide). The first cured isolate was a *Penicillium janczewskii* (MUT4358) which originally contained a Chrysovirus. From a distinct *P. janczweskii* isolate (MUT4359) that contained a second Chrysovirus and an Alternaria longipes-like virus we obtained a semi-cured strain. We also obtained 3 semi-cured strains starting from *P. aurantiogriseum* var. *viridicatum* (MUT4330), a fungus in which we identified the presence of 6 different viral species: we cured a bipartite virus (similar to Curvularia thermal tolerance virus), then from this, we cured a fusari-like virus, and finally we removed a partiti-like virus. The isolate we obtained still contained three distinct virus species. This collection of *P. aurantiogriseum* isolates allowed us to determine variation in viral titers according to the complexity of the virome present in the isolate revealing virus-virus regulation. Finally we obtained a cured isolate from the basidiomycetes *Wallemia sebi* (MUT4935) infected by a virus related to *Ustilago maydis virus H1*. Each set of virus-infected, cured or partially cured strains were grown in different conditions (up to 63) by combining different media, salinity concentrations and temperatures. A vast array of growth and developmental differences, including effects on secondary metabolites, could be associated with presence/absence of viruses. We are currently evaluating possible aspects of fungal-fungal (intra and interspecific), and fungal-bacterial interactions influenced by presence/absence of mycoviruses.

High-throughput Sequencing Uncovers Low Homogeneity in the Biogeography of Ssdna Viruses

Author Block:

V. Pearson, D. Rokyta; Florida State Univ., Tallahassee, FL

Abstract Body:

Regular emergence and re-emergence of viral pathogens emphasizes the importance of understanding viral biogeography and migration. Using new sequencing technologies to investigate the inter- and intra-population dynamics of non-human viral pathogens provides insight on how to effectively contain and mitigate future human outbreaks. Investigations utilizing high-throughput sequencing have determined that local viral diversity is extremely high, but does not scale to produce an exponentially higher global diversity. It follows that similar genotypes can be found great distances apart, although they may not be permanent constituents of any single population. Transient genotypes have been observed in temporal surveys of closed systems, where genotypes migrate between individual populations. This study focused on the population dynamics of single-stranded DNA (ssDNA) viruses in open systems at a single time-point; sampling wastewater treatment plants (WWTPs) from three neighboring cities in Northwest Florida which receive constant inflow and potentially receive the same viruses from the local environment. Given the increased potential for migration, expectations were that populations would be mostly homogenous with relatively few viruses that are unique to individual WWTP. Isolated ssDNA viruses were rolling circle amplified and sequenced on an Illumina HiSeq. Viral genotypes with genetic similarity to *Circoviridae*, *Geminiviridae*, and *Microviridae* were recovered from all three WWTPs, however <5% match genotypes previously recovered from the study area. It has been determined that <10% of the genotypes were present in all three plants and the majority of genotypes were specific to one WWTP. This result highlights the high level of diversity within each population, while the high observed heterogeneity indicates limited migration opportunities between the WWTPs.

Host Range Mutation Narrows Further Host Range Mutation Spectrum of Bacteriophage Phi6

Author Block:

L. Zhao[1], D. Stemate[2], S. Duffy[1]; [1]Rutgers Univ.-Sch. of Environmental and Biological Sci., New Brunswick, NJ, [2]Rutgers Univ., New Brunswick, NJ

Abstract Body:

Host range mutations are the key step in viral emergence, and are thus frequently studied in microbial evolution. Fortunately, host range mutants have easily distinguishable phenotypes with which to determine mutational spectra, reflecting underlying viral evolvability. However, the epistatic effect of preexisting host range mutations may suppress or spur further viral evolvability. We tested whether having an expanded host range mutation affected further host range expansion using the fast-evolving *Pseudomonas* dsRNA bacteriophage phi6, a model RNA virus frequently used in experimental evolution studies. The average per base mutation rate of phi6 is approximately 10^{-6} per generation and it has several known novel hosts available for these experiments. In this study, the mutations permitting growth on *Pseudomonas syringae* pv. *atrofaciens* (PA) were determined for two phi6 genotypes: wildtype and one carrying a host range mutation allowing infection of *P. syringae* pv. *tomato* and *P. pseudoalcaligenes* ERA (mutant E8G in the P3 attachment protein). Fifty single plaques of each genotype were isolated and raised on their typical laboratory hosts to obtain high titer lysates, which were then plated on PA. One host range mutant plaque per lysate was isolated at random and the P3 attachment protein was Sanger sequenced to identify mutation(s). Wild type phi6 has a considerably more diverse selection and dispersed distribution of mutations in its PA host range mutation spectrum than its isogenic E8G mutant. Eight single mutations appeared in the 50 wild type phi6 isolates, however only two of those showed up in the 50 E8G isolates. The same mutation (c398t) was the most frequent in both populations: 90% of E8G isolates, 26% of the wild type. In conclusion, novel host range mutation spectrum narrowed when a host range mutation is already present in the P3 attachment protein in phi6. Preexisting host range mutations may greatly influence development of further host range mutation spectra in RNA viruses.

Unique High Molecular Weight Phage Tail-Like Bacteriocins of Listeria Monocytogenes

Author Block:

G. Lee, U. Chakraborty, G. Govoni, D. Gebhart, D. Scholl; AvidBiotics Corp, S. San Francisco, CA

Abstract Body:

Introduction: *Listeria monocytogenes* is a foodborne human pathogen that can cause severe disease in certain high-risk individuals. These bacteria produce high molecular weight, phage tail-like bacteriocins (PTLBs), "monocins", upon induction of the SOS system. **Methods:** We purified, and characterized monocins and using MS we found peptides which allowed us identify the genetic locus encoding them. The monocin gene cluster which is 11.6 Kb in length and encodes 18 ORFs was cloned and expressed in *Bacillus subtilis*, producing high yields of functional bactericidal particles. Monocins were screened against a panel of *L. monocytogenes* isolates to ascertain the killing spectrum. The receptor binding protein, which determines target cell specificity, was identified and engineered to change the bactericidal spectrum. **Results:** Unlike the F-type pyocins of *Pseudomonas* which are related to lambda-like phage tails, we find that monocins are more closely related to TP901-1-like phage tails; structures not previously known to function as bacteriocins. The structures consist of an 80nm tube of stacked discs, at one end of which is a complex baseplate structure. One wild type monocin, M35152, was found to kill mainly serotype 4b strains. We were able to retarget the specificity to serotype 1/2a by fusing a phage receptor binding protein to the monocin counterpart. **Conclusions:** This discovery represents a new example of an envelope-penetrating nano-machine that has diverged to function as either DNA delivery (phage tail) or as a membrane-disrupting bacteriocin. While it may be assumed that these structures were co-opted from phages, we cannot rule out the opposite - that ancient phages co-opted complex bacteriocins from the cell which then underwent adaptions to become efficient at translocating DNA. Either way it appears that that multiple classes of phage tails and their related bacteriocins have co-evolved separately in parallel. A combination of a wild-type monocin and an engineered monocin together have a bactericidal spectrum that covers all of the major pathogenic serotypes of *L. monocytogenes*. We plan to develop this combination as a weapon to combat food born listeriosis.

Comparative Analyses of Forty-Four *Gordonia* Phage Genomes

Author Block:

D. Jacobs-Sera, M. Montgomery, C. A. Guerrero, D. A. Russell, J. Lapin, P. Rimple, A-K. Stanton, University of Pittsburgh SEA-PHAGES Students, W. H. Pope, G. F. Hatfull; Univ. of Pittsburgh, Pittsburgh, PA

Abstract Body:

Presented here is the characterization of 44 Gordonia phages. This includes plaque and virion particle morphologies along with comparative genomic analyses. Phages were isolated from soil using modified protocols developed for the isolation of mycobacteriophages. Forty-two of the 44 phages described here were isolated using *Gordonia terrae*, the remaining two phages were isolated using *Gordonia neofelifaecis*. In ongoing host range studies that include six different Gordonia species, these phages showed varying infection patterns across and amongst these hosts.Like the mycobacteriophages, the sequenced *Gordonia* phages were grouped together in clusters based on nucleotide similarity and protein families. The sequenced *Gordonia* phages comprise 13 new clusters, as well as 16 singletons. Interestingly, three *Gordonia* phages are included as members of Cluster A, a cluster with 376 mycobacteriophages. This is the first example of phages isolated on different Actinobacteria genera that share greater than 50% nucleotide similarity. The sequenced *Gordonia* phages exhibit a wide range of genome sizes, ranging from 17118 - 98136 bp. *Gordonia* phages also possess a gamut of GC%, ranging from 47.0% to 68.6%. From the comparative analyses of 44 *Gordonia* phages it is apparent that the population of *Gordonia* phages is as immense, diverse, and dynamic as that of mycobacteriophages, and provide a glimpse of the broader evolutionary relationship of the Actinobacteriophages.

A Longitudinal Survey for Phage-Encoded Toxin Genes in the Sewage-Impacted Environment Along the San Diego Coastline

Author Block:

T. Condeff, V. Casas, S. Maloy; San Diego State Univ., San Diego, CA

Abstract Body:

It is not uncommon for public beaches along San Diego's coastline to be closed after rain due to contamination. Sources of contamination include untreated sewage flowing from the Tijuana River and urban runoff from throughout San Diego. *Escherichia coli*, known to carry the phage-encoded shiga toxin gene (*stx*), is commonly found in human and animal feces and is a known human pathogen. We were interested in investigating and comparing the presence of *stx* in sewage-impacted areas along the San Diego coast during the dry and rainy seasons. From 2007-2015, sediment and water samples from the Tijuana River National Estuarine Research Reserve (TRNERR) and neighboring Imperial Beach were collected and screened via molecular assays for *stx*. Sediment and water samples from both locations frequently tested positive for *stx*. Overall, *stx* was detected in 78% of all samples. The *stx* gene was detected most frequently in samples collected from the area most highly impacted by sewage input—the estuary. The *stx* gene was detected more frequently in the water samples from the estuary (90%), versus the sediment samples, and vice versa for the Imperial Beach samples (82% in sediment vs. water). Comparing samples collected in the rainy season (October through March) versus the dry season (April through August), *stx* was detected most in the rainy season samples, with the greatest number detected in the samples from the estuary. No detectable variation in *stx* gene frequency was observed between samples collected from 2007 to 2015. Overall, the data indicates an increased presence of phage-encoded *stx* in the highly sewage-impacted area of the Tijuana River Estuary during the rainy season when local and international wastewater treatment is insufficient at treating the influx of raw sewage after heavy rains. Phage are highly mobile genetic elements and when they carry virulence genes such as *stx*, the transfer of these genes to new bacteria could lead to the evolution of novel human pathogens. It is therefore important to continue to monitor these impacted environments for phage-encoded genes, especially during the rainy season.

Publishing Title:

Assessment of Bacteriophage Diversity and Their Potential Controls on Heterotrophic Decomposition in Peatlands

Author Block:

J. Spring, H. Cadillo-Quiroz, A. Sarno; Arizona State Univ., Tempe, AZ

Abstract Body:

Little is known about the diversity and role of bacteriophages in carbon (C) rich ecosystems such as peatlands in tropical and temperate regions. To better understand how bacteriophages influence organic C cycling to final products like CO_2 and CH_4, phage communities and phage like particles were isolated or manipulated from freshwater sources from Amazon or Northern peatlands. Here we present initial findings on bacteriophages and their effects on heterotrophic bacteria, which in turn affects the decomposition and the C cycling towards CH_4 in peatlands. To assess diversity, phages were enriched from soil samples from temperate sites and water samples from Amazon peatlands by filtering to remove organic matter and bacteria, and iron flocculation to bind the phages and allow for capture on a filter. Phage community enrichments were screened using the cross-streaking method against 100 heterotrophic bacterial isolates obtained from the same sites to identify phage hosts. Once a host was found, the phage was isolated and a basic characterization was performed determining plaque morphology, and phage morphology via electron microscopy. Selected phages will be sequenced for accurate identification. To assess phage effects on decomposition, *in vitro* soil slurry incubations were done with the addition of tea extract and iron sulfate (TeaF), a virucidal agent, and rates of CO_2 and CH_4 formation were measured using temperate peat soils. In comparison to controls, slurries with TeaF had a major increase in CO_2 formation. The average rate of CO_2 production with the TeaF agent was 1.637 µg/hour while the control was 0.0958 µg/hour. The average rate of CH_4 with the TeaF was 0.207 µg/hour while the control was 0.111 µg/hour. This indicates that the putative TeaF inhibition of phages allowed for an increase in overall CO_2 production by heterotrophs from a reduced predation pressure exerted by phages. Nevertheless, the effects increased CH_4 formation rates were also apparent but after a lagging time of several days to a week while effects on CO_2 rates were noticeable within hours. Similar inhibition tests are underway for Amazon peatland soils. Our results provide the first assessment of bacteriophage diversity and abundance in Amazon peatlands and also evaluates their quantitative contribution or influence of organic carbon decomposition in peatland soils.

Detection of Halophilic Bacteriophage in Soils Near the Great Salt Lake

Author Block:

M. J. Domek, G. Ward, M. D. Culumber; Weber State Univ., Ogden, UT

Abstract Body:

Bacteriophages that target halophilic bacteria from the Great Salt Lake (GSL) have been isolated and studied previously; however, little is known about the distribution of bacteriophages in the soil surrounding the GSL. The objective of this study was to determine the presence of halophilic bacteriophage in the soils surrounding the GSL, facilitating a greater understanding of the role they play in the terrestrial ecosystem. A technique was developed to amplify bacteriophage from soil using host-bacteriophage pairs isolated from the GSL. The technique tested bacteriophage survival and attachment in soil and was also used to isolate new bacteriophage. Soil samples were collected from Antelope Island (in GSL) at various distances from the water. Previously isolated *Salinivibrio costicola* strains (SA36, SA39, SA40 and SA50) and their respective bacteriophage (DB01, NS01, JM01 and CW02) were incubated with GSL soil and halophilic media. After an overnight incubation the soil extract was diluted and a spot test assay was performed to detect the titer of bacteriophages. The technique tested known bacteriophage-host pairs and demonstrated that strains SA39 and SA40 amplified markedly more than the other bacteriophages suggesting that certain bacteriophages bind to soil particles or are inactivated by soil components. Bacteriophages in the GSL may be important in controlling the growth and ecology of the microbial populations in this highly saline environment. Additionally, two potentially new bacteriophages were isolated and amplified, then observed with an electron microscope.

Microbial Community Dynamics During Lake Ice Formation

Author Block:

T. Butler, A. Baldwin, A. Dwyer, **S. M. Techtmann**; Michigan Technological Univ., Houghton, MI

Abstract Body:

Microbial communities experience dramatic environmental changes on a seasonal basis. Many aquatic environments can transition from 20°C in summer months to persistent ice cover during winter months. The dynamics of microbial communities is poorly understood in aquatic settings and in particular little is known about changes in microbial community structure and abundance during times of persistent ice cover. The goal of this study is characterize the temporal dynamics of microbial communities during seasonal transition. Here we sought to perform a high-resolution time-series of the Keweenaw Waterway. Triplicate samples were collected five days per week from surface water in the Keweenaw Waterway between November and April. *In situ* environmental variables (Temp, pH, DO, Salinity, ORP) were measured at the time of sampling. Samples were collected for analysis of dissolved organic carbon, inorganic nutrients, microbial cell counts, and microbial community analysis. Abundance of bacteria (bacterial 16S rRNA), Archaea (Archaeal 16S rRNA), fungi (fungal ITS) and eukaryotes (eukaryotic 18S) were determined using qPCR. Microbial community structure was determined using massively parallel sequencing of the 16S rRNA gene using the Illumina MiSeq. The microbial community at initial time points was dominated by members of the Actinobacteria in the orders Actinomycetales (24% of recovered reads) and Acidomicrobiales (12%). Members of the Verrucomicrobia were also abundant during the initial time points (8%). Members of the Burkholderia (9%) and the Planctomycetes (7%) were also present at high abundance. We expect that there will be little variation in the microbial community from day-to-day, but will show dramatic shift in microbial abundance and diversity during the transition from fall into winter and from winter into spring. The results of this on-going study will help to elucidate how microbial abundance and diversity change over drastic seasonal transition and how ice cover affects microbial abundance and diversity. In the long term we hope to link temporal changes in environmental parameters with functional differences to better understand how seasonal variations affects biogeochemical cycling.

Flood and Infectious Diseases in an Endemic Setting - A Report from Chennai

Author Block:

D. Sureshkumar, MD[1], R. Gopalakrishnan, 600083[1], V. Ramasubramanian[1], A. Rajalakshmi, 600083[1], S. Saujanya, 600083[2]; [1]Apollo Hosp.,, Tamilnadu, India, [2]Manipal Hosp., Tamilnadu, India

Abstract Body:

Background: Following a flood, there exists the potential for transmission of water-borne diseases and for increased levels of vector-borne diseases. These infectious diseases outbreaks may have significant societal impacts, however, there is very little data from the developing world. This study aimed to quantify the infectious diseases reported from a tertiary care hospital before and after major floods.**Methods**: A cross sectional study was conducted in a tertiary care hospital, in Chennai (heavily flooded district in Southern India, during December 2015 floods). Information was collected from hospital notifiable disease records. The numbers of cases of acute gastroenteritis (AGE), typhoid fever, leptospirosis, dengue and malaria reported in the month of November 2015 and December 2015 were analyzed.**Results**: A total of 103 infectious cases were reported after floods (December), when compared to 145 cases reported before floods (November). However, there is major differences in the disease profile reported as shown in the table -1 below**Table-1: Infectious Disease Reported Before and After Floods**

	AGE	Typhoid	Leptospirosis	Dengue	Malaria	Total
November 2015	17	0	0	126	3	146
December 2015	43	3	0	56	1	103

Conclusion: There is nearly 30% (146 to 103) decrease in infectious diseases reported following floods in South India. However, there is 150 % (17 to 43) increase in the number of AGE cases reported and 55 % (126 to 56) drop in dengue cases reported after floods. These findings should be confirmed across other health care institutions and in community settings for better understanding and infectious disease preparedness for future disasters.

Short-Term Temporal Variation of Grassland Soil Microbial Communities Enlarged under Experimental Warming

Author Block:

M. M. Yuan, Z. Shi, J. Li, L. Wu, Z. He, J. Van Nostrand, J. Zhou; Univ. of Oklahoma, Norman, OK

Abstract Body:

Background: How microbial communities change over time is a fundamental, yet unsolved question in ecology, especially for highly diverse communities with complex structures. Previous studies have suggested that the long-term (over years) turnover rates for soil microbial communities are actually similar to macroscopic plant and animal communities. However, the temporal decay rates of microbial communities under strong seasonal fluctuations have not yet been evaluated.**Methods:** To assess such short-term diversity changes, and the influence of climate warming, soils were collected in a field experiment in a central Oklahoma tall grassland, where the humid subtropical climate features clear seasonal patterns. In 2012, surface (0-15cm) soil was sampled monthly from four replicated experimentally warmed (+3 °C continuously for 4 years) and control plots, and analyzed by MiSeq sequencing of 16S rRNA gene amplicons.**Results:** A total of 1.66 million high quality 16S rRNA amplicon sequences were obtained and clustered into 70,022 OTUs (97% identity cutoff). A comparison including all the samples revealed that both warming and sampling month significantly ($P<0.005$ by Adonis with Bray-Curtis distance) affected the soil microbial community structure. Separating the samples by treatment generated different turnover patterns in control and warmed soils. The changes in community structures (distance matrices) were correlated (by Mantel test $r = 0.085$, $P = 0.058$) with days between observations in warmed plots, but not in control plots. The species time relationship exponent (STR-w) was slightly higher in warmed than in control plots ($w = 0.609$ for control, $w=0.622$ for warming, $P = 0.076$ by t-test), suggesting a faster species accumulation over time in response to warming. Also, warmed communities had a higher β-diversity (Sørensen index, $P=0.02$) than control, confirming the higher temporal divergence of warmed communities.**Conclusions:** These results indicate that soil microbial communities change in structure along seasonal environmental fluctuations, and that experimental warming enlarged the short-term temporal variation.

Effects of Warming on Soil Microbial Communities in a Grassland Ecosystem

Author Block:

X. Zhou[1], Z. He[1], L. Wu[1], J. D. Van Nostrand[1], M. Yuan[1], D. Tilman[2], X. Liu[3], J. Zhou[1]; [1]Univ. of Oklahoma, Norman, OK, [2]Univ. of Minnesota, St. Paul, MN, [3]Central South Univ., Changsha, China

Abstract Body:

Elevated temperature causes ecosystem-level responses, including decreased soil moisture, increased primary productivity and litter decomposition. However, little is known about how soil microbiomes respond to warming. In this study, we surveyed the taxonomic and functional potential changes of soil microbial communities in a grassland field exposed to experimental warming (+3℃ at 1 cm belowground) for four years by MiSeq sequencing of 16S rRNA and internal transcribed spacer (ITS) gene amplicons, and by a functional gene array (GeoChip 5.0). Dissimilarity analysis of all samples showed that warming significantly ($P<0.05$) changed the overall functional composition, structure and potential of soil microbial communities, but not their corresponding taxonomic structures. The abundance of OTUs in the bacterial phyla, such as *Armatimonadetes*, *Firmicutes* and *Verrucomicrobia* was increased by warming, while that in *Acidobacteria, Proteobacteria, Phenylobacterium, Bacteroidetes* was decreased at 95% confidence interval. Besides, warming also altered the adundance of OTUs in the fungal phyla, e.g., *Ascomycota, Glomeromycota* and *Zygomycota*. The key functional genes involved in carbon degradation (e.g., *amyA, cdh, vdh, chitinase* gene) were enriched under warming, as well as the genes in nutrient-cycling process such as denitrification, ammonification and phosphorus utilization. Canonical correspondence analysis (CCA) indicated that microbial functional potential was highly correlated with annual temperature, carbon/nitrogen ratio, nitrate-nitrogen and aboveground plant and root biomass. These results provide new insights into our understanding of the response and feedback of soil microbial communities to warming.

Characterization of Microbial Communities and Soil Organic Carbon Degradation Associated with the Depth and Thawing Effects on Tundra Soil in Alaska

Author Block:

H. Park, H. Park, D. Kim; Korea Polar Res. Inst., Incheon, Korea, Republic of

Abstract Body:

Background: In high-latitude regions, temperature has risen twice as fast as the global average (0.3^{o}C per decade) and this leads to the increase in microbial degradability against soil organic carbon (SOC). Furthermore, the decomposed SOC is converted into green-house gases (CO_2 and CH_4) and their release could further increase the rate of climate change. Thus, understanding the microbial diversity and their functions linked with SOC degradation in soil-thawing model is necessary.**Methods:** In this study, we divided SOC-rich tundra soil from Council, Alaska into two depth regions (30−40 cm and 50−60 cm of depth) and incubated that for 108 days at 0^{o}C. We adopted a pyrosequencing technique to investigate the microbial community changes in parallel withdifferent depths and incubation period. Subsequently, humic acids (HA), main component of SOC, were extracted from the identical soils and analyzed to examine the changing patterns of SOC.**Results:** A total of 111,804 reads were obtained through a pyrosequencing-based metagenomic study during the microcosm experiments, and 574−1,128 of bacterial operational taxonomic units (OTUs) and 30−57 of archaeal OTUs were observed. Taxonomic analysis showed that the distribution of bacterial taxa was significantly different between two samples, while archaea was similar. In detail, the relative abundance of phyla *Actinobacteria* and *Firmicutes* largely increased in 30−40 cm and 50−60 cm of soil depths, respectively. Genera *Oryzihumus* (30−40 cm) and *Desulfosporosinus* (50−60 cm) were predominant in *Actinobacteria and Firmicutes*, respectively. Weight measurement and gel permeation chromatography of the SOC extracts demonstrated that further polymerization of HA occurred in both depths during the microcosm experiments.**Conclusions:** Taken together our results indicate that these two bacterial phyla could play a key function in SOC degradation and utilization in cold tundra soil.

Diversity and Distribution of Soil Fungal Community in the Ny-Ålesund Region, Svalbard (High Arctic)

Author Block:

T. Zhang, X. You, L. Yu; Inst. of Med.l Biotechnology, Chinese Academy of Med. Sci., Beijing, China

Abstract Body:

Background: The Arctic tundra is particularly sensitive and vulnerable to climate change. Understanding the structure of soil fungal communities is essential for predicting the response of the Arctic soil environment to climate change.**Methods:** This study assessed the fungal community composition and its relationships with properties of surface soils in the Ny-Ålesund Region (Svalbard, High Arctic). A total of thirteen soil samples were collected and soil fungal community was analyzed by 454 pyrosequencing with fungi-specific primers targeting the rDNA internal transcribed spacer (ITS) region. The following eight soil properties were analyzed: pH, organic carbon (C), organic nitrogen (N), ammonium nitrogen (NH_4^+-N), silicate silicon (SiO_4^{2-}-Si), nitrite nitrogen (NO_2^--N), phosphate phosphorus (PO_4^{3-}-P) and nitrate nitrogen (NO_3^--N).**Results:** A total of 57,952 reads belonging to 541 operational taxonomic units (OTUs) were found. Of these OTUs, 343 belonged to Ascomycota, 100 to Basidiomycota, 31 to Chytridiomycota, 22 to Glomeromycota, 11 to Zygomycota, 10 to Rozellomycota, whereas 24 belonged to unknown fungi. The dominant orders were Helotiales, Verrucariales, Agaricales, Lecanorales, Chaetothyriales, Lecideales, and Capnodiales. The common genera (>8 soil samples) were *Tetracladium*, *Mortierella*, *Fusarium*, *Cortinarius*, and *Atla*. Distance-based redundancy analysis (db-rda) and analysis of similarities (ANOSIM) revealed that soil pH ($p=0.001$) was the most significant factor in determining the soil fungal community composition. Members of Verrucariales were found to predominate in soils of pH 8-9, whereas Sordariales predominated in soils of pH 7-8 and Coniochaetales predominated in soil samples of pH 6-7.**Conclusions:** The results suggest the presence and distribution of diverse soil fungal communities in the High Arctic, which can provide reliable data for studying the ecological responses of soil fungal communities to climate changes in the Arctic.
